## Hewlett Packard Enterprise UniX (HPE-UX)

To forward events from Hewlett Packard Enterprise UniX (HPE-UX) to IBM QRadar, configure your HPE-UX device to send syslog events to QRadar.

### About this task

You can configure syslog on your HPE-UX device to forward events to QRadar.

### Procedure

1. Log in to the HPE-UX device command-line interface.
2. Open the following file:  
`/etc/syslog.conf`
3. Add the following line:  
`<facility>.<level><destination>`  
Where:
  - `<facility>` is auth.
  - `<level>` is info.
  - `<destination>` is the IP address of the QRadar Console.
4. Save and exit the file.
5. Type the following command to ensure that `syslogd` enforces the changes to the `syslog.conf` file.  
`kill -HUP `cat /var/run/syslog.pid``

**Tip:** Back quotation marks are used in the command-line.

### What to do next

Add a log source in QRadar.

#### Related concepts

[“Syslog log source parameters for Hewlett Packard Enterprise UniX \(HPE-UX\)” on page 896](#)

## Syslog log source parameters for Hewlett Packard Enterprise UniX (HPE-UX)

If QRadar does not automatically detect the log source, add a Hewlett Packard Enterprise UniX log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Hewlett Packard Enterprise UniX :

*Table 547. Syslog log source parameters for the Hewlett Packard Enterprise UniX DSM*

<b>Parameter</b>	<b>Value</b>
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	Hewlett Packard UniX
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for your Hewlett Packard Enterprise UniX device.

**Related tasks**

# Chapter 79. Huawei

IBM QRadar can integrate with several Huawei DSMs.

## Huawei AR Series Router

The Huawei AR Series Router DSM for IBM QRadar can accept events from Huawei AR Series Routers by using syslog.

QRadar records all relevant IPv4 events that are forwarded from Huawei AR Series Router. To integrate your device with QRadar, you must create a log source, then configure your AR Series Router to forward syslog events.

### Supported routers

The DSM supports events from the following Huawei AR Series Routers:

- AR150
- AR200
- AR1200
- AR2200
- AR3200

## Syslog log source parameters for Huawei AR Series Router

If QRadar does not automatically detect the log source, add a Huawei AR Series Router log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Huawei AR Series Router:

Table 548. Syslog log source parameters for the Huawei AR Series Router DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	Huawei AR Series Router
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address, host name, or name for the log source as an identifier for your Huawei AR Series Router.  Each log source that you create for your Huawei AR Series Router must include a unique identifier, such as an IP address or host name.

### Related tasks

[“Adding a log source” on page 5](#)

## Configuring Your Huawei AR Series Router

To forward syslog events to IBM QRadar, you must configure your Huawei AR Series Router as an information center, then configure a log host.

### About this task

The log host that you create for your Huawei AR Series Router can forward events to your QRadar Console or an Event Collector.

### Procedure

1. Log in to your Huawei AR Series Router command line Interface (CLI).

2. Type the following command to access the system view:

```
system-view
```

3. Type the following command to enable the information center:

```
info-center enable
```

4. Type the following command to send informational level log messages to the default channel:

```
info-center source default channel loghost log level informational debug  
state off trap state off
```

5. Optional: To verify your Huawei AR Series Router source configuration, type the command:

```
display channel loghost
```

6. Type the following command to configure the IP address for QRadar as the log host for your switch:

```
info-center loghost <IP address> facility <local>
```

Where:

- <IP address> is the IP address of the QRadar Console or Event Collector.

- <local> is the syslog facility, for example, local0.

For example,

```
info-center loghost <IP_address> facility local0
```

7. Type the following command to exit the configuration:

```
quit
```

The configuration is complete. You can verify events that are forwarded to QRadar by viewing events on the **Log Activity** tab.

## Huawei S Series Switch

The Huawei S Series Switch DSM for IBM QRadar can accept events from Huawei S Series Switch appliances by using syslog.

QRadar records all relevant IPv4 events that are forwarded from Huawei S Series Switches. To integrate your device with QRadar, you must configure a log source, then configure your S Series Switch to forward syslog events.

### Supported switches

The DSM supports events from the following Huawei S Series Switches:

- S5700
- S7700
- S9700

## Syslog log source parameters for Huawei S Series Switch

If QRadar does not automatically detect the log source, add a Huawei S Series Switch log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Huawei S Series Switch:

Table 549. Syslog log source parameters for the Huawei S Series Switch DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	Huawei S Series Switch
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	<p>Type the IP address, host name, or name for the log source as an identifier for your Huawei S Series Switch.</p> <p>Each log source that you create for your Huawei S Series Switch must include a unique identifier, such as an IP address or host name.</p>

### Related tasks

## Configuring Your Huawei S Series Switch

To forward syslog events to IBM QRadar, you must configure your Huawei S Series Switch as an information center, then configure a log host.

### About this task

The log host that you create for your Huawei S Series Switch can forward events to your QRadar Console or an Event Collector.

### Procedure

1. Log in to your Huawei S Series Switch command line Interface (CLI).
2. Type the following command to access the system view:

```
system-view
```

3. Type the following command to enable the information center:

```
info-center enable
```

4. Type the following command to send informational level log messages to the default channel:

```
info-center source default channel loghost log level informational debug  
state off trap state off
```

5. Optional: To verify your Huawei S Series Switch source configuration, type the command:

```
display channel loghost
```

6. Type the following command to configure the IP address for QRadar as the log host for your switch:

```
info-center loghost <IP address> facility <local>
```

Where:

- <IP address> is the IP address of the QRadar Console or Event Collector.
- <local> is the syslog facility, for example, local0.

For example,

```
info-center loghost <IP_address> facility local0
```

7. Type the following command to exit the configuration:

```
quit
```

The configuration is complete. You can verify events that are forwarded to QRadar by viewing events on the **Log Activity** tab.

## Huawei S Series Switch sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

### Huawei S Series Switch sample message when you use the Syslog protocol

**Important:** Due to formatting, paste the message format into a text editor and then remove any carriage return or line feed characters.

The following event shows that the source MAC address in the ARP packet is invalid.

```
May 22 2012 09:43:39huawei.sserieswitch.test%%01SECE/3/ARPS_DROP_PACKET_SRC_MAC(1):  
Invalidsourcemacaddress.(SourceMAC=0000-0000-0000,SourceIP=10.10.10.11,SourceInterface=  
XGigabitEthernet5/0/0,DropTime=2012/05/22 09:43:39)
```

Table 550. Highlighted fields

# Chapter 80. HyTrust CloudControl

The IBM QRadar DSM for HyTrust CloudControl collects events from HyTrust CloudControl devices.

The following table lists the specifications for the HyTrust CloudControl DSM:

Table 551. HyTrust CloudControl DSM specifications	
Specification	Value
Manufacturer	Hytrust
DSM name	HyTrust CloudControl
RPM file name	DSM-HyTrustCloudControl-Qradar_version-build_number.noarch.rpm
Supported versions	V3.0.2 through V3.6.0
Protocol	Syslog
Recorded event types	All events
Automatically discovered?	Yes
Includes identity?	Yes
Includes custom properties?	No
More information	<a href="http://www.hytrust.com">Hytrust web site</a> ( <a href="http://www.hytrust.com">http://www.hytrust.com</a> )

To collect HyTrust CloudControl events, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM
  - HyTrust CloudControl DSM RPM
2. Configure your HyTrust CloudControl device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a HyTrust CloudControl log source on the QRadar Console. The following table describes the parameters that require specific values that are required for HyTrust CloudControl event collection:

Table 552. HyTrust CloudControl log source parameters

Parameter	Value
Log Source type	HyTrust CloudControl
Protocol Configuration	Syslog

## Related tasks

To collect HyTrust CloudControl events, you must configure your third-party device to send events to IBM QRadar

[Adding a log source](#)

## Configuring HyTrust CloudControl to communicate with QRadar

---

To collect HyTrust CloudControl events, you must configure your third-party device to send events to IBM QRadar

### Procedure

1. Log in to HyTrust CloudControl.
2. From the HTA Management Console, select **Configuration > Logging**.
3. From the **HTA Logging Aggregation options**, select **External**.
4. From the **Logging Aggregation Template Type** options, select either **Proprietary** or **CEF**.
5. In the **HTA Syslog Servers** field, type the IP address for QRadar.

# Chapter 81. IBM

IBM QRadar supports a number of IBM DSMs.

## IBM AIX

IBM QRadar provides the IBM AIX Audit and IBM AIX Server DSMs to collect and parse audit or operating system events from IBM AIX devices.

### IBM AIX Server DSM overview

The IBM AIX Server DSM collects operating system and authentication events using syslog for users that interact or log in to your IBM AIX appliance.

The following table identifies the specifications for both IBM AIX DSM Server:

Table 553. IBM AIX Server DSM specifications	
Specification	Value
Manufacturer	IBM
DSM names	IBM AIX Server
RPM file names	DSM-IBMAIXServer-QRadar_version-build_number.noarch.rpm
Supported versions	V5.X, V6.X, and V7.X
Protocol type	Syslog
QRadar recorded event types	Login or logoff events Session opened or session closed events Accepted password and failed password events Operating system events
Automatically discovered?	Yes
Includes identity?	Yes
More information	<a href="http://www.ibm.com/">IBM website (http://www.ibm.com/)</a>

To integrate IBM AIX Server events with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - DSM Common RPM
  - IBM AIX Server DSM RPM
2. Configure your IBM AIX Server device to send syslog events to QRadar.
3. Configure a syslog-based log source for your IBM AIX Server device. Use the following protocol-specific parameters:

Parameter	Description
Log Source Type	IBM AIX Server
Protocol Configuration	Syslog

## Related tasks

### [Adding a DSM](#)

[Configuring your IBM AIX Server device to send syslog events to QRadar](#)

To collect syslog audit events from your IBM AIX Server device, redirect your audit log output from your IBM AIX device to the IBM QRadar Console or Event Collector.

### [Adding a log source](#)

[“Adding a DSM” on page 4](#)

To collect syslog audit events from your IBM AIX Server device, redirect your audit log output from your IBM AIX device to the IBM QRadar Console or Event Collector.

## Configuring your IBM AIX Server device to send syslog events to QRadar

To collect syslog audit events from your IBM AIX Server device, redirect your audit log output from your IBM AIX device to the IBM QRadar Console or Event Collector.

## Procedure

1. Log in to your IBM AIX appliance as a root user.

2. Open the /etc/syslog.conf file.

3. To forward the system authentication logs to QRadar, add the following line to the file:

```
auth.info @QRadar_IP_address
```

A tab must separate auth.info and the IP address of QRadar.

For example:

```
#HHHH# begin /etc/syslog.conf mail.debug /var/adm/maillogmail.none /var/adm/
maillogauth.notice /var/adm/authloglpr.debug /var/adm/lpd-errskern.debug /var/adm/
messages*.emerg;*.alert;*.crit;*.warning;*.err;*.notice;*.info /var/adm/
messagesauth.info      @<IP_address>#HHHH# end /etc/syslog.conf
```

4. Save and exit the file.

5. Restart the syslog service:

```
refresh -s syslogd
```

## IBM AIX Server sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## IBM AIX Server sample message when you use the Syslog protocol

The following sample event message shows that the sshd connection is closed.

```
<38>Nov 21 16:19:05 ibm.aix.test sshd[7471482]: Connection closed by 10.5.88.146 [preauth]
```

```
<38>Nov 21 16:19:05 ibm.aix.test sshd[7471482]: Connection closed by 10.5.88.146 [preauth]
```

Table 554. Highlighted fields	
QRadar field name	Highlighted payload field name
Event ID	sshd + Connection closed (extracted from the payload)
Device Time	Nov 21 16:19:05

*Table 554. Highlighted fields (continued)*

QRadar field name	Highlighted payload field name
Source IP	<b>10.5.88.146</b>

## IBM AIX Audit DSM overview

The IBM AIX Audit DSM collects detailed audit information for events that occur on your IBM AIX appliance.

The following table identifies the specifications for the IBM AIX Audit DSM:

*Table 555. IBM AIX Audit DSM specifications*

Specification	Value
Manufacturer	IBM
DSM names	IBM AIX Audit
RPM file names	DSM-IBMAIXAudit-QRadar_version-build_number.noarch.rpm
Supported versions	V6.1 and V7.1
Protocol type	Syslog Log File Protocol
QRadar recorded event types	Audit events
Automatically discovered?	Yes
Includes identity?	No
More information	<a href="http://www.ibm.com/">IBM website (http://www.ibm.com/)</a>

To integrate IBM AIX Audit events with QRadar, complete the following steps:

1. Download the latest version of the IBM AIX Audit DSM from the [IBM Support Website](#).
2. For syslog events, complete the following steps:
  - a. Configure your IBM AIX Audit device to send syslog events to QRadar. See “[Configuring IBM AIX Audit DSM to send syslog events to QRadar](#)” on page 909.
  - b. If QRadar does not automatically discover the log source, add an IBM AIX Audit log source. Use the following IBM AIX Audit-specific values in the log source configuration:

Parameter	Value
<b>Log Source Type</b>	IBM AIX Audit
<b>Protocol Configuration</b>	Syslog

3. For log file protocol events, complete the following steps:

- a. Configure your IBM AIX Audit device to convert audit logs to the log file protocol format.
- b. Configure a log file protocol-based log source for your IBM AIX Audit device. Use the following protocol-specific values in the log source configuration:

Parameter	Value
<b>Log Source Type</b>	IBM AIX Audit
<b>Protocol Configuration</b>	Log File

Parameter	Value
<b>Service Type</b>	The protocol to retrieve log files from a remote server.  <b>Important:</b> If you select the SCP and SFTP service type, ensure that the server that is specified in the <b>Remote IP or Hostname</b> parameter has the SFTP subsystem enabled.
<b>Remote Port</b>	If the host for your event files uses a non-standard port number for FTP, SFTP, or SCP, adjust the port value.
<b>SSH Key File</b>	If you select SCP or SFTP as the Service Type, use this parameter to define an SSH private key file. When you provide an SSH Key File, the <b>Remote Password</b> parameter is ignored.
<b>Remote Directory</b>	The directory location on the remote host where the files are retrieved. Specify the location relative to the user account you are using to log in.  <b>Restriction:</b> For FTP only. If your log files are in a remote user home directory, leave the remote directory blank to support operating systems where a change in the working directory (CWD) command is restricted.
<b>FTP File Pattern</b>	The FTP file pattern must match the name that you assigned to your AIX audit files with the <b>-n</b> parameter in the audit script. For example, to collect files that start with AIX_AUDIT and end with your time stamp value, type AIX_Audit_*.
<b>FTP Transfer Mode</b>	ASCII is required for text event logs that are retrieved by the log file protocol by using FTP.
<b>Processor</b>	NONE
<b>Change Local Directory?</b>	Leave this check box clear.
<b>Event Generator</b>	LineByLine  The Event Generator applies more processing to the retrieved event files. Each line of the file is a single event. For example, if a file has 10 lines of text, 10 separate events are created.

## Related tasks

[Adding a log source](#)

## Configuring IBM AIX Audit DSM to send syslog events to QRadar

To collect syslog audit events from your IBM AIX Audit device, redirect your audit log output from your IBM AIX device to the IBM QRadar Console or Event Collector.

### About this task

On an IBM AIX appliance, you can enable or disable classes in the audit configuration. The IBM AIX default classes capture a large volume of audit events. To prevent performance issues, you can tune your IBM AIX appliance to reduce the number of classes that are collected. For more information about audit classes, see your IBM AIX appliance documentation.

### Procedure

1. Log in to your IBM AIX appliance.

2. Open the audit configuration file:

```
/etc/security/audit/config
```

3. Edit the Start section to disable the **binmode** element and enable the **streammode** element:

```
binmode = off
```

```
streammode = on
```

4. Edit the Classes section to specify which classes to audit.

5. Save the configuration changes.

6. Open the streamcmds file:

```
/etc/security/audit/streamcmds
```

7. Add the following line to the file:

```
/usr/sbin/auditstream | /usr/sbin/auditselect -m -e "command != logger && command != auditstream && command != auditptr && command != auditselect" | auditptr -t0 -h eclrRdi -v | awk -u 'NR%2{printf "%s ",$0;next}{print;}' | /usr/bin/logger -p local0.debug -r &
```

8. Save the configuration changes.

9. Edit the syslog configuration file to specify a debug entry and the IP address of the QRadar Console or Event Collector:

```
*.debug @ip_address
```

**Tip:** A tab must separate \*.debug from the IP address.

10. Save the configuration changes.

11. Reload your syslog configuration:

```
refresh -s syslogd
```

12. Start the audit script on your IBM AIX appliance:

```
audit start
```

### What to do next

The IBM AIX Audit DSM automatically discovers syslog audit events that are forwarded from IBM AIX to QRadar and creates a log source. If the events are not automatically discovered, you can manually configure a log source.

# Configuring IBM AIX Audit DSM to send log file protocol events to QRadar

Configure the audit.pl script to run each time that you want to convert your IBM AIX audit logs to a readable event log format for QRadar.

## Before you begin

Ensure that Perl 5.8 or later is installed on your IBM AIX computer.

## About this task

To send log file protocol events from IBM AIX to QRadar, you must edit these files:

### Audit configuration file

The audit configuration file identifies the event classes that are audited and the location of the event log file on your IBM AIX appliance. The IBM AIX default classes capture many audit events. To prevent performance issues, you can configure the classes in the audit configuration file. For more information about configuring audit classes, see your IBM AIX documentation.

### Audit script

The audit script uses the audit configuration file to identify which audit logs to read and converts the binary logs to single-line events that QRadar can read. The log file protocol can then retrieve the event log from your IBM AIX appliance and import the events to QRadar. The audit script uses the audit.pr file to convert the binary audit records to event log files QRadar can read.

Run the audit script each time that you want to convert your audit records to readable events. You can use a cron job to automate this process. for example, you can add 0 \* \* \* \* /audit.pl to allow the audit script to run hourly. For more information, see your system documentation.

## Procedure

1. Log in to your IBM AIX appliance.

2. Configure the audit configuration file:

a) Open the audit configuration file:

```
etc/security/audit/config
```

b) Edit the Start section to enable the **binmode** element.

```
binmode = on
```

c) In the Start section, edit the configuration to determine which directories contain the binary audit logs.

The default configuration for IBM AIX auditing writes binary logs to the following directories:

```
trail = /audit/trail
bin1 = /audit/bin1
bin2 = /audit/bin2
binsize = 10240
cmds = /etc/security/audit/bincmds
```

In most cases, you do not have to edit the binary file in the bin1 and bin2 directories.

d) In the Classes section, edit the configuration to determine which classes are audited. For information on configuring classes, see your IBM AIX documentation.

e) Save the configuration changes.

3. Audit on your IBM AIX system:

```
audit start
```

4. Install the audit script:

a) From [IBM Fix Central](https://www.ibm.com/support/fixcentral/) (<https://www.ibm.com/support/fixcentral/>), search for the audit.pl.gz and select the download that corresponds to your version of QRadar.

- b) Download the audit.pl.gz file.
- c) Copy the audit script to a folder on your IBM AIX appliance.
- d) Extract the file:

```
tar -zxvf audit.pl.gz
```

- e) Start the audit script:

```
./audit.pl
```

You can add the following parameters to modify the command:

Parameter	Description
<b>-r</b>	Defines the results directory where the audit script writes event log files for QRadar. If you do not specify a results directory, the script writes the events to the following /audit/results/ directory. The results directory is used in the <b>Remote Directory</b> parameter in the log source configuration uses this value. To prevent errors, verify that the results directory exists on your IBM AIX system.
<b>-n</b>	Defines a unique name for the event log file that is generated by audit script. The <b>FTP File Pattern</b> parameter in the log source configuration uses this name to identify the event logs that the log source must retrieve in QRadar
<b>-l</b>	Defines the name of the last record file.
<b>-m</b>	Defines the maximum number of audit files to retain on your IBM AIX system. By default, the script retains 30 audit files. When the number of audit files exceeds the value of the <b>-m</b> parameter, the script deletes the audit file with the oldest time stamp.
<b>-t</b>	Defines the directory that contains the audit trail file. The default directory is /audit/trail.

## What to do next

The IBM AIX Audit DSM automatically discovers log file protocol audit events that are forwarded from IBM AIX to QRadar and creates a log source. If the events are not automatically discovered, you can manually configure a log source.

## IBM BigFix Detect

---

The IBM BigFix Detect DSM for QRadar is deprecated.

## IBM CICS

---

The IBM CICS DSM collects events from IBM Custom Information Control System (CICS®) on an IBM z/OS® mainframe that uses IBM Security zSecure.

When you use a zSecure process, events from the System Management Facilities (SMF) can be transformed into Log Event Extended Format (LEEF) events. These events can be sent near real-time by using UNIX Syslog protocol or IBM QRadar can retrieve the LEEF event log files by using the Log File protocol and then process the events. When you use the Log File protocol, you can schedule QRadar to retrieve events on a polling interval, which enables QRadar to retrieve the events on the schedule that you define.

To collect IBM CICS events, complete the following steps:

1. Verify that your installation meets any prerequisite installation requirements.  
For more information about prerequisite requirements, see the [IBM Security zSecure Suite 2.2.1 Prerequisites](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/prereqs_qradar.html) ([http://www.ibm.com/support/knowledgecenter/en/SS2RWS\\_2.2.1/com.ibm.zsecure.doc\\_2.2.0/installation/prereqs\\_qradar.html](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/prereqs_qradar.html)) .
2. Configure your IBM z/OS image to write events in LEEF format. For more information, see the [IBM Security zSecure Suite: CARLa-Driven Components Installation and Deployment Guide](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/setup_data_prep_qradar.html) ([http://www.ibm.com/support/knowledgecenter/en/SS2RWS\\_2.2.1/com.ibm.zsecure.doc\\_2.2.0/installation/setup\\_data\\_prep\\_qradar.html](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/setup_data_prep_qradar.html)).
3. Create a log source in QRadar for IBM CICS.
4. If you want to create a custom event property for IBM CICS in QRadar, for more information, see the [IBM Security Custom Event Properties for IBM z/OS technical note](http://public.dhe.ibm.com/software/security/products/qradar/documents/71MR1/SIEM/TechNotes/IBM_zOS_CustomEventProperties.pdf) ([http://public.dhe.ibm.com/software/security/products/qradar/documents/71MR1/SIEM/TechNotes/IBM\\_zOS\\_CustomEventProperties.pdf](http://public.dhe.ibm.com/software/security/products/qradar/documents/71MR1/SIEM/TechNotes/IBM_zOS_CustomEventProperties.pdf)).

## Before you begin

Before you can configure the data collection process, you must complete the basic zSecure installation process and complete the post-installation activities to create and modify the configuration.

The following prerequisites are required:

- You must ensure parmlib member IFAPRDxx is enabled for IBM Security zSecure Audit on your z/OS image.
- The SCKRLOAD library must be APF-authorized.
- If you are using the direct SMF INMEM real-time interface, you must have the necessary software installed (APAR OA49263) and set up the SMFPRMxx member to include the INMEM keyword and parameters. If you decide to use the CDP interface, you must also have CDP installed and running. For more information, see the [IBM Security zSecure Suite 2.2.1: Procedure for near real-time](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/smf_proc_real_time_qradar.html) ([http://www.ibm.com/support/knowledgecenter/en/SS2RWS\\_2.2.1/com.ibm.zsecure.doc\\_2.2.0/installation/smf\\_proc\\_real\\_time\\_qradar.html](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/smf_proc_real_time_qradar.html))
- You must configure a process to periodically refresh your CKFREEZE and UNLOAD data sets.
- If you are using the Log File protocol method, you must configure a SFTP, FTP, or SCP server on your z/OS image for QRadar to download your LEEF event files.
- If you are using the Log File protocol method, you must allow SFTP, FTP, or SCP traffic on firewalls that are located between QRadar and your z/OS image.

For instructions on installing and configuring zSecure, see the [IBM Security zSecure Suite: CARLa-Driven Components Installation and Deployment Guide](https://www.ibm.com/docs/en/SS2RWS_2.4.0/com.ibm.zsecure.doc_2.4.0/zsec_install.pdf) ([https://www.ibm.com/docs/en/SS2RWS\\_2.4.0/com.ibm.zsecure.doc\\_2.4.0/zsec\\_install.pdf](https://www.ibm.com/docs/en/SS2RWS_2.4.0/com.ibm.zsecure.doc_2.4.0/zsec_install.pdf)).

## Create a log source for near real-time event feed

The Syslog protocol enables IBM QRadar to receive System Management Facilities (SMF) events in near real-time from a remote host.

The following DSMs are supported:

- IBM z/OS
- IBM CICS
- IBM RACF
- IBM DB2
- CA Top Secret
- CA ACF2

If QRadar does not automatically detect the log source, add a log source for your DSM on the QRadar console.

The following table describes the parameters that require specific values for event collection for your DSM:

Table 556. Log source parameters	
Parameter	Value
Log Source type	Select your DSM name from the list.
Protocol Configuration	Syslog
Log Source Identifier	Type a unique identifier for the log source.

## Log File log source parameter

If QRadar does not automatically detect the log source, add a IBM z/OS, IBM CICS, IBM RACF, IBM DB2, Broadcom CA Top Secret, or Broadcom CA ACF2 log source on the QRadar Console by using the Log File Protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from IBM z/OS, IBM CICS, IBM RACF, IBM DB2, CA Top Secret, or CA ACF2:

Table 557. Log File log source parameters	
Parameter	Value
<b>Log Source name</b>	Type a name for your log source.
<b>Log Source description</b>	Type a description for the log source.
<b>Log Source type</b>	Select your DSM name.
<b>Protocol Configuration</b>	<b>Log File</b>

Table 557. Log File log source parameters (continued)

Parameter	Value
<b>Log Source Identifier</b>	<p>Type an IP address, host name, or name to identify the event source. IP addresses or host names are suggested as they allow QRadar to identify a log file to a unique event source.</p> <p>For example, if your network contains multiple devices, such as multiple z/OS images or a file repository that contains all of your event logs, you must specify a name, IP address, or host name for the image or location that uniquely identifies events for the DSM log source. This specification enables events to be identified at the image or location level in your network that your users can identify.</p>
<b>Service Type</b>	<p>From the <b>Service Type</b> list, select the protocol that you want to use when retrieving log files from a remote server. The default is SFTP.</p> <ul style="list-style-type: none"> <li>• SFTP - SSH File Transfer Protocol</li> <li>• FTP - File Transfer Protocol</li> <li>• SCP - Secure Copy</li> </ul> <p>The underlying protocol that is used to retrieve log files for the SCP and SFTP service type requires that the server that is specified in the <b>Remote IP or Hostname</b> field has the SFTP subsystem enabled.</p>
<b>Remote IP or Hostname</b>	<p>Type the IP address or host name of the device that stores your event log files.</p>
<b>Remote Port</b>	<p>Type the TCP port on the remote host that is running the selected <b>Service Type</b>. The valid range is 1 - 65535.</p> <p>The options include ports:</p> <ul style="list-style-type: none"> <li>• FTP - TCP Port 21</li> <li>• SFTP - TCP Port 22</li> <li>• SCP - TCP Port 22</li> </ul> <p>If the host for your event files is using a non-standard port number for FTP, SFTP, or SCP, you must adjust the port value.</p>

Table 557. Log File log source parameters (continued)

Parameter	Value
<b>Remote User</b>	<p>Type the user name or user ID necessary to log in to the system that contains your event files.</p> <ul style="list-style-type: none"> <li>If your log files are on your IBM z/OS image, type the user ID necessary to log in to your IBM z/OS. The user ID can be up to 8 characters in length.</li> <li>If your log files are on a file repository, type the user name necessary to log in to the file repository. The user name can be up to 255 characters in length.</li> </ul>
<b>Remote Password</b>	Type the password necessary to log in to the host.
<b>Confirm Password</b>	Confirm the password necessary to log in to the host.
<b>SSH Key File</b>	If you select <b>SCP</b> or <b>SFTP</b> as the <b>Service Type</b> , this parameter gives you the option to define an SSH private key file. When you provide an SSH Key File, the <b>Remote Password</b> field is ignored.
<b>Remote Directory</b>	Type the directory location on the remote host from which the files are retrieved, relative to the user account you are using to log in.
<b>Recursive</b>	<p>If you want the file pattern to search sub folders in the remote directory, select this check box. By default, the check box is clear.</p> <p>If you configure SCP as the Service Type, the Recursive option is ignored.</p>
<b>FTP File Pattern</b>	<p>If you select <b>SFTP</b> or <b>FTP</b> as the <b>Service Type</b>, you can configure the regular expression (regex) needed to filter the list of files that are specified in the <b>Remote Directory</b>. All matching files are included in the processing.</p> <p>The IBM z/OS mainframe that uses IBM Security zSecure Audit writes event files by using the pattern: <code>&lt;product_name&gt;.&lt;timestamp&gt;.gz</code></p> <p>The FTP file pattern that you specify must match the name that you assigned to your event files. For example, to collect files that start with <code>zOS</code> and end with <code>.gz</code>, type the following code:</p> <pre><code>zOS.*\.gz</code></pre> <p>Use of this parameter requires knowledge of regular expressions (regex). For more information about regex, see <a href="https://docs.oracle.com/javase/tutorial/essential/regex/">Lesson: Regular Expressions</a> (<a href="https://docs.oracle.com/javase/tutorial/essential/regex/">https://docs.oracle.com/javase/tutorial/essential/regex/</a>).</p>

Table 557. Log File log source parameters (continued)

Parameter	Value
<b>FTP Transfer Mode</b>	<p>This option displays only if you select <b>FTP</b> as the <b>Service Type</b>. From the list, select <b>Binary</b>.</p> <p>The binary transfer mode is needed for event files that are stored in a binary or compressed format, such as zip, gzip, tar, or tar+gzip archive files.</p>
<b>SCP Remote File</b>	If you select <b>SCP</b> as the <b>Service Type</b> you must type the file name of the remote file.
<b>Start Time</b>	<p>Type the time of day you want the processing to begin. For example, type 00 : 00 to schedule the Log File protocol to collect event files at midnight.</p> <p>This parameter functions with the Recurrence value to establish when and how often the Remote Directory is scanned for files. Type the start time, based on a 24-hour clock, in the following format: HH: MM.</p>
<b>Recurrence</b>	<p>Type the frequency, beginning at the Start Time, that you want the remote directory to be scanned. Type this value in hours (H), minutes (M), or days (D).</p> <p>For example, type 2H if you want the remote directory to be scanned every 2 hours from the start time. The default is 1H.</p>
<b>Run On Save</b>	<p>If you want the Log File protocol to run immediately after you click <b>Save</b>, select this check box.</p> <p>After the <b>Run On Save</b> completes, the Log File protocol follows your configured start time and recurrence schedule.</p> <p>Selecting <b>Run On Save</b> clears the list of previously processed files for the Ignore Previously Processed File parameter.</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The valid range is 100 to 5000.</p>

Table 557. Log File log source parameters (continued)

Parameter	Value
<b>Processor</b>	<p>From the list, select <b>gzip</b>.</p> <p>Processors enable event file archives to be expanded and contents are processed for events. Files are processed after they are downloaded to QRadar. QRadar can process files in zip, gzip, tar, or tar+gzip archive format.</p>
<b>Ignore Previously Processed File(s)</b>	<p>Select this check box to track and ignore files that are already processed by the Log File protocol.</p> <p>QRadar examines the log files in the remote directory to determine whether a file is previously processed by the Log File protocol. If a previously processed file is detected, the Log File protocol does not download the file for processing. All files that are not previously processed are downloaded.</p> <p>This option applies only to FTP and SFTP service types.</p>
<b>Change Local Directory?</b>	<p>Select this check box to define a local directory on your QRadar for storing downloaded files during processing.</p> <p>It is suggested that you leave this check box clear. When this check box is selected, the <b>Local Directory</b> field is displayed, which gives you the option to configure the local directory to use for storing files.</p>
<b>Event Generator</b>	<p>From the <b>Event Generator</b> list, select <b>LineByLine</b>.</p> <p>The Event Generator applies more processing to the retrieved event files. Each line is a single event. For example, if a file has 10 lines of text, 10 separate events are created.</p>

## IBM Cloud Activity Tracker

The IBM QRadar DSM for IBM Cloud Activity Tracker collects Apache Kafka events from an IBM Cloud Activity Tracker application.

To integrate IBM Cloud Activity Tracker with QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent versions of the RPMs from the [IBM support website](#) (<https://www.ibm.com/support>).
  - Kafka Protocol RPM
  - DSM Common RPM
  - IBM Cloud Activity Tracker DSM RPM
2. Configure your IBM Cloud Activity Tracker system to send events to QRadar. For more information, see [Configuring IBM Cloud Activity Tracker to communicate with QRadar](#).

3. If QRadar does not automatically detect the log source, add an IBM Cloud Activity Tracker log source on the QRadar Console. For more information, see [Apache Kafka log source parameters for IBM Cloud Activity Tracker](#).

## IBM Cloud Activity Tracker DSM specifications

When you configure the IBM Cloud Activity Tracker DSM, understanding the specifications for the DSM can help ensure a successful integration. For example, knowing what the supported event format for IBM Cloud Activity Tracker is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the IBM Cloud Activity Tracker DSM.

Table 558. IBM Cloud Activity Tracker DSM specifications	
Specification	Value
Manufacturer	IBM
DSM name	IBM Cloud Activity Tracker
RPM file name	<i>DSM-IBMCloudActivityTracker-QRadar_version-build_number.noarch.rpm</i>
Protocol	Apache Kafka
Event format	JSON
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="#">IBM Cloud Activity Tracker documentation</a> ( <a href="https://cloud.ibm.com/apidocs/activity-tracker">https://cloud.ibm.com/apidocs/activity-tracker</a> )

## Configuring IBM Cloud Activity Tracker to communicate with QRadar

Before you can add a log source in IBM QRadar, you must note the values in the event stream topic and service credentials of IBM Cloud Activity Tracker. You need these values when you configure the log source.

### Before you begin

IBM Cloud Activity Tracker must be configured with an event stream service instance that has at least one topic and two service credentials. For more information, see the [IBM Cloud documentation](#) topics about *Creating an Event Streams service instance*, *Create a topic*, and *Create credentials*.

### Procedure

1. Log in to [IBM Cloud](https://cloud.ibm.com) (<https://cloud.ibm.com>).
2. From the navigation menu, select **Resource List**.
3. Expand **Services and Software**, then select your event stream instance.
4. From the Event Streams menu, select **Topics**. Note the topic name that you want to link to QRadar. You need the topic name when you configure the **Topic List** parameter in QRadar.

- From the menu, select **Service credentials**.
- From the **Service credentials** list, expand the read service credential. Note the JSON object text. You need the values from the JSON object text when you configure the **Bootstrap Server List**, **SASL Username**, and **SASL Password** parameters in QRadar.

**Tip:** For more information about configuring IBM Cloud Activity Tracker to communicate with QRadar, see the [Configuring an Event Streams target documentation](https://cloud.ibm.com/docs/atracker?topic=atracker-getting-started-target-event-streams) (<https://cloud.ibm.com/docs/atracker?topic=atracker-getting-started-target-event-streams>).

[Adding a log source](#)

## Apache Kafka log source parameters for IBM Cloud Activity Tracker

If IBM QRadar does not automatically detect the log source, add an IBM Cloud Activity Tracker log source on the QRadar Console by using the Apache Kafka protocol.

When you use the Apache Kafka protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect Apache Kafka events from IBM Cloud Activity Tracker:

<i>Table 559. Apache Kafka log source parameters for the IBM Cloud Activity Tracker DSM</i>	
Parameter	Value
<b>Log Source type</b>	IBM Cloud Activity Tracker
<b>Protocol Configuration</b>	Apache Kafka
<b>Log Source Identifier</b>	Type a unique name for the log source. The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If more than one IBM Cloud Activity Tracker log source is configured, you might want to identify the first log source as <code>ibmactivitytracker1</code> and the second log source as <code>ibmactivitytracker2</code> .
<b>Bootstrap Server List</b>	The <b>kafka_brokers_sasl</b> field value from the JSON object text that you noted when you completed the <a href="#">Configuring IBM Cloud Activity Tracker to communicate with QRadar</a> procedure.
<b>Use SASL Authentication</b>	Enabled
<b>SASL Username</b>	The <b>user</b> field value from the JSON object text that you noted when you completed the <a href="#">Configuring IBM Cloud Activity Tracker to communicate with QRadar</a> procedure.
<b>SASL Password</b>	The <b>password</b> field value from the JSON object text that you noted when you completed the <a href="#">Configuring IBM Cloud Activity Tracker to communicate with QRadar</a> procedure.

For a complete list of Apache Kafka protocol parameters and their values, see [Apache Kafka protocol configuration options](#).

**Important:** The IBM Cloud Event Streams certificate must be renewed on a 90-day expiry cycle. For this reason, the certificate must be updated in the QRadar truststore for communication to continue. Choose one the following options:

- If you are a QRadar on-premises user, to add the certificate to the /opt/qradar/conf/trusted\_certificates/ directory, you need to run the **getcert.sh** command in the /opt/qradar/getcert.sh directory. Run the following commands:

```
cd /opt/qradar/conf/trusted_certificates/
```

```
/opt/qradar/bin/getcert.sh <Kafka URL>
```

The <Kafka URL> is similar to m4ydv39cxnxjm4pq.svc02.us-east.eventstreams.cloud.ibm.com.

- If you are a QRadar on Cloud user, contact IBM support and open a support case to get the renewed certificate placed in the truststore.

For more information about IBM Event Streams certificates, see the [IBM Event Streams documentation](#) (<https://ibm.github.io/event-streams/getting-started/connecting/>).

## IBM Cloud Platform (formerly known as IBM Bluemix Platform)

IBM Cloud Platform is formerly known as IBM Bluemix Platform. The name remains the same in IBM QRadar.

The IBM QRadar DSM for the IBM Cloud Platform collects events from your IBM Cloud Platform.

The following table identifies the specifications for the IBM Cloud Platform DSM:

Table 564. IBM Bluemix Platform DSM specifications

Specification	Value
Manufacturer	IBM
DSM name	IBM Bluemix Platform
RPM file name	DSM-IBMBluemixPlatform-QRadar_version-build_number.noarch.rpm
Supported versions	N/A
Protocol	Syslog, TLS Syslog
Recorded event types	All System (Cloud Foundry) events, some application events
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.ibm.com/cloud">IBM Cloud website</a> ( <a href="https://www.ibm.com/cloud">https://www.ibm.com/cloud</a> )

To integrate IBM Cloud Platform with QRadar, complete the following steps:

You must complete the installation, third-party configuration, and QRadar configuration procedures in the order listed. Installation must always be first, but you can invert the order of the other two procedures. In some cases, no action is required for the third-party configuration and you can omit the procedure.

- If automatic updates are not enabled, download and install the most recent version of the IBM Bluemix Platform DSM RPM from the [IBM Support Website](https://www.ibm.com/support) (<https://www.ibm.com/support>) onto your QRadar Console:
- Configure your IBM Cloud Platform device to send syslog events to QRadar.

3. If QRadar does not automatically detect the log source, add an IBM Cloud Platform log source on the QRadar Console.

#### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Configuring IBM Cloud Platform to communicate with QRadar

To collect IBM Cloud Platform events, you must configure your third-party instance to send events to QRadar.

### Before you begin

You must have an app running in IBM Cloud so that you can create log drains.

### Procedure

1. From the Cloud Foundry command-line interface, type the following command to create a drain:

```
cf cups drain_name -l syslog://QRadar_IP_Address:514
```

Alternatively, use the following command:

```
cf cups drain_name -l syslog-tls://QRadar_IP_Address:1513
```

1513 is the port that is used to communicate with QRadar.

2. Bind the service instance with the following command:

```
cf bind-service BusinessApp_name drain_name
```

## Integrating IBM Cloud Platform with QRadar

In most installations, there is only the RPM. For installations where there are multiple RPMs required, (for example a PROTOCOL RPM and a DSMCommon RPM), ensure that the installation sequence reflects RPM dependency.

### Procedure

1. If required, download and install the latest TLS Syslog RPM from the [IBM Support Website](#) (<https://www.ibm.com/support>) onto your QRadar Console. You can install a protocol by using the procedure to manually install a DSM. If automatic updates are configured to install protocol updates, this procedure is not necessary.
2. Download and install the latest DSMCommon RPM from the [IBM Support Website](#) (<https://www.ibm.com/support>) onto your QRadar Console. If automatic updates are configured to install DSM updates, this procedure is not necessary.
3. Download and install the latest IBM Bluemix Platform RPM from the [IBM Support Website](#) (<https://www.ibm.com/support>) onto your QRadar Console. If automatic updates are configured to install DSM updates, this procedure is not necessary.

### What to do next

Configure a log source in QRadar by using Syslog or TLS syslog.

## Syslog log source parameters for IBM Cloud Platform

If QRadar does not automatically detect the log source, add an IBM Cloud Platform log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from IBM Cloud Platform:

Table 565. Syslog log source parameters for the IBM Cloud Platform DSM	
Parameter	Value
<b>Log Source type</b>	IBM Bluemix Platform
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	The IP address of the Cloud Loggregator. <b>Important:</b> It might be necessary to include the IP address and the port, as the Log Source Identifier. For example, 192.0.2.1:1513.

### Related tasks

[“Adding a log source” on page 5](#)

## TLS Syslog log source parameters IBM Cloud Platform

If IBM QRadar does not automatically detect the log source, add an IBM Cloud Platform log source on the QRadar Console by using the TLS Syslog protocol.

When using the TLS Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect TLS Syslog events from IBM Cloud Platform:

Table 566. TLS Syslog log source parameters for the IBM Cloud Platform DSM	
Parameter	Value
<b>Log Source type</b>	IBM Bluemix Platform
<b>Protocol Configuration</b>	TLS Syslog
<b>Log Source Identifier</b>	Type the IP address of the IBM Cloud Loggregator. <b>Important:</b> It might be necessary to include the IP address and the port, as the Log Source Identifier. For example, 192.0.2.1:1513.

For more information about TLS syslog log source parameters, see [TLS syslog protocol configuration options](#).

[“Adding a log source” on page 5](#)

## IBM Cloud Platform sample event messages

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## IBM Cloud sample message when you use the Syslog protocol

The following sample event message shows that a route is unregistered.

```
Feb 22 20:00:39 ibm.bluemixplatform.test 10.59.107.50 [job=router index=1]
{"log_level":1,"timestamp":1519329639.0902693,"message":"unregister-route","source":"vcap.gorouter.subscriber","data":{"message":{"uris":["p-mysql.sys-pcf05.cf.example.com"], "host": "10.68.232.5", "port": 8081, "tags": null, "private_instance_id": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeee"}, "}}}
```

*Table 567. QRadar field names for the IBM Cloud Platform sample event*

QRadar field name	Highlighted values in the payload
Event ID	<b>unregister-route</b>
Category	This DSM doesn't have a category field to key from for the device in the payloads. QRadar provides the value <b>Cloud Foundry</b> as a static category.
Log Source Time	<b>1519329639.0902693</b>
Source IP	<b>10.68.232.5</b>
Source Port	<b>8081</b>

## IBM DataPower

The IBM QRadar DSM collects event logs from your IBM DataPower® system.

IBM DataPower is formerly known as IBM WebSphere® DataPower.

The following table identifies the specifications for the IBM DataPower DSM.

*Table 568. IBM DataPower DSM specifications*

Specification	Value
Manufacturer	IBM
DSM Name	DataPower
RPM file name	DSM-IBMDaDataPower-QRadar_version-build_number.noarch.rpm
Supported versions	FirmwareV6 and V7
Protocol	Syslog
QRadar recorded event types	All Events
Log source type in QRadar UI	IBM DataPower
Auto discovered?	Yes
Includes identity?	No
Includes custom properties?	No
For more information	<a href="http://www.ibm.com/">IBM web page</a> ( <a href="http://www.ibm.com/">http://www.ibm.com/</a> )

To send events from IBM DataPower to QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the IBM DataPower DSM from the [IBM Support Website](#) onto your QRadar Console.
2. For each instance of IBM DataPower, configure the IBM DataPower system to communicate with QRadar.

- If QRadar does not automatically discover IBM DataPower, create a log source for each instance of IBM DataPower on the QRadar Console. Use the following IBM DataPower specific values:

Parameter	Value
Log Source Type	IBM DataPower
Protocol Configuration	Syslog

To collect IBM DataPower events, configure your third-party system to send events to IBM QRadar.

#### Related information

[Adding a log source](#)

## Configuring IBM DataPower to communicate with QRadar

To collect IBM DataPower events, configure your third-party system to send events to IBM QRadar.

### Before you begin

Review the DataPower logging documents to determine which logging configuration changes are appropriate for your deployment. See [IBM Knowledge Center](#) ([https://www.ibm.com/docs/en/SS9H2Y\\_10cd/com.ibm.dp.doc/logtarget\\_logs.html](https://www.ibm.com/docs/en/SS9H2Y_10cd/com.ibm.dp.doc/logtarget_logs.html)).

### Procedure

- Log in to your IBM DataPower system.
- In the search box on the left navigation menu, type Log Target.
- Select the matching result.
- Click **Add**.
- In the **Main** tab, type a name for the log target.
- From the **Target Type** list, select **syslog**.
- In the **Local Identifier** field, type an identifier to be displayed in the **Syslog event payloads** parameter on the QRadar user interface.
- In the **Remote Host** field, type the IP address or host name of your QRadar Console or Event Collector.
- In the **Remote Port** field, type 514.
- Under **Event Subscriptions**, add a base logging configuration with the following parameters:

Parameter	Value
<b>Event Category</b>	all
<b>Minimum Event Priority</b>	warning  <b>Important:</b> To prevent a decrease in system performance, do not use more than one word for the <b>Minimum Event Priority</b> parameter.

- Apply the changes to the log target.
- Review and save the configuration changes.

## IBM DB2

---

The IBM DB2 DSM collects events from an IBM DB2 mainframe that uses IBM Security zSecure.

When you use a zSecure process, events from the System Management Facilities (SMF) can be transformed into Log Event Extended Format (LEEF) events. These events can be sent near real-time by using UNIX Syslog protocol or IBM QRadar can retrieve the LEEF event log files by using the Log File protocol and then process the events. When you use the Log File protocol, you can schedule QRadar to retrieve events on a polling interval, which enables QRadar to retrieve the events on the schedule that you define.

To collect IBM DB2 events, complete the following steps:

1. Verify that your installation meets any prerequisite installation requirements.  
For more information about prerequisite requirements, see the [IBM Security zSecure Suite 2.2.1 Prerequisites](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/prereqs_qradar.html) ([http://www.ibm.com/support/knowledgecenter/en/SS2RWS\\_2.2.1/com.ibm.zsecure.doc\\_2.2.0/installation/prereqs\\_qradar.html](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/prereqs_qradar.html)).
2. Configure your IBM DB2 image to write events in LEEF format. For more information, see the [IBM Security zSecure Suite: CARLa-Driven Components Installation and Deployment Guide](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/setup_data_prep_qradar.html) ([http://www.ibm.com/support/knowledgecenter/en/SS2RWS\\_2.2.1/com.ibm.zsecure.doc\\_2.2.0/installation/setup\\_data\\_prep\\_qradar.html](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/setup_data_prep_qradar.html)).
3. Create a log source in QRadar for IBM DB2.
4. If you want to create a custom event property for IBM DB2 in QRadar, for more information, see the [IBM Security Custom Event Properties for IBM z/OS technical note](http://public.dhe.ibm.com/software/security/products/qradar/documents/71MR1/SIEM/TechNotes/IBM_zOS_CustomEventProperties.pdf) ([http://public.dhe.ibm.com/software/security/products/qradar/documents/71MR1/SIEM/TechNotes/IBM\\_zOS\\_CustomEventProperties.pdf](http://public.dhe.ibm.com/software/security/products/qradar/documents/71MR1/SIEM/TechNotes/IBM_zOS_CustomEventProperties.pdf)).

### Before you begin

Before you can configure the data collection process, you must complete the basic zSecure installation process and complete the post-installation activities to create and modify the configuration.

The following prerequisites are required:

- You must ensure parmlib member IFAPRDxx is enabled for IBM Security zSecure Audit on your z/OS image.
- The SCKRLOAD library must be APF-authorized.
- If you are using the direct SMF INMEM real-time interface, you must have the necessary software installed (APAR OA49263) and set up the SMFPRMxx member to include the INMEM keyword and parameters. If you decide to use the CDP interface, you must also have CDP installed and running. For more information, see the [IBM Security zSecure Suite 2.2.1: Procedure for near real-time](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/smf_proc_real_time_qradar.html) ([http://www.ibm.com/support/knowledgecenter/en/SS2RWS\\_2.2.1/com.ibm.zsecure.doc\\_2.2.0/installation/smf\\_proc\\_real\\_time\\_qradar.html](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/smf_proc_real_time_qradar.html)).
- You must configure a process to periodically refresh your CKFREEZE and UNLOAD data sets.
- If you are using the Log File protocol method, you must configure a SFTP, FTP, or SCP server on your z/OS image for QRadar to download your LEEF event files.
- If you are using the Log File protocol method, you must allow SFTP, FTP, or SCP traffic on firewalls that are located between QRadar and your z/OS image.

For instructions on installing and configuring zSecure, see the [IBM Security zSecure Suite: CARLa-Driven Components Installation and Deployment Guide](https://www.ibm.com/docs/en/SS2RWS_2.4.0/com.ibm.zsecure.doc_2.4.0/zsec_install.pdf) ([https://www.ibm.com/docs/en/SS2RWS\\_2.4.0/com.ibm.zsecure.doc\\_2.4.0/zsec\\_install.pdf](https://www.ibm.com/docs/en/SS2RWS_2.4.0/com.ibm.zsecure.doc_2.4.0/zsec_install.pdf)).

### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Create a log source for near real-time event feed

The Syslog protocol enables IBM QRadar to receive System Management Facilities (SMF) events in near real-time from a remote host.

The following DSMs are supported:

- IBM z/OS
- IBM CICS
- IBM RACF
- IBM DB2
- CA Top Secret
- CA ACF2

If QRadar does not automatically detect the log source, add a log source for your DSM on the QRadar console.

The following table describes the parameters that require specific values for event collection for your DSM:

Table 569. Log source parameters	
Parameter	Value
Log Source type	Select your DSM name from the list.
Protocol Configuration	Syslog
Log Source Identifier	Type a unique identifier for the log source.

## Log File log source parameter

If QRadar does not automatically detect the log source, add a IBM z/OS, IBM CICS, IBM RACF, IBM DB2, Broadcom CA Top Secret, or Broadcom CA ACF2 log source on the QRadar Console by using the Log File Protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from IBM z/OS, IBM CICS, IBM RACF, IBM DB2, CA Top Secret, or CA ACF2:

Table 570. Log File log source parameters	
Parameter	Value
<b>Log Source name</b>	Type a name for your log source.
<b>Log Source description</b>	Type a description for the log source.
<b>Log Source type</b>	Select your DSM name.
<b>Protocol Configuration</b>	<b>Log File</b>

Table 570. Log File log source parameters (continued)

Parameter	Value
<b>Log Source Identifier</b>	<p>Type an IP address, host name, or name to identify the event source. IP addresses or host names are suggested as they allow QRadar to identify a log file to a unique event source.</p> <p>For example, if your network contains multiple devices, such as multiple z/OS images or a file repository that contains all of your event logs, you must specify a name, IP address, or host name for the image or location that uniquely identifies events for the DSM log source. This specification enables events to be identified at the image or location level in your network that your users can identify.</p>
<b>Service Type</b>	<p>From the <b>Service Type</b> list, select the protocol that you want to use when retrieving log files from a remote server. The default is SFTP.</p> <ul style="list-style-type: none"> <li>• SFTP - SSH File Transfer Protocol</li> <li>• FTP - File Transfer Protocol</li> <li>• SCP - Secure Copy</li> </ul> <p>The underlying protocol that is used to retrieve log files for the SCP and SFTP service type requires that the server that is specified in the <b>Remote IP or Hostname</b> field has the SFTP subsystem enabled.</p>
<b>Remote IP or Hostname</b>	<p>Type the IP address or host name of the device that stores your event log files.</p>
<b>Remote Port</b>	<p>Type the TCP port on the remote host that is running the selected <b>Service Type</b>. The valid range is 1 - 65535.</p> <p>The options include ports:</p> <ul style="list-style-type: none"> <li>• FTP - TCP Port 21</li> <li>• SFTP - TCP Port 22</li> <li>• SCP - TCP Port 22</li> </ul> <p>If the host for your event files is using a non-standard port number for FTP, SFTP, or SCP, you must adjust the port value.</p>

Table 570. Log File log source parameters (continued)

Parameter	Value
<b>Remote User</b>	<p>Type the user name or user ID necessary to log in to the system that contains your event files.</p> <ul style="list-style-type: none"> <li>If your log files are on your IBM z/OS image, type the user ID necessary to log in to your IBM z/OS. The user ID can be up to 8 characters in length.</li> <li>If your log files are on a file repository, type the user name necessary to log in to the file repository. The user name can be up to 255 characters in length.</li> </ul>
<b>Remote Password</b>	Type the password necessary to log in to the host.
<b>Confirm Password</b>	Confirm the password necessary to log in to the host.
<b>SSH Key File</b>	If you select <b>SCP</b> or <b>SFTP</b> as the <b>Service Type</b> , this parameter gives you the option to define an SSH private key file. When you provide an SSH Key File, the <b>Remote Password</b> field is ignored.
<b>Remote Directory</b>	Type the directory location on the remote host from which the files are retrieved, relative to the user account you are using to log in.
<b>Recursive</b>	<p>If you want the file pattern to search sub folders in the remote directory, select this check box. By default, the check box is clear.</p> <p>If you configure SCP as the Service Type, the Recursive option is ignored.</p>
<b>FTP File Pattern</b>	<p>If you select <b>SFTP</b> or <b>FTP</b> as the <b>Service Type</b>, you can configure the regular expression (regex) needed to filter the list of files that are specified in the <b>Remote Directory</b>. All matching files are included in the processing.</p> <p>The IBM z/OS mainframe that uses IBM Security zSecure Audit writes event files by using the pattern: <code>&lt;product_name&gt;.&lt;timestamp&gt;.gz</code></p> <p>The FTP file pattern that you specify must match the name that you assigned to your event files. For example, to collect files that start with <code>zOS</code> and end with <code>.gz</code>, type the following code:</p> <pre><code>zOS.*\.gz</code></pre> <p>Use of this parameter requires knowledge of regular expressions (regex). For more information about regex, see <a href="https://docs.oracle.com/javase/tutorial/essential/regex/">Lesson: Regular Expressions</a> (<a href="https://docs.oracle.com/javase/tutorial/essential/regex/">https://docs.oracle.com/javase/tutorial/essential/regex/</a>).</p>

Table 570. Log File log source parameters (continued)

Parameter	Value
<b>FTP Transfer Mode</b>	<p>This option displays only if you select <b>FTP</b> as the <b>Service Type</b>. From the list, select <b>Binary</b>.</p> <p>The binary transfer mode is needed for event files that are stored in a binary or compressed format, such as zip, gzip, tar, or tar+gzip archive files.</p>
<b>SCP Remote File</b>	If you select <b>SCP</b> as the <b>Service Type</b> you must type the file name of the remote file.
<b>Start Time</b>	<p>Type the time of day you want the processing to begin. For example, type 00 : 00 to schedule the Log File protocol to collect event files at midnight.</p> <p>This parameter functions with the Recurrence value to establish when and how often the Remote Directory is scanned for files. Type the start time, based on a 24-hour clock, in the following format: HH: MM.</p>
<b>Recurrence</b>	<p>Type the frequency, beginning at the Start Time, that you want the remote directory to be scanned. Type this value in hours (H), minutes (M), or days (D).</p> <p>For example, type 2H if you want the remote directory to be scanned every 2 hours from the start time. The default is 1H.</p>
<b>Run On Save</b>	<p>If you want the Log File protocol to run immediately after you click <b>Save</b>, select this check box.</p> <p>After the <b>Run On Save</b> completes, the Log File protocol follows your configured start time and recurrence schedule.</p> <p>Selecting <b>Run On Save</b> clears the list of previously processed files for the Ignore Previously Processed File parameter.</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The valid range is 100 to 5000.</p>

Table 570. Log File log source parameters (continued)

Parameter	Value
<b>Processor</b>	From the list, select <b>gzip</b> . Processors enable event file archives to be expanded and contents are processed for events. Files are processed after they are downloaded to QRadar. QRadar can process files in zip, gzip, tar, or tar+gzip archive format.
<b>Ignore Previously Processed File(s)</b>	Select this check box to track and ignore files that are already processed by the Log File protocol. QRadar examines the log files in the remote directory to determine whether a file is previously processed by the Log File protocol. If a previously processed file is detected, the Log File protocol does not download the file for processing. All files that are not previously processed are downloaded. This option applies only to FTP and SFTP service types.
<b>Change Local Directory?</b>	Select this check box to define a local directory on your QRadar for storing downloaded files during processing. It is suggested that you leave this check box clear. When this check box is selected, the <b>Local Directory</b> field is displayed, which gives you the option to configure the local directory to use for storing files.
<b>Event Generator</b>	From the <b>Event Generator</b> list, select <b>LineByLine</b> . The Event Generator applies more processing to the retrieved event files. Each line is a single event. For example, if a file has 10 lines of text, 10 separate events are created.

## Integrating IBM DB2 Audit Events

The IBM DB2 DSM allows you to integrate your DB2 audit logs into IBM QRadar for analysis.

The db2audit command creates a set of comma-delimited text files with a .del extension that defines the scope of audit data for QRadar when auditing is configured and enabled. Comma-delimited files created by the db2audit command include:

- audit.del
- checking.del
- context.del
- execute.del
- objmaint.del
- secmaint.del

- sysadmin.del
- validate.del

To integrate the IBM DB2 DSM with QRadar, you must:

1. Use the db2audit command to ensure the IBM DB2 records security events. See your *IBM DB2 vendor documentation* for more information.
2. Extract the DB2 audit data of events contained in the instance to a log file, depending on your version of IBM DB2.
3. Use the Log File protocol source to pull the output instance log file and send that information back to QRadar on a scheduled basis. QRadar then imports and processes this file.

#### **Related tasks**

[“Extracting audit data for DB2 v8.x to v9.4” on page 934](#)

You can extract audit data when you are using IBM DB2 v8.x to v9.4.

[“Extracting audit data for DB2 v9.5” on page 935](#)

You can extract audit data when you are using IBM DB2 v9.5.

## **Extracting audit data for DB2 v8.x to v9.4**

You can extract audit data when you are using IBM DB2 v8.x to v9.4.

### **Procedure**

1. Log into a DB2 account with SYSADMIN privilege.
2. Type the following start command to audit a database instance:

```
db2audit start
```

For example, the start command response might resemble the following output:

```
AUD00001 Operation succeeded.
```

3. Move the audit records from the instance to the audit log:

```
db2audit flush
```

For example, the flush command response might resemble the following output:

```
AUD00001 Operation succeeded.
```

4. Extract the data from the archived audit log and write the data to .del files:

```
db2audit extract delasc
```

For example, an archive command response might resemble the following output:

```
AUD00001 Operation succeeded.
```

**Note:** Double-quotation marks ("") are used as the default text delimiter in the ASCII files, do not change the delimiter.

5. Remove non-active records:

```
db2audit prune all
```

6. Move the .del files to a storage location where IBM QRadar can pull the file. The movement of the comma-delimited (.del) files should be synchronized with the file pull interval in QRadar.

You are now ready to create a log source in QRadar to collect DB2 log files.

## Extracting audit data for DB2 v9.5

You can extract audit data when you are using IBM DB2 v9.5.

### Procedure

1. Log in to a DB2 account with SYSADMIN privilege.
2. Move the audit records from the database instance to the audit log:

```
db2audit flush
```

For example, the flush command response might resemble the following output:

```
AUD00001 Operation succeeded.
```

3. Archive and move the active instance to a new location for future extraction:

```
db2audit archive
```

For example, an archive command response might resemble the following output:

```
Node AUD Archived or Interim Log File Message
```

```
- 0 AUD00001 dbsaudit.instance.log.0.20091217125028 AUD00001 Operation succeeded.
```

**Note:** In DB2 v9.5 and later, the archive command replaces the prune command.

The archive command moves the active audit log to a new location, effectively pruning all non-active records from the log. An archive command must be complete before an extract can be executed.

4. Extract the data from the archived audit log and write the data to .del files:

```
db2audit extract delasc from files db2audit.instance.log.0.200912171528
```

For example, an archive command response might resemble the following output:

```
AUD00001 Operation succeeded.
```

**Note:** Double-quotation marks ("") are used as the default text delimiter in the ASCII files, do not change the delimiter.

5. Move the .del files to a storage location where IBM QRadar can pull the file. The movement of the comma-delimited (.del) files should be synchronized with the file pull interval in QRadar.

You are now ready to create a log source in QRadar to collect DB2 log files.

## IBM DB2 sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### IBM DB2 sample message when you use the Syslog protocol or the Log File protocol

The following sample event message shows that there was a successful termination of a database connection.

```

## IBM Defender Data Protect

The IBM QRadar DSM for IBM Defender Data Protect parses events that are issued by IBM Defender Data Protect components.

To integrate IBM Defender Data Protect with QRadar, complete the following steps:

1. If automatic updates are not enabled, download the IBM DefenderDataProtect DSM RPM from the [IBM support website](https://www.ibm.com/support) (<https://www.ibm.com/support>).
2. Configure your IBM Defender Data Protect system to send events to QRadar. For more information, see [Configuring IBM Defender Data Protect to communicate with QRadar](#).
3. If QRadar does not automatically detect the log source, add an IBM Defender Data Protect log source on the QRadar Console. For more information, see [Syslog log source parameters for IBM Defender Data Protect DSM](#).

## IBM Defender Data Protect DSM specifications

When you configure the IBM Defender Data Protect DSM, understanding the specifications for the DSM can help ensure a successful integration.

The following table describes the specifications for the IBM Defender Data Protect DSM.

Table 572. IBM Defender Data Protect DSM specifications	
Specification	Value
Manufacturer	IBM
DSM name	IBM Defender Data Protect
RPM file name	DSM-IBMDefenderDataProtect-QRadar_version-Build_number.noarch.rpm
Supported protocols	Syslog
Event format	JSON
Recorded event types	API Audit Data Protection Events Cluster Audit
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://cloud.ibm.com/apidocs/activity-tracker">IBM website</a> . ( <a href="https://cloud.ibm.com/apidocs/activity-tracker">https://cloud.ibm.com/apidocs/activity-tracker</a> )

# Configuring IBM Defender Data Protect to communicate with QRadar

To add a Syslog server by using the Cohesity UI, complete the following steps.

## Procedure

1. Log in to [IBM Cloud](https://cloud.ibm.com) (<https://cloud.ibm.com>).
2. Click **+Add** at the upper-right of the page.
3. Specify values for the following fields:
  - **IP Address/Hostname:** Specify the hostname or IP address of the syslog server.
  - **Protocol:** Specify the protocol used by the syslog server. The default is TCP, but UDP is also supported.
  - **Port:** Specify the port where the syslog server listens.
  - **Stream:** Select the logs to be sent to the syslog server from the drop-down list.
  - **Authentication (Optional):** Enabling this option sends the logs of specific facilities to the syslog server.
  - **Syslog server is enabled:** Toggle to add the syslog server to the Cohesity cluster
4. Click **Add**.

## IBM DLC Metrics

The IBM QRadar DSM for IBM Disconnected Log Collector Metrics collects Syslog metric events from an IBM Disconnected Log Collector Metrics device.

To integrate IBM Disconnected Log Collector Metrics with QRadar, complete the following steps:

- If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - DSM Common RPM
  - IBM DLC Metrics DSM RPM
- Configure your IBM Disconnected Log Collector Metrics device to send events to QRadar. For more information, see the [IBM Disconnected Log Collector documentation](https://www.ibm.com/support/knowledgecenter/SS42VS_SHR/com.ibm.dlc.doc/c_dlc_overview.html) ([https://www.ibm.com/support/knowledgecenter/SS42VS\\_SHR/com.ibm.dlc.doc/c\\_dlc\\_overview.html](https://www.ibm.com/support/knowledgecenter/SS42VS_SHR/com.ibm.dlc.doc/c_dlc_overview.html)).
- If QRadar does not automatically detect the log source, add an IBM Disconnected Log Collector Metrics log source on the QRadar Console.

### Related tasks

[“Adding a log source” on page 5](#)

## IBM DLC Metrics DSM specifications

When you configure IBM Disconnected Log Collector, understanding the specifications for the IBM DLC Metrics DSM can help ensure a successful integration. For example, knowing what the supported

version of IBM Disconnected Log Collector is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the IBM DLC Metrics DSM.

Table 577. IBM DLC Metrics DSM specifications	
Specification	Value
Manufacturer	IBM
DSM name	IBM DLC Metrics
RPM file name	DSM-IBMDLCMetrics-QRadar_version-build_number.noarch.rpm
Supported version	1.5
Protocol	Syslog, Forwarded
Event format	LEEF
Recorded event types	All DLC Metrics event types
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.ibm.com/support/knowledgecenter/SS42VS_SHR/com.ibm.dlc.doc/c_dlc_overview.html">IBM Disconnected Log Collector documentation</a> ( <a href="https://www.ibm.com/support/knowledgecenter/SS42VS_SHR/com.ibm.dlc.doc/c_dlc_overview.html">https://www.ibm.com/support/knowledgecenter/SS42VS_SHR/com.ibm.dlc.doc/c_dlc_overview.html</a> )

## Configuring IBM Disconnected Log Collector to communicate with QRadar

To forward events to IBM QRadar, you must edit the configuration file on your Disconnected Log Collector (DLC) console.

### Before you begin

IBM Disconnected Log Collector must be configured to collect events and forward them to QRadar. For more information, see the [IBM Disconnected Log Collector documentation](https://www.ibm.com/support/knowledgecenter/SS42VS_SHR/com.ibm.dlc.doc/c_dlc_overview.html) ([https://www.ibm.com/support/knowledgecenter/SS42VS\\_SHR/com.ibm.dlc.doc/c\\_dlc\\_overview.html](https://www.ibm.com/support/knowledgecenter/SS42VS_SHR/com.ibm.dlc.doc/c_dlc_overview.html)).

### About this task

IBM Disconnected Log Collector 1.5 sends some metric events to QRadar to monitor some key statistics from your Disconnected Log Collector. Disconnected Log Collector sends 3 different metric events once every minute.

The following table describes the 3 metric event types that are sent to QRadar.

Table 578. Metric event types that are sent to QRadar		
Component name	Metric ID	Description
EventProcessingFilterQueue	SpillFilesCount	If the incoming event rate exceeds the capacity to process the events, the count increases.

*Table 578. Metric event types that are sent to QRadar (continued)*

Component name	Metric ID	Description
ecs-dlc_dlc_TCP_TO_QRADAR	SpillFilesCount	If DLC is disconnected, or the incoming event rate exceeds outgoing EPS setting in DLC, the count increases.
Source Monitor	EventRate	The current eps rate that is collected by DLC.

## Procedure

1. Log in to your Disconnected Log console. You must have permission to edit files and restart services.
2. Go to the /opt/ibm/si/services/dlc/conf/config.json file.
3. Change the line "DLCMetricsEventsEnabled":false" to "DLCMetricsEventsEnabled":true", and then save your changes.
4. To restart the Disconnected Log Collector service, type the following command:

```
systemctl restart dlc
```

## What to do next

If QRadar does not automatically detect the log source, add a [Forwarded log source](#) on the QRadar Console.

## Forwarded Log source parameters for IBM DLC Metrics

If QRadar does not automatically detect the log source, add an IBM Disconnected Log Collector Metrics log source on the QRadar Console by using the Forwarded protocol.

When you use the Forwarded protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Forwarded events from IBM Disconnected Log Collector Metrics:

*Table 579. Forwarded log source parameters for the IBM DLC Metrics DSM*

Parameter	Value
<b>Log Source type</b>	IBM DLC Metrics
<b>Protocol Configuration</b>	Forwarded
<b>Log Source Identifier</b>	The hostname of your IBM Disconnected Log Collector device. If Disconnected Log Collector is configured for TLS, add the UUID of the device. For example, qavm88-145.q1labs.lab277f291f-dca9-4c59-978a-9d6deb0223b0.

```

Table 580. QRadar field names and highlighted values in the event payload

QRadar field name	Highlighted values in the event payload
Event ID	<b>DLCMetrics</b>
Source IP	<b>10.0.2.3</b> is extracted from the <b>src</b> parameter.
Device time	<b>2020-07-30T15:01:00.759-04:00</b>
Log Source Identifier	<b>ibm.dlcmetrics.test</b>

**Tip:** The **Event Category** value in QRadar is always **IBMDLCMetrics**.

## IBM Federated Directory Server

The IBM QRadar DSM collects events from IBM Federated Directory Server systems.

The following table identifies the specifications for the IBM Federated Directory Server DSM:

Table 581. IBM Federated Directory Server DSM specifications

Specification	Value
Manufacturer	IBM
DSM name	IBM Federated Directory Server
RPM file name	DSM-IBMFederated_DirectoryServer-Qradar_version-build_number.noarch.rpm
Supported versions	V7.2.0.2 and later
Event format	LEEF
Recorded event types	FDS Audit
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	Security Directory Server information in the IBM Knowledge Center ( <a href="https://www.ibm.com/support/knowledgecenter/SSVJJU/welcome.html">https://www.ibm.com/support/knowledgecenter/SSVJJU/welcome.html</a> )

To send events from IBM Federated Directory Server to QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM

- IBM Federated Directory Server DSM RPM
- Configure QRadar monitoring on your IBM Federated Directory Server device.
  - If QRadar does not automatically detect the log source, add an IBM Federated Directory Server log source on the QRadar Console. The following table describes the parameters that require specific values for IBM Federated Directory Server event collection:

*Table 582. IBM Federated Directory Serve log source parameters*

Parameter	Value
Log Source type	IBM Federated Directory Server
Protocol Configuration	Syslog
Log Source Identifier	The source IP or host name of the IBM Federated Directory Server.

## Configuring IBM Federated Directory Server to monitor security events

Configure IBM Federated Directory Server to monitor security events, which are generated when an entry is added, modified, or deleted in the target

### Procedure

1. Log in to your IBM Federated Directory Server.
2. In the navigation pane, under **Common Settings**, click **Monitoring**.
3. On the **Monitoring** page, click the QRadar tab.
4. To indicate that you want to monitor security events, on the QRadar page, select **Enabled**.
5. Configure the parameters
6. In the **Map file** field, specify the path and file name of the map file that configures the various QRadar LEEF attributes for the event.
7. Click **Select** to browse for the map file. The default value points to the LDAPSsync/QRadar.map file.
8. In the **Date format mask** field, specify a standard Java SimpleDateFormat mask to use for date values that are written in mapped LEEF attributes.

This value controls both the value of the **devTimeFormat** attribute and the formatting of date values in the event. The default value is the ISO 8601 standard mask, MMM dd yy HH:mm:ss, which creates a string, Oct 16 12 15:15:57.

## IBM Guardium

IBM Guardium<sup>®</sup> is a database activity and audit tracking tool for system administrators to retrieve detailed auditing events across database platforms.

IBM QRadar collects informational, error, alert, and warnings from IBM Guardium by using syslog. IBM QRadar receives IBM Guardium Policy Builder events in the Log Event Extended Format (LEEF).

QRadar can only automatically discover and map events of the default policies that ship with IBM Guardium. Any user configured events that are required are displayed as unknowns in QRadar and you must manually map the unknown events.

## Configuration overview

The following list outlines the process that is required to integrate IBM Guardium with QRadar.

1. Create a syslog destination for policy violation events. For more information, see [“Creating a syslog destination for events” on page 944](#).
2. Configure your existing policies to generate syslog events. For more information, see [“Configuring policies to generate syslog events” on page 945](#).
3. Install the policy on IBM Guardium. For more information, see [“Installing an IBM Guardium Policy ” on page 945](#).
4. Configure the log source in QRadar. For more information, see [“Syslog log source parameters for IBM Guardium” on page 946](#).
5. Identify and map unknown policy events in QRadar. For more information, see [“Creating an event map for IBM Guardium events” on page 946](#).

## Creating a syslog destination for events

To create a syslog destination for these events on IBM Guardium, you must log in to the command line interface (CLI) and define the IP address for IBM QRadar.

### Procedure

1. Using SSH, log in to IBM Guardium as the default user.

Username: <username>

Password: <password>

2. Type the following command to configure the syslog destination for informational events:

```
store remote add daemon.info <IP address>:<port> <tcp|udp>
```

For example,

```
store remote add daemon.info <IP_address> tcp
```

Where:

- <IP address> is the IP address of your QRadar Console or Event Collector.
- <port> is the syslog port number that is used to communicate to the QRadar Console or Event Collector.
- <tcp|udp> is the protocol that is used to communicate to the QRadar Console or Event Collector.

3. Type the following command to configure the syslog destination for warning events:

```
store remote add daemon.warning <IP address>:<port> <tcp|udp>
```

Where:

- <IP address> is the IP address of your QRadar Console or Event Collector.
- <port> is the syslog port number that is used to communicate to the QRadar Console or Event Collector.
- <tcp|udp> is the protocol that is used to communicate to the QRadar Console or Event Collector.

4. Type the following command to configure the syslog destination for error events:

```
store remote add daemon.err <IP address>:<port> <tcp|udp>
```

Where:

- <IP address> is the IP address of your QRadar Console or Event Collector.
- <port> is the syslog port number that is used to communicate to the QRadar Console or Event Collector.

- <tcp|udp> is the protocol that is used to communicate to the QRadar Console or Event Collector.

5. Type the following command to configure the syslog destination for alert events:

```
store remote add daemon.alert <IP address>:<port> <tcp|udp>
```

Where:

- <IP address> is the IP address of your QRadar Console or Event Collector.
- <port> is the syslog port number that is used to communicate to the QRadar Console or Event Collector.
- <tcp|udp> is the protocol that is used to communicate to the QRadar Console or Event Collector.

You are now ready to configure a policy for IBM InfoSphere® Guardium.

## Configuring policies to generate syslog events

Policies in IBM Guardium are responsible for reacting to events and forwarding the event information to IBM QRadar.

### Procedure

1. Click the **Tools** tab.
2. From the left navigation, select **Policy Builder**.
3. From the **Policy Finder** pane, select an existing policy and click **Edit Rules**.
4. Click **Edit this Rule individually**.

The **Access Rule Definition** is displayed.

5. Click **Add Action**.
6. From the **Action** list, select one of the following alert types:
  - **Alert Per Match** - A notification is provided for every policy violation.
  - **Alert Daily** - A notification is provided the first time a policy violation occurs that day.
  - **Alert Once Per Session** - A notification is provided per policy violation for unique session.
  - **Alert Per Time Granularity** - A notification is provided per your selected time frame.
7. From the **Message Template** list, select QRadar.
8. From **Notification Type**, select **SYSLOG**.
9. Click **Add**, then click **Apply**.
10. Click **Save**.
11. Repeat “Configuring policies to generate syslog events” on page 945 for all rules within the policy that you want to forward to QRadar.

For more information on configuring a policy, see your *IBM InfoSphere Guardium* vendor documentation. After you have configured all of your policies, you are now ready to install the policy on your IBM Guardium system.

**Note:** Due to the configurable policies, QRadar can only automatically discover the default policy events. If you have customized policies that forward events to QRadar, you must manually create a log source to capture those events.

## Installing an IBM Guardium Policy

Any new or edited policy in IBM Guardium must be installed before the updated alert actions or rule changes can occur.

### Procedure

1. Click the **Administration Console** tab.

2. From the left navigation, select **Configuration > Policy Installation**.
3. From the **Policy Installer** pane, select a policy that you modified in “Configuring policies to generate syslog events” on page 945.
4. From the **drop-down** list, select **Install and Override**.

A confirmation is displayed to install the policy to all Inspection Engines.

5. Click **OK**.

For more information on installing a policy, see your *IBM InfoSphere Guardium* vendor documentation. After you install all of your policies, you are ready to configure the log source in IBM QRadar.

## Syslog log source parameters for IBM Guardium

If QRadar does not automatically detect the log source, add an IBM Guardium log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from IBM Guardium:

Table 583. Syslog log source parameters for the IBM Guardium DSM	
Parameter	Value
<b>Log Source type</b>	IBM Guardium
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the IBM InfoSphere Guardium appliance.

### Related tasks

[“Adding a log source” on page 5](#)

## Creating an event map for IBM Guardium events

Event mapping is needed for some IBM Guardium events. Due to the customizable nature of policy rules, most events, except the default policy events do not contain a predefined IBM QRadar Identifier (QID) map to categorize security events.

### About this task

You can individually map each event for your device to an event category in QRadar. Mapping events allows QRadar to identify, coalesce, and track recurring events from your network devices. Until you map an event, all events that are displayed in the **Log Activity** tab for IBM Guardium are categorized as unknown. Unknown events are easily identified as the **Event Name** column and **Low Level Category** columns display Unknown.

As your device forwards events to QRadar, it can take time to categorize all events for a device. Some events might not be generated immediately by the event source appliance or software. It is helpful to know how to quickly search for unknown events. When you know how to search for unknown events, we suggest that you repeat this search until you are satisfied that most of your events are identified.

### Procedure

1. Log in to QRadar.
2. Click the **Log Activity** tab.
3. Click **Add Filter**.
4. From the first list, select **Log Source**.

5. From the **Log Source Group** list, select the log source group or **Other**.

Log sources that are not assigned to a group are categorized as Other.

6. From the **Log Source** list, select your IBM Guardium log source.

7. Click **Add Filter**.

The **Log Activity** tab is displayed with a filter for your log source.

8. From the **View** list, select **Last Hour**.

Any events that are generated by the IBM Guardium DSM in the last hour are displayed. Events that are displayed as unknown in the **Event Name** column or **Low Level Category** column require event mapping in QRadar.

**Note:** You can save your existing search filter by clicking **Save Criteria**.

You are now ready to modify the event map.

## Modifying the event map

Modifying an event map allows for the manual categorization of events to a IBM QRadar Identifier (QID) map. Any event that is categorized to a log source can be remapped to a new QRadar Identifier (QID).

### About this task

IBM Guardium event map events that don't have a defined log source are not mapped to an event. Events without a log source display **SIM Generic Log** in the **Log Source** column.

### Procedure

1. On the **Event Name column**, double-click an unknown event for IBM Guardium.

The detailed event information is displayed.

2. Click **Map Event**.

3. From the **Browse for QID** pane, select any of the following search options to narrow the event categories for a QRadar Identifier (QID):

- From the **High-Level Category** list, select a high-level event categorization.
- For a full list of high-level and low-level event categories or category definitions, see the Event Categories section of the *IBM QRadar Administration Guide*.
- From the **Low-Level Category** list, select a low-level event categorization.
- From the **Log Source Type** list, select a log source type.

The **Log Source Type** list gives the option to search for QIDs from other log sources. Searching for QIDs by log source is useful when events are similar to another existing network device. For example, IBM Guardium provides policy events, you might select another product that likely captures similar events.

4. To search for a QID by name, type a name in the **QID/Name** field.

The **QID/Name** field gives the option to filter the full list of QIDs for a specific word, for example, policy.

5. Click **Search**.

A list of QIDs are displayed.

6. Select the QID you want to associate to your unknown event.

7. Click **OK**.

QRadar maps any additional events that are forwarded from your device with the same QID that matches the event payload. The event count increases each time that the event is identified by QRadar.

If you update an event with a new QRadar Identifier (QID) map, past events that are stored in QRadar are not updated. Only new events are categorized with the new QID.

## IBM Guardium sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### IBM Guardium sample message when you use the Syslog protocol

**Sample 1:** The following sample event message shows that an attempted login to the database is not successful.

```
<30>Aug 19 12:33:31 ibm.guardium.test guard_sender[4486]:

## IBM i

The IBM QRadar DSM for IBM i, formerly known as AS/400 iSeries, collects audit records and event information from IBM i systems.

The following table identifies the specifications for the IBM i DSM:

Table 586. IBM i DSM specifications

Specification	Value
Manufacturer	IBM
DSM name	IBM i
Supported versions	5R4
RPM file name	DSM-IBMi-QRadar_version-build_number.noarch.rpm
Protocol	Log File Protocol Syslog
Event Format	<ul style="list-style-type: none"> <li>Common Event Format (CEF) - CEF:0 is supported.</li> <li>Log Event Extended Format (LEEF) - LEEF:1.0 is supported.</li> </ul>
Recorded event types	Audit records and events
Automatically discovered?	No
Includes identity?	Yes
Includes custom properties?	No
More information	<a href="http://www.ibm.com/">IBM website (http://www.ibm.com/)</a>

To collect events from IBM i systems, complete the following steps:

- If automatic updates are not enabled, download and install the most recent version of the IBM i DSM RPM from the [IBM Support Website](#) onto your QRadar Console.
- Configure your IBM i system to communicate with QRadar.
- Add an IBM i log source on the QRadar Console by using the following table to configure the parameters that are required to collect IBM i events:

*Table 587. IBM i log source parameters*

Parameter	Value
Log Source Type	IBM i
Protocol Configuration	Log File If you are using the PowerTech Interact or LogAgent for System i software to collect CEF formatted syslog messages, you must select the <b>Syslog</b> option
Service Type	Secure File Transfer Protocol (SFTP)

For more information about configuring parameters for the Log File protocol, see [Log File protocol configuration options](#).

## Configuring IBM i to integrate with IBM QRadar

You can integrate IBM i with IBM QRadar.

### Procedure

- From IBM [Fix Central](http://www.ibm.com/support/fixcentral) (<http://www.ibm.com/support/fixcentral>), download the following file:  
**AJLIB.SAVF**
- Copy the AJLIB.SAVF file to a computer or terminal that has FTP access to IBM i.
- Create a generic online SAVF file on the IBM i by typing the following command:  
**CRTSAVF QGPL/SAVF**
- Use FTP on the computer or terminal to replace the IBM i generic SAVF file with the AJLIB.SAVF file that you downloaded.  
Type the following commands:  
**bin**  
**cd qgpl**  
**lcd c:\**  
**put ajlib.savf AJLIB**  
**quit**

If you are transferring your SAVF file from another IBM i system, send the file by placing the FTP sub-command mode **BINARY** before the **GET** or **PUT** statement.

- Restore the AJLIB file on IBM i by typing the following command:  
**RSTLIB SAVLIB(AJLIB) DEV(\*SAVF) SAVF(QGPL/AJLIB)**

AJLIB provides the mapping and data transfer support that is needed to send IBM i audit journal entries to QRadar.

## 6. Run **AJLIB/SETUP**

The setup screen is used to configure AJLIB for FTP, SFTP, or a local path to receive the processed entries.

The server user ID is required for FTP or SFTP, and a password is required for FTP. While FTP handles line delimiter conversions, you set the line feed to the expected value for the type of system that receives the SFTP transfers.

## 7. If you want to use SFTP, run **AJLIB/GENKEY**.

This command generates the SSH key pair that is required for SFTP authentication. If the key pair exists, it is not replaced. If you want to generate a new key pair, before you run this command, remove the existing key files from the /ajplib/.ssh directory.

For more information about SSH key pair configuration on the IBM i , see <http://www-01.ibm.com/support/docview.wss?uid=nas8N1012710>

## 8. After you generate a key pair, use the following steps to enable the use of the key pair on the server:

- a) Copy the id\_rsa.pub file from the /ajplib directory to the SSH server, and then install it in the appropriate folder.
- b) Ensure that the SSH server is added to the known\_hosts file of the user profile that runs the **AJLIB/AUDITJRN** command.

## 9. Use the appropriate user profile to do the following steps:

- a) Start a PASE (Portable Application Solutions Environment) shell by typing the following command:

```
call qp2term
```

- b) Start a session with the SSH server by typing the following command:

```
ssh -T <user>@<serveraddress>
```

- c) If prompted, accept the system key, and enter a password.

- d) Type exit, to close the SSH session.

If you want to run these steps under a different IBM i profile than the one that runs the **AJLIB/AUDITJRN** command, copy the .ssh directory and known\_hosts file to the home directory of the profile that is used to run this command.

## 10. To configure the filtering of specific entry types, use the **AJLIB/SETENTTYP** command.

## 11. Set up the data collection start date and time for the audit journal library (AJLIB) by typing the following command:

**AJLIB/DATETIME**

If you start the audit journal collector, a failure message is sent to QSYSOPR.

The setup function sets a default start date and time for data collection from the audit journal to 08:00:00 of the current day.

To preserve your previous start date and time information from a previous installation, you must run **AJLIB/DATETIME**. Record the previous start date and time and type those values when you run **AJLIB/SETUP**. The start date and time must contain a valid date and time in the six character system date and system time format. The end date and time must be a valid date and time or left blank.

## 12. Run **AJLIB/AUDITJRN**.

The audit journal collection program starts and sends the records to your remote FTP server: If the transfer to the FTP server fails, a message is sent to QSYSOPR. The process for starting **AJLIB/AUDITJRN** is typically automated by an IBM i job Scheduler, which collects records periodically.

If the FTP transfer is successful, the current date and time information is written into the start time for **AJLIB/DATETIME** to update the gather time, and the end time is set to blank. If the FTP transfer fails, the export file is erased and no updates are made to the gather date or time.

## What to do next

For more information about AJLIB field definitions, see [Commonly asked IBM i \(AS/400 iSeries\) DSM Integration Questions for QRadar](https://www.ibm.com/support/pages/node/246075) (<https://www.ibm.com/support/pages/node/246075>).

## Manually extracting journal entries for IBM i

You can run the DSPJRN command to extract journal entries for IBM i when an audit journal receiver chain is broken.

### About this task

Run the ALJIB/DATETIME command to set the Start Date to \*OUTF. This command forces the processing program to use the pre-built QTEMP/AUDITJRN outfile for parsing, instead of using the date time to extract journal entries. After you run the parsing program command AJLIB/AUDITJRN, the DATETIME is set to the new processing date.

### Procedure

1. Log in to your IBM i system command-line interface (CLI).
2. Run **DSPJRN**.

The only changeable parameters in the following example are **RCVRNG** and **ENTTYP**. Do not change any other command parameters. Ensure that **ENTTP** matches the **AJLIB/SETENTTYP** command settings.

```
DSPJRN JRN(QSYS/QAUDJRN) RCVRNG(AUDRCV0001 AUDRCV0003)
JRNCD((T)) ENTTYP(*ALL)
OUTPUT(*OUTFILE) OUTFILEFMT(*TYPE5) OUTFILE(QTEMP/AUDITJRN)
ENTDTALEN(*VARLEN 16000 100)
```

3. To set the **Date Time** to use outfile **\*OUTF** support, run the **AJLIB/DATETIME** command.

```
DSPJRN Start and End Times

F3 EXIT Without Update
ENTER Exit With Update

Blank End Date and/or Time will use current Date and/or Time

Start Date *OUTF
Start Time 113109
End Date _____
End Time _____

F3=Exit
```

Figure 45. DSPJRN Start and End Times

#### 4. Run **AJLIB/AUDITJRN**.

### Results

The **DATETIME** is set to the next start date.

## Pulling Data when you use the Log File Protocol

You can configure IBM i as the log source, and to use the log file protocol in IBM QRadar:

### Procedure

1. To configure QRadar to receive events from an IBM i system, you must select the IBM i option from the **Log Source Type** list when you add a log source in QRadar.
2. To configure the log file protocol for the IBM i DSM, you must select the **Log File** option from the **Protocol Configuration** list and define the location of your FTP server connection settings.

**Note:** If you are using the PowerTech Interact or LogAgent for System i software to collect CEF formatted syslog messages, you must select the **Syslog** option from the **Protocol Configuration** list.

3. Use the log file protocol option that you select a secure protocol for transferring files, such as Secure File Transfer Protocol (SFTP).

### What to do next

For a complete list of Log File protocol parameter options, see [Log File protocol configuration options](#).

### Related tasks

[“Adding a log source” on page 5](#)

# Configuring Townsend Security Alliance LogAgent to integrate with QRadar

You can collect all audit logs and system events from Townsend Security Alliance LogAgent. You must configure Alliance LogAgent for the IBM QRadar LEEF and configure a destination that specifies QRadar as the syslog server.

## Procedure

1. Log in to your Townsend Security Alliance LogAgent appliance.
2. Add the **ALLSYL100** to your library list by typing the following command: **addlibb allsy1100**.
3. To display the main menu select **go symain**.
4. Select the option for Configuration
5. Select **Configure Alliance LogAgent** and configure the following parameters.

Parameter	Description
<b>Interface version</b>	4=IBM QRadar LEEF
<b>Transmit</b>	1=Yes
<b>Data queue control</b>	1=Yes
<b>Format</b>	4=IBM QRadar LEEF

6. From the configuration menu, select **Work With TCP Clients**.
7. Select option 2 to change the **SYSLOGD** client and configure the following parameters.

Parameter	Description
<b>Status</b>	1=Active
<b>Autostart client</b>	1=Yes
<b>Remote IP address</b>	IP address of QRadar
<b>Remote port number</b>	514

8. From the **Configuration** menu, select **Start LogAgent Subsystem**. Events flow to QRadar.

## What to do next

After TCP services start, consider automatically starting the Alliance LogAgent subsystem by modifying your IPL QSTRUP program to include the following statements:

```
/* START ALLIANCE LOGAGENT */
QSYS/STRBS ALLSYL100/ALLSYL100
MONMSG MSGID(CPF0000)
```

For more information about installing and configuring for **Independent Auxiliary Storage Pool** operation, and more filter options for events, see your vendor documentation.

## IBM i sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage returns or line feed characters.

## IBM i sample message when you use the Syslog protocol

The following sample event message shows that DRDA Distributed Relational DB access is allowed.

**Important:** The logs that you send to QRadar must be tab-delimited. If you cut and paste the code from this sample, make sure that you press the tab key where indicated by the <tab> variables, then remove the variables.

## IBM IMS

The IBM Information Management System (IMS) DSM for IBM QRadar allows you to use an IBM mainframe to collect events and audit IMS database transactions.

To integrate IBM IMS events with QRadar, you must download scripts that allow IBM IMS events to be written to a log file.

Overview of the event collection process:

1. The IBM mainframe records all security events as Service Management Framework (SMF) records in a live repository.
2. The IBM IMS data is extracted from the live repository using the SMF dump utility. The SMF file contains all of the events and fields from the previous day in raw SMF format.
3. The qeximsloadlib.trs program pulls data from the SMF formatted file. The qeximsloadlib.trs program only pulls the relevant events and fields for QRadar and writes that information in a condensed format for compatibility. The information is saved in a location accessible by QRadar.
4. QRadar uses the log file protocol source to retrieve the output file information for QRadar on a scheduled basis. QRadar then imports and processes this file.

## Configuring IBM IMS

You can integrate IBM IMS with QRadar:

### Procedure

1. From the IBM support website (<http://www.ibm.com/support>), download the following compressed file:

`QexIMS_bundled.tar.gz`

2. On a Linux-based operating system, extract the file:

```
tar -zxf qexims_bundled.tar.gz
```

The following files are contained in the archive:

- `qexims_jcl.txt` - Job Control Language file
- `qeximsloadlib.trs` - Compressed program library (requires IBM TRSMAIN)
- `qexims_trsmain_JCL.txt` - Job Control Language for TRSMAIN to decompress the .trs file

- Load the files onto the IBM mainframe by using the following methods:

Upload the sample `qexims_trsmain_JCL.txt` and `qexims_jcl.txt` files by using the TEXT protocol.

- Upload the `qeximsloadlib.trs` file by using BINARY mode transfer and append to a pre-allocated data set. The `qeximsloadlib.trs` file is a terced file that contains the executable (the mainframe program QexIMS). When you upload the `.trs` file from a workstation, pre-allocate a file on the mainframe with the following DCB attributes: DSORG=PS, RECFM=FB, LRECL= 1024, BLKSIZE=6144. The file transfer type must be binary mode and not text.

**Note:** QexIMS is a small C mainframe program that reads the output of the IMS log file (EARLOUT data) line by line. QexIMS adds a header to each record that contains event information, for example, record descriptor, the date, and time. The program places each field into the output record, suppresses trailing blank characters, and delimits each field with the pipe character. This output file is formatted for QRadar and the blank suppression reduces network traffic to QRadar. This program does not need much CPU or I/O disk resources.

- Customize the `qexims_trsmain_JCL.txt` file according to your installation-specific information for parameters.

For example, jobcard, data set naming conventions, output destinations, retention periods, and space requirements.

The `qexims_trsmain_JCL.txt` file uses the IBM utility TRSMAN to extract the program that is stored in the `qeximsloadlib.trs` file.

An example of the `qexims_trsmain_JCL.txt` file includes:

```
//TRSMAN JOB (yourvalidjobcard),Q1labs,
// MSGCLASS=V
//DEL EXEC PGM=IEFBR14 //D1 DD DISP=(MOD,DELETE),DSN=<yourhlq>.QEXIMS.TRS
// UNIT=SYSDA, // SPACE=(CYL,(10,10))
//TRSMAN EXEC PGM=TRSMAN,PARM='UNPACK'
//SYSPRINT DD SYSOUT=*,DCB=(LRECL=133,BLKSIZE=12901,RECFM=FBA)
//INFILE DD DISP=SHR,DSN=<yourhlq>.QEXIMS.TRS
//OUTFILE DD DISP=(NEW,CATLG,DELETE),
// DSN=<yourhlq>.LOAD, // SPACE=(CYL,(1,1,5),RLSE),UNIT=SYSDA
//
```

The `.trs` input file is an IBM TERSE formatted library and is extracted by running the JCL, which calls the TRSMAN. This terced file, when extracted, creates a PDS linklib with the qexims program as a member.

- You can STEPLIB to this library or choose to move the program to one of the LINKLIBs that are in LINKLST. The program does not require authorization.
- The `qexims_jcl.txt` file is a text file that contains a sample JCL. You must configure the job card to meet your configuration.

The `qexims_jcl.txt` sample file includes:

```
//QEXIMS JOB (T,JXPO,JKSD0093),DEV,NOTIFY=Q1JACK,
// MSGCLASS=P,
// REGION=OM /* /*QEXIMS JCL VERSION 1.0 FEBRUARY 2011
///*
//***** Change dataset names to site specific dataset names *
//*****
//SET1 SET IMSOUT='Q1JACK.QEXIMS.OUTPUT',
// IMSIN='Q1JACK.QEXIMS.INPUT.DATA'
//*****
//** Delete old datasets *
//*****
//DEL EXEC PGM=IEFBR14 //DD1 DD DISP=(MOD,DELETE),DSN=&IMSOUT,
// UNIT=SYSDA, // SPACE=(CYL,(10,10)), // DCB=(RECFM=FB,LRECL=80)
//*****
//** Allocate new dataset
//*****
//ALLOC EXEC PGM=IEFBR14 //DD1 DD DISP=(NEW,CATLG),DSN=&IMSOUT,
// SPACE=(CYL,(21,2)),
```

```

// DCB=(RECFM=VB,LRECL=1028,BLKSIZE=6144)
//EXTRACT EXEC PGM=QEXIMS,DYNAMNBR=10,
// TIME=1440 //STEPLIB DD DISP=SHR,DSN=Q1JACK.C.LOAD
//SYSTSIN DD DUMMY
//SYSTSPRT DD SYSOUT=*
//SYSPRINT DD SYSOUT=* //IMSIN DD DISP=SHR,DSN=&IMSIN
//IMSOUT DD DISP=SHR,DSN=&IMSOUT
///*FTP EXEC PGM=FTP,REGION=3800K /*INPUT DD *
//*<target server>
//*<USER>
//*<PASSWORD>
//*ASCII /*PUT '<IMSOUT>' /TARGET DIRECTORY/<IMSOUT>
//*QUIT
//*OUTPUT DD SYSOUT=* /*SYSPRINT DD SYSOUT=*
//*

```

8. After the output file is created, you must make one of the following choices:

- Schedule a job to transfer the output file to an interim FTP server.
- Each time the job completes, the output file is forwarded to an interim FTP server. You must configure the following parameters in the sample JCL to successfully forward the output to an interim FTP server:

For example:

```

//*FTP EXEC PGM=FTP,REGION=3800K
//*INPUT DD *
//*<target server>
//*<USER>
//*<PASSWORD> /*ASCII /*PUT '<IMSOUT>'
/TARGET DIRECTORY/<IMSOUT>
//*QUIT //*OUTPUT DD SYSOUT=*
//*SYSPRINT DD SYSOUT=*

```

Where:

- <target server> is the IP address or host name of the interim FTP server to receive the output file.
- <USER> is the user name required to access the interim FTP server.
- <PASSWORD> is the password required to access the interim FTP server.
- <IMSOUT> is the name of the output file saved to the interim FTP server.

For example:

PUT 'Q1JACK.QEXIMS.OUTPUT.C320' /192.0.2.1/IMS/QEXIMS.OUTPUT.C320

**Note:** You must remove commented lines that begin with /\* for the script to properly forward the output file to the interim FTP server.

You are now ready to configure the log file protocol.

9. Schedule QRadar to retrieve the output file from IBM IMS.

If the mainframe is configured to serve files through FTP, SFTP, or allow SCP, then no interim FTP server is required and QRadar can pull the output file directly from the mainframe. The following text must be commented out using /\* or deleted from the qexims\_jcl.txt file:

```

//*FTP EXEC PGM=FTP,REGION=3800K /*INPUT DD *
//*<target server>
//*<USER> /*<PASSWORD> /*ASCII
///*PUT '<IMSOUT>' 
/<TARGET DIRECTORY/<IMSOUT>
//*QUIT //*OUTPUT DD SYSOUT=*
//*SYSPRINT DD SYSOUT=*

```

You are now ready to configure the log file protocol.

## Log File log source parameters for IBM IMS

If QRadar does not automatically detect the log source, add an IBM IMS log source on the QRadar Console by using the Log File protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from IBM IMS:

Table 589. Log File log source parameters for the IBM IMS DSM	
Parameter	Value
<b>Log Source type</b>	IBM IMS
<b>Protocol Configuration</b>	Log File
<b>Log Source Identifier</b>	Type the IP address or host name for the log source. The log source identifier must be unique for the log source type.

For a complete list of Log File protocol parameters and their values, see [Log File protocol configuration options](#).

### Related tasks

[“Adding a log source” on page 5](#)

## IBM Informix Audit

The IBM Informix® Audit DSM allows IBM QRadar to integrate IBM Informix audit logs into QRadar for analysis.

QRadar retrieves the IBM Informix archived audit log files from a remote host using the log file protocol configuration. QRadar records all configured IBM Informix Audit events.

When configuring your IBM Informix to use the log file protocol, make sure the host name or IP address configured in the IBM Informix is the same as configured in the **Remote Host** parameter in the log file protocol configuration.

You are now ready to configure the log source and protocol in QRadar:

- To configure QRadar to receive events from an IBM Informix device, you must select the IBM Informix Audit option from the **Log Source Type** list.
- To configure the log file protocol, you must select the **Log File** option from the **Protocol Configuration** list.

Use a secure protocol for transferring files, such as Secure File Transfer Protocol (SFTP).

### Related concepts

[“Log File protocol configuration options” on page 155](#)

To receive events from remote hosts, configure a log source to use the Log File protocol.

## IBM Lotus Domino

---

You can integrate an IBM Lotus Domino device with IBM QRadar. An IBM Lotus Domino device accepts events by using SNMP.

### Setting Up SNMP Services

Set up SNMP services on the IBM Lotus Domino server to accept events.

#### Procedure

1. Install the Lotus Domino SNMP Agent as a service. From the command prompt, go to the Lotus\Domino directory and type the following command:

```
Insnmp -SC
```

2. Confirm that the Microsoft SNMP service is installed.

3. Start the SNMP and LNSNMP services. From a command prompt, type the following commands:

- net start snmp
- net start lnsnmp

4. Select **Start > Program > Administrative Tools > Services** to open the **Services MMC**

5. Double-click on the **SNMP** service and select the **Traps** tab.

6. In the **Community name** field, type public and click **add to list**.

7. In the **Traps destinations** section, select **Add** and type the IP address of your IBM QRadar. Click **Add**.

8. Click **OK**.

9. Confirm that both SNMP agents are set to **Automatic** so they run when the server boots.

### Setting up SNMP in AIX

TCP/IP and SNMP must be properly installed and configured on the server before you set up SNMP in AIX.

#### Before you begin

You must log in as a root user.

#### Procedure

1. Stop the LNSNMP service with the following command:

```
lnsnmp.sh stop
```

2. Stop the SNMP subsystem with the following command:

```
stopsrc -s snmpd
```

3. Configure SNMP to accept LNSNMP as an SMUX peer. Add the following line to /etc/snmpd.conf  
"Lotus Notes Agent" 1.3.6.1.4.1.334.72 "NotesPasswd"

4. Configure SNMP to accept an SMUX association from LNSNMP. Add the following line to /etc/snmpd.conf or /etc/snmpdv3.conf

```
smux 1.3.6.1.4.1.334.72 NotesPasswd
```

5. Start the SNMP subsystem with the following command:

```
startsrc -s snmpd
```

6. Start the LNSNMP service with the following command:

```
lnsnmp.sh start
```

7. Create a link to the LNSNMP script

```
ln -f -s /opt/ibm/lotus/notes/latest/ibmpow/lnsnmp.sh /etc/lnsnmp.rc
```

- Configure LNSNMP service to start during the system restart. Add the following line to the end of /etc/rc.tcpip
- ```
/etc/linsnmp.rc start
```

## Starting the Domino Server Add-in Tasks

After you configure the SNMP services, you must start the Domino server add-in tasks for each Domino partition.

### Procedure

- Log in to the Domino Server console.
- To support SNMP traps for Domino events, type the following command to start the Event Interceptor add-in task:  

```
load intrcpt
```
- To support Domino statistic threshold traps, type the following command to start the Statistic Collector add-in task:  

```
load collect
```
- Arrange for the add-in tasks to be restarted automatically the next time that Domino is restarted. Add **intrcpt** and **collect** to the *ServerTasks* variable in Domino's *NOTES.INI* file.

## Configuring SNMP Services

You can configure SNMP services:

### About this task

Configurations might vary depending on your environment. See your vendor documentation for more information.

### Procedure

- Open the Domino Administrator utility and authenticate with administrative credentials.
- Click the **Files** tab, and the **Monitoring Configuration** (*events4.nsf*) document.
- Expand the **DDM Configuration** Tree and select **DDM Probes By Type**.
- Select **Enable Probes**, and then select **Enable All Probes In View**.

**Note:** You might receive a warning when you complete this action. This warning is a normal outcome, as some of the probes require more configuration.

- Select **DDM Filter**.

You can either create a new DDM Filter or edit the existing DDM Default Filter.

- Apply the DDM Filter to enhanced and simple events. Choose to log all event types.
- Depending on the environment, you can choose to apply the filter to all servers in a domain or only to specific servers.
- Click **Save**. Close when finished.

- Expand the **Event Handlers** tree and select **Event Handlers By Server**.

- Select **New Event Handler**.

- Configure the following parameters:

- Basic - Servers to monitor:** Choose to monitor either all servers in the domain or only specific servers.
- Basic - Notification trigger:** Any event that matches the criteria.
- Event - Criteria to match:** Events can be any type.

- **Event - Criteria to match:** Events must be one of these priorities (Check all the boxes).
- **Event - Criteria to match:** Events can have any message.
- **Action - Notification method:** SNMP Trap.
- **Action - Enablement:** Enable this notification.

12. Click **Save**. Close when finished.

You are now ready to configure the log source in IBM QRadar.

## SNMPv2 log source parameters for IBM Lotus Domino

If QRadar does not automatically detect the log source, add an IBM Lotus Domino log source on the QRadar Console by using the SNMPv2 protocol.

When using the SNMPv2 protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect SNMPv2 events from IBM Lotus Domino:

| Table 590. SNMPv2 log source parameters for the IBM Lotus Domino DSM |                                                                                                                                                                                                            |
|----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                            | Value                                                                                                                                                                                                      |
| <b>Log Source type</b>                                               | IBM Lotus Domino                                                                                                                                                                                           |
| <b>Protocol Configuration</b>                                        | SNMPv2                                                                                                                                                                                                     |
| <b>Log Source Identifier</b>                                         | <p>Type an IP address, host name, or name to identify the SNMPv2 event source.</p> <p>IP addresses or host names are recommended as they allow QRadar to identify a log file to a unique event source.</p> |

For a complete list of SNMPv2 protocol parameters and their values, see [“SNMPv2 protocol configuration options” on page 219](#).

## IBM Lotus Domino sample event messages

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### IBM Lotus Domino sample message when you use the SNMPv2 protocol

The following sample event message shows the successful authentication for SMTP server.

```
CN=w2k864d/0=q11abs 6 5 1248804028 SMTP Server: Authentication succeeded for user testuser;
connecting host example.com 17863
```

| Table 591. Highlighted fields in the IBM Lotus Domino event |                                                                           |
|-------------------------------------------------------------|---------------------------------------------------------------------------|
| QRadar field name                                           | Highlighted payload field name                                            |
| <b>Event ID</b>                                             | The event ID in QRadar is <b>smtp_auth_succeeded</b> .                    |
| <b>Username</b>                                             | <b>testuser</b>                                                           |
| <b>Device Time</b>                                          | The device time in QRadar is <b>Tuesday July 28, 2009 15:00:28 (pm)</b> . |

## IBM MaaS360 Security

The IBM MaaS360 Security DSM for IBM QRadar collects event logs from the MaaS360 Security console.

The following table identifies the specifications for the IBM MaaS360 Security DSM:

| Table 592. IBM MaaS360 Security DSM Specification |                                                                                          |
|---------------------------------------------------|------------------------------------------------------------------------------------------|
| Specification                                     | Value                                                                                    |
| Manufacturer                                      | IBM                                                                                      |
| DSM name                                          | IBM MaaS360 Security                                                                     |
| RPM file name                                     | DSM-IBMFiberlinkMaaS360                                                                  |
| Supported versions                                | N/A                                                                                      |
| Event format                                      | LEEF, JSON                                                                               |
| QRadar recorded event types                       | Compliance rule events<br>Device enrollment events<br>Action history events              |
| Automatically discovered?                         | No                                                                                       |
| Included identity?                                | Yes                                                                                      |
| Includes custom properties?                       | No                                                                                       |
| More information                                  | <a href="http://www.maas360.com/">MaaS360 Security website (http://www.maas360.com/)</a> |

To integrate IBM MaaS360 Security with QRadar, use the following steps:

1. If automatic updates are not enabled, download the most recent versions of the RPMs from the [IBM support website](https://www.ibm.com/support) (<https://www.ibm.com/support>).
  - DSMCommon RPM
  - IBM Fiberlink REST API Protocol RPM
  - IBM MaaS360 Security RPM
2. Configure your MaaS360 Security instance to enable communication with QRadar.
3. Add an IBM MaaS360 Security log source on the QRadar Console.

## IBM Fiberlink REST API log source parameters for IBM MaaS360 Security

If QRadar does not automatically detect the log source, add a IBM MaaS360 Security log source on the QRadar Console by using the IBM Fiberlink REST API protocol.

When using the IBM Fiberlink REST API protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect IBM Fiberlink REST API events from IBM MaaS360 Security:

| Table 593. IBM Fiberlink REST API log source parameters for the IBM MaaS360 Security DSM |                      |
|------------------------------------------------------------------------------------------|----------------------|
| Parameter                                                                                | Value                |
| <b>Log Source type</b>                                                                   | IBM MaaS360 Security |

Table 593. IBM Fiberlink REST API log source parameters for the IBM MaaS360 Security DSM (continued)

| Parameter                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Protocol Configuration</b> | IBM Fiberlink REST API                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Log Source Identifier</b>  | Type a unique identifier for the log source.<br>The <b>Log Source Identifier</b> can be set to any valid value and does not need to reference a specific server. You can set the <b>Log Source Identifier</b> to the same value as the Log Source Name. If you have more than one IBM MaaS360 Security log source that is configured, you might want to identify the first log source as <i>MaaS3601</i> , the second log source as <i>MaaS3602</i> , and the third log source as <i>MaaS3603</i> . |

For a complete list of IBM Fiberlink REST API protocol parameters and their values, see [IBM Fiberlink REST API protocol configuration options](#).

# IBM Manage Virtual Server

The IBM QRadar DSM for IBM Manage Virtual Server collects events that are generated by the QRadar IBM Manage Virtual Server process.

To integrate IBM Manage Virtual Server with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](#). Download and install the most recent version of the **IBMMangeVirtualServer DSM** RPM on your QRadar Console.
2. If QRadar does not automatically detect the log source, add an IBM Manage Virtual Server log source on the QRadar Console. For more information, see [“Syslog log source parameters for IBM Manage Virtual Server” on page 964](#).

## IBM Manage Virtual Server DSM specifications

The IBM QRadar DSM for IBM Manage Virtual Server supports events that are generated by the IBM Manage Virtual Server process with the help of Syslog protocol.

The following table lists the specifications for the IBM Manage Virtual Server DSM.

| Table 595. IBM Manage Virtual Server DSM specifications |                                                                  |
|---------------------------------------------------------|------------------------------------------------------------------|
| Specification                                           | Value                                                            |
| Manufacturer                                            | IBM                                                              |
| DSM name                                                | IBMMangeVirtualServer                                            |
| RPM file name                                           | DSM-IBMMangeVirtualServer-QRadar_version-Build_number.noarch.rpm |
| Supported protocols                                     | Syslog                                                           |
| Event format                                            | Log Event Extended Format (LEEF)                                 |
| Automatically discovered?                               | Yes                                                              |
| Includes identity?                                      | Yes                                                              |
| Includes custom properties?                             | No                                                               |

## Syslog log source parameters for IBM Manage Virtual Server

If QRadar does not automatically detect the log source, add an IBM Manage Virtual Server log source on the QRadar Console by using the Syslog protocol.

The following table describes the parameters that require specific values to collect Syslog events from the IBM Manage Virtual Server:

| Table 596. IBM Manage Virtual Server log source parameters |                                        |
|------------------------------------------------------------|----------------------------------------|
| Parameter                                                  | Value                                  |
| <b>Log Source Name</b>                                     | Type a name for the log source.        |
| <b>Log Source Description</b>                              | Type a description for the log source. |

*Table 596. IBM Manage Virtual Server log source parameters (continued)*

| Parameter                     | Value                   |
|-------------------------------|-------------------------|
| <b>Log Source Type</b>        | MVSCount                |
| <b>Protocol Configuration</b> | Syslog                  |
| <b>Log Source Identifier</b>  | ibm.managevirtualserver |

## IBM Privileged Session Recorder

The IBM QRadar DSM for IBM Privileged Session Recorder can collect event logs from your IBM Privileged Session Recorder device.

The following table lists the specifications for the IBM Privileged Session Recorder DSM.

*Table 601. IBM Privileged Session Recorder specifications*

| Specification               | Value                            |
|-----------------------------|----------------------------------|
| Manufacturer                | IBM                              |
| DSM name                    | Privileged Session Recorder      |
| RPM filename                | DSM-IBMPrivilegedSessionRecorder |
| Protocol                    | JDBC                             |
| QRadar recorded event types | Command Execution Audit Events   |
| Automatically discovered?   | No                               |
| Includes identity?          | No                               |

*Table 601. IBM Privileged Session Recorder specifications (continued)*

| Specification    | Value                                                               |
|------------------|---------------------------------------------------------------------|
| More information | <a href="http://www.ibm.com/">IBM website (http://www.ibm.com/)</a> |

To collect IBM Privileged Session Recorder events, use the following procedures:

1. If automatic updates are not enabled, download and install the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Protocol-JDBC RPM
  - IBM Privileged Session Recorder DSM RPM
2. On the IBM Security Privileged Identity Manager dashboard, obtain the database information for the Privileged Session Recorder data store and configure your IBM Privileged Session Recorder DB2 database to allow incoming TCP connections.
3. For each instance of IBM Privileged Session Recorder, create an IBM Privileged Session Recorder log source on the QRadar Console. Use the following table to define the Imperva SecureSphere parameters:

*Table 602. IBM Privileged Session Recorder log source parameters*

| Parameter               | Description                                                                                                |
|-------------------------|------------------------------------------------------------------------------------------------------------|
| Log Source Type         | IBM Privileged Session Recorder                                                                            |
| Protocol Configuration  | JDBC                                                                                                       |
| Log Source Identifier   | DATABASE@HOSTNAME                                                                                          |
| Database Type           | DB2                                                                                                        |
| Database Name           | The Session Recorder data store name that you configured on the IBM Privileged Identity Manager dashboard. |
| IP or Hostname          | The Session Recorder database server address.                                                              |
| Port                    | The port that is specified on IBM Privileged Identity Manager dashboard.                                   |
| Username                | The DB2 database user name                                                                                 |
| Password                | The DB2 database password                                                                                  |
| Predefined Query        | IBM Privileged Session Recorder                                                                            |
| Use Prepared Statements | This option must be selected.                                                                              |
| Start Date and Time     | The initial date and time for the JDBC retrieval.                                                          |

[Configuring IBM Privileged Session Recorder to communicate with QRadar](#)

## Configuring IBM Privileged Session Recorder to communicate with QRadar

Before you can configure a log source in IBM Privileged Session Recorder for IBM QRadar, obtain the database information for the Privileged Session Recorder data store. You must also configure your IBM Privileged Session Recorder DB2 database to allow incoming TCP connections from QRadar.

IBM Privileged Session Recorder is a component of IBM Security Privileged Identity Manager.

## Procedure

1. Log in to the IBM Security Privileged Identity Manager web user interface.
2. Select the **Configure Privileged Identity Manager** tab.
3. Select **Database Server Configuration** in the **Manage External Entities** section.
4. In the table, double-click the **Session Recording data store** row in the **Database Server Configuration** column.
5. Record the following parameters to use when you configure a log source in QRadar:

| IBM Privileged Session Recorder Field | QRadar Log Source Field |
|---------------------------------------|-------------------------|
| <b>Hostname</b>                       | IP or Hostname          |
| <b>Port</b>                           | Port                    |
| <b>Database name</b>                  | Database Name           |
| <b>Database administrator ID</b>      | Username                |

## JDBC log source parameters for IBM Privileged Session Recorder

If QRadar does not automatically detect the log source, add an IBM Privileged Session Recorder log source on the QRadar Console by using the JDBC protocol.

When using the JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from IBM Privileged Session Recorder:

*Table 603. JDBC log source parameters for the IBM Privileged Session Recorder DSM*

| Parameter                     | Value                           |
|-------------------------------|---------------------------------|
| <b>Log Source type</b>        | IBM Privileged Session Recorder |
| <b>Protocol Configuration</b> | JDBC                            |

For a complete list of JDBC protocol parameters and their values, see “[JDBC protocol configuration options](#)” on page 147.

## IBM Proventia

IBM QRadar supports IBM Proventia Management SiteProtector and IBM ISS Proventia DSMs.

## IBM Proventia Management SiteProtector

The IBM Proventia® Management SiteProtector DSM for IBM QRadar accepts SiteProtector events by polling the SiteProtector database.

The DSM allows QRadar to record Intrusion Prevention System (IPS) events and audit events directly from the IBM SiteProtector database.

**Note:** The IBM Proventia Management SiteProtector DSM requires the latest JDBC Protocol to collect audit events.

The IBM Proventia Management SiteProtector DSM for IBM QRadar can accept detailed SiteProtector events by reading information from the primary SensorData1 table. The SensorData1 table is generated with information from several other tables in the IBM SiteProtector database. SensorData1 remains the primary table for collecting events.

IDP events include information from SensorData1, along with information from the following tables:

- SensorDataAVP1
- SensorDataReponse1

Audit events include information from the following tables:

- AuditInfo
- AuditTrail

Audit events are not collected by default and make a separate query to the AuditInfo and AuditTrail tables when you select the **Include Audit Events** check box. For more information about your SiteProtector database tables, see your vendor documentation.

Before you configure QRadar to integrate with SiteProtector, we suggest that you create a database user account and password in SiteProtector for QRadar.

Your QRadar user must have read permissions for the SensorData1 table, which stores SiteProtector events. The JDBC - SiteProtector protocol allows QRadar to log in and poll for events from the database. Creating a QRadar account is not required, but it is recommended for tracking and securing your event data.

**Note:** Ensure that no firewall rules are blocking the communication between the SiteProtector console and QRadar.

## JDBC log source parameters for IBM Proventia Management SiteProtector

If QRadar does not automatically detect the log source, add an IBM Proventia Management SiteProtector log source on the QRadar Console by using the JDBC protocol.

When using the JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from IBM Proventia Management SiteProtector:

| Table 604. JDBC log source parameters for the IBM Proventia Management SiteProtector DSM |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Log Source type</b>                                                                   | IBM Proventia Management SiteProtector                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Protocol Configuration</b>                                                            | JDBC                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Log Source Identifier</b>                                                             | Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.<br><br>If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2. |

For a complete list of JDBC protocol parameters and their values, see [JDBC protocol configuration options](#).

## IBM ISS Proventia

The IBM Integrated Systems Solutions® (ISS) Proventia DSM for IBM QRadar records all relevant IBM Proventia® events by using SNMP.

### Procedure

1. In the **Proventia Manager** user interface navigation pane, expand the **System node**.
  2. Select **System**.
  3. Select **Services**.  
The **Service Configuration** page is displayed.
  4. Click the **SNMP** tab.
  5. Select **SNMP Traps Enabled**.
  6. In the **Trap Receiver** field, type the IP address of your QRadar you want to monitor incoming SNMP traps.
  7. In the **Trap Community** field, type the appropriate community name.
  8. From the **Trap Version** list, select the trap version.
  9. Click **Save Changes**.  
You are now ready to configure QRadar to receive SNMP traps.
10. To configure QRadar to receive events from an ISS Proventia device. From the **Log Source Type** list, select **IBM Proventia Network Intrusion Prevention System (IPS)**.

For more information about your ISS Proventia device, see your vendor documentation.

### Related concepts

[“SNMPv2 protocol configuration options” on page 219](#)

You can configure a log source to use the SNMPv2 protocol to receive SNMPv2 events.

[“SNMPv3 protocol configuration options” on page 220](#)

You can configure a log source to use the SNMPv3 protocol to receive SNMPv3 events.

## IBM QRadar Packet Capture

The IBM QRadar DSM for IBM QRadar Packet Capture collects events from an IBM Security Packet Capture device.

The following table describes the specifications for the IBM QRadar Packet Capture DSM:

| Table 605. IBM QRadar Packet Capture DSM specifications |                                                                                        |

To integrate IBM QRadar Packet Capture with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM
  - IBM QRadar Packet Capture DSM RPM
2. Configure your IBM QRadar Packet Capture device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add an IBM QRadar Packet Capture log source on the QRadar Console. The following table describes the parameters that require specific values to collect events from IBM QRadar Packet Capture:

*Table 606. IBM QRadar Packet Capture log source parameters*

| Parameter              | Value                     |
|------------------------|---------------------------|
| Log Source type        | IBM QRadar Packet Capture |
| Protocol Configuration | Syslog                    |

4. To verify that QRadar is configured correctly, review the following tables to see examples of parsed event messages.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

The following table shows a sample event message from IBM QRadar Packet Capture:

*Table 607. IBM QRadar Packet Capture sample message*

| Event name | Low level category | Sample log message                                                                                                                                                                                                                                                                                                                                                           |

## Configuring IBM QRadar Packet Capture to communicate with QRadar

To collect IBM QRadar Packet Capture events, you must configure event forwarding to a remote syslog server.

### Procedure

1. Using SSH, log in to your IBM QRadar Packet Capture device as the root user.
2. Choose one of the following options to enable syslog.
  - a) Option 1: Open the /etc/rsyslog.conf file in a text editor such as vi:

```
vi /etc/rsyslog.conf
```

Then add the following line at the end of the file:

```
*.* @@<QRadar Event collector IP>:514
```

- b) Option 2: Create the <filename>.conf file in the /etc/rsyslog.d/ directory, and then add the following line to the file that you created:

```
*.* @@<QRadar Event collector IP>:514
```

3. Restart the Syslog service by typing the following command:

```
service rsyslog restart
```

The message logs are sent to the QRadar Event Collector and local copies are saved.

**Note:** QRadar parses only LEEF events for IBM QRadar Packet Capture. On the **Log Activity** tab in QRadar, the **Event Name** displays as **IBM QRadar Packet Capture Message** and the **Low Level Category** displays as **Stored** for all other events.

## What to do next

To verify that LEEF events are being logged on your IBM QRadar Packet Capture device, inspect /var/log/messages.

```
tail /var/log/messages
```

## Configuring IBM QRadar Network Packet Capture to communicate with QRadar

To collect IBM QRadar Network Packet Capture events, you must configure a remote Syslog server for your IBM QRadar Network Packet Capture appliance.

### Procedure

1. Log in to your IBM QRadar Network Packet Capture appliance as administrator.
2. Click **Admin**.
3. In the **REMOTE SYSLOG SETUP** pane, enable **system logging**.
4. Enable the **UPD** or **TCP** protocol, depending on your transfer settings.
5. In the **Remote Syslog Server Port** field, type the port number that you want to use to send remote syslog events. The default port number for remote syslog is 514.
6. In the **Remote Syslog Server** field, type the IP address for your QRadar Event Collector to which you want to send events.
7. Click **Apply**.

**Note:** QRadar parses only LEEF events for IBM QRadar Network Packet Capture. On the **Log Activity** tab in QRadar, the **Event Name** displays as **IBM QRadar Packet Capture Message** and the **Low Level Category** displays as **Stored** for all other events.

## IBM QRadar Network Security XGS

The IBM QRadar Network Security XGS DSM accepts events by using the Log Event Extended Format (LEEF), which enables IBM QRadar to record all relevant events.

The following table identifies the specifications for the IBM QRadar Network Security XGS DSM:

| Table 609. IBM QRadar Network Security XGS specifications |                                                                        |
|-----------------------------------------------------------|------------------------------------------------------------------------|
| Specification                                             | Value                                                                  |
| Manufacturer                                              | IBM                                                                    |
| DSM                                                       | QRadar Network Security XGS                                            |
| RPM file name                                             | DSM-IBMQRadarNetworkSecurityXGS-QRadar_version-build_number.noarch,rpm |
| Supported versions                                        | v5.0 with fixpack 7 to v5.4                                            |
| Protocol                                                  | Syslog                                                                 |
| Event format                                              | LEEF                                                                   |
| QRadar recorded events                                    | All relevant system, access, and security events                       |
| Automatically discovered                                  | Yes                                                                    |
| Includes identity                                         | No                                                                     |

*Table 609. IBM QRadar Network Security XGS specifications (continued)*

| Specification    | Value                                                                                                                                                                           |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| More information | <a href="https://www.ibm.com/support/knowledgecenter/SSHLHV_5.4.0/com.ibm.alps.doc/alps_collateral/alps_dochome_stg.htm">IBM QRadar Network Security (XGS) Knowledge Center</a> |

Before you configure a Network Security XGS appliance in QRadar, you must configure remote syslog alerts for your IBM QRadar Network Security XGS rules or policies to forward events to QRadar.

## Configuring IBM QRadar Network Security XGS Alerts

All event types are sent to IBM QRadar by using a remote syslog alert object that is LEEF enabled.

### About this task

Remote syslog alert objects can be created, edited, and deleted from each context in which an event is generated. Log in to the IBM QRadar Network Security XGS local management interface as admin to configure a remote syslog alert object, and go to one of the following menus:

- **Manage > System Settings > System Alerts** (System events)
- **Secure > Network Access Policy** (Access events)
- **Secure > IPS Event Filter Policy** (Security events)
- **Secure > Intrusion Prevention Policy** (Security events)
- **Secure > Network Access Policy > Inspection > Intrusion Prevention Policy**

In the **IPS Objects**, the **Network Objects** pane, or the **System Alerts** page, complete the following steps.

### Procedure

1. Click **New > Alert > Remote Syslog**.
2. Select an existing remote syslog alert object, and then click **Edit**.
3. Configure the following options:

*Table 610. Syslog configuration parameters*

| Option                              | Description                                                                                                                                                                                                                                      |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>                         | Type a name for the syslog alert configuration.                                                                                                                                                                                                  |
| <b>Remote Syslog Collector</b>      | Type the IP address of your QRadar Console or Event Collector.                                                                                                                                                                                   |
| <b>Remote Syslog Collector Port</b> | Type 514 for the <b>Remote Syslog Collector Port</b> .                                                                                                                                                                                           |
| <b>Remote LEEF Enabled</b>          | Select this check box to enable LEEF formatted events. This is a required field.<br><br>If you do not see this option, verify that you have software version 5.0 with fixpack 7 to v5.4 installed on your IBM QRadar Security Network appliance. |
| <b>Comment</b>                      | Typing a comment for the syslog configuration is optional.                                                                                                                                                                                       |

4. Click **Save Configuration**.

The alert is added to the **Available Objects** list.

5. To update your IBM QRadar Network Security XGS appliance, click **Deploy**.

6. Add the LEEF alert object for QRadar to the following locations:

- One or more rules in a policy
- **Added Objects** pane on the **System Alerts** page

7. Click **Deploy**

For more information about the Network Security XGS device, click **Help** in the QRadar Network Security XGS local management interface browser client window or access the online *IBM QRadar Network Security XGS documentation*.

## Syslog log source parameters for IBM QRadar Network Security XGS

If QRadar does not automatically detect the log source, add a IBM QRadar Network Security XGS log source on the QRadar Console by using the Syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from IBM QRadar Network Security XGS:

| Table 611. Syslog log source parameters for the IBM QRadar Network Security XGS DSM |                                                                                                                            |
|-------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                                           | Value                                                                                                                      |
| <b>Log Source Name</b>                                                              | Type a name for your log source.                                                                                           |
| <b>Log Source Type</b>                                                              | IBM QRadar <b>Network Security XGS</b>                                                                                     |
| <b>Protocol Configuration</b>                                                       | <b>Syslog</b>                                                                                                              |
| <b>Log Source Identifier</b>                                                        | Type the IP address or host name for the log source as an identifier for events from your IBM QRadar Network Security XGS. |

## IBM RACF

The IBM RACF DSM collects events from an IBM z/OS mainframe by using IBM Security zSecure.

When you use a zSecure process, events from the System Management Facilities (SMF) can be transformed into Log Event Extended Format (LEEF) events. These events can be sent near real-time by using UNIX Syslog protocol or IBM QRadar can retrieve the LEEF event log files by using the Log File protocol and then process the events. When you use the Log File protocol, you can schedule QRadar to retrieve events on a polling interval, which enables QRadar to retrieve the events on the schedule that you define.

To collect IBM RACF events, complete the following steps:

1. Verify that your installation meets any prerequisite installation requirements.

For more information about prerequisite requirements, see the [IBM Security zSecure Suite 2.2.1 Prerequisites](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/prereqs_qradar.html) ([http://www.ibm.com/support/knowledgecenter/en/SS2RWS\\_2.2.1/com.ibm.zsecure.doc\\_2.2.0/installation/prereqs\\_qradar.html](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/prereqs_qradar.html)) .

2. Configure your IBM z/OS image to write events in LEEF format. For more information, see the [IBM Security zSecure Suite: CARLa-Driven Components Installation and Deployment Guide](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/setup_data_prep_qradar.html) ([http://www.ibm.com/support/knowledgecenter/en/SS2RWS\\_2.2.1/com.ibm.zsecure.doc\\_2.2.0/installation/setup\\_data\\_prep\\_qradar.html](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/setup_data_prep_qradar.html)).

3. Create a log source in QRadar for IBM RACF.

- If you want to create a custom event property for IBM RACF in QRadar, for more information, see the [IBM Security Custom Event Properties for IBM z/OS technical note](http://public.dhe.ibm.com/software/security/products/qradar/documents/71MR1/SIEM/TechNotes/IBM_zOS_CustomEventProperties.pdf) ([http://public.dhe.ibm.com/software/security/products/qradar/documents/71MR1/SIEM/TechNotes/IBM\\_zOS\\_CustomEventProperties.pdf](http://public.dhe.ibm.com/software/security/products/qradar/documents/71MR1/SIEM/TechNotes/IBM_zOS_CustomEventProperties.pdf)).

## Before you begin

Before you can configure the data collection process, you must complete the basic zSecure installation process and complete the post-installation activities to create and modify the configuration.

The following prerequisites are required:

- You must ensure parmlib member IFAPRDxx is enabled for IBM Security zSecure Audit on your z/OS image.
- The SCKRLOAD library must be APF-authorized.
- If you are using the direct SMF INMEM real-time interface, you must have the necessary software installed (APAR OA49263) and set up the SMFPRMxx member to include the INMEM keyword and parameters. If you decide to use the CDP interface, you must also have CDP installed and running. For more information, see the [IBM Security zSecure Suite 2.2.1: Procedure for near real-time](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/smf_proc_real_time_qradar.html) ([http://www.ibm.com/support/knowledgecenter/en/SS2RWS\\_2.2.1/com.ibm.zsecure.doc\\_2.2.0/installation/smf\\_proc\\_real\\_time\\_qradar.html](http://www.ibm.com/support/knowledgecenter/en/SS2RWS_2.2.1/com.ibm.zsecure.doc_2.2.0/installation/smf_proc_real_time_qradar.html))
- You must configure a process to periodically refresh your CKFREEZE and UNLOAD data sets.
- If you are using the Log File protocol method, you must configure a SFTP, FTP, or SCP server on your z/OS image for QRadar to download your LEEF event files.
- If you are using the Log File protocol method, you must allow SFTP, FTP, or SCP traffic on firewalls that are located between QRadar and your z/OS image.

For instructions on installing and configuring zSecure, see the [IBM Security zSecure Suite: CARLa-Driven Components Installation and Deployment Guide](https://www.ibm.com/docs/en/SS2RWS_2.4.0/com.ibm.zsecure.doc_2.4.0/zsec_install.pdf) ([https://www.ibm.com/docs/en/SS2RWS\\_2.4.0/com.ibm.zsecure.doc\\_2.4.0/zsec\\_install.pdf](https://www.ibm.com/docs/en/SS2RWS_2.4.0/com.ibm.zsecure.doc_2.4.0/zsec_install.pdf)).

## Log File log source parameter

If QRadar does not automatically detect the log source, add a IBM z/OS, IBM CICS, IBM RACF, IBM DB2, Broadcom CA Top Secret, or Broadcom CA ACF2 log source on the QRadar Console by using the Log File Protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from IBM z/OS, IBM CICS, IBM RACF, IBM DB2, CA Top Secret, or CA ACF2:

| <i>Table 612. Log File log source parameters</i> |                                        |
|--------------------------------------------------|----------------------------------------|
| Parameter                                        | Value                                  |
| <b>Log Source name</b>                           | Type a name for your log source.       |
| <b>Log Source description</b>                    | Type a description for the log source. |
| <b>Log Source type</b>                           | Select your DSM name.                  |
| <b>Protocol Configuration</b>                    | <b>Log File</b>                        |

Table 612. Log File log source parameters (continued)

| Parameter                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source Identifier</b> | <p>Type an IP address, host name, or name to identify the event source. IP addresses or host names are suggested as they allow QRadar to identify a log file to a unique event source.</p> <p>For example, if your network contains multiple devices, such as multiple z/OS images or a file repository that contains all of your event logs, you must specify a name, IP address, or host name for the image or location that uniquely identifies events for the DSM log source. This specification enables events to be identified at the image or location level in your network that your users can identify.</p> |
| <b>Service Type</b>          | <p>From the <b>Service Type</b> list, select the protocol that you want to use when retrieving log files from a remote server. The default is SFTP.</p> <ul style="list-style-type: none"> <li>• SFTP - SSH File Transfer Protocol</li> <li>• FTP - File Transfer Protocol</li> <li>• SCP - Secure Copy</li> </ul> <p>The underlying protocol that is used to retrieve log files for the SCP and SFTP service type requires that the server that is specified in the <b>Remote IP or Hostname</b> field has the SFTP subsystem enabled.</p>                                                                           |
| <b>Remote IP or Hostname</b> | <p>Type the IP address or host name of the device that stores your event log files.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Remote Port</b>           | <p>Type the TCP port on the remote host that is running the selected <b>Service Type</b>. The valid range is 1 - 65535.</p> <p>The options include ports:</p> <ul style="list-style-type: none"> <li>• FTP - TCP Port 21</li> <li>• SFTP - TCP Port 22</li> <li>• SCP - TCP Port 22</li> </ul> <p>If the host for your event files is using a non-standard port number for FTP, SFTP, or SCP, you must adjust the port value.</p>                                                                                                                                                                                     |

Table 612. Log File log source parameters (continued)

| Parameter               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Remote User</b>      | <p>Type the user name or user ID necessary to log in to the system that contains your event files.</p> <ul style="list-style-type: none"> <li>If your log files are on your IBM z/OS image, type the user ID necessary to log in to your IBM z/OS. The user ID can be up to 8 characters in length.</li> <li>If your log files are on a file repository, type the user name necessary to log in to the file repository. The user name can be up to 255 characters in length.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Remote Password</b>  | Type the password necessary to log in to the host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Confirm Password</b> | Confirm the password necessary to log in to the host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SSH Key File</b>     | If you select <b>SCP</b> or <b>SFTP</b> as the <b>Service Type</b> , this parameter gives you the option to define an SSH private key file. When you provide an SSH Key File, the <b>Remote Password</b> field is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Remote Directory</b> | Type the directory location on the remote host from which the files are retrieved, relative to the user account you are using to log in.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Recursive</b>        | <p>If you want the file pattern to search sub folders in the remote directory, select this check box. By default, the check box is clear.</p> <p>If you configure SCP as the Service Type, the Recursive option is ignored.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>FTP File Pattern</b> | <p>If you select <b>SFTP</b> or <b>FTP</b> as the <b>Service Type</b>, you can configure the regular expression (regex) needed to filter the list of files that are specified in the <b>Remote Directory</b>. All matching files are included in the processing.</p> <p>The IBM z/OS mainframe that uses IBM Security zSecure Audit writes event files by using the pattern: &lt;product_name&gt;.&lt;timestamp&gt;.gz</p> <p>The FTP file pattern that you specify must match the name that you assigned to your event files. For example, to collect files that start with zOS and end with .gz, type the following code:</p> <pre>zOS.*\.gz</pre> <p>Use of this parameter requires knowledge of regular expressions (regex). For more information about regex, see <a href="https://docs.oracle.com/javase/tutorial/essential/regex/">Lesson: Regular Expressions</a> (<a href="https://docs.oracle.com/javase/tutorial/essential/regex/">https://docs.oracle.com/javase/tutorial/essential/regex/</a>).</p> |

Table 612. Log File log source parameters (continued)

| Parameter                | Value                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FTP Transfer Mode</b> | <p>This option displays only if you select <b>FTP</b> as the <b>Service Type</b>. From the list, select <b>Binary</b>.</p> <p>The binary transfer mode is needed for event files that are stored in a binary or compressed format, such as zip, gzip, tar, or tar+gzip archive files.</p>                                                                                              |
| <b>SCP Remote File</b>   | If you select <b>SCP</b> as the <b>Service Type</b> you must type the file name of the remote file.                                                                                                                                                                                                                                                                                    |
| <b>Start Time</b>        | <p>Type the time of day you want the processing to begin. For example, type 00 : 00 to schedule the Log File protocol to collect event files at midnight.</p> <p>This parameter functions with the Recurrence value to establish when and how often the Remote Directory is scanned for files. Type the start time, based on a 24-hour clock, in the following format: HH: MM.</p>     |
| <b>Recurrence</b>        | <p>Type the frequency, beginning at the Start Time, that you want the remote directory to be scanned. Type this value in hours (H), minutes (M), or days (D).</p> <p>For example, type 2H if you want the remote directory to be scanned every 2 hours from the start time. The default is 1H.</p>                                                                                     |
| <b>Run On Save</b>       | <p>If you want the Log File protocol to run immediately after you click <b>Save</b>, select this check box.</p> <p>After the <b>Run On Save</b> completes, the Log File protocol follows your configured start time and recurrence schedule.</p> <p>Selecting <b>Run On Save</b> clears the list of previously processed files for the Ignore Previously Processed File parameter.</p> |
| <b>EPS Throttle</b>      | <p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The valid range is 100 to 5000.</p>                                                                                     |

Table 612. Log File log source parameters (continued)

| Parameter                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Processor</b>                           | <p>From the list, select <b>gzip</b>.</p> <p>Processors enable event file archives to be expanded and contents are processed for events. Files are processed after they are downloaded to QRadar. QRadar can process files in zip, gzip, tar, or tar+gzip archive format.</p>                                                                                                                                                                                                                  |
| <b>Ignore Previously Processed File(s)</b> | <p>Select this check box to track and ignore files that are already processed by the Log File protocol.</p> <p>QRadar examines the log files in the remote directory to determine whether a file is previously processed by the Log File protocol. If a previously processed file is detected, the Log File protocol does not download the file for processing. All files that are not previously processed are downloaded.</p> <p>This option applies only to FTP and SFTP service types.</p> |
| <b>Change Local Directory?</b>             | <p>Select this check box to define a local directory on your QRadar for storing downloaded files during processing.</p> <p>It is suggested that you leave this check box clear. When this check box is selected, the <b>Local Directory</b> field is displayed, which gives you the option to configure the local directory to use for storing files.</p>                                                                                                                                      |
| <b>Event Generator</b>                     | <p>From the <b>Event Generator</b> list, select <b>LineByLine</b>.</p> <p>The Event Generator applies more processing to the retrieved event files. Each line is a single event. For example, if a file has 10 lines of text, 10 separate events are created.</p>                                                                                                                                                                                                                              |

## Create a log source for near real-time event feed

The Syslog protocol enables IBM QRadar to receive System Management Facilities (SMF) events in near real-time from a remote host.

The following DSMs are supported:

- IBM z/OS
- IBM CICS
- IBM RACF
- IBM DB2
- CA Top Secret
- CA ACF2

If QRadar does not automatically detect the log source, add a log source for your DSM on the QRadar console.

The following table describes the parameters that require specific values for event collection for your DSM:

| Table 613. Log source parameters |                                              |
|----------------------------------|----------------------------------------------|
| Parameter                        | Value                                        |
| Log Source type                  | Select your DSM name from the list.          |
| Protocol Configuration           | Syslog                                       |
| Log Source Identifier            | Type a unique identifier for the log source. |

## Integrate IBM RACF with IBM QRadar by using audit scripts

The IBM RACF DSM collects events and audit transactions on the IBM mainframe with the Log File protocol.

QRadar records all relevant and available information from the event.

**Note:** zSecure integration is the only integration that provides custom events to the log source. Custom events can be displayed even when you collect events by using the Native QEXRACF integration.

Use the following procedure to integrate the IBM RACF events into QRadar:

1. The IBM mainframe system records all security events as Service Management Framework (SMF) records in a live repository.
2. At midnight, the IBM RACF data is extracted from the live repository by using the SMF dump utility. The RACFICE utility IRRADU00 (an IBM utility) creates a log file that contains all of the events and fields from the previous day in an SMF record format.
3. The QEXRACF program pulls data from the SMF formatted file. The program pulls only the relevant events and fields for QRadar and writes that information in a condensed format for compatibility. The information is also saved in a location accessible by QRadar.
4. QRadar uses the Log File protocol source to pull the QEXRACF output file and retrieves the information on a scheduled basis. QRadar then imports and processes this file.

## Configuring IBM RACF that uses audit scripts to integrate with IBM QRadar

IBM QRadar uses scripts to audit events from IBM RACF installations, which are collected by using the Log File protocol.

### Procedure

1. Download the `qexracf_bundled.tar.gz` from the [IBM support website](#).
2. On a Linux-based operating system, use the following command to extract the file:

```
tar -zxvf qexracf_bundled.tar.gz
```

The following files are contained in the archive:

- `qexracf_jcl.txt`
- `qexracfloadlib.trs`
- `qexracf_trsmain_JCL.txt`

3. Load the files onto the IBM mainframe by using any terminal emulator file transfer method.

Upload the `qexracf_trsmain_JCL.txt` and `qexracf_jcl.txt` files by using the TEXT protocol.

Upload the QexRACF loadlib.trs file by using binary mode and append to a preallocated data set. The QexRACF loadlib.trs file is a terced file that contains the executable (the mainframe program QEXRACF).

When you upload the .trs file from a workstation, preallocate a file on the mainframe with the following DCB attributes: DSORG=PS, RECFM=FB, LRECL=1024, BLKSIZE=6144. The file transfer type must be binary mode and not text.

4. Customize the qexracf\_trsmain\_JCL.txt file according to your installation-specific requirements.

The qexracf\_trsmain\_JCL.txt file uses the IBM utility Trsmain to decompress the program that is stored in the QexRACF loadlib.trs file.

The following is an example of the qexracf\_trsmain\_JCL.txt file includes the following code:

```
//TRSMAIN JOB (yourvalidjobcard),Q1labs,  
// MSGCLASS=V //DEL EXEC PGM=IEFBR14  
//D1 DD DISP=(MOD,DELETE) ,DSN=<yourhlq>.QEXRACF.TRS // UNIT=SYSDA,  
// SPACE=(CYL,(10,10))  
//TRSMAIN EXEC PGM=TRSMAIN,PARM='UNPACK'  
//SYSPRINT DD SYSOUT=*,DCB=(LRECL=133,BLKSIZE=12901,RECFM=FBA)  
//INFILE DD DISP=SHR,DSN=<yourhlq>.QEXRACF.TRS  
//OUTFILE DD DISP=(NEW,CATLG,DELETE),  
// DSN=<yourhlq>.LOAD,  
// SPACE=(CYL,(10,10,5),RLSE),UNIT=SYSDA //
```

You must update the file with your installation specific information for parameters, such as, jobcard, data set naming conventions, output destinations, retention periods, and space needs.

The .trs input file is an IBM TERSE formatted library and is extracted by running the JCL, which calls the TRSMAIN. This terced file, when extracted, creates a PDS linklib with the QEXRACF program as a member.

5. You can STEPLIB to this library or choose to move the program to one of the LINKLIBs that are in the LINKLST. The program does not require authorization.
6. When the upload is complete, copy the program to an existing link listed library or add a STEPLIB DD statement that has the correct dataset name of the library that will contain the program.
7. The qexracf\_jcl.txt file is a text file that contains a sample JCL deck to provide you with the necessary JCL to run the IBM IRRADU00 utility. This allows QRadar to obtain the necessary IBM RACF events. Configure the job card to meet your local standards.

An example of the qexracf\_jcl.txt file has the following code.

```
//QEXRACF JOB (<your valid jobcard>),Q1LABS,  
// MSGCLASS=P, // REGION=OM /*  
//**QEXRACF JCL version 1.0 April 2009 **//  
//*****  
//** Change below dataset names to sites specific datasets names *  
//*****  
//SET1 SET SMFOUT='<your hlq>.CUSTNAME.IRRADU00.OUTPUT',  
// SMFIN='<your SMF dump ouput dataset>',  
// QRACFOUT='<your hlq>.QEXRACF.OUTPUT'  
//*****  
//** Delete old datasets *  
//*****  
//DEL EXEC PGM=IEFBR14 //DD2 DD DISP=(MOD,DELETE) ,DSN=&QRACFOUT,  
// UNIT=SYSDA, // SPACE=(TRK,(1,1)), // DCB=(RECFM=FB,LRECL=80)  
//*****  
//** Allocate new dataset *  
  
//*****  
//ALLOC EXEC PGM=IEFBR14  
//DD1 DD DISP=(NEW,CATLG) ,DSN=&QRACFOUT,  
// SPACE=(CYL,(1,10)),UNIT=SYSDA,  
// DCB=(RECFM=VB,LRECL=1028,BLKSIZE=6144)  
//*****  
//** Execute IBM IRRADU00 utility to extract RACF smf records *  
//*****  
//IRRADU00 EXEC PGM=IFASMFDP  
//SYSPRINT DD SYSOUT=*  
//ADUPRINT DD SYSOUT=*  
//OUTDD DD DSN=&SMFOUT,SPACE=(CYL,(100,100)),DISP=(,CATLG),
```

```

// DCB=(RECFM=FB,LRECL=8192,BLKSIZE=40960),
// UNIT=SYSALLDA
//SMFDATA DD DISP=SHR,DSN=&SMFIN
//SMFOUT DD DUMMY
//SYSIN DD *INDD(SMFDATA,OPTIONS(DUMP))
OUTDD(SMFOUT,TYPE(30:83)) ABEND(NORETRY)
USER2(IRRADU00) USER3(IRRADU86) /*
//EXTRACT EXEC PGM=QEXRACF,DYNAMNBR=10,
// TIME=1440
//*STEPLIB DD DISP=SHR,DSN=
<the loadlib containing the QEXRACF program if not in LINKLST>
//SYSTSIN DD DUMMY //SYSTSPRT DD SYSOUT=*
//SYSPRINT DD SYSOUT=*
//RACIN DD DISP=SHR,DSN=&SMFOUT
//RACOUT DD DISP=SHR,DSN=&QRACFOUT /**
//*****  

//** FTP Output file from C program (Qexracf) to an FTP server *
//** QRadar will go to that FTP Server to get file *
//** Note you need to replace <user>, <password>, <serveripaddr>*
//** <THEIPOFTHEMAINFRAMEDEVICE> and <QEXRACFOUTDSN> *
//*****  

//**FTP EXEC PGM=FTP,REGION=3800K /*INPUT DD *
//**<FTPSERVERIPADDR>
//**<USER>
//**<PASSWORD>
//**ASCII /*PUT '<QEXRACFOUTDSN>'  

/<THEIPOFTHEMAINFRAMEDEVICE>/<QEXRACFOUTDSN>
//**QUIT /*OUTPUT DD SYSOUT=*
//**SYSPRINT DD SYSOUT=/* /* */

```

8. After the output file is created, you must send this file to an FTP server.

This action ensures that every time you run the utility, the output file is sent to a specific FTP server for processing at the end of the script. If the z/OS platform is configured to serve files through FTP or SFTP, or allow SCP, then no interim server is needed and QRadar can pull those files directly from the mainframe. If an interim FTP server is needed, QRadar requires a unique IP address for each IBM RACF log source or they are joined as one system.

## IBM Red Hat OpenShift

---

The IBM QRadar DSM for Red Hat® OpenShift® collects auditing and infrastructure events from a Red Hat OpenShift cluster.

To integrate Red Hat OpenShift with QRadar, complete the following steps:

- If automatic updates are not enabled, download the most recent versions of the RPMs from the [IBM support website](https://www.ibm.com/support) (<https://www.ibm.com/support>).
  - DSM Common RPM
  - Kubernetes Auditing DSM RPM
  - IBM Red Hat OpenShift DSM RPM
- Configure Red Hat OpenShift to forward events to QRadar. See [“Configuring Red Hat OpenShift to communicate with QRadar” on page 984](#).
- If QRadar does not automatically detect the log source, add a log source on the QRadar Console. See [“IBM Red Hat OpenShift Syslog log source parameters” on page 984](#).

For more information about adding a log source, see [Adding a log source](#).

## IBM Red Hat OpenShift DSM specifications

When you configure Red Hat OpenShift, understanding the specifications for the IBM Red Hat OpenShift DSM can help ensure a successful integration. For example, knowing what the supported version of Red Hat OpenShift is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the IBM Red Hat OpenShift DSM.

| Table 614. IBM Red Hat OpenShift DSM specifications |                                                                                                                                                                                                                                                                                                                                           |

## Configuring Red Hat OpenShift to communicate with QRadar

To send events from Red Hat OpenShift to QRadar, you must specify QRadar as the syslog server.

### Procedure

1. A Red Hat OpenShift cluster must be running on your system. For more information about creating a logging instance cluster, see the Red Hat OpenShift documentation about [Understanding the logging subsystem for Red Hat OpenShift](https://docs.openshift.com/container-platform/4.10/logging/cluster-logging.html) (<https://docs.openshift.com/container-platform/4.10/logging/cluster-logging.html>).
2. To forward logs to QRadar, see the Red Hat OpenShift documentation about [Forwarding logs to external third-party logging systems](https://docs.openshift.com/container-platform/4.10/logging/cluster-logging-external.html) (<https://docs.openshift.com/container-platform/4.10/logging/cluster-logging-external.html>).

## IBM Red Hat OpenShift Syslog log source parameters

Add an IBM Red Hat OpenShift log source that uses the Syslog protocol in IBM QRadar.

When you use the Syslog protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect Syslog events from Red Hat OpenShift:

*Table 615. Syslog protocol parameters for the IBM Red Hat OpenShift DSM*

| Parameter                     | Value                                                       |
|-------------------------------|-------------------------------------------------------------|
| <b>Log source type</b>        | IBM Red Hat OpenShift                                       |
| <b>Protocol Configuration</b> | Syslog                                                      |
| <b>Log source identifier</b>  | The IP address or hostname of the Red Hat OpenShift server. |

## IBM Red Hat OpenShift sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### IBM Red Hat OpenShift sample message when you use the Syslog protocol

**Sample 1:** The following sample event message shows that audit type events are received from the cluster.

```

## IBM SAN Volume Controller

The IBM QRadar DSM for IBM SAN Volume Controller collects events from IBM SAN Volume Controller.

**Important:** This DSM supports only the Cloud Auditing Data Federation (CADF) event format that includes monitoring and protection related to cloud account's create, update, removal and cloud backup activity events from IBM SAN Volume Controller.

The following table describes the specifications for the IBM SAN Volume Controller DSM:

| Table 618. IBM SAN Volume Controller DSM specifications |                                                                                                                                                                                                                                                                            |

| Includes custom properties?                             | No                                                                                                                                                                                                                                                                         |
| More information                                        | <a href="http://www-03.ibm.com/systems/storage/software/virtualization/svc/">IBM SAN Volume Controller website</a> ( <a href="http://www-03.ibm.com/systems/storage/software/virtualization/svc/">http://www-03.ibm.com/systems/storage/software/virtualization/svc/</a> ) |

To integrate IBM SAN Volume Controller with QRadar, complete the following steps:

- If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#), in the order that they are listed, on your QRadar Console:
  - DSMCommon RPM
  - IBM SAN Volume Controller DSM RPM
- Configure your IBM SAN Volume Controller server to send syslog events to QRadar.
- If QRadar does not automatically detect the log source, add an IBM SAN Volume Controller log source on the QRadar Console. The following table describes the parameters that require specific values for IBM SAN Volume Controller event collection:

*Table 619. IBM SAN Volume Controller log source parameters*

| Parameter              | Value                                                                |
|------------------------|----------------------------------------------------------------------|
| Log Source type        | IBM SAN Volume Controller                                            |
| Protocol Configuration | Syslog                                                               |
| Log Source Identifier  | The IP address or host name of the IBM SAN Volume Controller server. |

4. To verify that QRadar is configured correctly, review the following table to see an example of a parsed event message.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

The following table shows a sample event message for IBM SAN Volume Controller:

*Table 620. IBM SAN Volume Controller sample message*

| Event name        | Low level category        | Sample log message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Configuring IBM SAN Volume Controller to communicate with QRadar

To collect events from IBM SAN Volume Controller, you must configure IBM SAN Volume Controller (SVC) cluster to send events to QRadar from a syslog server.

## Procedure

1. Use SSH to log in to the SVC cluster command-line interface (CLI).
2. Type the following command to configure a remote syslog server to send CADF events to QRadar:

```
svctask mksyslogserver -ip <QRadar_Event_Collector_IP_Address> error  
<on_or_off> -warning <on_or_off> -info <on_or_off> -cadf on
```

The following example shows a command that is used to configure a remote syslog server to send CADF events:

```
svctask mksyslogserver -ip 192.0.2.1 -error on -warning on -info on -cadf on
```

**Note:** The error and warning flags are CADF event types that SVC sends to syslog servers.

## IBM Security Access Manager for Enterprise Single Sign-On

---

You can use the IBM® Security Access Manager for Enterprise Single Sign-On DSM for IBM QRadar to receive events that are forwarded by using syslog.

QRadar can collect events from IBM Security Access Manager for Enterprise Single Sign-On version 8.1 or 8.2.

Events that are forwarded by the IBM Security Access Manager for Enterprise Single Sign-On include audit, system, and authentication events.

Events are read from the following database tables and forwarded by using syslog:

- IMSLOGUserService
- IMSLOGUserAdminActivity
- IMSLOGUserActivity

All events that are forwarded to QRadar from IBM Security Access Manager for Enterprise Single Sign-On use ### as a syslog field-separator. IBM Security Access Manager for Enterprise Single Sign-On forwards events to QRadar by using UDP on port 514.

## Before you begin

To configure syslog forwarding for events, you must be an administrator or your user account must include credentials to access the IMS Configuration Utility.

Any firewalls that are configured between your IBM Security Access Manager for Enterprise Single Sign-On and QRadar are ideally configured to allow UDP communication on port 514. This configuration requires you to restart your IBM Security Access Manager for Enterprise Single Sign-On appliance.

## Configuring a log server type

IBM Security Access Manager for Enterprise Single Sign-On appliance requires you to configure a log server type to forward syslog formatted events:

## Procedure

1. Log in to the IMS Configuration Utility for IBM Security Access Manager for Enterprise Single Sign-On.  
For example, <https://localhost:9043/webconf>
2. From the navigation menu, select **Advanced Settings** > **IMS Server** > **Logging** > **Log Server Information**.
3. From the **Log server types** list, select **syslog**.
4. Click **Add**.
5. Click **Update** to save the configuration.

## Configuring syslog forwarding

To forward events to QRadar, you must configure a syslog destination on your IBM Security Access Manager for Enterprise Single Sign-On appliance.

### Procedure

1. Log in to the IMS Configuration Utility for IBM Security Access Manager for Enterprise Single Sign-On. For example, <https://localhost:9043/webconf>.
2. From the navigation menu, select **Advanced Settings > IMS Server > Logging > Syslog**.
3. Configure the following syslog parameter options:

*Table 621. Syslog parameters*

| Field                          | Description                                                                                                                                                                                                                                        |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable syslog</b>           | From the <b>Available Tables</b> list, you must select the following tables, and click <b>Add</b> . <ul style="list-style-type: none"><li>• <b>logUserService</b></li><li>• <b>logUserActivity</b></li><li>• <b>logUserAdminActivity</b></li></ul> |
| <b>Syslog server port</b>      | Type 514 as the port number used for forwarding events to QRadar.                                                                                                                                                                                  |
| <b>Syslog server hostname</b>  | Type the IP address or host name of your QRadar Console or Event Collector.                                                                                                                                                                        |
| <b>Syslog logging facility</b> | Type an integer value to specify the facility of the events that are forwarded to QRadar. The default value is 20.                                                                                                                                 |
| <b>Syslog field-separator</b>  | Type <b>#:#</b> as the characters used to separate name-value pair entries in the syslog payload.                                                                                                                                                  |

4. Click **Update** to save the configuration.
5. Restart your IBM Security Access Manager for Enterprise Single Sign-On appliance.

### Results

The log source is added to QRadar as IBM Security Access Manager for Enterprise Single Sign-On syslog events are automatically discovered. Events that are forwarded to QRadar are displayed on the **Log Activity** tab.

## Syslog log source parameters for IBM Security Access Manager for Enterprise Single Sign-On

If QRadar does not automatically detect the log source, add an IBM Security Access Manager for Enterprise Single Sign-On log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from IBM Security Access Manager for Enterprise Single Sign-On:

*Table 622. Syslog log source parameters for the IBM Security Access Manager for Enterprise Single Sign-On DSM*

| Parameter                     | Value                                                                                                                                                          |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source type</b>        | IBM Security Access Manager for Enterprise Single Sign-On                                                                                                      |
| <b>Protocol Configuration</b> | Syslog                                                                                                                                                         |
| <b>Log Source Identifier</b>  | Type the IP address or host name for the log source as an identifier for events from your IBM Security Access Manager for Enterprise Single Sign-On appliance. |

| Automatically discovered?   | Yes                                                                                                                                                                                                                                                                       |
| Includes identity?          | No                                                                                                                                                                                                                                                                        |
| Includes custom properties? | No                                                                                                                                                                                                                                                                        |
| More information            | <a href="http://www.ibm.com/software">www.ibm.com/software</a> ( <a href="http://www-03.ibm.com/software/products/en/access-mgr-mobile">http://www-03.ibm.com/software/products/en/access-mgr-mobile</a> ).                                                               |

To integrate IBM Security Access Manager for Mobile with QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:

TLS Syslog Protocol RPM

IBM Security Access Manager for Mobile DSM RPM

2. Configure your IBM Security Access Manager for Mobile device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add an IBM Security Access Manager for Mobile log source on the QRadar console. The following table describes the parameters that require specific values for IBM Security Access Manager for Mobile and IBM Identity as a Service event collection:

*Table 624. IBM Security Access Manager for Mobile log source parameters*

| Parameter              | Value                                                                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Log Source type        | IBM Security Access Manager for Mobile or IBM Identity as a Service                                                                            |
| Protocol Configuration | TLS Syslog                                                                                                                                     |
| Log Source Identifier  | The IP address or host name in the Syslog header. Use the packet IP address, if the Syslog header does not contain an IP address or host name. |
| TLS Listen Port        | Type the port number to accept incoming TLS Syslog Event.                                                                                      |

4. Saving the log source creates a listen port for incoming TLS Syslog events and generates a certificate for the network devices. The certificate must be copied to any device on your network that can forward encrypted syslog. Additional network devices with a syslog-tls certificate file and the TLS listen port number can be automatically discovered as a TLS syslog log source in QRadar.

## Configuring IBM Security Access Manager for Mobile to communicate with QRadar

Configure IBM Security Access Manager for Mobile to send audit logs to IBM QRadar through TLS syslog.

### Before you begin

Ensure that IBM Security Access Manager for Mobile has access to QRadar for TLS syslog communication.

### Procedure

1. Select **Monitor Analysis and Diagnosis > Logs > Audit Configuration**.
2. Click the **Syslog** tab and enter the information in the following table.

| Field                                           | Value                                                                                                                                                        |
|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable audit log</b>                         | Click <b>Enable audit log</b> .                                                                                                                              |
| <b>Enable verbose audit events</b>              | Click <b>Enable verbose audit events</b> .<br>Audit events that are not verbose do not contain the JSON payload, which contains details of user activity.    |
| <b>Location of syslog server</b>                | Select <b>On a remote server</b>                                                                                                                             |
| <b>Host</b>                                     | The QRadar server host name or IP.                                                                                                                           |
| <b>Port</b>                                     | The port number that you want to use for QRadar to accept incoming TLS syslog events.                                                                        |
| <b>Protocol</b>                                 | Select <b>TLS</b>                                                                                                                                            |
| <b>Certificate database (truststore)</b>        | The truststore that validates the syslog server certificate.                                                                                                 |
| <b>Enable client certificate authentication</b> | Click <b>Enable client certificate authentication</b> .<br>The client can do client certificate authentication during the SSL handshake upon server request. |
| <b>Certificate database (keystore)</b>          | The keystore for client certificate authentication.                                                                                                          |
| <b>Certificate label</b>                        | The personal certificate for client certificate authentication                                                                                               |
| <b>Enable disk failover</b>                     | Clear <b>Enable disk failover</b> .                                                                                                                          |

3. Click **Save**.
4. Click **Click here to review the changes or apply them to the system** to review pending changes.
5. Click **Deploy Changes**.

The runtime server restarts automatically if any of the new changes require a restart.

## Configuring IBM IDaaS Platform to communicate with QRadar

You can enable IBM IDaaS Platform audit events to be generated in LEEF format on your IBM IDaaS console.

### Before you begin

Ensure that IBM IDaaS Platform is installed and configured on your WAS console.

### Procedure

1. Access the IDaaS Platform configuration file on your WAS console. <WAS\_home>/profiles/<profile\_name>/config/idaas/platform.config.properties
2. If the platform.config.properties file does not contain a set of audit properties, configure the following options:

| Property                                                                                 | Description                                           |
|------------------------------------------------------------------------------------------|-------------------------------------------------------|
| <b>audit.enabled=true</b>                                                                | Audit property is enabled.                            |
| <b>audit.syslog.message.format=leef</b><br><b>audit.syslog.server=&lt;IP_address&gt;</b> | Valid type is LEEF.                                   |
| <b>audit.syslog.transport=TRANSPORT_UDP</b><br><b>audit.syslog.server.port=514</b>       | Transport values are TRANSPORT_UDP and TRANSPORT_TLS. |

3. Restart the IBM IDaaS Platform application on your WAS console.

## Configuring an IBM IDaaS console to communicate with QRadar

You can enable audit events to be generated in LEEF Syslog format on your IBM IDaaS console.

### Before you begin

Ensure that your IBM IDaaS console is installed and configured.

### Procedure

1. Select **Secure Access Control > Advanced Configuration**.
2. Type idaaS.audit.event in the **Filter** text box. The default format is Syslog.
3. Click **Edit**.
4. Select **LEEFSyslog**
5. Click **Save**.
6. Click **Deploy Changes**.

## IBM Security Verify Directory

The IBM QRadar DSM for IBM Security Verify Directory collects event logs from your IBM Security Verify Directory.

To integrate IBM Security Verify Directory with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent versions of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM
  - IBM Security Verify Directory DSM RPM

- Configure each IBM Security Verify Directory system in your network to enable communication with QRadar.
- If QRadar does not automatically detect the log source, add a log source on the QRadar Console.

## IBM Security Verify Directory DSM specifications

When you configure the IBM Security Verify Directory DSM, understanding the specifications for the IBM Security Verify Directory DSM can help ensure a successful integration. For example, knowing what protocol to use before you begin can help reduce frustration during the configuration process.

The following table identifies the specifications for the IBM Security Verify Directory DSM:

| Table 625. IBM Security Verify Directory DSM specifications |                                                                                 |
|-------------------------------------------------------------|---------------------------------------------------------------------------------|
| Specification                                               | Value                                                                           |
| Manufacturer                                                | IBM                                                                             |
| DSM                                                         | IBM Security Verify Directory (formerly known as IBM Security Directory Server) |
| RPM file name                                               | DSM-IBMSecurityDirectoryServer-build_number.noarch.rpm                          |
| Supported version                                           | 6.3.1 or later                                                                  |
| Protocol                                                    | Syslog (LEEF)                                                                   |
| QRadar recorded events                                      | All relevant events                                                             |
| Automatically discovered                                    | Yes                                                                             |
| Includes identity                                           | Yes                                                                             |
| For more information                                        | <a href="#">IBM website</a>                                                     |

## Configuring IBM Security Verify Directory to communicate with QRadar

IBM QRadar can collect LEEF formatted audit events from your IBM Security Verify Directory.

#### About this task

To configure IBM Security Verify Directory to send logs to IBM QRadar, you must use the IBM Security Verify Directory command line to add an auxiliary object class and then set values for the QRadar log management attributes.

#### Procedure

- Create a file (file\_name) on the IBM Security Verify Directory or IBM Security Director Server with the following content:

```
dn: cn=Audit, cn=Log Management, cn=Configuration
changetype: modify
add: objectclass
objectclass: ibm-slapdQRadarConfig
```

- To add the auxiliary object class `ibm-slapdQRadarConfig` for QRadar configuration attributes to `cn=Audit,cn=Log Management,cn=Configuration`, run the following command:

```
# idsldapmodify -h host_name -p portnumber -D cn=RDN_value -w password -f file_name
```

- Create a new file (`new_file`) with the following content:

```
dn: cn= specific_log_name, cn=Log Management, cn=configuration
changetype: modify
add:ibm-slapdLogEventQRadarEnabled
ibm-slapdLogEventQRadarEnabled: true
-
add:ibm-slapdLogEventQRadarHostName
ibm-slapdLogEventQRadarHostName: host_name_of_qradar_instance
-
add: ibm-slapdLogEventQRadarPort
ibm-slapdLogEventQRadarPort: port_of_qradar_instance
-
add: ibm-slapdLogEventQRadarMapFilesLocation
ibm-slapdLogEventQRadarMapFilesLocation: directory_location_of_qradar_mapfiles
```

- Replace the following values in the `new_file` content:

- Replace `host_name_of_qradar_instance` with the destination QRadar Event Collector hostname or IP address.
- Replace `port_of_qradar_instance` with 514.
- If IBM Security Directory Server or IBM Security Verify Directory is installed, replace `directory_location_of_qradar_mapfiles` with `/opt/ibm/ldap/<INSTALLED_VERSION>/idstools/idslogmgmt/`.
- If V6.3.1 is installed, replace `directory_location_of_qradar_mapfiles` with `/opt/ibm/ldap/V6.3.1/idstools/idslogmgmt/`.
- If V6.4 is installed, replace `directory_location_of_qradar_mapfiles` with `/opt/ibm/ldap/V6.4/idstools/idslogmgmt/`.

For example:

```
dn: cn= specific_log_name, cn=Log Management, cn=configuration
changetype: modify
add:ibm-slapdLogEventQRadarEnabled
ibm-slapdLogEventQRadarEnabled: true
-
add:ibm-slapdLogEventQRadarHostName
ibm-slapdLogEventQRadarHostName: qradar-collector.example.com
-
add: ibm-slapdLogEventQRadarPort
ibm-slapdLogEventQRadarPort: 514
-
add: ibm-slapdLogEventQRadarMapFilesLocation
ibm-slapdLogEventQRadarMapFilesLocation: /opt/ibm/ldap/V6.3.1/idstools/idslogmgmt/
```

- To set the attribute values for QRadar integration, run the following command:

```
# idsldapmodify -h host_name -p portnumber -D cn=RDN_value -w password -f new_file
```

- To start an instance, run the following command:

```
# ibmslapd -I <instance_name> -n
```

- Optional: To start log management locally, run the following command:

```
# idslogmgmt -I <instance_name>
```

To start, get status, and stop log management remotely, run the following commands:

```
# ibmdirctl -D <adminDN> -w <password> -h <host_name> -p <administration server port number> startlogmgmt# ibmdirctl -D <adminDN> -w <password> -h <host_name> -p <administration server port number> statuslogmgmt# ibmdirctl -D <adminDN> -w <password> -h <host_name> -p <administration server port number> stoplogmgmt
```

## Syslog log source parameters for IBM Security Verify Directory

If QRadar does not automatically detect the log source, add an IBM Security Verify Directory log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from IBM Security Verify Directory:

*Table 626. Syslog log source parameters for the IBM Security Verify Directory DSM*

| Parameter                     | Value                         |
|-------------------------------|-------------------------------|
| <b>Log Source type</b>        | IBM Security Verify Directory |
| <b>Protocol Configuration</b> | Syslog                        |

## IBM Security Guardium Insights

IBM Security Guardium Insights is a modern data security solution. It is built to adapt to changing environments, connect to critical IT and security tools, streamline compliance and audit processes, and intelligently respond to data threats.

The IBM Security Guardium Insights DSM collects rules alerts that are forwarded from IBM Security Guardium Insights.

IBM QRadar collects informational, error, alert, and warnings from IBM Guardium by using syslog. QRadar receives IBM Guardium Policy Builder events in the Log Event Extended Format (LEEF).

QRadar can only automatically discover and map events of the default rules that are included with IBM Security Guardium Insights. Any user-configured events that are needed are displayed as unknowns in QRadar and you must manually map the unknown events.

To integrate IBM Security Guardium Insights with QRadar, complete the following steps:

1. In IBM Security Guardium Insights, configure a syslog alert Integration that Includes the QRadar LEEF header in templates. For more information, see [Configuring syslog alerts](#) (<https://www.ibm.com/docs/en/guardium-insights/3.2.x?topic=integrations-configuring-syslog-alerts>).
2. Create a policy rule action in IBM Security Guardium Insights that uses the syslog alert integration. For more information, see [Creating a custom policy](#) (<https://www.ibm.com/docs/en/guardium-insights/3.2.x?topic=policies-creating-custom-policy>).
3. Configure an IBM Security Guardium Insights log source in QRadar. For more information, see [Syslog log source parameters for IBM Security Guardium Insights](#).
4. Identify and map unknown events for IBM Security Guardium Insights in QRadar . For more information, see [Creating an event map for IBM Guardium events](#).
5. You can use sample event messages to verify a successful integration with QRadar. For more information, see [IBM Security Guardium Insights sample event messages](#).

## Syslog log source parameters for IBM Security Guardium Insights

If QRadar does not automatically detect the log source, add an IBM Guardium log source on the QRadar Console by using the Syslog protocol.

When you use the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from IBM Guardium:

Table 628. Syslog log source parameters for the IBM Guardium DSM

| Parameter                     | Value                                                                      |
|-------------------------------|----------------------------------------------------------------------------|
| <b>Log Source type</b>        | IBM Security Guardium Insights                                             |
| <b>Protocol Configuration</b> | Syslog                                                                     |
| <b>Log Source Identifier</b>  | Type the IP address or hostname for the IBM InfoSphere Guardium appliance. |

## Creating an event map for IBM Guardium events

Event mapping is needed for some IBM Guardium events. Due to the customizable nature of policy rules, most events, except the default policy events do not contain a predefined IBM QRadar Identifier (QID) map to categorize security events.

#### About this task

You can individually map each event for your device to an event category in QRadar. Mapping events allows QRadar to identify, coalesce, and track recurring events from your network devices. Until you map an event, all events that are displayed in the **Log Activity** tab for IBM Guardium are categorized as unknown. Unknown events are easily identified as the **Event Name** column and **Low Level Category** columns display Unknown.

As your device forwards events to QRadar, it can take time to categorize all events for a device. Some events might not be generated immediately by the event source appliance or software. It is helpful to know how to quickly search for unknown events. When you know how to search for unknown events, we suggest that you repeat this search until you are satisfied that most of your events are identified.

#### Procedure

1. Log in to QRadar.
2. Click the **Log Activity** tab.
3. Click **Add Filter**.
4. From the first list, select **Log Source**.
5. From the **Log Source Group** list, select the log source group or **Other**.

Log sources that are not assigned to a group are categorized as Other.

6. From the **Log Source** list, select your IBM Guardium log source.
7. Click **Add Filter**.

The **Log Activity** tab is displayed with a filter for your log source.

8. From the **View** list, select **Last Hour**.

Any events that are generated by the IBM Guardium DSM in the last hour are displayed. Events that are displayed as unknown in the **Event Name** column or **Low Level Category** column require event mapping in QRadar.

**Note:** You can save your existing search filter by clicking **Save Criteria**.

You are now ready to modify the event map.

## Modifying the event map

Modifying an event map allows for the manual categorization of events to a IBM QRadar Identifier (QID) map. Any event that is categorized to a log source can be remapped to a new QRadar Identifier (QID).

### About this task

IBM Guardium event map events that don't have a defined log source are not mapped to an event. Events without a log source display **SIM Generic Log** in the **Log Source** column.

### Procedure

1. On the **Event Name column**, double-click an unknown event for IBM Guardium.

The detailed event information is displayed.

2. Click **Map Event**.

3. From the **Browse for QID** pane, select any of the following search options to narrow the event categories for a QRadar Identifier (QID):

- From the **High-Level Category** list, select a high-level event categorization.
- For a full list of high-level and low-level event categories or category definitions, see the Event Categories section of the *IBM QRadar Administration Guide*.
- From the **Low-Level Category** list, select a low-level event categorization.
- From the **Log Source Type** list, select a log source type.

The **Log Source Type** list gives the option to search for QIDs from other log sources. Searching for QIDs by log source is useful when events are similar to another existing network device. For example, IBM Guardium provides policy events, you might select another product that likely captures similar events.

4. To search for a QID by name, type a name in the **QID/Name** field.

The **QID/Name** field gives the option to filter the full list of QIDs for a specific word, for example, policy.

5. Click **Search**.

A list of QIDs are displayed.

6. Select the QID you want to associate to your unknown event.

7. Click **OK**.

QRadar maps any additional events that are forwarded from your device with the same QID that matches the event payload. The event count increases each time that the event is identified by QRadar.

If you update an event with a new QRadar Identifier (QID) map, past events that are stored in QRadar are not updated. Only new events are categorized with the new QID.

## IBM Security Guardium Insights sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### IBM Security Guardium Insights sample message when you use the Syslog protocol

**Sample 1:** The following sample event message shows that an attempted login to the database is not successful.

## IBM Security Identity Governance

The IBM QRadar DSM for IBM Security Identity Governance collects audit events from IBM Security Governance servers.

The following table identifies the specifications for the IBM Security Identity Governance DSM:

Table 631. IBM Security Identity Governance (ISIG) DSM specifications

| Specification | Value                            |
|---------------|----------------------------------|
| Manufacturer  | IBM                              |
| DSM name      | IBM Security Identity Governance |

*Table 631. IBM Security Identity Governance (ISIG) DSM specifications (continued)*

| <b>Specification</b>        | <b>Value</b>                                                             |
|-----------------------------|--------------------------------------------------------------------------|
| RPM file name               | DSM-IBMSecurityIdentityGovernance-QRadar_version-build_number.noarch.rpm |
| Supported versions          | IBM Security Identity Governance V5.1.1                                  |
| Protocol                    | JDBC                                                                     |
| Event format                | NVP                                                                      |
| Recorded event types        | Audit                                                                    |
| Automatically discovered?   | No                                                                       |
| Includes identity?          | No                                                                       |
| Includes custom properties? | No                                                                       |
| More information            | <a href="https://www.ibm.com">IBM website (https://www.ibm.com)</a>      |

To integrate IBM Security Identity Governance with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console. If multiple DSM RPMs are required, the integration sequence must reflect the DSM RPM dependency.
  - IBM Security Identity Governance (ISIG) DSM RPM
  - JDBC Protocol RPM
2. Configure a JDBC log source to poll for events from your IBM Security Identity Governance database.
3. Ensure that no firewall rules block communication between QRadar and the database that is associated with IBM Security Identity Governance.
4. If QRadar does not automatically detect the log source, add an IBM Security Identity Governance log source on the QRadar Console. The following table describes the parameters that require specific values for IBM Security Identity Governance event collection:

*Table 632. IBM Security Identity Governance DSM log source parameters*

| <b>Parameter</b>              | <b>Value</b>                           |
|-------------------------------|----------------------------------------|
| <b>Log Source Name</b>        | Type a unique name for the log source. |
| <b>Log Source Description</b> | Type a description for the log source. |
| <b>Log Source Type</b>        | IBM Security Identity Governance       |
| <b>Protocol Configuration</b> | JDBC                                   |

Table 632. IBM Security Identity Governance DSM log source parameters (continued)

| Parameter                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source Identifier</b> | Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.<br><br>If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2. |
| <b>Database Type</b>         | Select <b>Oracle</b> or <b>DB2</b> for the database that you want to use as the event source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Database Name</b>         | The name of the database to which you want to connect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>IP or Hostname</b>        | The IP address or host name of the IBM Security Governance database server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Port</b>                  | Enter the JDBC port. The JDBC port must match the listener port that is configured on the remote database. The database must permit incoming TCP connections. The valid range is 1 - 65535.<br><br>The defaults are: <ul style="list-style-type: none"> <li>• MSDE - 1433</li> <li>• Postgres - 5432</li> <li>• MySQL - 3306</li> <li>• Sybase - 1521</li> <li>• Oracle - 1521</li> <li>• Informix - 9088</li> <li>• DB2 - 50000</li> </ul> If a database instance is used with the MSDE database type, you must leave the <b>Port</b> field blank.                                                                                                           |
| <b>Username</b>              | A user account for QRadar in the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Password</b>              | The password that is required to connect to the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Predefined Query</b>      | Select a predefined database query for the log source. If a predefined query is not available for the log source type, administrators can select the <b>none</b> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Table Name</b>            | AUDIT_LOG                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Table 632. IBM Security Identity Governance DSM log source parameters (continued)

| Parameter                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## JDBC log source parameters for IBM Security Identity Governance

If QRadar does not automatically detect the log source, add a IBM Security Identity Governance log source on the QRadar Console by using the JDBC protocol.

When using the JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from IBM Security Identity Governance:

Table 633. JDBC log source parameters for the IBM Security Identity Governance DSM

| Parameter                     | Value                            |
|-------------------------------|----------------------------------|
| <b>Log Source type</b>        | IBM Security Identity Governance |
| <b>Protocol Configuration</b> | JDBC                             |
| <b>Table Name</b>             | AUDIT_LOG                        |
| <b>Compare Field</b>          | ID                               |

For a complete list of JDBC protocol parameters and their values, see “[JDBC protocol configuration options](#)” on page 147.

## IBM Security Identity Manager

The IBM QRadar DSM for IBM Security Identity Manager accepts audit, recertification, and system events from IBM Security Identity Manager appliances.

To integrate IBM Security Identity Manager with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the DSM Common RPM on your QRadar Console.
2. Configure your IBM Security Identity Manager to send events to QRadar.
3. If QRadar does not automatically detect the log source, add a IBM Security Identity Manager log source on the QRadar Console.

To collect events with QRadar, you must have the IBM Security Identity Manager JDBC protocol that is installed, which allows QRadar to poll for event information in the ITIMDB database. IBM Security Identity Manager events are generated from the audit table along with several other tables from the database.

Before you configure QRadar to integrate with IBM Security Identity Manager, create a database user account and password in IBM Security Identity Manager for QRadar. Your QRadar user needs read permission for the ITIMDB database, which stores IBM Security Identity Manager events.

The IBM Security Identity Manager protocol allows QRadar to log in and poll for events from the database. Creating a QRadar account is not required, but it is suggested for tracking and securing your event data.

**Note:** Ensure that no firewall rules are blocking the communication between your IBM Security Identity Manager appliance and QRadar.

## IBM Security Identity Manager JDBC log source parameters for IBM Security Identity Manager

If QRadar does not automatically detect the log source, add an IBM Security Identity Manager log source on the QRadar Console by using the IBM Security Identity Manager JDBC protocol.

When using the IBM Security Identity Manager JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from IBM Security Identity Manager:

*Table 634. IBM Security Identity Manager JDBC log source parameters for the IBM Security Identity Manager DSM*

| Parameter                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Log Source type</b>        | IBM Security Identity Manager                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Protocol Configuration</b> | IBM Security Identity Manager JDBC                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Log Source Identifier</b>  | Type the IP address or host name for the log source as an identifier for events from your IBM Security Identity Manager devices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Database Type</b>          | <p>From the <b>Database Type</b> list, select a database to use for the event source.</p> <p>The options include the following databases:</p> <ul style="list-style-type: none"> <li>• DB2 - Select this option if DB2 is the database type on your IBM Security Identity Manager appliance. DB2 is the default database type.</li> <li>• <b>MSDE</b> - Select this option if MSDE is the database type on your IBM Security Identity Manager appliance.</li> <li>• <b>Oracle</b> - Select this option if Oracle is the database type on your IBM Security Identity Manager appliance.</li> </ul>                                                                                                                          |
| <b>Database Name</b>          | The name of the database to which you want to connect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>IP or Hostname</b>         | Type the IP address or host name of the IBM Security Identity Manager appliance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Port</b>                   | <p>Type the port number that is used by the database server. The default that is displayed depends on the selected <b>Database Type</b>. The valid range is 0 - 65536. The default for DB2 is port 50000.</p> <p>The JDBC configuration port must match the listener port of the database. The database must have incoming TCP connections that are enabled to communicate with QRadar.</p> <p>The default port number for all options include:</p> <ul style="list-style-type: none"> <li>• DB2 - 50000</li> <li>• MSDE - 1433</li> <li>• Oracle - 1521</li> </ul> <p>If you define a database Instance when you use MSDE as the database type, you must leave the <b>Port</b> parameter blank in your configuration.</p> |
| <b>Username</b>               | Type the database user name. The user name can be up to 255 alphanumeric characters in length. The user name can also include underscores (_).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

*Table 634. IBM Security Identity Manager JDBC log source parameters for the IBM Security Identity Manager DSM (continued)*

| Parameter                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Password</b>                       | Type the database password.<br>The password can be up to 255 characters in length.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Schema Name</b>                    | Type ISIMUSER in the <b>Schema Name</b> field.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Table Name</b>                     | Type AUDIT_EVENT as the name of the table or view that includes the event records. If you change the value of this field from the default, events cannot be properly collected by the IBM Security Identity Manager JDBC protocol.<br><br>The table name can be up to 255 alphanumeric characters in length. The table name can include the following special characters: dollar sign (\$), number sign (#), underscore (_), en dash (-), and period(.) .                                   |
| <b>Select List</b>                    | Type * to include all fields from the table or view.<br><br>You can use a comma-separated list to define specific fields from tables or views, if needed for your configuration. The list must contain the field that is defined in the <b>Compare Field</b> parameter. The comma-separated list can be up to 255 alphanumeric characters in length. The list can include the following special characters: dollar sign (\$), number sign (#), underscore (_), en dash (-), and period(.) . |
| <b>Compare Field</b>                  | Type TIMESTAMP to identify new events added between queries to the table by their time stamp.<br><br>The compare field can be up to 255 alphanumeric characters in length. The list can include the special characters: dollar sign (\$), number sign (#), underscore (_), en dash (-), and period(.) .                                                                                                                                                                                     |
| <b>Start Date and Time (Optional)</b> | Configure the start date and time for database polling.<br><br>The <b>Start Date and Time</b> parameter must be formatted as yyyy-MM-dd HH: mm with HH specified by using a 24-hour clock. If the start date or time is clear, polling begins immediately and repeats at the specified polling interval.                                                                                                                                                                                    |

*Table 634. IBM Security Identity Manager JDBC log source parameters for the IBM Security Identity Manager DSM (continued)*

| Parameter                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Polling Interval</b>      | Type the polling interval in seconds, which is the amount of time between queries to the database table. The default polling interval is 30 seconds.<br><br>You can define a longer polling interval by appending H for hours or M for minutes to the numeric value. The maximum polling interval is 1 week in any time format. Numeric values without an H or M designator poll in seconds.                                                         |
| <b>EPS Throttle</b>          | The maximum number of events per second that QRadar ingests.<br><br>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.<br><br>The default is 5000.                                                                                                                                                                     |
| <b>Authentication Domain</b> | If you select <b>MSDE</b> as the <b>Database Type</b> , the <b>Authentication Domain</b> field is displayed. If your network is configured to validate users with domain credentials, you must define a Windows Authentication Domain. Otherwise, leave this field blank.<br><br>The authentication domain must contain alphanumeric characters. The domain can include the following special characters: underscore (_), en dash (-), and period(.) |
| <b>Database Instance</b>     | If you select <b>MSDE</b> as the <b>Database Type</b> , the <b>Database Instance</b> field is displayed.<br><br>Type the instance to which you want to connect, if you have multiple SQL server instances on one server.<br><br>If you use a non-standard port in your database configuration, or access to port 1434 for SQL database resolution is blocked, you must leave the <b>Database Instance</b> parameter blank in your configuration.     |

*Table 634. IBM Security Identity Manager JDBC log source parameters for the IBM Security Identity Manager DSM (continued)*

| Parameter                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Use Named Pipe Communication</b> | If you select <b>MSDE</b> as the <b>Database Type</b> , the <b>Use Named Pipe Communication</b> check box is displayed. By default, this check box is clear.<br><br>Select this check box to use an alternative method to a TCP/IP port connection.<br><br>When you use Named Pipe connection, the user name and password must be the appropriate Windows authentication user name and password and not the database user name and password. Also, you must use the default Named Pipe.   |
| <b>Use NTLMv2</b>                   | If you select <b>MSDE</b> as the <b>Database Type</b> , the <b>Use NTLMv2</b> check box is displayed.<br><br>Select the <b>Use NTLMv2</b> check box to force MSDE connections to use the NTLMv2 protocol when they communicate with SQL servers that require NTLMv2 authentication. The default value of the check box is selected.<br><br>If the <b>Use NTLMv2</b> check box is selected, it has no effect on MSDE connections to SQL servers that do not require NTLMv2 authentication. |
| <b>Database Cluster Name</b>        | If you select the <b>Use Named Pipe Communication</b> check box, the <b>Database Cluster Name</b> parameter is displayed. If you are running your SQL server in a cluster environment, define the cluster name to ensure Named Pipe communication functions properly.                                                                                                                                                                                                                     |

## IBM Security Network IPS (GX)

The IBM Security Network IPS (GX) DSM for IBM Security QRadar collects LEEF-based events from IBM Security Network IPS appliances by using the syslog protocol.

The following table identifies the specifications for the IBM Security Network IPS (GX) DSM:

| Parameter          | Value                                                            |
|--------------------|------------------------------------------------------------------|
| Manufacturer       | IBM                                                              |
| DSM                | Security Network IPS (GX)                                        |
| RPM file name      | DSM-IBMSecurityNetworkIPS-QRadar_version-Build_number.noarch.rpm |
| Supported versions | v4.6 and later (UDP)<br>v4.6.2 and later (TCP)                   |
| Protocol           | syslog (LEEF)                                                    |

| Parameter                 | Value                                                                                                                                                                     |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QRadar recorded events    | Security alerts (including IPS and SNORT)<br>Health alerts<br>System alerts<br>IPS events (Including security, connection, user defined, and OpenSignature policy events) |
| Automatically discovered? | Yes                                                                                                                                                                       |
| Includes identity?        | No                                                                                                                                                                        |

To integrate the IBM Security Network IPS (GX) appliance with QRadar, use the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the IBM Security Network IPS (GX) RPMs from the [IBM Support Website](#) onto your QRadar Console.
2. For each instance of IBM Security Network IPS (GX), configure your IBM Security Network IPS (GX) appliance to enable communication with QRadar.
3. If QRadar does not automatically discover the log source, create a log source for each instance of IBM Security Network IPS (GX) on your network.

## Configuring your IBM Security Network IPS (GX) appliance for communication with QRadar

To collect events with QRadar, you must configure your IBM Security Network IPS (GX) appliance to enable syslog forwarding of LEEF events.

### Before you begin

Ensure that no firewall rules block the communication between your IBM Security Network IPS (GX) appliance and QRadar.

### Procedure

1. Log in to your IPS Local Management Interface.
2. From the navigation menu, select **Manage System Settings > Appliance > LEEF Log Forwarding**.
3. Select the **Enable Local Log** check box.
4. In the **Maximum File Size** field, configure the maximum file size for your LEEF log file.
5. From the Remote Syslog Servers pane, select the **Enable** check box.
6. In the **Syslog Server IP/Host** field, type the IP address of your QRadar Console or Event Collector.
7. In the **TCP Port** field, type 514 as the port for forwarding LEEF log events.

**Note:** If you use v4.6.1 or earlier, use the **UDP Port** field.

8. From the event type list, enable any event types that are forwarded to QRadar.
9. If you use a TCP port, configure the **crm.leef.fullavp** tuning parameter:
  - a) From the navigation menu, select **Manage System Settings > Appliance > Tuning Parameters**.
  - b) Click **Add Tuning Parameters**.
  - c) In the **Name** field, type **crm.leef.fullavp**.
  - d) In the **Value** field, type **true**.
  - e) Click **OK**.

## Syslog log source parameters for IBM Security Network IPS (GX)

If QRadar does not automatically detect the log source, add an IBM Security Network IPS (GX) log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from IBM Security Network IPS (GX):

*Table 635. Syslog log source parameters for the IBM Security Network IPS (GX) DSM*

| Parameter                     | Value                                                                                                                         |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source type</b>        | IBM Security Network IPS (GX)                                                                                                 |
| <b>Protocol Configuration</b> | Syslog                                                                                                                        |
| <b>Log Source Identifier</b>  | The IP address or host name for the log source as an identifier for events from your IBM Security Network IPS (GX) appliance. |

| More information            | <a href="#">IBM Security Privileged Identity Manager website</a> ( <a href="https://www.ibm.com/support/knowledgecenter/en/SSRQBP/welcome.html">https://www.ibm.com/support/knowledgecenter/en/SSRQBP/welcome.html</a> ) |

To collect events from IBM Security Privileged Identity Manager, complete the following steps:

- If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - JDBC Protocol Rational® Portfolio Manager
  - IBM Security Privileged Identity Manager DSM RPM
- Configure IBM Security Privileged Identity Manager to communicate with QRadar.
- Add an IBM Security Privileged Identity Manager log source on the QRadar Console. The following table describes the parameters that require specific values for event collection:

*Table 637. IBM Security Privileged Identity Manager JDBC log source parameters*

| Parameter                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source Name</b>                   | Type a unique name for the log source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Log Source Description (Optional)</b> | Type a description for the log source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Log Source type</b>                   | IBM Security Privileged Identity Manager                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Protocol Configuration</b>            | JDBC                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Log Source Identifier</b>             | <p>Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.</p> <p>If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2.</p> |
| <b>Database Type</b>                     | MSDE                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Database Name</b>                     | The database name must match the database name that is specified in the <b>Log Source Identifier</b> field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>IP or Hostname</b>                    | Must match the value in the <b>Hostname</b> field in IBM Security Privileged Identity Manager.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Port</b>                              | Must match the value in the <b>Port</b> field in IBM Security Privileged Identity Manager.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Username</b>                          | Must match the value in the <b>Database administrator ID</b> field in IBM Security Privileged Identity Manager.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Password</b>                          | The password that is used to connect to the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Authentication Domain</b>             | <p>If you did not select <b>Use Microsoft JDBC</b>, <b>Authentication Domain</b> is displayed.</p> <p>The domain for MSDE databases that are a Windows domain. If your network does not use a domain, leave this field blank.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                    |

Table 637. IBM Security Privileged Identity Manager JDBC log source parameters (continued)

| Parameter                             | Value                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Database Instance</b>              | The database instance, if required. MSDE databases can include multiple SQL server instances on one server.<br><br>When a non-standard port is used for the database or access is blocked to port 1434 for SQL database resolution, the <b>Database Instance</b> parameter must be blank in the log source configuration.                                         |
| <b>Predefined Query</b>               | Select <b>None</b> .                                                                                                                                                                                                                                                                                                                                              |
| <b>Table Name</b>                     | <DB2ADMIN>.V_PIM_AUDIT_EVENT<br><br>Replace DB2ADMIN with the actual database schema name as identified in the <b>Database Administrator ID</b> parameter in IBM Security Privileged Identity Manager.                                                                                                                                                            |

## Configuring IBM Security Privileged Identity Manager to communicate with QRadar

To communicate with IBM QRadar, the IBM Security Privileged Identity Manager DB2 database must have incoming TCP connections enabled.

### Procedure

1. Log in to IBM Security Privileged Identity Manager.
2. Click the **Configure Privileged Identity Manager** tab.
3. In the **Manage External Entities** pane, select **Database Server Configuration**.
4. Double-click the **Identity data store** row in the **Database Server Configuration** column.
5. Record the values for the following parameters. You need these values when you configure a log source in QRadar.
  - Host name
  - Port
  - Database name
  - Database Administrator ID

- 6. Important:** If you are using ISPM 2.0.2 FP 6 and later, do not complete this step.

Create a view in IBM Security Privileged Identity Manager DB2 database in the same schema as identified in the **Database Administrator ID** parameter, by running the following SQL statement:

```
CREATE view V_PIM_AUDIT_EVENT ASSELECT ae.ID, ae.itim_event_category as event_category,
ae.ENTITY_NAME, service.NAME service_name, ae.ENTITY_DN, ae.ENTITY_TYPE, ae.ACTION,
ae.INITIATOR_NAME, ae.INITIATOR_DN, ae.CONTAINER_NAME, ae.CONTAINER_DN, ae.RESULT_SUMMARY,
ae.TIMESTAMP, lease.POOL_NAME, lease.LEASE_DN, lease.LEASE_EXPIRATION_TIME,
lease.JUSTIFICATION, ae.COMMENTS, ae.TIMESTAMP2, ae.WORKFLOW_PROCESS_IFROM AUDIT_EVENT aeLEFT
OUTER JOIN AUDIT_MGMTLEASE lease ON (ae.id = lease.event_id)LEFT OUTER JOIN
SA_EVALUATION_CREDENTIAL cred ON (LOWER(ae.entity_dn) = LOWER(cred.DN))LEFT OUTER JOIN
V_SA_EVALUATION_SERVICE service ON (LOWER(cred.service_dn) = LOWER(service.dn));
```

## IBM Security Privileged Identity Manager sample event message

Use this sample event message as a way of verifying a successful integration with QRadar.

The following table provides a sample event message when you use the JDBC protocol for the IBM Security Privileged Identity Manager DSM:

*Table 638. IBM Security Privileged Identity Manager sample message supported by the IBM Security Privileged Identity DSM.*

| Event name                                           | Low-level category | Sample log message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## IBM Security QRadar EDR

Enrich SIEM logs with high-fidelity endpoint alerts by using the IBM Security QRadar EDR DSM.

IBM Security QRadar EDR is formerly known as IBM Security ReaQta. The DSM RPM name remains as IBM Security ReaQta.

### Integrating IBM Security QRadar EDR with QRadar SIEM

**Tip:** You can integrate IBM Security QRadar EDR with QRadar SIEM with no impact to your EPS count. Contact your IBM sales representative or IBM Business Partner for details.

To integrate QRadar EDR with QRadar, complete the following steps:

- If automatic updates are not enabled, download the most recent versions of the RPMs from the [IBM support website](https://www.ibm.com/support) (<https://www.ibm.com/support>).
  - PROTOCOL IBMSecurityReaQtaRESTAPI RPM
  - DSM - IBMSecurityReaQta DSM RPM

- Configure your QRadar EDR platform to send alerts to QRadar. See [Configuring IBM Security QRadar EDR to communicate with QRadar](#).
- Add a QRadar EDR log source that uses the IBM Security QRadar EDR protocol on the QRadar Console. See [“IBM Security QRadar EDR REST API data source parameters for QRadar EDR” on page 1016](#).  
For more information about adding a log source, see [Adding a log source](#).
- Configure QRadar to collect only the first username from the QRadar EDR alert for the username parameter value. See [Configuring QRadar to collect only the first username from the alert](#).

## Adding your additional EPS

When you have entitlements to both IBM QRadar and IBM Security QRadar EDR, you are entitled to an extra 100 EPS to use in QRadar. To add this additional EPS in QRadar, follow these steps:

- Contact your local sales representative and provide them with your sales order numbers to obtain the license key.
- [Upload the license key in QRadar](#).
- [Allocate the license key to a host](#).
- [Deploy the changes](#).

## Configuring QRadar EDR to communicate with QRadar

To send events from IBM Security QRadar EDR to IBM QRadar, you need an API ID and a Secret Key.

### Procedure

1. Log in to your QRadar EDR console.
2. Go to **Administration > API Applications**.
3. Click **Create Application**.
4. In the **Application Name** field, type a name for the application, then click **Create**.
5. Copy and save the **App ID** and the **Secret Key** values. You need these values when you add a log source in QRadar.

## IBM Security QRadar EDR REST API data source parameters for QRadar EDR

Add an IBM Security QRadar EDR log source that uses the IBM Security QRadar EDR REST API protocol in IBM QRadar.

When you use the IBM Security QRadar EDR REST API protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect IBM Security QRadar EDR REST API events from QRadar EDR.

Table 640. IBM Security QRadar EDR REST API protocol parameters for the IBM Security QRadar EDR DSM

| Parameter                     | Value                                                                                                     |
|-------------------------------|-----------------------------------------------------------------------------------------------------------|
| <b>Log source type</b>        | IBM Security QRadar EDR                                                                                   |
| <b>Protocol Configuration</b> | IBM Security QRadar EDR REST API                                                                          |
| <b>Log source identifier</b>  | The <b>Log source identifier</b> must match the server address or the server name of the QRadar EDR hive. |
| <b>Server Address</b>         | The IP or hostname of the QRadar EDR server.                                                              |

| Table 640. IBM Security QRadar EDR REST API protocol parameters for the IBM Security QRadar EDR DSM (continued) |                                                                                                                                     |
|-----------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                                                                       | Value                                                                                                                               |
| <b>App ID</b>                                                                                                   | The <b>App ID</b> value that you saved when you completed the “Configuring QRadar EDR to communicate with QRadar” on page 1016.     |
| <b>Secret Key</b>                                                                                               | The <b>Secret Key</b> value that you saved when you completed the “Configuring QRadar EDR to communicate with QRadar” on page 1016. |

Full a complete list of IBM Security QRadar EDR REST API protocol parameters and their values, see [IBM Security QRadar EDR REST API protocol](#).

## Related tasks

“Adding a log source” on page 5

[“Configuring ORadar EDR to communicate with ORadar” on page 1016](#)

To send events from IBM Security QRadar EDR to IBM QRadar, you need an API ID and a Secret Key.

## Configuring QRadar to collect only the first username from the alert

If you want to change the way that IBM QRadar processes IBM Security QRadar EDR events, use the DSM Editor to collect only the first username from the alert.

By default, the QRadar EDR DSM collects all usernames from the alert, combines them into a comma-separated list and places them in the **username** field.

## Procedure

1. On the **Admin** tab, in the **Data Sources** section, click **DSM Editor**.
  2. From the **Select Log Source Type** window, select **IBM Security QRadar EDR** from the list, and click **Select**.
  3. On the **Configuration** tab, set **Display DSM Parameters Configuration** to **on**.
  4. From the **Event Collector** list, select the event collector for the log source.
  5. Set **Get First Username** to **on**.
  6. Click **Save** and close the DSM Editor.

# QRadar EDR sample event messages

Use these sample event messages to verify a successful integration with IBM ORadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## **IBM Security QRadar EDR sample message when you use the IBM Security QRadar EDR REST API protocol**

The following sample event message shows the alert that was generated when a customer successfully enrolled with QRadar EDR.

```

## IBM Security Randori Recon

The IBM QRadar DSM for IBM Security Randori Recon collects alerts from Randori Recon.

To integrate Randori Recon with QRadar, complete the following steps:

- If automatic updates are not enabled, download the most recent versions of the RPMs from the [IBM support website](https://www.ibm.com/support) (<https://www.ibm.com/support>).

- PROTOCOL IBMSecurityRandoriRESTAPI RPM
- DSM IBMSecurityRandoriRESTAPI DSM RPM

2. Add a Randori Recon log source that uses the IBM Security Randori REST API protocol on the QRadar Console. See “IBM Security Randori REST API protocol log source parameters for IBM Security Randori Recon” on page 1019.

**Tip:** Before you can configure a log source for Randori Recon in QRadar, you must obtain an API Key from the Randori web portal. You need to have a Randori account to access the portal. For more information about obtaining this value, see [How to Add an API token](https://www.ibm.com/docs/en/SSD5I5K/intapi_api_AddAPIToken.html) ([https://www.ibm.com/docs/en/SSD5I5K/intapi\\_api\\_AddAPIToken.html](https://www.ibm.com/docs/en/SSD5I5K/intapi_api_AddAPIToken.html)).

For more information about adding a log source in QRadar, see [Adding a log source](#).

## IBM Security Randori Recon DSM specifications

When you configure the IBM Security Randori Recon DSM, understanding the specifications for the DSM can help ensure a successful integration. For example, knowing what the supported protocols for Randori Recon are before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the IBM Security Randori Recon DSM.

| <i>Table 642. IBM Security Randori Recon DSM specifications</i> |                                                                           |
|-----------------------------------------------------------------|---------------------------------------------------------------------------|
| <b>Specification</b>                                            | <b>Value</b>                                                              |
| Manufacturer                                                    | IBM Security                                                              |
| DSM name                                                        | IBM Security Randori Recon                                                |
| RPM file name                                                   | <i>DSM-IBMSecurityRandoriRecon-QRadar_version-build_number.noarch.rpm</i> |
| Protocol                                                        | IBM Security Randori REST API                                             |
| Event format                                                    | JSON                                                                      |
| Recorded event types                                            | Detections                                                                |
| Automatically discovered?                                       | Yes                                                                       |
| Includes identity?                                              | No                                                                        |
| Includes custom properties?                                     | No                                                                        |

## IBM Security Randori REST API protocol log source parameters for IBM Security Randori Recon

Add an IBM Security Randori Recon log source that uses the IBM Security Randori REST API protocol.

When you use the IBM Security Randori REST API protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect IBM Security Randori REST API events from Randori Recon:

| <i>Table 643. IBM Security Randori REST API source parameters for the IBM Security Randori Recon DSM</i> |                               |
|----------------------------------------------------------------------------------------------------------|-------------------------------|
| <b>Parameter</b>                                                                                         | <b>Value</b>                  |
| <b>Log Source type</b>                                                                                   | IBM Security Randori Recon    |
| <b>Protocol Configuration</b>                                                                            | IBM Security Randori REST API |

*Table 643. IBM Security Randori REST API source parameters for the IBM Security Randori Recon DSM (continued)*

| Parameter                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source Identifier</b> | The <b>Log Source identifier</b> can be any valid value and does not need to reference a specific server. It can also be the same value as the Log Source Name. If you have more than one configured IBM Security Randori REST API data source, ensure that you give each one a unique name.                                                                                                                                                            |
| <b>API Key</b>               | The <b>API key</b> that is used to access the IBM Security Randori REST API. You must have Randori access to obtain the API key value.<br>For more information about obtaining this value, see <a href="https://www.ibm.com/docs/en/SSD5I5K/intapi_api_AddAPIToken.html">How to Add an API token</a> ( <a href="https://www.ibm.com/docs/en/SSD5I5K/intapi_api_AddAPIToken.html">https://www.ibm.com/docs/en/SSD5I5K/intapi_api_AddAPIToken.html</a> ). |

For a complete list of IBM Security Randori REST API protocol parameters and their values, see [IBM Security Randori REST API protocol configuration options](#).

## IBM Security Trusteer

The IBM QRadar DSM for IBM Security Trusteer® collects HTTP Receiver events from an IBM Security Trusteer device.

To integrate IBM Security Trusteer with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - Protocol Common RPM
  - IBM Security Trusteer DSM RPM
  - HTTP Receiver Protocol RPM
2. Contact your IBM Security Trusteer deployment manager to configure IBM Security Trusteer to forward events to QRadar.
3. If QRadar does not automatically detect the log source, add an IBM Security Trusteer log source on the QRadar Console.

## IBM Security Trusteer DSM specifications

When you configure the IBM Security Trusteer DSM, understanding the specifications for the IBM Security Trusteer DSM can help ensure a successful integration. For example, knowing what the supported version of IBM Security Trusteer is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the IBM Security Trusteer DSM.

*Table 645. IBM Security Trusteer DSM specifications*

| Specification             | Value                                                          |
|---------------------------|----------------------------------------------------------------|
| Manufacturer              | IBM                                                            |
| DSM name                  | IBM Security Trusteer                                          |
| RPM file name             | DSM-IBMSecurityTrusteer-QRadar_version-build_number.noarch.rpm |
| Supported version         | N/A                                                            |
| Protocol                  | HTTP Receiver                                                  |
| Event format              | JSON                                                           |
| Recorded event types      | Trusteer alerts                                                |
| Automatically discovered? | Yes                                                            |
| Includes identity?        | No                                                             |

Table 645. IBM Security Trusteer DSM specifications (continued)

| Specification               | Value                                                                                                                                                    |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Includes custom properties? | No                                                                                                                                                       |

## HTTP Receiver log source parameters for IBM Security Trusteer

If QRadar does not automatically detect the log source, add a IBM Security Trusteer log source on the QRadar Console by using the HTTP Receiver protocol.

When using the HTTP Receiver protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect HTTP Receiver events from IBM Security Trusteer:

Table 646. HTTP Receiver log source parameters for the IBM Security Trusteer DSM

| Parameter                     | Value                                                                                                                                                                                                                                                                                 |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source type</b>        | IBM Security Trusteer                                                                                                                                                                                                                                                                 |
| <b>Protocol Configuration</b> | HTTP Receiver                                                                                                                                                                                                                                                                         |
| <b>Log Source Identifier</b>  | The IP address, hostname, or any name to identify the device.<br>The name must be unique for the log source type.                                                                                                                                                                     |
| <b>Listen Port</b>            | The port that is used by QRadar to accept incoming HTTP Receiver events. The port must match the port that is configured on your IBM Security Trusteer device. The default port is 12469.<br><b>Important:</b> Do not use port 514. Port 514 is used by the standard Syslog listener. |

For a complete list of HTTP Receiver protocol parameters and their values, see [HTTP Receiver protocol configuration options](#).

## IBM Security Trusteer Apex Advanced Malware Protection

The IBM Security Trusteer Apex Advanced Malware Protection DSM collects and forwards event data from a Trusteer Apex Advanced Malware Protection system to IBM QRadar.

QRadar collects the following items from the Trusteer Apex Advanced Malware Protection system:

- Syslog events
- Log files (from an intermediary server that hosts flat feed files from the system.)
- Syslog events through SSL/TLS authentication

The following table lists the specifications for the IBM Security Trusteer Apex Advanced Malware Protection DSM:

*Table 649. IBM Security Trusteer Apex Advanced Malware Protection DSM specifications*

| Specification | Value                                                  |
|---------------|--------------------------------------------------------|
| Manufacturer  | IBM                                                    |
| DSM name      | IBM Security Trusteer Apex Advanced Malware Protection |

Table 649. IBM Security Trusteer Apex Advanced Malware Protection DSM specifications (continued)

| Specification               | Value                                                                                                                                                                                                                                                                                                         |

| Automatically discovered?   | Yes                                                                                                                                                                                                                                                                                                           |
| Includes identity?          | No                                                                                                                                                                                                                                                                                                            |
| Includes custom properties? | No                                                                                                                                                                                                                                                                                                            |
| More information            | <a href="http://www-03.ibm.com/software/products/en/trusteer-apex-adv-malware">IBM Security Trusteer Apex Advanced Malware Protection website</a> ( <a href="http://www-03.ibm.com/software/products/en/trusteer-apex-adv-malware">http://www-03.ibm.com/software/products/en/trusteer-apex-adv-malware</a> ) |

To configure IBM Security Trusteer Apex Advanced Malware Protection event collection, complete the following steps:

- If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM
  - Log File Protocol RPM
  - TLS Syslog Protocol RPM
  - IBM Security Trusteer Apex Advanced Malware Protection DSM RPM
- Choose one of the following options:
  - To send syslog events to QRadar, see “[Configuring IBM Security Trusteer Apex Advanced Malware Protection to send syslog events to QRadar](#)” on page 1028.

- To send syslog events by using TLS Syslog Protocol to QRadar, see “[Configuring IBM Security Trusteer Apex Advanced Malware Protection to send TLS Syslog events to QRadar](#)” on page 1029
  - To collect log files from IBM Security Trusteer Apex Advanced Malware Protection through an intermediary server, see “[Configuring a Flat File Feed service](#)” on page 1031.
3. If QRadar doesn't automatically discover the log source, add an IBM Security Trusteer Apex Advanced Malware Protection log source on the QRadar Console.

The following table describes the parameters that require specific values for IBM Security Trusteer Apex Advanced Malware Protection syslog event collection:

| <i>Table 650. IBM Security Trusteer Apex Advanced Malware Protection log source parameters for Syslog protocol</i> |                                                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Log Source Identifier</b>                                                                                           | The IP address or host name from the syslog header. If the syslog header doesn't contain an IP address or a host name, use the packet IP address.                                                                                                                                                                                                                                                                                                                                                             |
| <b>TLS Listen Port</b>                                                                                                 | The default port is 6514.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Authentication Mode</b>                                                                                             | TLS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Certificate Type</b>                                                                                                | Select the <b>Provide Certificate</b> option from the list.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Maximum Connections</b>                                                                                             | The Maximum Connections parameter controls how many simultaneous connections the TLS Syslog protocol can accept for each Event Collector. For each Event Collector, there is a limit of 1000 connections across all TLS syslog log source configurations. The default for each device connection is 50.<br><br><b>Note:</b> Automatically discovered log sources that share a listener with another log source count only one time towards the limit. For example, the same port on the same event collector. |

*Table 651. IBM Security Trusteer Apex Advanced Malware Protection log source parameters for TLS Syslog protocol (continued)*

| Parameter                               | Value                                                                                                     |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------|
| <b>TLS Protocols</b>                    | Select the version of TLS installed on the client from the drop down list.                                |
| <b>Provided Server Certificate Path</b> | Absolute path of server certificate. For example, /opt/qradar/conf/trusted_certificates/apex-alm-tls.cert |
| <b>Provided Private Key Path</b>        | Absolute path of PKCS#8 private key. For example, /etc/pki/tls/private/apex-alm-tls.pk8                   |

**Important:** When you use the TLS syslog, and you want to use an FQDN to access the system, you must generate your own certificate for the listener, and then specify it in the TLS syslog configuration.

The following table describes the parameters that require specific values for IBM Security Trusteer Apex Advanced Malware Protection log file collection:

*Table 652. IBM Security Trusteer Apex Advanced Malware Protection log source parameters for Log File Protocol*

| Parameter                     | Value                                                                                  |
|-------------------------------|----------------------------------------------------------------------------------------|
| <b>Log Source Type</b>        | IBM Security Trusteer Apex Advanced Malware Protection                                 |
| <b>Protocol Configuration</b> | <b>Log File</b>                                                                        |
| <b>Log Source Identifier</b>  | The IP address or host name of the server that hosts the Flat File Feed.               |
| <b>Service Type</b>           | <b>SFTP</b>                                                                            |
| <b>Remote IP or Hostname</b>  | The IP address or host name of the server that hosts the Flat File Feed.               |
| <b>Remote Port</b>            | 22                                                                                     |
| <b>Remote User</b>            | The user name that you created for QRadar on the server that hosts the Flat File Feed. |
| <b>SSH Key File</b>           | If you use a password, leave this field blank.                                         |
| <b>Remote Directory</b>       | The log file directory where the Flat File Feed is stored.                             |
| <b>Recursive</b>              | To avoid pulling the same file repeatedly to QRadar, do not select this option.        |
| <b>FTP File Pattern</b>       | "trusteer_feeds_.*?_[0-9]{8}_[0-9]*\\.csv"                                             |
| <b>Start Time</b>             | The time that you want your log file protocol to start collecting log files.           |
| <b>Recurrence</b>             | The polling interval for log file retrieval.                                           |
| <b>Run On Save</b>            | Must be enabled.                                                                       |
| <b>Processor</b>              | <b>None</b>                                                                            |

*Table 652. IBM Security Trusteer Apex Advanced Malware Protection log source parameters for Log File Protocol (continued)*

| Parameter                                | Value             |
|------------------------------------------|-------------------|
| <b>Ignore Previously Processed Files</b> | Must be enabled.  |
| <b>Event Generator</b>                   | <b>LINEBYLINE</b> |
| <b>File Encoding</b>                     | <b>UTF-8</b>      |

## Configuring IBM Security Trusteer Apex Advanced Malware Protection to send syslog events to QRadar

You can configure IBM Security Trusteer Apex Advanced Malware Protection to send syslog events to IBM QRadar.

### Before you begin

Install an Apex Local Manager on your Trusteer Management Application (TMA).

For more information about configuring your IBM Security Trusteer Apex Advanced Malware Protection to communicate with QRadar, see:

- *IBM Security Trusteer Apex Advanced Malware Protection Local Manager - Hybrid Solution Reference Guide*
- *IBM Security Trusteer Apex Advanced Malware Protection Feeds Reference Guide*

**Note:** SSL/TLS authentication is not supported.

### Procedure

1. Log in to Trusteer Management Application (TMA).
2. Select **Apex Local Manager & SIEM Settings**.
3. Optional: If the Apex Local Manager wizard doesn't automatically display, click **Add**.
4. Type the name of the Apex Local Manager.
5. Select the **Enable** check box and click **Next**.
6. Type the server settings for QRadar and click **Next**.
7. Optional: If you use a separate syslog server for the Apex Local Manager system events, type the settings.
8. Click **Finish**.

# Configuring IBM Security Trusteer Apex Advanced Malware Protection to send TLS Syslog events to QRadar

You can configure IBM Security Trusteer Apex Advanced Malware Protection to send syslog events through secure socket layer (SSL) or transport layer security (TLS) to IBM QRadar.

Complete the following steps to establish a secure channel for transmitting logs between Apex Trusteer and QRadar:

1. Create TLS/SSL Server Certificates and private key.
2. Create Client Authentication certificates in a PKCS#12 container for Apex Local Manager.
3. Configure the QRadar log source for IBM Security Trusteer Apex Advanced Malware Protection.
4. Configure the Apex Local Manager(AML).

## Creating a TLS/SSL server certificate and private key

To establish a communication between QRadar and Apex Local Manager (ALM) by using TLS encryption, you must create a self-signed certificate with public and private key pairs.

### Procedure

1. Log in to QRadar as a root user by using SSH.
2. Create a self-signed certificate. For example:

```
openssl req -new -x509 -newkey rsa:2048 -days 3650 -sha512 -nodes -x509 -subj "/C=US/  
ST=<State>/L=<City>/O=IBM/OU=IBM Security/CN=qradar FQDN or ip address" -keyout apex-alm-  
tls.key -out apex-alm-tls.cert
```

3. Convert the private key to the required DER encode PKCS#8 format:

```
openssl pkcs8 -topk8 -inform PEM -outform DER -in apex-alm-tls.key -out apex-alm-tls.pk8  
-nocrypt
```

#### Note:

- Use a unique filename if a certificate needs to be changed or updated.
- Put the certificate file in /opt/qradar/conf/trusted\_certificates.
- Do not place the PKCS#8 formatted key file in /opt/qradar/conf/trusted\_certificates.

**Warning:** Make sure that you complete this step so that the connection works between ALM and QRadar.

## Creating Client Authentication certificates and keys for Apex Local Manager

Configuring an ALM for TLS Syslog authentication requires a PKCS#12 file that contains the certificate and private key.

### Procedure

1. Create a self-signed certificate and private key. For example,

```
openssl req -new -x509 -newkey rsa:2048 -days 3650 -sha512 -nodes -x509 -subj "/C=US/  
ST=<State>/L=<City>/O=IBM/OU=IBM Security/CN=ALM FQDN or IP Address" -keyout alm-client-  
syslog-tls.key -out alm-client-syslog-tls.cert
```

2. Create the PKCS#12 container:

```
openssl pkcs12 -export -inkey alm-client-syslog-tls.key -in alm-client-syslog-tls.cert -out  
alm-client-syslog-tls.p12 -name "alm-client-syslog-tls"
```

**Attention:** Make note of the password that you entered. The password is required when you configure the Apex Local Manager.

## Configuring the Apex Local Manager

Configure the Apex Local Manager through a customer-assigned Apex Trusteer Management Application (TMA) original server.

### Procedure

1. Log in to the Apex TMA.
2. From the left navigation menu, click the **Administration** accordion to expand the options available.
3. Click the **Apex Local Manager & SIEM Settings**.
4. Click **Add** and complete the following steps:
  - a) Select the option to enable this Apex Local Manager.
  - b) Enter a unique name.
5. Click **Next**.
6. From the **SIEM/Syslog Server Settings** page, provide a value for the following parameters:

Table 653. Apex Local Manager SIEM/Syslog server setting parameters

| Parameter                  | Description                                                                                                         |
|----------------------------|---------------------------------------------------------------------------------------------------------------------|
| Type                       | IBM Security Q-Radar SIEM (LEEF)                                                                                    |
| Hostname                   | <fqdn of the QRadar appliance>                                                                                      |
| Port                       | Default is 6514.                                                                                                    |
| Protocol                   | <b>TCP with SSL/TLS</b>                                                                                             |
| PKCS#12 Upload File        | Upload the local PKCS#12 file                                                                                       |
| Encryption Password        | The password that was entered during the creation of the client authentication certificates for Apex Local Manager. |
| CA Certificate Upload File | Upload local certificate file. For example, apex-alm-tls.cert                                                       |

7. Click **Next**.
8. From the **System Events Setting** page, provide a value for the following parameters:

Table 654. System events setting parameters

| Parameter                  | Description                                                                                                         |
|----------------------------|---------------------------------------------------------------------------------------------------------------------|
| Hostname                   | <QRadar FQDN or IP Address>                                                                                         |
| Port                       | Default is 6514                                                                                                     |
| Protocol                   | <b>Syslog with SSL/TLS</b>                                                                                          |
| PKCS#12 Upload File        | Upload the local PKCS#12 file. For example, alm-client-syslog.tls.p12                                               |
| Encryption Password        | The password that was entered during the creation of the client authentication certificates for Apex Local Manager. |
| CA Certificate Upload File | Upload local certificate file. For example, apex-alm-tls.cert                                                       |

9. Click **Finish** to save the configuration.
10. Select the new entry.
11. Copy the **Provisioning key**.

## What to do next

See "["Configuring the ALM instance" on page 1031](#)"

## Configuring the ALM instance

Configure the ALM instance by using the provisioning key copied from the Apex Local Manager.

### Procedure

1. Log in to the Apex Local Manager at:

```
https://ipaddress:8443
```

2. From the **General Settings** page, paste the provisioning key into the field and click the **Synchronize Settings**.

**Note:** A message will be displayed that states that the settings synchronized successfully.

3. Click the **Test Connection** to send test event to QRadar and validate the connection.

## Configuring a Flat File Feed service

For IBM QRadar to retrieve log files from IBM Security Trusteer Apex Advanced Malware Protection, you must set up a flat file feed service on an intermediary SFTP-enabled server. The service enables the intermediary server to host the flat files that it receives from IBM Security Trusteer Apex Advanced Malware Protection and allows for connections from external devices so that QRadar can retrieve the log files.

To configure IBM Security Trusteer Apex Advanced Malware Protection to send flat file feed to the intermediary server, contact IBM Trusteer support.

### About this task

Flat file feed use a CSV format. Each feed item is written to the file on a separate line, which contains several comma-separated fields. Each field contains data that describes the feed item. The first field in each feed line contains the feed type.

### Procedure

1. Enable an SFTP-enabled server and ensure that external devices can reach it.
2. Log in to the SFTP-enabled server.
3. Create a user account on the server for IBM Security Trusteer Apex Advanced Malware Protection.
4. Create a user account for QRadar.
5. Optional: Enable SSH key-based authentication.

## What to do next

After you set up the intermediary server, record the following details:

- Target SFTP server name and IP addresses
- SFTP server port (standard port is 22)
- The file path for the target directory
- SFTP user name if SSH authentication is not configured

- Upload frequency (from 1 minute to 24 hours)
- SSH public key in RSA format

IBM Trusteer support uses the intermediary server details when they configure IBM Security Trusteer Apex Advanced Malware Protection to send flat file feed.

## IBM Security Trusteer Apex Local Event Aggregator

---

IBM QRadar can collect and categorize malware, exploit, and data exfiltration detection events from Trusteer Apex Local Event Aggregator.

To collect syslog events, you must configure your Trusteer Apex Local Event Aggregator to forward syslog events to QRadar. Administrators can use the Apex L.E.A. management console interface to configure a syslog target for events. QRadar automatically discovers and creates log sources for syslog events that are forwarded from Trusteer Apex Local Event Aggregator appliances. QRadar supports syslog events from Trusteer Apex Local Event Aggregator V1304.x and later.

To integrate events with QRadar, administrators can complete the following tasks:

1. On your Trusteer Apex Local Event Aggregator appliance, configure syslog server.
2. On your QRadar system, verify that the forwarded events are automatically discovered.

## Configuring syslog for Trusteer Apex Local Event Aggregator

To collect events, you must configure a syslog server on your Trusteer Apex Local Event Aggregator to forward syslog events.

### Procedure

1. Log in to the Trusteer Apex L.E.A. management console.
2. From the navigation menu, select **Configuration**.
3. To export the current Trusteer Apex Local Event Aggregator configuration, click **Export** and save the file.
4. Open the configuration file with a text editor.
5. From the `syslog.event_targets` section, add the following information:

```
{  
  host": "<QRadar IP address>", "port": "514", "proto": "tcp"  
}
```
6. Save the configuration file.
7. From the navigation menu, select **Configuration**.
8. Click **Choose file** and select the new configuration file that contains the event target IP address.
9. Click **Import**.

As syslog events are generated by the Trusteer Apex Local Event Aggregator, they are forwarded to the target specified in the configuration file. The log source is automatically discovered after enough events are forwarded to QRadar. It typically takes a minimum of 25 events to automatically discover a log source.

### What to do next

Administrators can log in to the QRadar Console and verify that the log source is created. The **Log Activity** tab displays events from Trusteer Apex Local Event Aggregator.

## IBM Security Verify (formerly known as IBM Cloud Identity)

---

IBM Security Verify is formerly known as IBM Cloud Identity. The DSM RPM name remains as IBM Cloud Identity.

The IBM QRadar DSM for IBM Security Verify collects JSON events from an IBM Security Verify service.

To integrate IBM Security Verify with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - Protocol Common RPM
  - IBM Security Verify Event Service protocol RPM
  - IBM Cloud Identity DSM RPM
2. Configure your IBM Security Verify server to send events to QRadar. For more information, see [“Configuring QRadar to pull events from IBM Security Verify” on page 1034](#).
3. Add an IBM Security Verify log source on the QRadar Console. For more information about IBM Security Verify log source parameters, see [“IBM Security Verify Event Service log source parameters for IBM Security Verify” on page 1035](#).

## IBM Security Verify DSM Specifications

When you configure IBM Security Verify, understanding the specifications for the IBM Security Verify DSM can help ensure a successful integration. For example, knowing what the supported version of IBM Security Verify is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the IBM Security Verify DSM.

| Table 655. IBM Security Verify DSM specifications |                                                             |
|---------------------------------------------------|-------------------------------------------------------------|
| Specification                                     | Value                                                       |
| Manufacturer                                      | IBM                                                         |
| DSM name                                          | IBM Security Verify                                         |
| RPM file name                                     | DSM-IBMCloudIdentity-QRadar_version-build_number.noarch.rpm |
| Supported version                                 | 1.0                                                         |
| Protocol                                          | IBM Security Verify Event Service                           |
| Event format                                      | JSON                                                        |

Table 655. IBM Security Verify DSM specifications (continued)

| Specification               | Value                                                                                                                                                                                                                                                                                                                                                                                |

## Configuring QRadar to pull events from IBM Security Verify

To send JSON events to QRadar by using the REST API, you must create an API Client for the QRadar system that connects to the IBM Security Verify service.

### Procedure

1. Ensure that you can access your IBM Security Verify tenant's administrative portal.
  2. Complete the steps to generate credentials for use with the REST API in IBM Security Verify. For more information about the Getting Credentials procedure, see [Getting Started](https://www.ibm.com/blogs/security-identity-access/getting-started-with-ibm-cloud-identity-rest-apis/) (<https://www.ibm.com/blogs/security-identity-access/getting-started-with-ibm-cloud-identity-rest-apis/>).
- Important:** Record the **Client ID** and **Client Secret** values from the Getting Credentials procedure in Step 2. You need these values when you add a log source in QRadar.
3. Ensure that the API Client you use for the IBM Security Verify Event Service protocol has **Read reports** or **Manage reports** access permission.

### What to do next

## IBM Security Verify Event Service log source parameters for IBM Security Verify

If IBM QRadar does not automatically detect the log source, add an IBM Security Verify log source on the QRadar Console by using the IBM Security Verify Event Service protocol.

When using the IBM Security Verify Event Service protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect IBM Security Verify Event Service events from IBM Security Verify:

| Table 656. IBM Security Event Service log source parameters for the IBM Security Verify DSM |                                                                             |
|---------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| Parameter                                                                                   | Value                                                                       |
| <b>Log Source type</b>                                                                      | IBM Security Verify                                                         |
| <b>Protocol Configuration</b>                                                               | IBM Security Verify Event Service                                           |
| <b>Log Source Identifier</b>                                                                | <code>https://&lt;your tenant&gt;.ice.ibmcloud.com/v1.0/applications</code> |

For a complete list of IBM Security Verify Event Service protocol parameters and their values, see [IBM Security Verify Event Service protocol configuration options](#).

## IBM Sense

The IBM QRadar DSM for IBM Sense collects notable events from a local or external system that generates Sense events.

The following table describes the specifications for the IBM Sense DSM:

| Table 658. IBM Sense DSM specifications |                                                                                                                              |
|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| Specification                           | Value                                                                                                                        |

| Automatically discovered?               | Yes                                                                                                                          |
| Includes identity?                      | No                                                                                                                           |
| Includes custom properties?             | No                                                                                                                           |
| More information                        | <a href="http://www.ibm.com">IBM website (http://www.ibm.com)</a>                                                            |

To integrate IBM Sense with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:

- IBM Sense DSM RPM
- DSMCommon RPM

The following table shows a sample event message for IBM Sense:

Table 659. IBM Sense sample message.

| Event name      | Low level category | Sample log message                                                                                                                                                                                                                                                                                                                                           |

## Configuring IBM Sense to communicate with QRadar

The User Behavior Analytics (UBA) app uses the IBM Sense DSM to add user risk scores and offenses into QRadar. When the app is installed, an IBM Sense log source is automatically created and configured by the app. No user input or configuration is required.

## IBM SmartCloud Orchestrator

The IBM QRadar DSM for IBM SmartCloud® Orchestrator collects audit logs from the SmartCloud Orchestrator system.

The following table identifies specifications for the IBM SmartCloud Orchestrator DSM.

Table 660. IBM SmartCloud Orchestrator specifications

| Specification                    | Value                                                                |
|----------------------------------|----------------------------------------------------------------------|
| Manufacturer                     | IBM                                                                  |
| DSM name                         | SmartCloud Orchestrator                                              |
| RPM file name                    | DSM-IBMSmartCloudOrchestrator-Qradar_version_build number.noarch.rpm |
| Supported versions               | V2.3 FP1 and later                                                   |
| Protocol type                    | IBM SmartCloud Orchestrator REST API                                 |
| QRadar recorded event types      | Audit Records                                                        |
| Log source type in the QRadar UI | IBM SmartCloud Orchestrator                                          |
| Automatically discovered?        | No                                                                   |
| Includes identity?               | Yes                                                                  |
| Includes custom properties       | No                                                                   |
| More information                 | <a href="http://ibm.com">http://ibm.com</a>                          |

To integrate IBM SmartCloud Orchestrator with QRadar, complete the following steps:

- If automatic updates are not enabled, download and install the most recent version of the following RPMS from the [IBM Support Website](#) onto your QRadar Console:
  - IBM SmartCloud Orchestrator RPM
  - IBM SmartCloud Orchestrator RESTAPI protocol RPM
- Create an IBM SmartCloud Orchestrator log source on the QRadar Console. Use the following values for the SmartCloud-specific parameters:

| Parameter              | Description                                                   |
|------------------------|---------------------------------------------------------------|
| Log Source Type        | IBM SmartCloud Orchestrator.                                  |
| Protocol Configuration | IBM SmartCloud Orchestrator REST API                          |
| IP or Hostname         | The IP address or server name of the SmartCloud Orchestrator. |

No action is required on the IBM SmartCloud Orchestrator system. After you create the log source, QRadar starts collecting logs from IBM SmartCloud Orchestrator.

## Installing IBM SmartCloud Orchestrator

Integrate SmartCloud Orchestrator with IBM QRadar

#### Procedure

- Download and install the latest DSMCommon RPM from the [IBM Support Website](#) onto your QRadar Console. If automatic updates are configured to install DSM updates, this step is not necessary.
- Download and install the latest IBM SmartCloud Orchestrator RESTAPI Protocol RPM from the [IBM Support Website](#) onto to your QRadar Console.
- Download and install the latest IBM SmartCloud Orchestrator RPM from the [IBM Support Website](#) onto your QRadar Console. If automatic updates are configured to install DSM updates, this step is not necessary.

## IBM SmartCloud Orchestrator log source parameters

If QRadar does not automatically detect the log source, add a IBM SmartCloud Orchestrator log source on the QRadar Console by using the IBM SmartCloud Orchestrator REST API protocol.

When using the IBM SmartCloud Orchestrator REST API protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect IBM SmartCloud Orchestrator events:

| Table 661. IBM SmartCloud Orchestrator log source parameters |                                                               |
|--------------------------------------------------------------|---------------------------------------------------------------|
| Parameter                                                    | Value                                                         |
| <b>Log Source type</b>                                       | <b>IBM SmartCloud Orchestrator</b>                            |
| <b>Protocol Configuration</b>                                | IBM SmartCloud <b>Orchestrator REST API</b>                   |
| <b>IP or Hostname</b>                                        | The IP address or server name of the SmartCloud Orchestrator. |
| <b>Username</b>                                              | The user name of the SmartCloud Orchestrator console user.    |

Table 661. IBM SmartCloud Orchestrator log source parameters (continued)

| Parameter               | Value                                                                                                                                                                                                                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Password</b>         | The password of the SmartCloud Orchestrator console user.                                                                                                                                                                                                                               |
| <b>Confirm Password</b> | This option confirms that the password was entered correctly.                                                                                                                                                                                                                           |
| <b>EPS Throttle</b>     | <p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The default is 5000.</p> |
| <b>Recurrence</b>       | How often this log source attempts to obtain data. Can be in Minutes, Hours, Days (default 5 minutes).                                                                                                                                                                                  |

## IBM Tivoli Access Manager for e-business

The IBM Tivoli® Access Manager for e-business DSM for IBM QRadar accepts access, audit, and HTTP events forwarded from IBM Tivoli Access Manager.

QRadar collects audit, access, and HTTP events from IBM Tivoli Access Manager for e-business by using syslog. Before you can configure QRadar, you must configure Tivoli Access Manager for e-business to forward events to a syslog destination.

Tivoli Access Manager for e-business supports WebSEAL, a server that applies fine-grained security policy to the Tivoli Access Manager protected Web object space. For more information about WebSEAL, see [IBM Tivoli Access Manager WebSEAL overview](http://publib.boulder.ibm.com/tividd/td/ITAME/SC32-1359-00/en_US/HTML/am51_webseal_guide10.htm#j1031993) ([http://publib.boulder.ibm.com/tividd/td/ITAME/SC32-1359-00/en\\_US/HTML/am51\\_webseal\\_guide10.htm#j1031993](http://publib.boulder.ibm.com/tividd/td/ITAME/SC32-1359-00/en_US/HTML/am51_webseal_guide10.htm#j1031993)).

## Configuring Tivoli Access Manager for e-business

You can configure syslog on your Tivoli Access Manager for e-business to forward events.

### Procedure

1. Log in to Tivoli Access Manager's IBM Security Web Gateway.
2. From the navigation menu, select **Secure Reverse Proxy Settings > Manage > Reverse Proxy**.

The **Reverse Proxy** pane is displayed.

3. From the **Instance column**, select an instance.

4. Click the **Manage** list and select **Configuration > Advanced**.

The text of the WebSEAL configuration file is displayed.

5. Locate the Authorization API Logging configuration.

The remote syslog configuration begins with logcfg.

For example, to send authorization events to a remote syslog server:

```
# logcfg = audit.azn:rsyslog server=<IP address>,port=514,log_id=<log name>
```

6. Copy the remote syslog configuration (logcfg) to a new line without the comment (#) marker.

7. Edit the remote syslog configuration.

For example,

```
logcfg = audit.azn:rsyslog server=<IP address>,port=514,log_id=<log name>
logcfg = audit.authn:rsyslog server=<IP address>,port=514,log_id=<log name>
logcfg = http:rsyslog server=<IP address>,port=514,log_id=<log name>
```

Where:

- <IP address> is the IP address of your QRadar Console or Event Collector.
- <Log name> is the name assigned to the log that is forwarded to QRadar. For example, log\_id=WebSEAL-log.

8. Customize the `request.log` file.

For example,

```
request-log-format = isam-http-request-log|client-ip=%a|server-
ip=%A|client-logname=%l|remote-user=%u|time=%t|port=%p|protocol=%H|request-
method=%m|response-status=%s|url=%U|bytes=%b|remote-host=%h|request=%r
```

9. Click **Submit**.

The **Deploy** button is displayed in the navigation menu.

10. From the navigation menu, click **Deploy**.

11. Click **Deploy**.

You must restart the reverse proxy instance to continue.

12. From the **Instance** column, select your instance configuration.

13. Click the **Manage** list and select **Control > Restart**.

A status message is displayed after the restart completes. For more information on configuring a syslog destination, see your *IBM Tivoli Access Manager for e-business* vendor documentation. You are now ready to configure a log source in QRadar.

## Syslog log source parameters for IBM Tivoli Access Manager for e-business

If QRadar does not automatically detect the log source, add an IBM Tivoli Access Manager for e-business log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from IBM Tivoli Access Manager for e-business:

| Table 662. Syslog log source parameters for the IBM Tivoli Access Manager for e-business DSM |                                                                                                                                                                                                                               |
|----------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                                                    | Value                                                                                                                                                                                                                         |
| <b>Log Source name</b>                                                                       | Type a name of your log source.                                                                                                                                                                                               |
| <b>Log Source description</b>                                                                | Type a description for your log source.                                                                                                                                                                                       |
| <b>Log Source type</b>                                                                       | IBM Tivoli <b>Access Manager for e-business</b>                                                                                                                                                                               |
| <b>Protocol Configuration</b>                                                                | <b>Syslog</b>                                                                                                                                                                                                                 |
| <b>Log Source Identifier</b>                                                                 | Type the IP address or host name for your IBM Tivoli Access Manager for e-business appliance.<br><br>The IP address or host name identifies your IBM Tivoli Access Manager for e-business as a unique event source in QRadar. |

## IBM Tivoli Access Manager for e-business sample event message

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### IBM Tivoli Access Manager for e-business sample message when you use the Syslog protocol

The following sample event message shows that an HTTP GET request received a response with a status code of 200, indicating a successful request.

```
<134>Aug 22 08:48:41 ibm.tivoliaccessmanager.test isam-http-request-log|client-ip=172.16.3.226|server-ip=172.16.3.235|clientlogname=-|remote-user=unauthenticated|time=22/Aug/2018:08:48:27 -0300|port=443|request-method=GET|response-status=200|url=/QRadar/images/botones/ibm.png|bytes=6631|remote-host=172.16.3.226|Session-Index=acc3ef2e-a5ff-11e8-ad5b-0050568a5f8e|X-Forwarded-For=192.168.0.1|Host-Header=ibm.tivoli.test|Junction=/qradar|Transaction-Identifier=474|
```

*Table 663. Highlighted fields in the IBM Tivoli Access Manager for e-business event*

| QRadar field name | Highlighted field name                                                                                                |
|-------------------|-----------------------------------------------------------------------------------------------------------------------|
| Source IP         | <b>X-Forwarded-For</b><br><b>Important:</b> If this field is not present, the <b>client-ip</b> field is used instead. |
| Destination IP    | <b>server-ip</b>                                                                                                      |

## IBM Tivoli Endpoint Manager

IBM Tivoli® Endpoint Manager is now known as IBM BigFix.

### Related concepts

[“HCL BigFix \(formerly known as IBM BigFix\)” on page 885](#)

## IBM WebSphere Application Server

The IBM WebSphere® Application Server DSM for IBM QRadar accepts events using the log file protocol source.

QRadar records all relevant application and security events from the WebSphere Application Server log files.

## Configuring IBM WebSphere

You can configure IBM WebSphere Application Server events for IBM QRadar.

### Procedure

1. Using a web browser, log in to the IBM WebSphere administrative console.
2. Click **Environment > WebSphere Variables**.
3. Define Cell as the Scope level for the variable.
4. Click **New**.
5. Configure the following values:

- **Name** - Type a name for the cell variable.
- **Description** - Type a description for the variable (optional).
- **Value** - Type a directory path for the log files.

For example:

```
{QRADAR_LOG_ROOT} = /opt/IBM/WebSphere/AppServer/profiles/Custom01/logs/
QRadar
```

You must create the target directory that is specified in [“Configuring IBM WebSphere” on page 1044](#) before proceeding.

6. Click **OK**.

7. Click **Save**.

8. You must restart the WebSphere Application Server to save the configuration changes.

**Note:** If the variable you created affects a cell, you must restart all WebSphere Application Servers in the cell before you continue.

## What to do next

You are now ready to customize the logging option for the IBM WebSphere Application Server DSM.

## Customizing the Logging Option

You must customize the logging option for each application server WebSphere uses and change the settings for the JVM Logs (Java Virtual Machine logs).

### Procedure

1. **Select Servers > Application Servers.**
2. Select your WebSphere Application Server to load the server properties.
3. **Select Logging and Tracing > JVM Logs.**
4. Configure a name for the JVM log files.

For example:

System.out log file name:

```
 ${QRADAR_LOG_ROOT}/${WAS_SERVER_NAME}-SystemOut.log
```

System.Err log file name:

```
 ${QRADAR_LOG_ROOT}/${WAS_SERVER_NAME}-SystemErr.log
```

5. Select a time of day to save the log files to the target directory.
6. Click **OK**.
7. You must restart the WebSphere Application Server to save the configuration changes.

**Note:** If the JVM Logs changes affect the cell, you must restart all of the WebSphere Application Servers in the cell before you continue.

You are now ready to import the file into IBM QRadar using the log file protocol.

## Log File log source parameters for IBM WebSphere

If QRadar does not automatically detect the log source, add a IBM WebSphere log source on the QRadar Console by using the Log File protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from IBM WebSphere:

Table 664. Log File log source parameters for the IBM WebSphere DSM

| Parameter                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source name</b>        | Type a name of your log source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Log Source description</b> | Type a description for your log source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Log Source type</b>        | IBM WebSphere <b>Application Server</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Protocol Configuration</b> | <b>Log File</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Log Source Identifier</b>  | <p>Type an IP address, host name, or name to identify your IBM WebSphere Application Server as an event source in QRadar. IP addresses or host names are recommended as they allow QRadar to identify a log file to a unique event source.</p> <p>For example, if your network contains multiple IBM WebSphere Application Servers that provides logs to a file repository, specify the IP address or host name of the device that created the event log. This allows events to be identified at the device level in your network, instead of identifying the file repository.</p> |
| <b>Service Type</b>           | <p>From the list, select the protocol that you want to use when retrieving log files from a remote server. The default is SFTP.</p> <ul style="list-style-type: none"> <li>• <b>SFTP</b> - SSH File Transfer Protocol</li> <li>• <b>FTP</b> - File Transfer Protocol</li> <li>• <b>SCP</b> - Secure Copy</li> </ul> <p>The underlying protocol that is used to retrieve log files for the SCP and SFTP service type requires that the server specified in the <b>Remote IP or Hostname</b> field has the SFTP subsystem enabled.</p>                                               |
| <b>Remote IP or Hostname</b>  | Type the IP address or host name of your IBM WebSphere Application Server storing your event log files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Remote Port</b>            | <p>Type the TCP port on the remote host that is running the selected Service Type. The valid range is 1 - 65535.</p> <p>The options include FTP ports:</p> <ul style="list-style-type: none"> <li>• <b>FTP</b> - TCP Port 21</li> <li>• <b>SFTP</b> - TCP Port 22</li> <li>• <b>SCP</b> - TCP Port 22</li> </ul> <p>If the host for your event files is using a non-standard port number for FTP, SFTP, or SCP, you must adjust the port value.</p>                                                                                                                                |
| <b>Remote User</b>            | <p>Type the user name necessary to log in to the host that contains your event files.</p> <p>The user name can be up to 255 characters in length.</p>                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Remote Password</b>        | Type the password necessary to log in to the host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Confirm Password</b>       | Confirm the password necessary to log in to the host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

Table 664. Log File log source parameters for the IBM WebSphere DSM (continued)

| Parameter                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SSH Key File</b>      | If you select <b>SCP</b> or <b>SFTP</b> as the <b>Service Type</b> , this parameter allows for the definition of an SSH private key file.<br><br>The <b>Remote Password</b> field is ignored when you provide an SSH Key File.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Remote Directory</b>  | Type the directory location on the remote host to the cell and file path you specified in “Configuring IBM WebSphere” on page 1044. This is the directory that you created containing your IBM WebSphere Application Server event files.<br><br>For FTP only. If your log files are located in the remote user's home directory, you can leave the remote directory blank. This is to support operating systems where a change in the working directory (CWD) command is restricted.                                                                                                                                                                                                                                                                                                              |
| <b>Recursive</b>         | Select this check box if you want the file pattern to search sub folders. By default, the check box is clear.<br><br>The <b>Recursive</b> option is ignored if you configure <b>SCP</b> as the <b>Service Type</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>FTP File Pattern</b>  | If you select <b>SFTP</b> or <b>FTP</b> as the <b>Service Type</b> , this option allows for the configuration of the regular expression (regex) to filter the list of files that are specified in the <b>Remote Directory</b> . All matching files are included in the processing.<br><br>The FTP file pattern that you specify must match the name that you assigned to your JVM logs in “Customizing the Logging Option” on page 1045. For example, to collect system logs, type the following code:<br><br>System.*\log<br><br>Use of this parameter requires knowledge of regular expressions (regex). For more information, see the following website: <a href="http://download.oracle.com/javase/tutorial/essential/regex/">http://download.oracle.com/javase/tutorial/essential/regex/</a> |
| <b>FTP Transfer Mode</b> | This option appears only if you select <b>FTP</b> as the <b>Service Type</b> . The <b>FTP Transfer Mode</b> parameter allows for the definition of the file transfer mode when log files are retrieved over FTP.<br><br>From the list, select the transfer mode that you want to apply to this log source: <ul style="list-style-type: none"> <li>• <b>Binary</b> - Select <b>Binary</b> for log sources that require binary data files or compressed zip, gzip, tar, or tar+gzip archive files.</li> <li>• <b>ASCII</b> - Select <b>ASCII</b> for log sources that require an ASCII FTP file transfer.</li> </ul> You must select <b>None</b> for the Processor parameter and <b>LINEBYLINE</b> the <b>Event Generator</b> parameter when you use ASCII as the <b>FTP Transfer Mode</b> .        |
| <b>SCP Remote File</b>   | If you select <b>SCP</b> as the <b>Service Type</b> you must type the file name of the remote file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

Table 664. Log File log source parameters for the IBM WebSphere DSM (continued)

| Parameter                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Start Time</b>                          | Type the time of day you want the processing to begin. This parameter functions with the <b>Recurrence</b> value to establish when and how often the <b>Remote Directory</b> is scanned for files. Type the start time, based on a 24-hour clock, in the following format: HH: MM.                                                                                                                                                                                                                                                                                                         |
| <b>Recurrence</b>                          | <p>Type the frequency, beginning at the Start Time, that you want the remote directory to be scanned. Type this value in hours (H), minutes (M), or days (D). For example, type 2H if you want the directory to be scanned every 2 hours. The default is 1H.</p> <p>When you schedule a log file protocol, select a recurrence time for the log file protocol shorter than the scheduled write interval of the WebSphere Application Server log files. This ensures that WebSphere events are collected by the log file protocol before the new log file overwrites the old event log.</p> |
| <b>Run On Save</b>                         | <p>Select this check box if you want the log file protocol to run immediately after you click Save. After the Run On Save completes, the log file protocol follows your configured start time and recurrence schedule.</p> <p>Selecting Run On Save clears the list of previously processed files for the Ignore Previously Processed File parameter.</p>                                                                                                                                                                                                                                  |
| <b>EPS Throttle</b>                        | <p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The valid range is 100 to 5000.</p>                                                                                                                                                                                                                                                                                         |
| <b>Processor</b>                           | If the files on the remote host are stored in a zip, gzip, tar, or tar+gzip archive format, select the processor that allows the archives to be expanded and the contents to be processed.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Ignore Previously Processed File(s)</b> | <p>Select this check box to track files that are processed. Files that are previously processed are not processed a second time.</p> <p>This check box applies only to FTP and SFTP Service Types.</p>                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Change Local Directory?</b>             | Select this check box to define the local directory on your QRadar that you want to use for storing downloaded files during processing. We recommend that you leave the check box clear. When the check box is selected, the <b>Local Directory</b> field is displayed, which gives the option of configuring the local directory to use for storing files.                                                                                                                                                                                                                                |
| <b>Event Generator</b>                     | <p>From the <b>Event Generator</b> list, select WebSphere <b>Application Server</b>.</p> <p>The Event Generator applies more processing, which is specific to retrieved event files for IBM WebSphere Application Server events.</p>                                                                                                                                                                                                                                                                                                                                                       |

For a complete list of Log File protocol parameters and their values, see [Log File protocol configuration options](#).

## IBM WebSphere sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### IBM WebSphere sample message when you use the Syslog protocol

The following sample event message shows a failed login.

```
WebSphere::EVENT_TIME=8/1/12 12:01:59:603 EDT EVENT_ID=null EVENT_TYPE=W RAW_EVENT=[8/1/12  
12:01:59:603 EDT] 00000032 LogonAction W org.apache.commons.logging.impl.Jdk14Logger warn Bad  
username/password from someone claiming to be 'hayfordk' from address 10.0.8.108
```

*Table 665. QRadar field names and highlighted values in the IBM WebSphere event payload*

| QRadar field name | Highlighted values in the event payload |
|-------------------|-----------------------------------------|
| Event ID          | The value in QRadar is Login Fail       |
| Event Category    | W                                       |
| SRC IP            | 10.0.8.108                              |
| Event Time        | 8/1/12 12:01:59:603 EDT                 |

## IBM Storage Protect

The IBM QRadar DSM for IBM Storage Protect parses messages and events that are issued by IBM Storage Protect components.

To integrate IBM Storage Protect with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPM from the [IBM Support Website](#) onto your QRadar Console:
  - IBM Storage Protect DSM RPM
2. Configure your IBM Storage Protect server to send events to QRadar. For more information, see [“Configure IBM Storage Protect” on page 1050](#).
3. If QRadar does not automatically detect the log source, add an IBM Storage Protect log source on the QRadar Console. For more information, see [“Syslog log source parameters for IBM Storage Protect” on page 1050](#).

## IBM Storage Protect DSM specifications

The IBM QRadar DSM for IBM Storage Protect supports events that are issued from IBM Storage Protect with the help of Syslog protocol.

The following table describes the specifications for the IBM Storage Protect DSM:

| Table 666. IBM Storage Protect DSM specifications |                                                              |
|---------------------------------------------------|--------------------------------------------------------------|
| Specification                                     | Value                                                        |
| Manufacturer                                      | IBM                                                          |
| DSM name                                          | IBM Storage Protect                                          |
| RPM file name                                     | DSM-IBMStorageProtect-QRadar_version-Build_number.noarch.rpm |
| Protocol                                          | Syslog                                                       |
| Event format                                      | Name Value Pair (NVP)                                        |

*Table 666. IBM Storage Protect DSM specifications (continued)*

| Specification               | Value                                                             |
|-----------------------------|-------------------------------------------------------------------|
| Automatically discovered?   | Yes                                                               |
| Includes identity?          | No                                                                |
| Includes custom properties? | No                                                                |
| More information            | <a href="http://www.ibm.com">IBM website (http://www.ibm.com)</a> |

## Configure IBM Storage Protect

To collect IBM Storage Protect events, configure your IBM Storage Protect servers to send events to QRadar.

Configure your IBM Storage Protect environment so it can forward the syslog events. To configure IBM Storage Protect, complete the following steps:

1. Edit the `/etc/rsyslog.conf` file to add the following line at the end:

```
*.*@<QRadarIP>:514
```

Where:

- `*` specifies instruction to send all logs.
- `@` is the TCP/UDP protocol.
- `<QRadarIP>` is the IP of your QRadar server through port 514.

2. Restart the Syslog service by running the following command:

```
systemctl restart rsyslog
```

## Syslog log source parameters for IBM Storage Protect

If IBM QRadar does not automatically detect the log source, add IBM Storage Protect log source on QRadar Console by using the Syslog protocol.

The following table describes the parameters that require specific values to events from IBM Storage Protect.

*Table 667. IBM Storage Protect DSM specifications*

| Parameter              | Value                                  |
|------------------------|----------------------------------------|
| Log Source type        | IBM Storage Protect                    |
| Protocol Configuration | Syslog                                 |
| Log Source Identifier  | Type a unique name for the log source. |

## Sample event message for IBM Storage Protect

The following sample event message shows events that are collected from IBM Storage Protect.

### Sample 1

```
<86>Aug 23 09:55:54 ibm.storageprotect.test sshd[2219152]: Connection closed by invalid
user Administrator 10.0.0.2 port 52887 [preauth]
```

*Table 668. Highlighted values in the IBM Storage Protect sample event*

| <b>QRadar field name</b> | <b>Highlighted payload field name</b> |
|--------------------------|---------------------------------------|
| Event ID                 | Connection closed                     |
| Source IP                | 10.0.0.2                              |
| Source Port              | 52887                                 |

## Sample 2

```
<11>Aug 23 09:57:28 ibm.storageprotect.test dsmerv[1838509]: IBM-STORAGEPROTECT-TEST-01:  
ANR8213E Socket 93 aborted due to send error; error 104.
```

*Table 669. Highlighted values in the IBM Storage Protect sample event*

| <b>QRadar field name</b> | <b>Highlighted payload field name</b> |
|--------------------------|---------------------------------------|
| Event ID                 | ANR8213E                              |

## IBM WebSphere DataPower

IBM WebSphere DataPower is now known as IBM Datapower.

### Related concepts

[IBM DataPower](#)

## IBM z/OS

The IBM z/OS DSM collects events from an IBM z/OS® mainframe that uses IBM Security zSecure or IBM Z Security and Compliance Center.

When you use a zSecure process, events from the System Management Facilities (SMF) can be transformed into Log Event Extended Format (LEEF) events. These events can be sent near real-time by using UNIX Syslog protocol or IBM QRadar can collect the LEEF event log files by using the Log File protocol and then process the events. When you use the Log File protocol, you can schedule QRadar to collect events on a polling interval, which enables QRadar to collect the events on the schedule that you define.

To collect IBM z/OS events, complete the following steps:

1. Verify that your installation meets any prerequisite installation requirements. For more information about the requirements, see [zSecure CARLa-Driven Components Installation and Deployment Guide: Prerequisites](#) or [IBM Z Security and Compliance Center: System requirements](#).
2. Configure your IBM z/OS image to write events in LEEF format. For more information, see the [zSecure CARLa-Driven Components Installation and Deployment Guide: Data preparation for SIEM](#).
3. Create a log source in QRadar for IBM z/OS.
4. If you want to create a custom event property for IBM z/OS in QRadar, for more information, see the [IBM Security Custom Event Properties for IBM z/OS technical note](#).

### Before you begin

Before you can configure the data collection process, you must complete the basic zSecure installation process and complete the post-installation activities to create and modify the configuration.

The following prerequisites are required:

- You must ensure parmlib member IFAPRDxx is enabled for IBM Security zSecure Audit on your z/OS image.
- The SCKRLOAD library must be APF-authorized.

- If you are using the direct SMF INMEM real-time interface, you must have the necessary software installed (APAR OA49263) and set up the SMFPRMxx member to include the INMEM keyword and parameters. If you decide to use the CDP interface, you must also have CDP installed and running. For more information, see the [zSecure CARLa-Driven Components Installation and Deployment Guide: Procedure for near real-time](#).
- You must configure a process to periodically refresh your CKFREEZE and UNLOAD data sets.
- If you are using the Log File protocol method, you must configure a SFTP, FTP, or SCP server on your z/OS image for QRadar to download your LEEF event files.
- If you are using the Log File protocol method, you must allow SFTP, FTP, or SCP traffic on firewalls that are located between QRadar and your z/OS image.

For instructions on installing and configuring zSecure, see the [IBM Security zSecure CARLa-Driven Components Installation and Deployment Guide](#).

For instructions about installing and configuring IBM Z Security and Compliance Center, see the [Z Security and Compliance Center Guide](#).

## **Create a log source for near real-time event feed**

The Syslog protocol enables IBM QRadar to receive System Management Facilities (SMF) events in near real-time from a remote host.

The following DSMs are supported:

- IBM z/OS
- IBM CICS
- IBM RACF
- IBM DB2
- CA Top Secret
- CA ACF2

If QRadar does not automatically detect the log source, add a log source for your DSM on the QRadar console.

The following table describes the parameters that require specific values for event collection for your DSM:

| <i>Table 670. Log source parameters</i> |                                              |
|-----------------------------------------|----------------------------------------------|
| <b>Parameter</b>                        | <b>Value</b>                                 |
| Log Source type                         | Select your DSM name from the list.          |
| Protocol Configuration                  | Syslog                                       |
| Log Source Identifier                   | Type a unique identifier for the log source. |

## **Log File log source parameter**

If QRadar does not automatically detect the log source, add a IBM z/OS, IBM CICS, IBM RACF, IBM DB2, Broadcom CA Top Secret, or Broadcom CA ACF2 log source on the QRadar Console by using the Log File Protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from IBM z/OS, IBM CICS, IBM RACF, IBM DB2, CA Top Secret, or CA ACF2:

Table 671. Log File log source parameters

| Parameter                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source name</b>        | Type a name for your log source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Log Source description</b> | Type a description for the log source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Log Source type</b>        | Select your DSM name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Protocol Configuration</b> | <b>Log File</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Log Source Identifier</b>  | <p>Type an IP address, host name, or name to identify the event source. IP addresses or host names are suggested as they allow QRadar to identify a log file to a unique event source.</p> <p>For example, if your network contains multiple devices, such as multiple z/OS images or a file repository that contains all of your event logs, you must specify a name, IP address, or host name for the image or location that uniquely identifies events for the DSM log source. This specification enables events to be identified at the image or location level in your network that your users can identify.</p> |
| <b>Service Type</b>           | <p>From the <b>Service Type</b> list, select the protocol that you want to use when retrieving log files from a remote server. The default is SFTP.</p> <ul style="list-style-type: none"> <li>• SFTP - SSH File Transfer Protocol</li> <li>• FTP - File Transfer Protocol</li> <li>• SCP - Secure Copy</li> </ul> <p>The underlying protocol that is used to retrieve log files for the SCP and SFTP service type requires that the server that is specified in the <b>Remote IP or Hostname</b> field has the SFTP subsystem enabled.</p>                                                                           |
| <b>Remote IP or Hostname</b>  | Type the IP address or host name of the device that stores your event log files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Remote Port</b>            | <p>Type the TCP port on the remote host that is running the selected <b>Service Type</b>. The valid range is 1 - 65535.</p> <p>The options include ports:</p> <ul style="list-style-type: none"> <li>• FTP - TCP Port 21</li> <li>• SFTP - TCP Port 22</li> <li>• SCP - TCP Port 22</li> </ul> <p>If the host for your event files is using a non-standard port number for FTP, SFTP, or SCP, you must adjust the port value.</p>                                                                                                                                                                                     |

Table 671. Log File log source parameters (continued)

| Parameter               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Remote User</b>      | Type the user name or user ID necessary to log in to the system that contains your event files. <ul style="list-style-type: none"> <li>If your log files are on your IBM z/OS image, type the user ID necessary to log in to your IBM z/OS. The user ID can be up to 8 characters in length.</li> <li>If your log files are on a file repository, type the user name necessary to log in to the file repository. The user name can be up to 255 characters in length.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Remote Password</b>  | Type the password necessary to log in to the host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Confirm Password</b> | Confirm the password necessary to log in to the host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SSH Key File</b>     | If you select <b>SCP</b> or <b>SFTP</b> as the <b>Service Type</b> , this parameter gives you the option to define an SSH private key file. When you provide an SSH Key File, the <b>Remote Password</b> field is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Remote Directory</b> | Type the directory location on the remote host from which the files are retrieved, relative to the user account you are using to log in.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Recursive</b>        | If you want the file pattern to search sub folders in the remote directory, select this check box. By default, the check box is clear.<br><br>If you configure SCP as the Service Type, the Recursive option is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>FTP File Pattern</b> | If you select <b>SFTP</b> or <b>FTP</b> as the <b>Service Type</b> , you can configure the regular expression (regex) needed to filter the list of files that are specified in the <b>Remote Directory</b> . All matching files are included in the processing.<br><br>The IBM z/OS mainframe that uses IBM Security zSecure Audit writes event files by using the pattern: <product_name>.<timestamp>.gz<br><br>The FTP file pattern that you specify must match the name that you assigned to your event files. For example, to collect files that start with zOS and end with .gz, type the following code:<br><br>zOS.*\.gz<br><br>Use of this parameter requires knowledge of regular expressions (regex). For more information about regex, see <a href="https://docs.oracle.com/javase/tutorial/essential/regex/">Lesson: Regular Expressions</a> ( <a href="https://docs.oracle.com/javase/tutorial/essential/regex/">https://docs.oracle.com/javase/tutorial/essential/regex/</a> ). |

Table 671. Log File log source parameters (continued)

| Parameter                | Value                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FTP Transfer Mode</b> | <p>This option displays only if you select <b>FTP</b> as the <b>Service Type</b>. From the list, select <b>Binary</b>.</p> <p>The binary transfer mode is needed for event files that are stored in a binary or compressed format, such as zip, gzip, tar, or tar+gzip archive files.</p>                                                                                              |
| <b>SCP Remote File</b>   | If you select <b>SCP</b> as the <b>Service Type</b> you must type the file name of the remote file.                                                                                                                                                                                                                                                                                    |
| <b>Start Time</b>        | <p>Type the time of day you want the processing to begin. For example, type 00 : 00 to schedule the Log File protocol to collect event files at midnight.</p> <p>This parameter functions with the Recurrence value to establish when and how often the Remote Directory is scanned for files. Type the start time, based on a 24-hour clock, in the following format: HH: MM.</p>     |
| <b>Recurrence</b>        | <p>Type the frequency, beginning at the Start Time, that you want the remote directory to be scanned. Type this value in hours (H), minutes (M), or days (D).</p> <p>For example, type 2H if you want the remote directory to be scanned every 2 hours from the start time. The default is 1H.</p>                                                                                     |
| <b>Run On Save</b>       | <p>If you want the Log File protocol to run immediately after you click <b>Save</b>, select this check box.</p> <p>After the <b>Run On Save</b> completes, the Log File protocol follows your configured start time and recurrence schedule.</p> <p>Selecting <b>Run On Save</b> clears the list of previously processed files for the Ignore Previously Processed File parameter.</p> |
| <b>EPS Throttle</b>      | <p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The valid range is 100 to 5000.</p>                                                                                     |

Table 671. Log File log source parameters (continued)

| Parameter                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Processor</b>                           | From the list, select <b>gzip</b> .<br>Processors enable event file archives to be expanded and contents are processed for events. Files are processed after they are downloaded to QRadar. QRadar can process files in zip, gzip, tar, or tar+gzip archive format.                                                                                                                                                                                                                     |
| <b>Ignore Previously Processed File(s)</b> | Select this check box to track and ignore files that are already processed by the Log File protocol.<br><br>QRadar examines the log files in the remote directory to determine whether a file is previously processed by the Log File protocol. If a previously processed file is detected, the Log File protocol does not download the file for processing. All files that are not previously processed are downloaded.<br><br>This option applies only to FTP and SFTP service types. |
| <b>Change Local Directory?</b>             | Select this check box to define a local directory on your QRadar for storing downloaded files during processing.<br><br>It is suggested that you leave this check box clear. When this check box is selected, the <b>Local Directory</b> field is displayed, which gives you the option to configure the local directory to use for storing files.                                                                                                                                      |
| <b>Event Generator</b>                     | From the <b>Event Generator</b> list, select <b>LineByLine</b> .<br><br>The Event Generator applies more processing to the retrieved event files. Each line is a single event. For example, if a file has 10 lines of text, 10 separate events are created.                                                                                                                                                                                                                             |

## IBM zSecure Alert

The IBM QRadar DSM for IBM zSecure Alert collects Syslog events from a IBM zSecure Alert.

To integrate IBM zSecure Alert with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](#). Download and install the most recent version of the DSM Common RPM on your QRadar Console:
2. Configure your IBM zSecure Alert to send events to QRadar.
3. If QRadar does not automatically detect the log source, add a IBM zSecure Alert log source on the QRadar Console.

The alert configuration on your IBM zSecure Alert appliance determines which alert conditions you want to monitor and forward to QRadar. To collect events in QRadar, you must configure your IBM zSecure Alert appliance to forward events in a UNIX syslog event format by using the QRadar IP address as the destination. For information on configuring UNIX syslog alerts and destinations, see the [IBM Security zSecure Alert User Reference Manual](#).

## Syslog log source parameters for IBM zSecure Alert

If QRadar does not automatically detect the log source, add an IBM zSecure Alert log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from IBM zSecure Alert:

*Table 673. Syslog log source parameters for the IBM zSecure Alert DSM*

| Parameter              | Value             |
|------------------------|-------------------|
| <b>Log Source type</b> | IBM zSecure Alert |

*Table 673. Syslog log source parameters for the IBM zSecure Alert DSM (continued)*

| Parameter                     | Value                                                                                                        |
|-------------------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Protocol Configuration</b> | Syslog                                                                                                       |
| <b>Log Source Identifier</b>  | Type the IP address or host name for the log source as an identifier for events from your IBM zSecure Alert. |

# Chapter 82. ISC BIND

The IBM QRadar DSM for Internet System Consortium (ISC) BIND collects Syslog events from your ISC BIND device.

Complete the following steps to configure ISC BIND to communicate with QRadar.

## About this task

You can configure syslog on your ISC BIND device to forward events to QRadar.

## Procedure

1. Log in to your ISC BIND device.
2. Open the following file to add a logging clause:

```
named.conf

logging {
    channel <channel_name> {
        syslog <syslog_facility>;
        severity <critical | error | warning | notice | info | debug [level ] | dynamic >;
        print-category yes;
        print-severity yes;
        print-time yes;
    };
    category queries {
        <channel_name>;
    };
    category notify {
        <channel_name>;
    };
    category network {
        <channel_name>;
    };
    category client {
        <channel_name>;
    };
}
```

For Example:

```
logging {
    channel QRadar {
        syslog local3;
```

```

severity info;
};

category queries {
QRadar;
};

category notify {
QRadar;
};

category network {
QRadar;
};

category client {
QRadar;
};

};

```

3. Save and exit the file.

4. Edit the syslog configuration to log to your QRadar using the facility you selected in [Chapter 82, “ISC BIND,” on page 1059](#):

`<syslog_facility>.* @<IP_address>`

Where `<IP Address>` is the IP address of your QRadar.

For example:

`local3.* @<IP_address>`

**Note:** QRadar only parses logs with a severity level of info or higher.

5. Restart the following services.

```

service syslog restart
service named restart

```

## What to do next

Add a log source in QRadar.

## ISC BIND DSM specifications

When you configure ISC BIND, understanding the specifications for the ISC BIND DSM can help ensure a successful integration. For example, knowing what the supported version of ISC BIND is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the ISC BIND DSM.

| Table 674. ISC BIND DSM specifications |                                   |
|----------------------------------------|-----------------------------------|
| Specification                          | Value                             |
| Manufacturer                           | Internet Systems Consortium (ISC) |

Table 674. ISC BIND DSM specifications (continued)

| Specification               | Value                                                                                                                  |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------|
| DSM name                    | ISC BIND                                                                                                               |
| RPM file name               | DSM-IscBind-QRadar_version-build_number.noarch.rpm                                                                     |
| Supported versions          | 9.9, 9.11, 9.12                                                                                                        |
| Protocol                    | Syslog                                                                                                                 |
| Recorded event types        | All events                                                                                                             |
| Automatically discovered?   | Yes                                                                                                                    |
| Includes identity?          | No                                                                                                                     |
| Includes custom properties? | No                                                                                                                     |
| More information            | <a href="https://www.isc.org/bind/">ISC BIND</a> ( <a href="https://www.isc.org/bind/">https://www.isc.org/bind/</a> ) |

## Syslog log source parameters for ISC BIND

If QRadar does not automatically detect the log source, add an ISC BIND log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from ISC Bind:

Table 675. Syslog log source parameters for the ISC Bind DSM

| Parameter                     | Value                                                                                                         |
|-------------------------------|---------------------------------------------------------------------------------------------------------------|
| <b>Log Source Name</b>        | Type a name for your log source.                                                                              |
| <b>Log Source Description</b> | Type a description for the log source.                                                                        |
| <b>Log Source Type</b>        | ISC Bind                                                                                                      |
| <b>Protocol Configuration</b> | Syslog                                                                                                        |
| <b>Log Source Identifier</b>  | Type the IP address or host name for the log source as an identifier for events from your ISC Bind appliance. |

| Includes custom properties?                                      | No                                                                                                                      |
| More information                                                 | <a href="https://www.illumio.com">Illumio website</a> ( <a href="https://www.illumio.com">https://www.illumio.com</a> ) |

To integrate Illumio Adaptive Security Platform with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto, in the order that they are listed, on your QRadar Console:
  - DSMCommon RPM
  - Illumio Adaptive Security Platform DSM RPM
2. Configure your Illumio PCE to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add an Illumio Adaptive Security Platform log source on the QRadar Console. The following table describes the parameters that require specific values for Illumio Adaptive Security Platform event collection:

Table 678. Illumio Adaptive Security Platform log source parameters

| Parameter              | Value                                   |
|------------------------|-----------------------------------------|
| Log Source type        | Illumio Adaptive Security Platform      |
| Protocol Configuration | Syslog                                  |
| Log Source Identifier  | A unique identifier for the log source. |

4. To verify that QRadar is configured correctly, review the following table to see an example of a parsed event message.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

The following table shows a sample event message from Illumio Adaptive Security Platform:

| Table 679. Illumio Adaptive Security Platform sample message |                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Event name                                                   | Low level category | Sample log message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

[“Adding a log source” on page 5](#)

## Configuring Illumio Adaptive Security Platform to communicate with QRadar

To forward events to IBM QRadar, you must configure Exporting Events to Syslog and Syslog Forwarding for your Illumio PCE.

#### Related tasks

[“Configuring Exporting Events to Syslog for Illumio PCE” on page 1065](#)

All audit and traffic summaries are sent to syslog in JSON format by default. The default configuration must be updated so that the events are exported in LEEF format.

[“Configuring Syslog Forwarding for Illumio PCE” on page 1065](#)

Because the PCE software exports logs to a local syslog, you must configure either rsyslog or syslog-ng service on each node in your PCE cluster to forward these logs to QRadar.

## Configuring Exporting Events to Syslog for Illumio PCE

All audit and traffic summaries are sent to syslog in JSON format by default. The default configuration must be updated so that the events are exported in LEEF format.

### Procedure

1. Stop the PCE software so that changes to the PCE `runtime_env.yml` file can be made.
2. Enable LEEF formatting by configuring the PCE `runtime_env.yml` parameter **`syslog_event_export_format`**.

```
syslog_event_export_format:leef
```

3. Export traffic summaries to Syslog by configuring the PCE `runtime_env.yml` parameter **`export_flow_summaries_to_syslog`**:

```
export_flow_summaries_to_syslog:  
  accepted  
  potentially_blocked  
  blocked
```

**Tip:** By default, the PCE exports all audit events to Syslog. Therefore, no configuration is required to enable exporting audit events.

The **`export_flow_summaries_to_syslog`** parameter should be considered experimental and the mechanism for configuring this feature might change in a future release.

**Note:** The **`export_flow_summaries_to_syslog`** parameter should be considered experimental and the mechanism for configuring this feature might change in a future release.

4. Type the **`./illumio-pce-env check`** command to validate the syntax of the configuration file.
5. Start the PCE software.

### What to do next

[Configure Syslog Forwarding](#)

## Configuring Syslog Forwarding for Illumio PCE

Because the PCE software exports logs to a local syslog, you must configure either rsyslog or syslog-ng service on each node in your PCE cluster to forward these logs to QRadar.

### Procedure

1. If you want to configure rsyslog, complete the following steps.
  - a) Edit the `/etc/rsyslog.conf` file by adding the following entries or uncomment if they are already present. Replace *<QRadar Event Collector IP>* with the IP address of the QRadar event collector:

```
#### LEEF (flow data, audit events) ####  
if $syslogseverity <= 6 \  
and $syslogtag startswith 'illumio_pce/collector[' \  
and $msg contains 'LEEF:' \  
and $msg contains '|Illumio|PCE|' \  
and $msg contains 'cat=flow_summary' \  
then @@<QRadar Event Collector IP>:514  
  
if $syslogseverity <= 6 \  
and $syslogtag startswith 'illumio_pce/' \  
and $msg contains 'LEEF:' \  
and $msg contains '|Illumio|PCE|' \  
and $msg contains 'cat=audit' \  
then @@<QRadar Event Collector IP>:514
```

```
and $msg contains 'audit_events' \
then @@<QRadar Event Collector IP>:514
```

- b) Restart the rsyslog service.

```
service rsyslog restart
```

2. If you want to configure syslog-ng, complete the following steps.

- a) Edit the /etc/syslog-*ng*/syslog-*ng*.conf file by adding the following entries or uncomment if they are already present. Replace <QRadar Event Collector IP> with the IP address of the QRadar event collector:

```
#destination d_net { tcp("<QRadar Event
    Collector IP>" port(514) flush_lines(1)); };
#log { source(s_src); filter(flow_events);
    destination(d_net); };#log { source(s_src);
    filter(audit_events); destination(d_net); };

##### LEEF (flow data, audit events) #####
filter flow_events {
    level(info..emerg)
    and program("^illumio_pce/collector$")
    and message('LEEF:[^\n]+\\|Illumio\\|PCE\\|')
    and message('cat=flow_summary');
};

filter audit_events {
    level(info..emerg)
    and program("^illumio_pce/")
    and message('LEEF:[^\n]+\\|Illumio\\|PCE\\|')
    and message('cat=[^ #]*audit_events');
};
```

- b) Restart the syslog-*ng* service.

```
service syslog-ng restart
```

# Chapter 84. Imperva Incapsula

The IBM QRadar DSM for Imperva Incapsula collects logs from an Imperva Incapsula service.

The following table describes the specifications for the Imperva Incapsula DSM:

| Table 680. Imperva Incapsula DSM specifications |                                                                                                 |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------|
| Specification                                   | Value                                                                                           |
| Manufacturer                                    | Imperva                                                                                         |

| RPM file name                                   | DSM-ImpervaIncapsula-QRadar_version-build_number.noarch.rpm                                     |
| Supported versions                              | N/A                                                                                             |
| Protocol                                        | Syslog                                                                                          |
| Event format                                    | LEEF                                                                                            |
| Recorded event types                            | Access events and Security alerts                                                               |
| Automatically discovered?                       | Yes                                                                                             |
| Includes identity?                              | No                                                                                              |
| Includes custom properties?                     | No                                                                                              |
| More information                                | <a href="https://www.incapsula.com/">Imperva Incapsula website (https://www.incapsula.com/)</a> |

To integrate Imperva Incapsula with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM
  - Imperva Incapsula DSM RPM
2. Configure the Log download utility to collect logs and then forward the logs to QRadar.
3. If QRadar does not automatically detect the log source, add an Imperva Incapsula log source on the QRadar Console. The following table describes the parameters that require specific values to collect event from Imperva Incapsula:

Table 681. Imperva Incapsula log source parameters

| Parameter              | Value             |
|------------------------|-------------------|
| Log Source type        | Imperva Incapsula |
| Protocol Configuration | Syslog            |

4. Verify that QRadar is configured correctly.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

The following table shows a sample normalized event message from Imperva Incapsula:

Table 682. Imperva Incapsula sample message

| Event name | Low level category | Sample log message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Configuring Imperva Incapsula to communicate with QRadar

To collect events from Imperva Incapsula, a Python script is required.

The script, configuration files, and instructions, can be obtained from the [GitHub website](https://github.com/imperva/incapsula/logs-downloader) (<https://github.com/imperva/incapsula/logs-downloader>).

## Procedure

1. Install the script dependencies by using a package manager such as apt-get or pip. The script dependencies must be installed on an intermediary server that is not QRadar. The following dependencies might require additional modules, depending on your operating system:
  - M2Crypto
  - loggerglue
  - crypto.cipher
2. To collect log events, run the script.
  - a) Create a new local directory or use the default directory to store the script configuration file. The `Settings.Config` file is stored in this local directory. The default directory is `/etc/incapsula/logs/config`. To get the `Settings.Config` file, go to the [GitHub website](https://github.com/imperva/incapsula-logs-downloader) (<https://github.com/imperva/incapsula-logs-downloader>).
  - b) Configure the parameter values for the `Settings.Config` configuration file.

*Table 683. Parameter values for the `Settings.Config` configuration file*

| Parameter      | Value                                                                                                                                                                            |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| APIID          | Your API ID.                                                                                                                                                                     |
| APIKEY         | Your API key.                                                                                                                                                                    |
| SAVE_LOCALLY   | A Yes or No value that instructs Incapsula whether to maintain the log files after they are processed. When set to No, the files are deleted.<br>The default is YES.             |
| PROCESS_DIR    | The directory where Incapsula automatically saves the logs after extracting them.<br>The default is <code>/tmp/processed/</code>                                                 |
| BASEURL        | The URL of your logs repository in the Incapsula cloud. This URL is displayed in the <b>Incapsula Administration Console Settings</b> window as the <b>Log Server URL</b> field. |
| USEPROXY       | Specify YES to use a proxy to download the files.<br>The default is NO.                                                                                                          |
| PROXYSERVER    | If you choose to use a proxy server, when you type the proxy URL, use the <code>&lt;https://1.1.1.1:8080&gt;</code> format.                                                      |
| SYSLOG_ENABLE  | Type YES.<br>A Yes or No value that instructs Incapsula about whether to send the files by using syslog.<br>The default is YES.                                                  |
| SYSLOG_ADDRESS | The IP address for QRadar                                                                                                                                                        |
| SYSLOG_PORT    | 514                                                                                                                                                                              |

Table 683. Parameter values for the `Settings.Config` configuration file (continued)

| Parameter          | Value                                                                      |
|--------------------|----------------------------------------------------------------------------|
| USE_CUSTOM_CA_FILE | In case the service's certificate is not in the bundle, the default is NO. |
| CUSTOM_CA_FILE     | The file path for the custom certificate file.                             |

- Run the following command to start the LogsDownloader script and retrieve logs:

```
python LogsDownloader.py -c <path_to_config_folder> -l <path_to_system_logs_folder> -v
<system_logs_level>
```

The -c, -l, and -v parameters are optional. If the parameter values are not specified, the following table describes the default values that are used:

Table 684. `LogsDownloader.py` parameter values

| Parameter                    | Value                                                                                                                                                                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <path_to_config_folder>      | The default is<br>/etc/incapsula/logs/config                                                                                                                                                                                         |
| <path_to_system_logs_folder> | The <path_to_system_logs_folder> is the folder where the <code>LogsDownloader.py</code> script output log file is stored. This parameter does not refer to your Incapsula logs.<br>The default is /var/log/incapsula/logsDownloader/ |
| <system_logs_level>          | The logging level for the script output log. Supported values are info, debug, and error.<br>The default value is <b>info</b> .                                                                                                      |

**Note:**

- If the **SAVE\_LOCALLY** parameter is set to YES, the downloaded log files can be found in the `PROCESS_DIR` directory.
- After the files are downloaded, the script saves the name of the last file it collects as `LastKnownDownloadedFileId.txt` in the `<path_to_config_folder>` directory. If you want to collect all of the historical logs, you must delete this file.
- For more information about setting up an intermediary server, see Imperva Incapsula's [Web Protection - Log Integration](https://docs.imperva.com/bundle/cloud-application-security/page/settings/log-integration.htm) (<https://docs.imperva.com/bundle/cloud-application-security/page/settings/log-integration.htm>).

# Chapter 85. Imperva SecureSphere

The IBM QRadar DSM for Imperva SecureSphere collects all relevant syslog events from your Imperva SecureSphere devices.

The following table lists the specifications for the Imperva SecureSphere DSM:

| Table 685. Imperva SecureSphere DSM |                                                                                                                      |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| Specification                       | Value                                                                                                                |
| Manufacturer                        | Imperva                                                                                                              |
| DSM name                            | SecureSphere                                                                                                         |
| RPM file name                       | DSM-ImpervaSecuresphere-QRadar-version-Build_number.noarch.rpm                                                       |
| Supported versions                  | v6.2 and v7.x to v13 Release Enterprise Edition (Syslog)<br>v9.5 to v13 (LEEF)                                       |
| Event format                        | syslog<br>LEEF                                                                                                       |
| QRadar recorded event types         | Firewall policy events                                                                                               |
| Automatically discovered?           | Yes                                                                                                                  |
| Includes identity?                  | Yes                                                                                                                  |
| Includes custom properties?         | No                                                                                                                   |
| More information                    | <a href="http://www.imperva.com">Imperva website</a> ( <a href="http://www.imperva.com">http://www.imperva.com</a> ) |

To send events from Imperva SecureSphere devices to QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the Imperva SecureSphere DSM RPM from the [IBM Support Website](#) onto your QRadar Console.
2. For each instance of Imperva SecureSphere, configure the Imperva SecureSphere appliance to communicate with QRadar. On your Imperva SecureSphere appliance, complete the following steps
  - a. Configure an alert action.
  - b. Configure a system event action.
3. If QRadar does not automatically discover the Imperva SecureSphere log source, create a log source for each instance of Imperva SecureSphere on your network. Use the following table to define the Imperva SecureSphere-specific parameters:

Table 686. Imperva SecureSphere log source parameters

| Parameter              | Description          |
|------------------------|----------------------|
| Log Source Type        | Imperva SecureSphere |
| Protocol Configuration | Syslog               |

Configure your Imperva SecureSphere appliance to forward syslog system policy events to QRadar.

#### [“Configuring Imperva SecureSphere V11.0 to V13 to send database audit records to QRadar” on page 1075](#)

To send database audit records from Imperva SecureSphere V11.0 to V13 IBM QRadar, create a custom action set, add an action interface, and then configure an audit policy.

## Configuring an alert action for Imperva SecureSphere

Configure your Imperva SecureSphere appliance to forward syslog events for firewall policy alerts to QRadar.

### About this task

Use the following list to define a message string in the **Message** field for each event type you want to forward:

**Tip:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters. Paste as a single line in the **Custom Format** column.

#### Database alerts (V9.5 and V10 to V13)

```
LEEF:1.0|Imperva|SecureSphere|${SecureSphereVersion}|${Alert.alertType} ${Alert.immediateAction}|Alert ID=${Alert.dn}|devTimeFormat=[see note]|devTime=${Alert.createTime}|Alert type=${Alert.alertType}|src=${Alert.sourceIp}|usrName=${Event.struct.user.user}|Application name=${Alert.applicationName}|dst=${Event.destInfo.serverIp}|Alert Description=${Alert.description}|Severity=${Alert.severity}|Immediate Action=${Alert.immediateAction}|SecureSphere Version=${SecureSphereVersion}
```

#### File server alerts (V9.5 and V10 to V13)

```
LEEF:1.0|Imperva|SecureSphere|${SecureSphereVersion}|${Alert.alertType} ${Alert.immediateAction}|Alert ID=${Alert.dn}|devTimeFormat=[see note]|devTime=${Alert.createTime}|Alert type=${Alert.alertType}|src=${Alert.sourceIp}|usrName=${Event.struct.user.username}|Domain=${Event.struct.user.domain}|Application name=${Alert.applicationName}|dst=${Event.destInfo.serverIp}|Alert Description=${Alert.description}|Severity=${Alert.severity}|Immediate Action=${Alert.immediateAction}|SecureSphere Version=${SecureSphereVersion}
```

#### Web application firewall alerts (V9.5 and V10 to V13)

```
LEEF:1.0|Imperva|SecureSphere|${SecureSphereVersion}|${Alert.alertType} ${Alert.immediateAction}|Alert ID=${Alert.dn}|devTimeFormat=[see note]|devTime=${Alert.createTime}|Alert type=${Alert.alertType}|src=${Alert.sourceIp}|srcPort=$!{Event.sourceInfo.sourcePort}|usrName=${Alert.username}|Application name=${Alert.applicationName}|dst=${Event.destInfo.serverIp}|dstPort=$!{Event.destInfo.serverPort}|Service name=${Alert.serviceName}|Event Description=${Alert.description}|Severity=${Alert.severity}|Simulation Mode=${Alert.simulationMode}|Immediate Action=${Alert.immediateAction}
```

#### All alerts (V6.2 and V7 to V13 Release Enterprise Edition)

```
DeviceType=ImpervaSecuresphere Alert|an=$!{Alert.alertMetadata.alertName}|at=SecuresphereAlert|sp=$!{Event.sourceInfo.sourcePort}|s=$!{Event.sourceInfo.sourceIp}|d=$!{Event.destInfo.serverIp}|dp=$!{Event.destInfo.serverPort}|u=$!{Alert.username}|g=$!{Alert.serverGroupName}|ad=$!{Alert.description}
```

**Tip:** The **devTimeFormat** parameter does not include a value because you can configure the time format on the SecureSphere appliance. Review the time format of your SecureSphere appliance and specify the appropriate time format.

## Procedure

1. Log in to SecureSphere by using administrative privileges.
  2. Click the **Policies** tab.
  3. Click the **Action Sets** tab.
  4. Generate events for each alert that the SecureSphere device generates:
    - a) Click **New** to create a new action set for an alert.
    - b) Move the action to the **Selected Actions** list.
    - c) Expand the **System Log** action group.
    - d) In the **Action Name** field, type a name for your alert action.
    - e) From the **Apply to event type** list, select **Any event type**.
    - f) In the **Syslog host** field, type the IP address of the QRadar appliance to which you want to send events.
    - g) In the **Syslog log level** list, select **INFO**.
    - h) In the **Message** field, define a message string for your event type.
      - i) In the **Facility** field, type **syslog**.
      - j) Select the **Run on Every Event** check box.
      - k) Click **Save**.
  5. To trigger syslog events, associate each of your firewall policies to an alert action:
    - a) From the navigation menu, click **Policies > Security > Firewall Policy**.
    - b) Select the policy that you want to use for the alert action.
    - c) Click the **Policy** tab.
    - d) From the **Followed Action** list, select your new action and configure the parameters.
- Tip:** Configure established connections as either blocked, inbound, or outbound. Always allow applicable service ports.
- e) Ensure that your policy is configured as enabled and is applied to the appropriate server groups.
  - f) Click **Save**.

## Configuring a system event action for Imperva SecureSphere

Configure your Imperva SecureSphere appliance to forward syslog system policy events to QRadar.

### About this task

Use the following list to define a message string in the **Message** field for each event type you want to forward:

**Tip:** Line breaks in code examples can cause configurations to fail. For each alert, copy the code blocks into a text editor, remove any line breaks, and paste as a single line in the **Custom Format** column.

### System events (V9.5 and V10 to V13)

```
LEEF:1.0|Imperva|SecureSphere|${SecureSphereVersion}|${Event.eventType}|Event  
ID=${Event.dn}|devTimeFormat=[see note]|devTime=${Event.createTime}|  
Event_Type=${Event.eventType}|Message=${Event.message}|Severity=${  
Event.severity.displayName}|userName=${Event.username}|SecureSphere Version=${  
SecureSphereVersion}
```

## Database audit records (V9.5 and V10 to V13)

```
LIEEEF:1.0|Imperva|SecureSphere|${SecureSphereVersion}|${Event.struct.eventType}|Server Group=${Event.serverGroup}|Service Name=${Event.serviceName}|Application Name=${Event.applicationName}|Source Type=${Event.sourceInfo.eventSourceType}|User Type=${Event.struct.user.userType}|usrName=${Event.struct.user.user}|User Group=${Event.struct.userGroup}|Authenticated=${Event.struct.user.authenticated}|App User=${Event.struct.applicationUser}|src=${Event.sourceInfo.sourceIp}|Application=${Event.struct.application.application}|OS User=${Event.struct.osUser.osUser}|Host=${Event.struct.host.host}|Service Type=${Event.struct.serviceType}|dst=${Event.destInfo.serverIp}|Event Type=${Event.struct.eventType}|Operation=${Event.struct.operations.name}|Operation type=${Event.struct.operations.operationType}|Object name=${Event.struct.operations.objects.name}|Object type=${Event.struct.operations.objectType}|Subject=${Event.struct.operations.subjects.name}|Database=${Event.struct.databases.databaseName}|Schema=${Event.struct.databases.schemaName}|Table Group=${Event.struct.tableGroups.displayName}|Sensitive=${Event.struct.tableGroups.sensitive}|Privileged=${Event.struct.operations.privileged}|Stored Proc=${Event.struct.operations.storedProcedure}|Completed Successfully=${Event.struct.complete.completeSuccessful}|Parsed Query=${Event.struct.query.parsedQuery}|Bind Variables=${Event.struct.rawQuery.bindVariables}|Error=${Event.struct.complete.errorValue}|Response Size=${Event.struct.complete.responseSize}|Response Time=${Event.struct.complete.responseTime}|Affected Rows=${Event.struct.query.affectedRows}| devTimeFormat=[see note]|devTime=${Event.createTime}
```

## All events (V6.2 and V7.x to V13 Release Enterprise Edition)

```
DeviceType=ImpervaSecuresphere Event|et=$!{Event.eventType}|dc=Securesphere System Event|sp=$!{Event.sourceInfo.sourcePort}|s=$!{Event.sourceInfo.sourceIp}|d=$!{Event.destInfo.serverIp}|dp=$!{Event.destInfo.serverPort}|u=$!{Event.username}|t=$!{Event.createTime}|sev=$!{Event.severity}|m=$!{Event.message}
```

**Note:** The **devTimeFormat** parameter does not include a value because you can configure the time format on the SecureSphere appliance. Review the time format of your SecureSphere appliance and specify the appropriate time format.

## Procedure

1. Log in to SecureSphere by using administrative privileges.
2. Click the **Policies** tab.
3. Click the **Action Sets** tab.
4. Generate events for each alert that the SecureSphere device generates:
  - a) Click **New** to create a new action set for an alert.
  - b) Type a name for the new action set.
  - c) Move the action to the **Selected Actions** list.
  - d) Expand the **System Log** action group.
  - e) In the **Action Name** field, type a name for your alert action.
  - f) From the **Apply to event type** list, select **Any event type**.
  - g) In the **Syslog host** field, type the IP address of the QRadar appliance to which you want to send events.
  - h) In the **Syslog log level** list, select **INFO**.
  - i) In the **Message** field, define a message string for your event type.
  - j) In the **Facility** field, type **syslog**.
  - k) Select the **Run on Every Event** check box.
  - l) Click **Save**.
5. To trigger syslog events, associate each of your system event policies to an alert action:
  - a) From the navigation menu, click **Policies > System Events**.
  - b) Select or create the system event policy that you want to use for the alert action.
  - c) Click the **Followed Action** tab.

- d) From the **Followed Action** list, select your new action and configure the parameters.
- Tip:** Configure established connections as either blocked, inbound, or outbound. Always allow applicable service ports.
- e) Click **Save**.

## Configuring Imperva SecureSphere V11.0 to V13 to send database audit records to QRadar

---

To send database audit records from Imperva SecureSphere V11.0 to V13 IBM QRadar, create a custom action set, add an action interface, and then configure an audit policy.

### Procedure

1. Create a custom action set:
  - a) Log in to your Imperva SecureSphere system.
  - b) In the **Main** workspace, select **Policies > Action Sets**.
  - c) In the **Action Sets** pane, click the green plus sign icon.
  - d) In the **Action Set** text box, type a name for the action set. For example, **QRadar SIEM**.
  - e) From the **Apply to event type** list, select **Audit**.
  - f) Click **Create**.
2. Add the action interface that you want to be part of the action set to the **Selected Actions** pane:
  - a) Click the green up arrow icon, and then select **Gateway System Log > log audit event to System Log (Gateway System Log)**.
  - b) Configure the following action interface parameters:

| Parameter               | Value                                                                                           |
|-------------------------|-------------------------------------------------------------------------------------------------|
| <b>Name</b>             | Type the name that you created for the action set. For example, <b>QRadar SIEM</b> .            |
| <b>Protocol</b>         | Select <b>UDP</b> .                                                                             |
| <b>Host</b>             | Type the IP address or the host name of the QRadar appliance for which you want to send events. |
| <b>Port</b>             | 514                                                                                             |
| <b>Syslog Log Level</b> | Info                                                                                            |
| <b>Facility</b>         | syslog                                                                                          |

| Parameter      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Message</b> | <p><b>Tip:</b> The line breaks in the code example might cause this configuration to fail. For each alert, copy the code block below into a text editor, remove the line breaks, and paste as a single line in the <b>Message</b> field.</p> <pre>LEEEF:1.0 Imperva SecureSphere \${SecureSphereVersion} \${Alert.alertType} \${Alert.immediateAction} Alert ID=\${Alert.dn} devTimeFormat=yyyy-MM-dd HH:mm:ss.S devTime=\${Alert.createTime} Alert type=\${Alert.alertType} src=\${Alert.sourceIp} usrName=\${Event.struct.user.user} Application name=\${Alert.applicationName} dst=\${Event.destInfo.serverIp} Alert Description=\${Alert.description} Severity=\${Alert.severity} Immediate Action=\${Alert.immediateAction} SecureSphere Version=\${SecureSphereVersion}</pre> |

- a) Select the **Run on Every Event** check box.
- 3. Configure an audit policy for the events that you want to send to QRadar:
  - a) In the Main workspace, click **Policies > Audit**.
  - b) Click **Create DB Service**.
  - c) Type a name for the policy.
  - d) Select **Use Existing**, and then select a policy from the list.
  - e) Click the **Match Criteria** tab, and then enter the criteria for the policy.
  - f) Click the **Apply To** tab, and then select the server group.
  - g) Click the **External Logger** tab.
  - h) From the **Syslog** list, select the **QRadar SIEM** that you configured.
  - i) Optional: If you select a pre-defined policy from the **Syslog** list, configure the **Apply to** and **External Logger** fields.
  - j) Click **Save**.

## What to do next

You must define an audit policy or configure a pre-defined policy for each type of audit event that you want to send to QRadar.

# Chapter 86. Infoblox NIOS

The IBM QRadar DSM for Infoblox NIOS collects Syslog events from an Infoblox NIOS device.

To integrate Infoblox NIOS with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - DSM Common RPM
  - Infoblox DSM RPM
2. Configure your Infoblox device to send syslog events to QRadar. For more information about sending syslog events from Infoblox, see your [Infoblox NIOS documentation](https://docs.infoblox.com/display/ILP/NIOS) (<https://docs.infoblox.com/display/ILP/NIOS>).
3. Add an Infoblox log source on the QRadar Console. The following table describes the parameters that require specific values to collect Syslog events from Infoblox NIOS:

*Table 687. Infoblox NIOS Syslog log source parameters*

| Parameter                         | Value                                  |
|-----------------------------------|----------------------------------------|
| <b>Log Source Name</b>            | Type a unique name for the log source. |
| <b>Log Source Type</b> (Optional) | Type a description for the log source. |
| <b>Log Source type</b>            | Infoblox NIOS                          |
| <b>Protocol Configuration</b>     | Syslog                                 |

# Chapter 87. iT-CUBE agileSI

The iT-CUBE agileSI DSM for IBM QRadar can accept security-based and audit SAP events from agileSI installations that are integrated with your SAP system.

QRadar uses the event data that is defined as security risks in your SAP environment to generate offenses and correlate event data for your security team. SAP security events are written in Log Event Extended Format (LEEF) to a log file produced by agileSI. QRadar retrieves the new events by using the SMB Tail protocol. To retrieve events from agileSI, you must create a log source by using the SMB Tail protocol and provide QRadar credentials to log in and poll the LEEF formatted agileSI event file. QRadar is updated with new events each time the SMB Tail protocol polls the event file for new SAP events.

## Configuring agileSI to forward events

To configure agileSI, you must create a logical file name for your events and configure the connector settings with the path to your agileSI event log.

### About this task

The location of the LEEF formatted event file must be in a location viewable by Samba and accessible with the credentials you configure for the log source in IBM QRadar.

### Procedure

1. In agileSI core system installation, define a logical file name for the output file that contains your SAP security events.

SAP provides a concept that gives you the option to use platform-independent logical file names in your application programs. Create a logical file name and path by using transaction "FILE" (Logical File Path Definition) according to your organization's requirements.

2. Log in to agileSI.

For example, `http://<sap-system-url:port>/sap/bc/webdynpro/itcube/ ccf?sap-client=<client>&sap-language=EN`

Where:

- `<sap-system-url>` is the IP address and port number of your SAP system, such as `<IP_address>:50041`.
- `<client>` is the agent in your agileSI deployment.

3. From the menu, click **Display/Change** to enable change mode for agileSI.

4. From the toolbar, select **Tools > Core Consumer Connector Settings**.

The Core Consumer Connector Settings are displayed.

5. Configure the following values:

From the **Consumer Connector** list, select **Q1 Labs**.

6. Select the **Active** check box.

7. From the **Connector Type** list, select **File**.

8. From the **Logical File Name** field, type the path to your logical file name you configured in "Configuring agileSI to forward events" on page 1079.

For example, `/ITCUBE/LOG_FILES`.

The file that is created for the agileSI events is labeled `LEEFYYYYDDMM.TXT` where `YYYYDDMM` is the year, day, and month. The event file for the current day is appended with new events every time the extractor runs. *iT-CUBE* agileSI creates a new LEEF file for SAP events daily.

**9. Click **Save**.**

The configuration for your connector is saved. Before you can complete the agileSI configuration, you must deploy the changes for agileSI by using extractors.

**10. From the toolbar, select **Tools > Extractor Management**.**

The Extractor Management settings are displayed.

**11. Click **Deploy all**.**

The configuration for agileSI events is complete. You are now ready to configure a log source in QRadar.

## SMB Tail log source parameters for iT-CUBE agileSI

---

If QRadar does not automatically detect the log source, add an iT-CUBE agileSI log source on the QRadar Console by using the SMB Tail protocol.

When using the SMB Tail protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect SMB Tail events from iT-CUBE agileSI:

| Table 689. SMB Tail log source parameters for the iT-CUBE agileSI DSM |                                                                                                                     |
|-----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Parameter                                                             | Value                                                                                                               |
| <b>Log Source Name</b>                                                | Type a name for your log source.                                                                                    |
| <b>Log Source Description</b>                                         | Type a description for the log source.                                                                              |
| <b>Log Source Type</b>                                                | iT-CUBE agileSI                                                                                                     |
| <b>Protocol Configuration</b>                                         | SMB Tail                                                                                                            |
| <b>Log Source Identifier</b>                                          | Type the IP address, host name, or name for the log source as an identifier for your <i>iT-CUBE agileSI</i> events. |

For a complete list of SMB Tail protocol parameters and their values, see [c\\_logsource\\_SMBtailprotocol.dita](#).

# Chapter 88. Itron Smart Meter

The Itron Smart Meter DSM for IBM QRadar collects events from an Itron Openway Smart Meter by using syslog.

The Itron Openway Smart Meter sends syslog events to QRadar by using Port 514. For details of configuring your meter for syslog, see your *Ittron Openway Smart Meter* documentation.

## Syslog log source parameters for Itron Smart Meter

If QRadar does not automatically detect the log source, add an Itron Smart Meter log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Itron Smart Meter:

| Table 690. Syslog log source parameters for the Itron Smart Meter DSM |                                                                                                                                   |
|-----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                             | Value                                                                                                                             |
| <b>Log Source Name</b>                                                | Type a name for your log source.                                                                                                  |
| <b>Log Source Description</b>                                         | Type a description for the log source.                                                                                            |
| <b>Log Source Type</b>                                                | Itron Smart Meter                                                                                                                 |
| <b>Protocol Configuration</b>                                         | Syslog                                                                                                                            |
| <b>Log Source Identifier</b>                                          | Type the IP address or host name for the log source as an identifier for events from your Itron Openway Smart Meter installation. |

# Chapter 89. Juniper Networks

IBM QRadar supports a range of Juniper Networks DSMs.

**Note:** Juniper Networks deprecated some DSMs. However, the deprecated DSMs are still available for download. To get data from the deprecated sources, you can use Juniper Networks Junos OS DSM.

Juniper Networks deprecated the following DSMs:

- Juniper Networks AVT
- Juniper Networks DX Application Acceleration Platform
- Juniper Networks EX Series Ethernet Switch
- Juniper Networks IDP
- Juniper Networks Infranet Controller
- Juniper Networks Firewall and VPN
- Juniper Networks and Security Manager
- Juniper Networks Security Binary Log Collector
- Juniper Networks Steel-Belted Radius
- Juniper Networks vGW Virtual Gateway
- Juniper Networks Junos WebApp Secure
- Juniper Networks WLC Series Wireless LAN Controller

## Juniper Networks AVT (deprecated)

The Juniper Networks Application Volume Tracking (AVT) DSM for IBM QRadar accepts events by using Java Database Connectivity (JDBC) protocol.

### About this task

QRadar records all relevant events. To integrate with Juniper Networks NSM AVT data, you must create a view in the database on the Juniper Networks NSM server. You must also configure the Postgres database configuration on the Juniper Networks NSM server to allow connections to the database since, by default, only local connections are allowed.

**Note:** This procedure is provided as a guideline. For specific instructions, see your vendor documentation.

### Procedure

1. Log in to your Juniper Networks AVT device command-line interface (CLI).
2. Open the following file:  
`/var/netscreen/DevSvr/pgsql/data/pg_hba.conf` file
3. Add the following line to the end of the file:  
`host all all <IP address>/32 trust`  
Where: `<IP address>` is the IP address of your QRadar Console or Event Collector that you want to connect to the database.
4. Reload the Postgres service:  
`su - nsm -c "pg_ctl reload -D /var/netscreen/DevSvr/pgsql/data"`
5. As the Juniper Networks NSM user, create the view by using the following input:

```

create view strm_avt_view as SELECT a.name, a.category, v.srcip,v.dstip,v.dstport, v."last",
u.name as userinfo, v.id, v.device, v.vlan,v.sessionid, v.bytecnt,v.pktcnt, v."first" FROM
avt_part v JOIN app a ON v.app =a.id JOIN userinfo u ON v.userinfo = u.id;

```

The view is created.

You are now ready to configure the log source in QRadar.

## JDBC log source parameters for Juniper Networks AVT

If QRadar does not automatically detect the log source, add a Juniper Networks AVT log source on the QRadar Console by using the JDBC protocol.

When using the JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from Juniper Networks AVT:

| Table 691. JDBC log source parameters for the Juniper Networks AVT DSM |                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>IP or Hostname</b>                                                  | The IP address or host name of the SQL server that hosts the Juniper Networks AVT database.                                                                                                                                                                                                                                                                                               |
| <b>Username</b>                                                        | Type the user name the log source can use to access the Juniper Networks AVT database.                                                                                                                                                                                                                                                                                                    |
| <b>Password</b>                                                        | Type the password the log source can use to access the Juniper Networks AVT database.<br>The password can be up to 255 characters in length.                                                                                                                                                                                                                                              |
| <b>Predefined Query</b>                                                | From the list, select <b>Juniper Networks AVT</b> .                                                                                                                                                                                                                                                                                                                                       |
| <b>Use Prepared Statements</b>                                         | The <b>Use Prepared Statements</b> check box must be clear. The Juniper Networks AVT DSM does not support prepared statements.                                                                                                                                                                                                                                                            |
| <b>Polling Interval</b>                                                | Type the polling interval, which is the amount of time between queries to the view you created. The default polling interval is 10 seconds.<br><br>You can define a longer polling interval by appending H for hours or M for minutes to the numeric value. The maximum polling interval is 1 week in any time format. Numeric values that are entered without an H or M poll in seconds. |

Table 691. JDBC log source parameters for the Juniper Networks AVT DSM (continued)

| Parameter           | Value                                                                                                                                                                                                                                                                          |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EPS Throttle</b> | The maximum number of events per second that QRadar ingests.<br>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.<br>The default is 20,000 EPS. |

**Note:** Selecting a parameter value greater than 5 for the **Credibility** parameter weights your Juniper Networks AVT log source with a higher importance that is compared to other log sources in QRadar.

For a complete list of JDBC parameters and their values, see [c\\_logsource\\_JDBCprotocol.dita](#).

## Juniper Networks DDoS Secure

Juniper Networks DDoS Secure is now known as NCC Group DDoS Secure.

#### Related concepts

[“NCC Group DDoS Secure” on page 1251](#)

The IBM QRadar DSM for NCC Group DDoS Secure collects events from NCC Group DDoS Secure devices.

## Juniper Networks DX Application Acceleration Platform (deprecated)

The Juniper DX Application Acceleration Platform DSM for IBM QRadar uses syslog to receive events. QRadar records all relevant status and network condition events. Before you configure QRadar, you must configure your Juniper device to forward syslog events.

The Juniper Networks DX Platform product is end of life (EOL), and is no longer supported by Juniper.

#### Procedure

1. Log in to the Juniper DX user interface.
2. Browse to the wanted cluster configuration (Services - Cluster Name), Logging section.
3. Select the **Enable Logging** check box.
4. Select your log format.

QRadar supports Juniper DX logs by using the common and perf2 formats only.

5. Select the log delimiter format.

QRadar supports comma delimited logs only.

6. In the **Log Host** section, type the IP address of your QRadar system.
7. In the **Log Port** section, type the UDP port on which you want to export logs.
8. You are now ready to configure the log source in QRadar.

# Configuring IBM QRadar to receive events from a Juniper DX Application Acceleration Platform

## About this task

You can configure QRadar to receive events from a Juniper DX Application Acceleration Platform.

## Procedure

From the **Log Source Type** list, select the **Juniper DX Application Acceleration Platform** option.

## Juniper Networks EX Series Ethernet Switch (deprecated)

---

The Juniper EX Series Ethernet Switch DSM for IBM QRadar accepts events by using syslog.

## About this task

The Juniper EX Series Ethernet Switch DSM supports Juniper EX Series Ethernet Switches running Junos OS. Before you can integrate QRadar with a Juniper EX Series Ethernet Switch, you must configure your Juniper EX Series Switch to forward syslog events.

## Procedure

1. Log in to the Juniper EX Series Ethernet Switch command line interface (CLI).
2. Type the following command:

```
configure
```

3. Type the following command:

```
set system syslog host <IP address> <option> <level>
```

Where:

- <IP address> is the IP address of your QRadar.
- <level> is info, error, warning, or any.
- <option> is one of the following options from [Table 692 on page 1086](#).

*Table 692. Juniper Networks EX Series switch options*

| Option               | Description                |
|----------------------|----------------------------|
| <b>any</b>           | All facilities             |
| <b>authorization</b> | Authorization system       |
| <b>change-log</b>    | Configuration change log   |
| <b>conflict-log</b>  | Configuration conflict log |
| <b>daemon</b>        | Various system processes   |
| <b>dfc</b>           | Dynamic flow capture       |

Table 692. Juniper Networks EX Series switch options (continued)

| Option                      | Description                                     |
|-----------------------------|-------------------------------------------------|
| <b>explicit-priority</b>    | Include priority and facility in messages       |
| <b>external</b>             | Local external applications                     |
| <b>facility-override</b>    | Alternative facility for logging to remote host |
| <b>firewall</b>             | Firewall filtering system                       |
| <b>ftp</b>                  | FTP process                                     |
| <b>interactive-commands</b> | Commands run by the UI                          |
| <b>kernel</b>               | Kernel                                          |
| <b>log-prefix</b>           | Prefix for all logging to this host             |
| <b>match</b>                | Regular expression for lines to be logged       |
| <b>pfe</b>                  | Packet Forwarding Engine                        |
| <b>user</b>                 | User processes                                  |

For example:

```
set system syslog host <IP_address> firewall info
```

This command example configures the Juniper EX Series Ethernet Switch to send info messages from firewall filter systems to your QRadar.

4. Repeat steps 1-3 to configure any additional syslog destinations and options. Each additional option must be identified by using a separate syslog destination configuration.
5. You are now ready to configure the Juniper EX Series Ethernet Switch in QRadar.

## Configuring IBM QRadar to receive events from a Juniper EX Series Ethernet Switch

You can configure QRadar to receive events from a Juniper EX Series Ethernet Switch:

### Procedure

From the **Log Source Type** list, select **Juniper EX-Series Ethernet Switch** option.

### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Juniper Networks IDP (deprecated)

The Juniper IDP DSM for IBM QRadar accepts events using syslog. QRadar records all relevant Juniper IDP events.

### About this task

You can configure a sensor on your Juniper IDP to send logs to a syslog server:

## Procedure

1. Log in to the Juniper NSM user interface.
2. In NSM, double-click the **Sensor in Device Manager**.
3. Select **Global Settings**.
4. Select **Enable Syslog**.
5. Type the Syslog Server IP address to forward events to QRadar.
6. Click **OK**.
7. Use **Update Device** to load the new settings onto the IDP Sensor.

The format of the syslog message that is sent by the IDP Sensor is as follows:

```
<day id>, <record id>, <timeReceived>, <timeGenerated>, <domain>, <domainVersion>, <deviceName>, <deviceIpAddress>, <category>, <subcategory>, <src zone>, <src interface>, <src addr>, <src port>, <nat src addr>, <nat src port>, <dstzone>, <dst interface>, <dst addr>, <dst port>, <nat dst addr>, <nat dst port>, <protocol>, <rule domain>, <rule domainVersion>, <policyname>, <rulebase>, <rulenumber>, <action>, <severity>, <is alert>, <elapsed>, <bytes in>, <bytes out>, <bytestotal>, <packet in>, <packet out>, <packet total>, <repeatCount>, <hasPacketData>, <varData Enum>, <misc-str>, <user str>, <application str>, <uri str>
```

See the following syslog example:

```
[syslog@juniper.net dayId="20061012" recordId="0" timeRecv="2006/10/12 21:52:21" timeGen="2006/10/12 21:52:21" domain="" devDomVer2="0" device_ip="<IP_address>" cat="Predefined" attack="TROJAN:SUBSEVEN:SCAN" srcZn="NULL" srcIntf="NULL" srcAddr="<Source_IP_address>" srcPort="63396" natSrcAddr="NULL" natSrcPort="0" dstZn="NULL" dstIntf="NULL" dstAddr="<Destination_IP_address>" dstPort="27374" natDstAddr="NULL" natDstPort="0" protocol="TCP" ruleDomain="" ruleVer="5" policy="Policy2" rulebase="IDS" ruleNo="4" action="NONE" severity="LOW" alert="no" elaspedTime="0" inbytes="0" outbytes="0" totBytes="0" inPak="0" outPak="0" totPak="0" repCount="0" packetData="no" varEnum="31" misc="<017>'interface=eth2" user="NULL" app="NULL" uri="NULL"]
```

## Configure a log source

Juniper NSM is a central management server for Juniper IDP. You can configure IBM QRadar to collect and represent the Juniper IDP alerts as coming from a central NSM, or QRadar can collect syslog from the individual Juniper IDP device.

To configure QRadar to receive events from Juniper Networks Secure Access device:

From the **Log Source Type** list, select **Juniper Networks Intrusion Detection and Prevention (IDP)**.

. For more information about Juniper IDP, see your *Network and Security Manager* documentation.

## Juniper Networks Infranet Controller (deprecated)

The Juniper Networks Infranet Controller DSM for IBM QRadar is now known as Pulse Secure Infranet Controller.

### Related concepts

[“Pulse Secure Infranet Controller” on page 1403](#)

The Pulse Secure Infranet Controller DSM for IBM QRadar accepts DHCP events by using syslog. QRadar records all relevant events from a Pulse Secure Infranet Controller.

## Juniper Networks Firewall and VPN (deprecated)

---

The Juniper Networks Firewall and VPN DSM for IBM QRadar accepts Juniper Firewall and VPN events by using UDP syslog.

### About this task

QRadar records all relevant firewall and VPN events.

**Note:** TCP syslog is not supported. You must use UDP syslog.

You can configure your Juniper Networks Firewall and VPN device to export events to QRadar.

### Procedure

1. Log in to your **Juniper Networks Firewall and VPN** user interface.
2. Select **Configuration > Report Settings > Syslog**.
3. Select the **Enable Syslog Messages** check box.
4. Type the IP address of your QRadar Console or Event Collector.
5. Click **Apply**.

You are now ready to configure the log source in QRadar.

| Event ID          | <b>Admin + user + logged on via Telnet</b> |

## Juniper Networks Junos OS

The Juniper Junos OS Platform DSM for IBM QRadar accepts events that use syslog, structured-data syslog, or PCAP (SRX Series only). QRadar records all valid syslog or structured-data syslog events.

### About this task

The Juniper Junos OS Platform DSM supports the following Juniper devices that are running Junos OS:

- Juniper M Series Multiservice Edge Routing
- Juniper MX Series Ethernet Services Router
- Juniper T Series Core Platform
- Juniper SRX Series Services Gateway

For information on configuring PCAP data that uses a Juniper Networks SRX Series appliance, see [“Configure the PCAP Syslog Protocol” on page 1092](#).

**Note:** For more information about structured-data syslog, see RFC 5424 at the Internet Engineering Task Force: <http://www.ietf.org/>

Before you configure QRadar to integrate with a Juniper device, you must forward data to QRadar using syslog or structured-data syslog.

### Procedure

1. Log in to your Juniper platform command-line interface (CLI).
2. Include the following syslog statements at the set system hierarchy level:

```
[set system] syslog {host (hostname) {facility <severity>; explicit-priority; any any; authorization any; firewall any; } source-address source-address; structured-data {brief;} }
```

The following table lists and describes the configuration setting variables to be entered in the syslog statement.

List of Syslog Configuration Setting Variables

| Parameter   | Description                                                          |
|-------------|----------------------------------------------------------------------|
| <b>host</b> | Type the IP address or the fully qualified host name of your QRadar. |

List of Syslog Configuration Setting Variables

(continued)

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Facility</b>        | Define the severity of the messages that belong to the named facility with which it is paired. Valid severity levels are: <ul style="list-style-type: none"> <li>• Any</li> <li>• None</li> <li>• Emergency</li> <li>• Alert</li> <li>• Critical</li> <li>• Error</li> <li>• Warning</li> <li>• Notice</li> <li>• Info</li> </ul> Messages with the specified severity level and higher are logged. The levels from emergency through info are in order from highest severity to lowest. |
| <b>Source-address</b>  | Type a valid IP address configured on one of the router interfaces for system logging purposes.<br><br>The source-address is recorded as the source of the syslog message send to QRadar. This IP address is specified in the <b>host</b> host name statement <code>set system syslog hierarchy</code> level; however, this is not for messages directed to the other routing engine, or to the TX Matrix platform in a routing matrix.                                                  |
| <b>structured-data</b> | Inserts structured-data syslog into the data.                                                                                                                                                                                                                                                                                                                                                                                                                                            |

You can now configure the log source in QRadar.

The following devices are auto discovered by QRadar as a Juniper Junos OS Platform devices:

- Juniper M Series Multiservice Edge Routing
- Juniper MX Series Ethernet Services Router
- Juniper SRX Series
- Juniper EX Series Ethernet Switch
- Juniper T Series Core Platform

**Note:** Due to logging similarities for various devices in the JunOS family, expected events might not be received by the correct log source type when your device is automatically discovered. Review the automatically created log source for your device and then adjust the configuration manually. You can add any missed log source type or remove any incorrectly added log source type.

## Syslog log source parameters for Juniper Junos OS

If QRadar does not automatically detect the log source, add a Juniper Junos OS log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Juniper Junos OS:

*Table 694. Syslog log source parameters for the Juniper Junos OS DSM*

| Parameter                     | Value                    |
|-------------------------------|--------------------------|
| <b>Log Source type</b>        | • Juniper JunOS Platform |
| <b>Protocol Configuration</b> | Syslog                   |

For more information about your Juniper device, see your vendor documentation.

### Related tasks

[“Adding a log source” on page 5](#)

## TLS Syslog log source parameters for Juniper Junos OS

If IBM QRadar does not automatically detect the log source, add a Juniper Junos OS log source on the QRadar Console by using the TLS syslog protocol.

When using the TLS syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect TLS syslog events from Juniper Junos OS:

*Table 695. TLS Syslog log source parameters for the Juniper Junos OS DSM*

| Parameter                     | Value                    |
|-------------------------------|--------------------------|
| <b>Log Source type</b>        | • Juniper JunOS Platform |
| <b>Protocol Configuration</b> | TLS Syslog               |

For more information about your Juniper device, see your vendor documentation.

### Related tasks

[“Adding a log source” on page 5](#)

## Configure the PCAP Syslog Protocol

The Juniper SRX Series appliance supports forwarding of packet capture (PCAP) and syslog data to IBM QRadar.

Syslog data is forwarded to QRadar on port 514. The IP address and outgoing PCAP port number are configured on the Juniper Networks SRX Series appliance interface. The Juniper Networks SRX Series appliance must be configured in the following format to forward PCAP data:

`<IP Address>:<Port>`

Where,

- `<IP Address>` is the IP address of QRadar.
- `<Port>` is the outgoing port address for the PCAP data.

**Note:**

QRadar supports receiving PCAP data only from a single Juniper Networks SRX Series appliance for each event collector.

For more information about Configuring Packet Capture, see your *Juniper Networks Junos OS documentation*.

You are now ready to configure the new Juniper Networks SRX Log Source with PCAP protocol in QRadar.

**Note:** The RPM name for *PCAP Protocol* is now *PCAPSyslog Protocol*:

```
RPM Name: PROTOCOL-PCAPSyslog-<QRadar_version-Build_number>.noarch.rpm
```

#### Related concepts

[“PCAP Syslog Combination log source parameters for Juniper SRX Series” on page 1093](#)

## PCAP Syslog Combination log source parameters for Juniper SRX Series

If QRadar does not automatically detect the log source, add a Juniper SRX Series log source on the QRadar Console by using the PCAP Syslog Combination protocol.

QRadar detects the syslog data and adds the log source automatically. The PCAP data can be added to QRadar as Juniper SRX Series Services Gateway log source by using the PCAP Syslog combination protocol. Adding the PCAP Syslog Combination protocol after QRadar auto discovers the Junos OS syslog data adds a log source to your existing log source limit. Deleting the existing syslog entry, then adding the PCAP Syslog Combination protocol adds both syslog and PCAP data as single log source.

When using the PCAP Syslog Combination protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect PCAP Syslog Combination events from Juniper SRX Series:

Table 696. PCAP Syslog Combination log source parameters for the Juniper SRX Series DSM

| Parameter       | Value                               |
|-----------------|-------------------------------------|
| Log Source type | Juniper SRX-series Services Gateway |

For a complete list of PCAP Syslog Combination protocol parameters and their values, see [c\\_logsource\\_PCAPprotocol.dita](#).

## Juniper Networks Network and Security Manager (deprecated)

The Juniper Networks Network and Security Manager (NSM) DSM for IBM QRadar accepts Juniper Networks NSM and Juniper Networks Secure Service Gateway (SSG) logs. All Juniper SSG logs must be forwarded through Juniper NSM to QRadar. All other Juniper devices logs can be forwarded directly to QRadar.

For more information on advanced filtering of Juniper Networks NSM logs, see your *Juniper Networks* vendor documentation.

To integrate a Juniper Networks NSM device with QRadar, you must complete the following tasks:

- [“Configuring Juniper Networks NSM to export logs to syslog” on page 1094](#)
- [“Juniper NSM log source parameters for Juniper Networks Network and Security Manager” on page 1094](#)

### Configuring Juniper Networks NSM to export logs to syslog

Juniper Networks NSM uses the syslog server to export qualified log entries to syslog.

#### About this task

Configuring the syslog settings for the management system defines only the syslog settings for the management system. It does not export logs from the individual devices. You can enable the management system to export logs to syslog.

#### Procedure

1. Log in to the **Juniper Networks NSM** user interface.
2. From the **Action Manager** menu, select **Action Parameters**.
3. Type the IP address for the syslog server that you want to send qualified logs.
4. Type the syslog server facility for the syslog server to which you want to send qualified logs.
5. From the **Device Log Action Criteria** node, select the **Actions** tab.
6. Select **Syslog Enable** for **Category**, **Severity**, and **Action**.

You are now ready to configure the log source in IBM QRadar.

### Juniper NSM log source parameters for Juniper Networks Network and Security Manager

If QRadar does not automatically detect the log source, add a Juniper Networks Network and Security Manager log source on the QRadar Console by using the Juniper NSM protocol.

When using the Juniper NSM protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Juniper NSM events from Juniper Networks Network and Security Manager:

*Table 698. Juniper NSM log source parameters for the Juniper Networks Network and Security Manager DSM*

| Parameter                             | Value                                                                                                                                                  |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source Type</b>                | Juniper Networks Network and Security Manager                                                                                                          |
| <b>Protocol Configuration</b>         | Juniper NSM                                                                                                                                            |
| <b>Log Source Identifier</b>          | Type the IP address or host name for the log source.<br><br>The <b>Log Source Identifier</b> must be unique for the log source type.                   |
| <b>IP</b>                             | Type the IP address or host name of the Juniper Networks NSM server.                                                                                   |
| <b>Inbound Port</b>                   | Type the <b>Inbound Port</b> to which the Juniper Networks NSM sends communications. The valid range is 0 - 65536. The default is 514.                 |
| <b>Redirection Listen Port</b>        | Type the port to which traffic is forwarded. The valid range is 0 - 65,536. The default is 516.                                                        |
| <b>Use NSM Address for Log Source</b> | Select this check box to use the Juniper NSM management server IP address instead of the log source IP address. By default, the check box is selected. |

**Note:** In the QRadar interface, the Juniper NSM protocol configuration provides the option to use the Juniper Networks NSM IP address by selecting the **Use NSM Address for Log Source** check box. If you wish to change the configuration to use the originating IP address (clear the check box), you must log in to your QRadar Console, as a root user, and restart the Console (for an all-in-one system) or the Event Collector hosting the log sources (in a distributed environment) by using the **shutdown -r now** command.

For a complete list of Juniper NSM parameters and their values, see [c\\_logsource\\_NSMprotocol.dita](#).

## Juniper Networks Secure Access (deprecated)

Juniper Networks Secure Access is now known as Pulse Secure Pulse Connect Secure.

#### Related concepts

[“Pulse Secure Pulse Connect Secure” on page 1403](#)

The IBM QRadar DSM for Pulse Secure Pulse Connect Secure collects syslog and WebTrends Enhanced Log File (WELF) formatted events from Pulse Secure Pulse Connect Secure mobile VPN devices.

## Juniper Networks Security Binary Log Collector (deprecated)

The Juniper Security Binary Log Collector DSM for IBM QRadar can accept audit, system, firewall, and intrusion prevention system (IPS) events in binary format from Juniper SRX or Juniper Networks J Series appliances.

The Juniper Networks binary log file format is intended to increase performance when large amounts of data are sent to an event log. To integrate your device with QRadar, you must configure your Juniper appliance to stream binary formatted events, then configure a log source in QRadar.

# Configuring the Juniper Networks Binary Log Format (deprecated)

The binary log format from Juniper SRX or J Series appliances are streamed to IBM QRadar by using the UDP protocol. You must specify a unique port for streaming binary formatted events, because the standard syslog port for QRadar cannot understand binary formatted events.

## About this task

The default port that is assigned to QRadar for receiving streaming binary events from Juniper appliances is port 40798.

**Note:** The Juniper Binary Log Collector DSM supports only events that are forwarded in Streaming mode. The Event mode is not supported.

## Procedure

1. Log in to your Juniper SRX or J Series by using the command-line interface (CLI).
2. Type the following command to edit your device configuration:

```
configure
```

3. Type the following command to configure the IP address and port number for streaming binary formatted events:

```
set security log stream <Name> host <IP address> port <Port>
```

Where:

- <Name> is the name that is assigned to the stream.
- <IP address> is the IP address of your QRadar Console or Event Collector.
- <Port> is a unique port number that is assigned for streaming binary formatted events to QRadar. By default, QRadar listens for binary streaming data on port 40798. For a list of ports that are used by QRadar, see the *IBM QRadar Common Ports List technical note*.

4. Type the following command to set the security log format to binary:

```
set security log stream <Name> format binary
```

Where: <Name> is the name that you specified for your binary format stream in [“Configuring the Juniper Networks Binary Log Format \(deprecated\)” on page 1096](#).

5. Type the following command to enable security log streaming:

```
set security log mode stream
```

6. Type the following command to set the source IP address for the event stream:

```
set security log source-address <IP address>
```

Where: <IP address> is the IP address of your Juniper SRX Series or Juniper J Series appliance.

7. Type the following command to save the configuration changes:

```
commit
```

8. Type the following command to exit the configuration mode:

```
exit
```

## What to do next

The configuration of your Juniper SRX or J Series appliance is complete. You can now configure a log source in QRadar.

## Juniper Security Binary Log Collector log source parameters for Juniper Networks Security Binary Log Collector

If QRadar does not automatically detect the log source, add a Juniper Security Binary Log Collector log source on the QRadar Console by using the Juniper Security Binary Log Collector protocol.

When using the Juniper Security Binary Log Collector protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Juniper Security Binary Log Collector events from Juniper Security Binary Log Collector:

| <i>Table 699. Juniper Security Binary Log Collector log source parameters for the Juniper Security Binary Log Collector DSM</i> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

# Juniper Networks Steel-Belted Radius (deprecated)

The Juniper Steel-Belted Radius DSM for IBM QRadar accepts syslog forwarded events from Windows when you run the WinCollect agent. You can also collect events from Linux-based operating systems by using the Syslog, TLS syslog, or the Log File protocol.

QRadar records all successful and unsuccessful login attempts. You can integrate Juniper Networks Steel-Belted Radius with QRadar by using one of the following methods:

- Configure Juniper Steel Belted-Radius to use WinCollect on Microsoft Windows operating systems. For more information, go to [Configuring Juniper Networks Steel-Belted Radius to forward Windows events to QRadar](#).
- Configure Juniper Steel-Belted Radius on Linux-based operating systems.

## Configuring Juniper Networks Steel-Belted Radius to forward Syslog events to QRadar

Before you can add a log source in QRadar, configure your Juniper Networks Steel-Belted Radius device to send Syslog events to QRadar.

### Procedure

1. Use SSH to log in to your Juniper Steel-Belted Radius device, as a root user.

2. Edit the following file:

`/etc/syslog.conf`

3. Add the following information:

`<facility>.<priority>@<IP address>`

Where:

- `<facility>` is the syslog facility, for example, local3.
- `<priority>` is the syslog priority, for example, info.
- `<IP address>` is the IP address of QRadar.

4. Save the file.

5. From the command-line, type the following command to restart syslog:

`service syslog restart`

### What to do next

You are now ready to add a log source in QRadar.

## Configuring a Juniper Steel-Belted Radius log source by using the Log File protocol

If you want to collect Juniper Steel-Belted Radius logs from Juniper Steel-Belted Radius, configure a log source on the QRadar Console so that Juniper Steel-Belted Radius can communicate with QRadar by using the Log File protocol.

### Procedure

- If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console.
  - Protocol Common RPM
  - Log File protocol RPM
  - JuniperSteelBeltedRadius DSM RPM
- Add a Log File protocol log source on the QRadar Console.

The following table describes the parameters that require specific values to collect Juniper Steel-Belted Radius events from Juniper Steel-Belted Radius by using the Log File protocol:

*Table 704. Log File protocol log source parameters*

| Parameter                     | Description                                                |
|-------------------------------|------------------------------------------------------------|
| <b>Log Source Type</b>        | <b>Juniper Steel-Belted Radius</b>                         |
| <b>Protocol Configuration</b> | <b>Log File</b>                                            |
| <b>Service Type</b>           | <b>FTP</b>                                                 |
| <b>Remote Directory</b>       | The default directory is /opt/JNPRsblr/radius/authReports/ |
| <b>FTP File Pattern</b>       | .*\*.csv                                                   |

*Table 704. Log File protocol log source parameters (continued)*

| Parameter       | Description        |
|-----------------|--------------------|
| Event Generator | <b>Juniper SBR</b> |

#### Related concepts

[Juniper Networks Steel-Belted Radius \(deprecated\)](#)

The Juniper Steel-Belted Radius DSM for IBM QRadar accepts syslog forwarded events from Windows when you run the WinCollect agent. You can also collect events from Linux-based operating systems by using the Syslog, TLS syslog, or the Log File protocol.

[“Log File protocol configuration options” on page 155](#)

To receive events from remote hosts, configure a log source to use the Log File protocol.

## Juniper Steel Belted Radius sample event message

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Juniper Steel Belted Radius sample message when you use the Syslog protocol

The following sample event message shows a successful authentication.

```
<13>Oct 30 18:13:36 juniper.sbr.test AgentDevice=JuniperSBR AgentLogFile=accepts
Date=2007-10-30 Time=12:25:53 RADIUS-Client=Testt Full-Name=Test T
User-Name=Test Nas-IP-Address=10.100.10.3 Calling-Station-Id=192.168.2.1 NAS-Port-
Type=1115551213
```

*Table 705. Highlighted fields in the Juniper Steel Belted Radius sample event*

| QRadar field name | Highlighted values in the event payload |
|-------------------|-----------------------------------------|
| Event ID          | accepts                                 |
| Event Category    | JuniperSBR                              |
| Source IP         | 10.100.10.3                             |

## Juniper Networks vGW Virtual Gateway (deprecated)

The Juniper Networks vGW Virtual Gateway DSM for IBM QRadar accepts events by using syslog and NetFlow from your vGW management server or firewall.

The Juniper Networks vGW Virtual Gateway product is end of life (EOL), and is no longer supported by Juniper.

#### About this task

QRadar records all relevant events, such as admin, policy, IDS logs, and firewall events. Before you configure a Juniper Networks vGW Virtual Gateway in QRadar, you must configure vGW to forward syslog events.

#### Procedure

1. Log in to your Juniper Networks vGW user interface.
2. Select **Settings**.

3. From **Security Settings**, select **Global**.
4. From **External Logging**, select one of the following options:
  - **Send Syslog from vGW management server** - Central logging with syslog event provided from a management server.
  - **Send Syslog from Firewalls** - Distribute logging with each Firewall Security VM providing syslog events.

If you select the option **Send Syslog from vGW management server**, all events that are forwarded to QRadar contain the IP address of the vGW management server.

5. Type values for the following parameters:

*Table 706. Syslog parameters*

| Parameter                 | Description                                                                                                                                                                                                |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syslog Server</b>      | Type the IP address of your vGW management server if you selected to <b>Send Syslog from vGW management server</b> . Or, type the IP address of QRadar if you selected <b>Send Syslog from Firewalls</b> . |
| <b>Syslog Server Port</b> | Type the port address for syslog. This port is typically port 514.                                                                                                                                         |

6. From the **External Logging** pane, click **Save**.

Only the changes that are made to the **External Logging** section are stored when you click **Save**. Any changes that are made to NetFlow require that you save by using the button within **NetFlow Configuration** section.

7. From the **NetFlow Configuration** pane, select the **enable** check box.

NetFlow does not support central logging from a vGW management server. From the **External Logging** section, you must select the option **Send Syslog from Firewalls**.

8. Type values for the following parameters:

*Table 707. Netflow parameters*

| Parameter                        | Description                             |
|----------------------------------|-----------------------------------------|
| <b>NetFlow collector address</b> | Type the IP address of QRadar.          |
| <b>Syslog Server Port</b>        | Type a port address for NetFlow events. |

**Note:** QRadar typically uses port 2055 for NetFlow event data on QFlow Collectors. You must configure a different NetFlow collector port on your Juniper Networks vGW Series Virtual Gateway for NetFlow.

9. From the **NetFlow Configuration**, click **Save**.

10. You can now configure the log source in QRadar.

QRadar automatically detects syslog events that are forwarded from Juniper Networks vGW. If you want to manually configure QRadar to receive syslog events:

From the **Log Source Type** list, select **Juniper vGW**.

For more information, see your *Juniper Networks vGW* documentation.

## **Juniper Networks Junos WebApp Secure (deprecated)**

---

The Juniper WebApp Secure DSM for IBM QRadar accepts events that are forwarded from Juniper Junos WebApp Secure appliances by using syslog.

Juniper Junos WebApp Secure provides incident logging and access logging events to QRadar. Before you can receive events in QRadar, you must configure event forwarding on your Juniper Junos WebApp Secure, then define the events that you want to forward.

### **Configuring syslog forwarding**

To configure a remote syslog server for Juniper Junos WebApp Secure, you must use SSH to connect to a configuration interface. You can use the configuration interface to set up or configure core settings on your Juniper Junos WebApp Secure appliance.

#### **Procedure**

1. Use SSH on port 2022 to log in to your Juniper Junos WebApp device.

`https://<IP address>:<port>`

Where:

- <IP address> is the IP address of your Juniper Junos WebApp Secure appliance.
- <Port> is the port number of your Juniper Junos WebApp Secure appliance configuration interface.

The default SSH configuration port is 2022.

2. From the **Choose a Tool** menu, select **Logging**.
3. Click **Run Tool**.
4. From the **Log Destination** menu, select **Remote Syslog Server**.
5. In the **Syslog Server** field, type the IP address of your QRadar Console or Event Collector.
6. Click **Save**.
7. From the **Choose a Tool** menu, select **Quit**.
8. Type **Exit** to close your SSH session.

#### **What to do next**

You are now ready to configure event logging on your Juniper Junos WebApp Secure appliance.

### **Configuring event logging**

The Juniper Junos WebApp Secure appliance must be configured to determine which logs are forwarded to IBM QRadar.

#### **Procedure**

1. Using a web browser, log in to the configuration site for your Juniper Junos WebApp Secure appliance.

`https://<IP address>:<port>`

Where:

- <IP address> is the IP address of your Juniper Junos WebApp Secure appliance.
- <Port> is the port number of your Juniper Junos WebApp Secure appliance.

The default configuration uses a port number of 5000.

2. From the navigation menu, select **Configuration Manager**.
3. From the configuration menu, select **Basic Mode**.
4. Click the **Global Configuration** tab and select **Logging**.
5. Click the link **Show Advanced Options**.

6. Configure the following parameters:

*Table 708. Juniper Junos WebApp Secure logging parameters*

| Parameter                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Access logging: Log Level</b>                                     | <p>Click this option to configure the level of information that is logged when access logging is enabled.</p> <p>The options include the following levels:</p> <ul style="list-style-type: none"> <li>• <b>0</b> - Access logging is disabled.</li> <li>• <b>1</b> - Basic logging.</li> <li>• <b>2</b> - Basic logging with headers.</li> <li>• <b>3</b> - Basic logging with headers and body.</li> </ul> <p><b>Note:</b> Access logging is disabled by default. It is suggested that you enable access logging only for debugging purposes. For more information, see your <i>Juniper Junos WebApp Secure documentation</i>.</p>                                                                            |
| <b>Access logging: Log requests before processing</b>                | Click this option and select <b>True</b> to log the request before it is processed, then forward the event to QRadar.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Access logging: Log requests to access log after processing</b>   | Click this option and select <b>True</b> to log the request after it is processed. After Juniper Junos WebApp Secure processes the event, then it is forwarded to QRadar.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Access logging: Log responses to access log after processing</b>  | Click this option and select <b>True</b> to log the response after it is processed. After Juniper Junos WebApp Secure processes the event, then the event is forwarded to QRadar.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Access logging: Log responses to access log before processing</b> | Click this option and select <b>True</b> to log the response before it is processed, then forward the event to QRadar.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Incident severity log level</b>                                   | <p>Click this option to define the severity of the incident events to log. All incidents at or above the level that is defined are forwarded to QRadar.</p> <p>The options include the following levels:</p> <ul style="list-style-type: none"> <li>• <b>0</b> - Informational level and later incident events are logged and forwarded.</li> <li>• <b>1</b> - Suspicious level and later incident events are logged and forwarded.</li> <li>• <b>2</b> - Low level and later incident events are logged and forwarded.</li> <li>• <b>3</b> - Medium level and later incident events are logged and forwarded.</li> <li>• <b>4</b> - High level and later incident events are logged and forwarded.</li> </ul> |
| <b>Log incidents to the syslog</b>                                   | Click this option and select <b>Yes</b> to enable syslog forwarding to QRadar.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

The configuration is complete. The log source is added to QRadar as Juniper Junos WebApp Secure events are automatically discovered. Events that are forwarded to QRadar by Juniper Junos WebApp Secure are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Juniper Networks Junos WebApp Secure

If QRadar does not automatically detect the log source, add a Juniper Networks Junos WebApp Secure log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Juniper Networks Junos WebApp Secure:

| Table 709. Syslog log source parameters for the Juniper Networks Junos WebApp Secure DSM |                                                                                                                                  |
|------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                                                | Value                                                                                                                            |
| <b>Log Source type</b>                                                                   | Type a name for your log source.                                                                                                 |
| <b>Log Source type</b>                                                                   | Type a description for the log source.                                                                                           |
| <b>Log Source type</b>                                                                   | Juniper Junos WebApp Secure                                                                                                      |
| <b>Protocol Configuration</b>                                                            | Syslog                                                                                                                           |
| <b>Log Source Identifier</b>                                                             | Type the IP address or host name for the log source as an identifier for events from your Juniper Junos WebApp Secure appliance. |

# Juniper Networks WLC Series Wireless LAN Controller (deprecated)

---

IBM QRadar can collect and categorize syslog events from Juniper Networks WLC Series Wireless LAN Controllers.

To collect syslog events, you must configure your Juniper Networks Wireless LAN Controller to forward syslog events to QRadar. Administrators can use either the RingMaster interface or the command-line interface to configure syslog forwarding for their Juniper Networks Wireless LAN Controller appliance. QRadar automatically discovers and creates log sources for syslog events that are forwarded from Juniper Networks WLC Series Wireless LAN Controllers. QRadar supports syslog events from Juniper WLAN devices that run on Mobility System Software (MSS) V7.6.

To integrate Juniper WLC events with QRadar, administrators can complete the following tasks:

1. On your Juniper WLAN appliance, configure syslog server.
2. Use one of the following methods:
  - To use the RingMaster user interface to configure a syslog server, see [“Configuring a syslog server from the Juniper WLC user interface” on page 1108](#).
  - To use the command-line interface to configure a syslog server, see [“Configuring a syslog server with the command-line interface for Juniper WLC” on page 1109](#).
3. On your QRadar system, verify that the forwarded events are automatically discovered.

## Configuring a syslog server from the Juniper WLC user interface

To collect events, you must configure a syslog server on your Juniper WLC system to forward syslog events to IBM QRadar.

### Procedure

1. Log in to the RingMaster software.
2. From the **Organizer** panel, select a Wireless LAN Controller.
3. From the **System** panel, select **Log**.
4. From the **Task** panel, select **Create Syslog Server**.
5. In the **Syslog Server** field, type the IP address of your QRadar system.
6. In the **Port** field, type 514.
7. From the **Severity Filter** list, select a severity.

Logging debug severity events can negatively affect system performance on the Juniper WLC appliance. It is a good practice for administrators to log events at the error or warning severity level and slowly increase the level to get the data you need. The default severity level is error.

8. From the **Facility Mapping** list, select a facility between local 0 - local 7.
9. Click **Finish**.

As events are generated by the Juniper WLC appliance, they are forwarded to the syslog destination you specified. The log source is automatically discovered after enough events are forwarded to QRadar. It typically takes a minimum of 25 events to automatically discover a log source.

### What to do next

Administrators can log in to the QRadar Console and verify that the log source is created on the QRadar Console. The **Log Activity** tab displays events from the Juniper WLC appliance.

## Configuring a syslog server with the command-line interface for Juniper WLC

To collect events, configure a syslog server on your Juniper WLC system to forward syslog events to IBM QRadar.

### Procedure

1. Log in to the command-line interface of the Juniper WLC appliance.
2. To configure a syslog server, type the following command:

```
set log server <ip-addr> [port 514 severity <severity-level> local-facility <facility-level>]
```

Example:

```
set log server 1.1.1.1 port 514 severity error local-facility local0.
```

3. To save the configuration, type the following command:

```
save configuration
```

As events are generated by the Juniper WLC appliance, they are forwarded to the syslog destination you specified. The log source is automatically discovered after enough events are forwarded to QRadar. It typically takes a minimum of 25 events to automatically discover a log source.

### What to do next

Administrators can log in to the QRadar Console and verify that the log source is created. The **Log Activity** tab displays events from the Juniper WLC appliance.

# Chapter 90. Kisco Information Systems SafeNet/i

The IBM QRadar DSM for Kisco Information Systems SafeNet/i collects event logs from IBM i systems.

The following table identifies the specifications for the Kisco Information Systems SafeNet/i DSM:

| Table 711. Kisco Information Systems SafeNet/i DSM specifications |                                                                                                                                     |
|-------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Specification                                                     | Value                                                                                                                               |
| Manufacturer                                                      | Kisco Information Systems                                                                                                           |
| DSM name                                                          | Kisco Information Systems SafeNet/i                                                                                                 |
| RPM file name                                                     | DSM-KiscoInformationSystemsSafeNetI-Qradar_version-build_number.noarch.rpm                                                          |
| Supported versions                                                | V10.11                                                                                                                              |
| Protocol                                                          | Log File                                                                                                                            |
| Recorded event types                                              | All events                                                                                                                          |
| Automatically discovered?                                         | No                                                                                                                                  |
| Includes identity?                                                | No                                                                                                                                  |
| Includes custom properties?                                       | No                                                                                                                                  |
| More information                                                  | <a href="http://www.kisco.com/safenet/summary.htm">Kisco Information Systems website (http://www.kisco.com/safenet/summary.htm)</a> |

To collect Kisco Information Systems SafeNet/i events, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM
  - Log File Protocol RPM
  - Kisco Information Systems SafeNet/i DSM RPM
2. Configure your Kisco Information Systems SafeNet/i device to communicate with QRadar.
3. Add a Kisco Information Systems SafeNet/i log source on the QRadar Console. The following table describes the parameters that require specific values for Kisco Information Systems SafeNet/i event collection:

Table 712. Kisco Information Systems SafeNet/i log source parameters

| Parameter              | Value                                                                                 |
|------------------------|---------------------------------------------------------------------------------------|
| Log Source type        | Kisco Information Systems SafeNet/i                                                   |
| Protocol Configuration | Log File                                                                              |
| Service Type           | FTP                                                                                   |
| Remote IP or Hostname  | The IP or host name of Kisco Information systems SafeNet/i device.                    |
| Remote Port            | 21                                                                                    |
| Remote User            | The IBM i User ID that you created for QRadar in Kisco Information Systems SafeNet/i. |

Table 712. Kisco Information Systems SafeNet/i log source parameters (continued)

| Parameter         | Value                   |
|-------------------|-------------------------|
| Remote Directory  | Leave this field empty. |
| FTP File Pattern  | . *                     |
| FTP Transfer Mode | BINARY                  |
| Processor         | NONE                    |
| Event Generator   | LINEBYLINE              |
| File Encoding     | US-ASCII                |

[Adding a DSM](#)

[Configuring Kisco Information Systems SafeNet/i to communicate with QRadar](#)

To collect SafeNet/i events, configure your IBM i system to accept FTP GET requests from your QRadar through Kisco Information Systems SafeNet/i.

[Adding a log source](#)

## Configuring Kisco Information Systems SafeNet/i to communicate with QRadar

To collect SafeNet/i events, configure your IBM i system to accept FTP GET requests from your QRadar through Kisco Information Systems SafeNet/i.

#### About this task

Use the following table when you configure the FTP access settings:

Table 713. FTP access settings

| Parameter                   | Value             |
|-----------------------------|-------------------|
| Initial Name Format         | *PATH             |
| Initial List Format         | *UNIX             |
| Initial Library             | *USRPRF           |
| Initial Home Directory Path | The IFS directory |

#### Procedure

1. Create an IFS directory on your IBM i system.
  - a) Log in to your IBM i system.
  - b) Create an IFS Directory to hold the Kisco Information Systems SafeNet/i QRadar alert files.  
Example: /SafeNet/QRadar/  
c) Set up a user profile for QRadar to use to FTP into the IFS Directory through SafeNet/i.  
Example: QRADARUSER
2. Configure FTP access for the QRadar user profile.
  - a) Log in to Kisco Information Systems SafeNet/i.
  - b) Type **GO SN7** and select **Work with User to Server Security**.
  - c) Type the user profile name that you created for QRadar, for example, QRADARUSER.

- d) Type 1 for the **FTP Server Request Validation** \*FTPSERVER and **FTP Server Logon** \*FTPLOGON3 servers.
- e) Press F3 and select **Work with User to FTP Statement Security** and type the user profile name again.
- f) Type 1 for the **List Files** and **Receiving Files** FTP operations.
- g) Press F4 and configure FTP access parameters for the user. See [Table 713 on page 1112](#).
- h) Press F3 and select **Work with User to Long Paths**.
- i) Press F6 and provide the path to the IFS directory.  
Ensure that the path is followed by an asterisk, for example, /SafeNet/QRadar/\*

- j) Type X under the **R** column.
- k) Press F3 to exit.

3. Type CHGRDRSET and then press F4.

4. Configure the following parameters:

| Parameter                            | Value                                            |
|--------------------------------------|--------------------------------------------------|
| <b>Activate QRADAR Integration</b>   | Yes                                              |
| <b>This Host Identifier</b>          | The IP address or host name of the IBM i system. |
| <b>IFS Path to QRADAR Alert File</b> | Use the following format: /SafeNet/QRadar/       |

5. Type CHGNOTIFY and press F4.

6. Configure the following parameters:

| Parameter                        | Value |
|----------------------------------|-------|
| <b>Alert Notification Status</b> | On    |
| <b>Summarized Alerts?</b>        | Yes   |

# Chapter 91. Kubernetes Auditing

The IBM QRadar DSM for Kubernetes collects auditing events from a Kubernetes master node Kube-apiserver.

To integrate Kubernetes with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - DSM Common RPM
  - Kubernetes Auditing DSM RPM
2. Configure your Kubernetes master node Kube-apiserver to send events to QRadar.
3. Create a copy of the audit policy file. For more information, see Kubernetes documentation about [Audit Policy](#) (<https://kubernetes.io/docs/tasks/debug-application-cluster/audit/#audit-policy>).
4. Configure rsyslog on your Kubernetes master hosted Linux system. For more information about configuring rsyslog, see [Configuring rsyslog on a logging server](#) ([https://access.redhat.com/documentation/en-us/red\\_hat\\_enterprise\\_linux/7/html/system\\_administrators\\_guide/ch-viewing\\_and\\_managing\\_log\\_files#s1-configuring\\_rsyslog\\_on\\_a\\_logging\\_server](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/7/html/system_administrators_guide/ch-viewing_and_managing_log_files#s1-configuring_rsyslog_on_a_logging_server)).
5. If QRadar does not automatically detect the log source, add a Kubernetes Auditing log source on the QRadar Console.

**Note:** The Kubernetes auditing event payload can be over 32,000 bytes. The default QRadar syslog payload length is 4,096 bytes. You can increase the QRadar syslog payload size to 32,000 bytes. For more information about increasing the QRadar maximum payload size, see [QRadar: TCP Syslog Maximum Payload Message Length for QRadar Appliances](#) (<https://www.ibm.com/support/pages/qradar-tcp-syslog-maximum-payload-message-length-qradar-appliances>).

If Kubernetes audit events are larger than 32,000 bytes, the events are truncated by QRadar. To keep the events from being truncated, tune your Kubernetes audit policy to return less data.

## Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

[“Configuring Kubernetes Auditing to communicate with QRadar” on page 1116](#)

To collect all events from Kubernetes Auditing, you must specify IBM QRadar as the syslog server.

## Kubernetes Auditing DSM specifications

When you configure Kubernetes Auditing, understanding the specifications for the Kubernetes Auditing DSM can help ensure a successful integration. For example, knowing what the supported version of Kubernetes is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Kubernetes Auditing DSM.

| <i>Table 714. Kubernetes Auditing DSM specifications</i> |                                                               |
|----------------------------------------------------------|---------------------------------------------------------------|
| Specification                                            | Value                                                         |
| Manufacturer                                             | Kubernetes                                                    |
| DSM name                                                 | Kubernetes Auditing                                           |
| RPM file name                                            | DSM-KubernetesAuditing-QRadar_version-build_number.noarch.rpm |
| Supported version                                        | Kubernetes API 1.19                                           |

| Table 714. Kubernetes Auditing DSM specifications (continued) |                                                                                                                                                   |
|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| Specification                                                 | Value                                                                                                                                             |
| Protocol                                                      | Syslog                                                                                                                                            |
| Event format                                                  | JSON                                                                                                                                              |
| Recorded event types                                          | RequestReceived, ResponseStarted, ResponseComplete                                                                                                |
| Automatically discovered?                                     | Yes                                                                                                                                               |
| Includes identity?                                            | No                                                                                                                                                |
| Includes custom properties?                                   | Yes                                                                                                                                               |

## Configuring Kubernetes Auditing to communicate with QRadar

To collect all events from Kubernetes Auditing, you must specify IBM QRadar as the syslog server.

### Before you begin

A Kubernetes cluster must be running on your system. For more information, see Kubernetes documentation about [Creating a single control-plane cluster with kubeadm](#) (<https://kubernetes.io/docs/setup/production-environment/tools/kubeadm/create-cluster-kubeadm/>).

Create a copy of the Kubernetes audit policy file. For more information, see Kubernetes documentation about [Audit Policy](#) (<https://kubernetes.io/docs/tasks/debug-application-cluster/audit/#audit-policy>).

If you are using the Container or the Kubernetes content extensions, you need the QRadar audit policy file. For more information about the Container content extension, see [Container](#) (<https://www.ibm.com/docs/en/qradar-common?topic=extensions-container>). For more information about the Kubernetes content extension, see [Kubernetes](#) (<https://www.ibm.com/docs/en/qradar-common?topic=extensions-kubernetes>).

Make sure that rsyslog is installed and running on your system. For more information, see the [rsyslog documentation](#) (<https://www.rsyslog.com>).

### About this task

#### Procedure

1. Use SSH to log in to your Kubernetes Auditing console.
2. In the `/etc/Kubernetes/maifests/kube-apiserver.yaml` file, define the **audit-policy-file** and **audit-log-path** parameters.

```
apiVersion: v1
kind: Pod
metadata:
  creationTimestamp: null
  labels:
    component: kube-apiserver
  tier: control-plane
  name: kube-apiserver
  namespace: kube-system
spec:
  containers:
    - command:
      - kube-apiserver
      ...
      - --audit-policy-file=/etc/kubernetes/audit-policy.yaml
      - --audit-log-path=/var/log/apiserver/audit.log
      ...
```

3. Configure the `rsyslog /etc/rsyslog.conf` file to forward events that are logged in the `audit.log` file to QRadar.

```
##### MODULES #####$ModLoad imfile## ## begin forwarding rule
##$InputFileName /var/log/apiserver/audit.log$InputFileSeverity notice$InputFileFacility
local0$InputRunFileMonitorlocal0.* @@QRADAR_EVENT_COLLECTOR_IP:514
```

4. Restart rsyslog by typing the following command: `service rsyslog restart`.

## Kubernetes Auditing log source parameters

---

When you add a Kubernetes Auditing log source on the QRadar Console by using the Syslog protocol, there are specific parameters you must use.

The following table describes the parameters that require specific values to collect Syslog events from Kubernetes Auditing:

| Table 715. Kubernetes Auditing Syslog log source parameters for the Kubernetes Auditing DSM |                         |
|---------------------------------------------------------------------------------------------|-------------------------|
| Parameter                                                                                   | Value                   |
| <b>Log Source type</b>                                                                      | Kubernetes Auditing     |
| <b>Protocol Configuration</b>                                                               | Syslog                  |
| <b>Log Source Identifier</b>                                                                | IP address or host name |

## Kubernetes Auditing sample event message

---

Use this sample event message as a way of verifying a successful integration with QRadar.

The following table provides a sample event message when you use the Syslog protocol for the Kubernetes Auditing DSM.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

Table 716. Kubernetes Auditing sample message supported by the Kubernetes Auditing DSM

| Event name                   | Low-level category      | Sample log message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

# Chapter 92. Lastline Enterprise

The IBM QRadar DSM for Lastline Enterprise receives anti-malware events from Lastline Enterprise systems.

The following table identifies the specifications for the Lastline Enterprise DSM:

| Table 717. Lastline Enterprise DSM specifications |                                                                                                                          |
|---------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| Specification                                     | Value                                                                                                                    |
| Manufacturer                                      | Lastline                                                                                                                 |
| DSM name                                          | Lastline Enterprise                                                                                                      |
| RPM file name                                     | DSM-LastlineEnterprise-Qradar_version-build_number.noarch.rpm                                                            |
| Supported versions                                | 6.0                                                                                                                      |
| Protocol                                          | LEEF                                                                                                                     |
| Recorded event types                              | Anti-malware                                                                                                             |
| Automatically discovered?                         | Yes                                                                                                                      |
| Includes identity?                                | No                                                                                                                       |

| More information                                  | <a href="http://www.lastline.com">Lastline website</a> ( <a href="http://www.lastline.com">http://www.lastline.com</a> ) |

To send Lastline Enterprise events to QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM
  - Lastline Enterprise DSM RPM
2. Configure your Lastline Enterprise device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a Lastline Enterprise log source on the QRadar Console. The following table describes the parameters that require specific values that are required for Lastline Enterprise event collection:

Table 718. Lastline Enterprise log source parameters

| Parameter              | Value               |
|------------------------|---------------------|
| Log Source type        | Lastline Enterprise |
| Protocol Configuration | Syslog              |

## Configuring Lastline Enterprise to communicate with QRadar

---

On the Lastline Enterprise system, use the SIEM settings in the notification interface to specify a SIEM appliance where Lastline can send events.

### Procedure

1. Log in to your Lastline Enterprise system.
2. On the sidebar, click **Admin**.
3. Click **Reporting > Notifications**.
4. To add a notification, click the **Add a notification** (+) icon.
5. From the **Notification Type** list, select **SIEM**.
6. In the **SIEM Server Settings** pane, configure the parameters for your QRadar Console or Event Collector. Ensure that you select **LEEF** from the **SIEM Log Format** list.
7. Configure the triggers for the notification:
  - a) To edit existing triggers in the list, click the **Edit trigger** icon, edit the parameters, and click **Update Trigger**.
  - b) To add a trigger to the list, click the **Add Trigger** (+) icon, configure the parameters, and click **Add Trigger**.
8. Click **Save**.

# Chapter 93. Lieberman Random Password Manager

The Lieberman Random Password Manager DSM gives the option to integrate IBM QRadar with Lieberman Enterprise Random Password Manager and Lieberman Random Password Manager software by using syslog events in the Log Event Extended Format (LEEF).

## About this task

The Lieberman Random Password Manager uses Port 514 to forward syslog events to QRadar. QRadar records all relevant password management events. For information on configuring syslog forwarding, see your vendor documentation.

QRadar automatically detects syslog events that are forwarded from Lieberman Random Password Manager and Lieberman Enterprise Random Password Manager devices. However, if you want to manually configure QRadar to receive events from these devices:

## Procedure

From the **Log Source Type** list, select **Lieberman Random Password Manager**.

| More information                               | <a href="https://www.lightcyber.com">LightCyber website</a> ( <a href="https://www.lightcyber.com">https://www.lightcyber.com</a> ) |

To integrate LightCyber Magna with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM
  - LightCyber Magna DSM RPM
2. Configure your LightCyber Magna device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a LightCyber Magna log source on the QRadar Console. The following table describes the parameters that require specific values to collect events from LightCyber Magna:

Table 720. LightCyber Magna log source parameters

| Parameter              | Value            |
|------------------------|------------------|
| Log Source type        | LightCyber Magna |
| Protocol Configuration | Syslog           |

*Table 720. LightCyber Magna log source parameters (continued)*

| Parameter                    | Value                                        |
|------------------------------|----------------------------------------------|
| <b>Log Source Identifier</b> | Type a unique identifier for the log source. |

4. To verify that QRadar is configured correctly, review the following table to see an example of a normalized audit event message.

The following table shows a sample event message from LightCyber Magna:

*Table 721. LightCyber Magna sample message*

| Event name          | Low level category | Sample log message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Configuring LightCyber Magna to communicate with QRadar

To collect LightCyber Magna events, configure your LightCyber Magna device to send syslog events to QRadar.

#### Procedure

1. Log in to the LightCyber Magna interface as administrator.
2. Click **Configuration > Syslog**.

3. Enable **Yes**.

4. Configure the following parameters:

*Table 722. LightCyber Magna configuration parameters*

| Parameter       | Value                                                      |
|-----------------|------------------------------------------------------------|
| <b>Host</b>     | The IP address or host name of the QRadar Event Collector. |
| <b>Port</b>     | 514                                                        |
| <b>Protocol</b> | TCP                                                        |
| <b>Format</b>   | LIEEEF                                                     |

5. Click **Save**.

# Chapter 95. Linux

IBM QRadar supports the a range of Linux DSMs.

## Linux DHCP Server

The Linux DHCP Server DSM for IBM QRadar collects DHCP events by using syslog.

To integrate Linux DHCP Server with IBM QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent versions of the RPMs from the IBM support website (<http://www.ibm.com/support>).
  - DSM Common RPM
  - GNU Linux DHCP DSM RPM
  - Protocol Common RPM
2. Configure your Linux DHCP server to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a Linux DHCP Server logsource log source on the QRadar Console. For more information about configuring your Linux DHCP Server, consult the Linux man pages or associated documentation for your DHCP daemon.

## Linux DHCP Server DSM specifications

When you configure Linux DHCP Server, understanding the specifications for the Linux DHCP Server DSM can help ensure a successful integration. For example, knowing what the supported version of Linux DHCP Server is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Linux DHCP Server DSM.

| Table 723. Linux DHCP DSM specifications |                                                                                                                                            |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Specification                            | Value                                                                                                                                      |
| Manufacturer                             | Linux                                                                                                                                      |

## Syslog log source parameters for Linux DHCP

If QRadar does not automatically detect the log source, add a Linux DHCP log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Linux DHCP servers:

| Table 724. Syslog log source parameters for the Linux DHCP DSM |                                                                                                              |
|----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| Parameter                                                      | Value                                                                                                        |
| <b>Log Source type</b>                                         | Linux DHCP Server                                                                                            |
| <b>Protocol Configuration</b>                                  | Syslog                                                                                                       |
| <b>Log Source Identifier</b>                                   | Type the IP address or host name for the log source as an identifier for events from your Linux DHCP Server. |

## Linux IPtables

The Linux IPtables DSM for IBM QRadar accepts firewall IPtables events by using syslog.

QRadar records all relevant from Linux IPtables where the syslog event contains any of the following words: Accept, Drop, Deny, or Reject. Creating a customized log prefix in the event payload enables QRadar to easily identify IPtables behavior.

# Configuring IPTables

IPtables is a powerful tool, which is used to create rules on the Linux kernel firewall for routing traffic.

## About this task

To configure IPTables, you must examine the existing rules, modify the rule to log the event, and assign a log identifier to your IPTables rule that can be identified by IBM QRadar. This process is used to determine which rules are logged by QRadar. QRadar includes any logged events that include the words: accept, drop, reject, or deny in the event payload.

## Procedure

1. Using SSH, log in to your Linux Server as a root user.
2. Edit the IPTables file in the following directory:

```
/etc/iptables.conf
```

**Note:** The file that contains the IPTables rules can vary according to the specific Linux operating system you are configuring. For example, a system using Red Hat Enterprise has the file in the /etc/sysconfig/iptables directory. Consult your *Linux operating system documentation* for more information about configuring IPTables.

3. Review the file to determine the IPTables rule you want to log.

For example, if you want to log the rule that is defined by the entry, use:

```
-A INPUT -i eth0 --dport 31337 -j DROP
```

4. Insert a matching rule immediately before each rule you want to log:

```
-A INPUT -i eth0 --dport 31337 -j DROP
```

```
-A INPUT -i eth0 --dport 31337 -j DROP
```

5. Update the target of the new rule to LOG for each rule you want to log, For example:

```
-A INPUT -i eth0 --dport 31337 -j LOG
```

```
-A INPUT -i eth0 --dport 31337 -j DROP
```

6. Set the log level of the LOG target to a SYSLOG priority level, such as info or notice:

```
-A INPUT -i eth0 --dport 31337 -j LOG --log-level info
```

```
-A INPUT -i eth0 --dport 31337 -j DROP
```

7. Configure a log prefix to identify the rule behavior. Set the log prefix parameter to :

```
Q1Target=<rule>
```

Where <rule> is one of the following IPtable firewall actions: **fw\_accept**, **fw\_drop**, **fw\_reject**, or **fw\_deny**.

For example, if the rule that is logged by the firewall targets dropped events, the log prefix setting is:

```
Q1Target=fw_drop
```

```
-A INPUT -i eth0 --dport 31337 -j LOG --log-level info --log-prefix "Q1Target=fw_drop" -A  
INPUT -i eth0 --dport 31337 -j DROP
```

**Note:** You must have a trailing space before the closing quotation mark.

8. Save and exit the file.
  9. Restart IPTables using the following command:
- ```
/etc/init.d/iptables restart
```
10. Open the syslog.conf file.
  11. Add the following line:

`kern.<log level>@<IP address>`

Where:

- `<log level>` is the previously set log level.
- `<IP address>` is the IP address of QRadar.

12. Save and exit the file.

13. Restart the syslog daemon by using the following command:

```
/etc/init.d/syslog restart
```

After the syslog daemon restarts, events are forwarded to QRadar. IPtable events that are forwarded from Linux Servers are automatically discovered and displayed in the **Log Activity** tab of QRadar.

## Syslog log source parameters for Linux IPtables

If QRadar does not automatically detect the log source, add a Linux IPtables log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Linux IPtables firewalls:

Table 726. Syslog log source parameters for the Linux IPtables DSM	
Parameter	Value
<b>Log Source type</b>	Linux IPtables Firewall
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Linux IPtables firewall.

## Linux OS

The Linux OS DSM for IBM QRadar records Linux operating system events and forwards the events using syslog or syslog-ng.

If you are using syslog on a UNIX host, upgrade the standard syslog to a more recent version, such as, syslog-ng.

**Note:** Do not run both syslog and syslog-ng at the same time.

To integrate Linux OS with QRadar, select one of the following syslog configurations for event collection:

- [“Configuring syslog on Linux OS” on page 1131](#)
- [“Configuring syslog-ng on Linux OS” on page 1131](#)

You can also configure your Linux operating system to send audit logs to QRadar. For more information, see [“Configuring Linux OS to send audit logs” on page 1132](#).

### Supported event types

The Linux OS DSM supports the following event types:

- cron
- HTTPS

- FTP
- NTP
- Simple Authentication Security Layer (SASL)
- SMTP
- SNMP
- SSH
- Switch User (SU)
- Pluggable Authentication Module (PAM) events.

## **Configuring syslog on Linux OS**

Configuring Linux OS to forward events by using the syslog protocol.

#### **Procedure**

1. Log in to your Linux OS device, as a root user.
2. Open the /etc/syslog.conf file and add the following facility information:

```
authpriv.* @<ip_address>
```

where:

<ip\_address> is the IP address of IBM QRadar.

3. Save the file.
4. Restart syslog by typing the following command:  
**service syslog restart**
5. Log in to the QRadar Console.
6. Add a Linux OS log source on the QRadar Console.

For more information about syslog, see the [Linux documentation](#) (<https://www.linux.com/what-is-linux/>).

## **Configuring syslog-ng on Linux OS**

If you are using syslog on a UNIX host to forward events, upgrade the standard syslog to syslog-ng, which is a more recent version.

#### **Procedure**

1. Log in to your Linux OS device, as a root user.
2. Open the /etc/syslog-ng/syslog-ng.conf file and add the following facility information:

```
source qr_source {
    internal();
    system();
};

filter qr_filter {
    facility(auth, authpriv);
};

destination qr_destination {
    tcp("<qradar_ip_address>" port(514));
};

log{
    source(qr_source);
    filter(qr_filter);
```

```
    destination(qr_destination);  
};
```

where:

<qradar\_ip\_address> is the IP address of IBM QRadar.

3. Save the file.
4. Restart syslog-ng by typing the following command:  
**service syslog-ng restart**
5. Log in to the QRadar Console.
6. Add a Linux OS log source on the QRadar Console.

For more information about syslog-ng, see the [Linux documentation](https://www.linux.com/what-is-linux/) (<https://www.linux.com/what-is-linux/>).

## Configuring Linux OS to send audit logs

Configure Linux OS to send audit logs to QRadar.

### About this task

This task applies to Red Hat Enterprise Linux (RHEL) v6 to v8 operating systems.

If you use a SUSE, Debian, or Ubuntu operating system, see your vendor documentation for specific steps for your operating system.

### Procedure

1. Log in to your Linux OS device, as a root user.
2. Type the following commands:

```
yum install audit  
service auditd start  
chkconfig auditd on
```

3. Optional: If you are using RHEL v6 to v7.9, open the /etc/audisp/plugins.d/syslog.conf file and verify that the parameters match the following values:

```
active = yes  
direction = out  
path = builtin_syslog  
type = builtin  
args = LOG_LOCAL6  
format = string
```

4. Optional: If you are using RHEL v8, open the /etc/audit/plugins.d/syslog.conf file and verify that the parameters match the following values:

```
active = yes  
direction = out  
path = builtin_syslog  
type = builtin  
args = LOG_LOCAL6
```

- ```
format = string
```
5. Open the /etc/rsyslog.conf file and add the following line at the end of the file:  
`local6.* @@<QRadar_Collector_IP_address>`
  6. Type the following commands:

```
service auditd restart  
service syslog restart
```

7. Log in to the QRadar Console.
8. Add a Linux OS log source on the QRadar Console.

## Linux OS Sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage returns or line feed characters.

### Linux OS sample event messages when you use the syslog protocol

**Sample 1:** The following sample event message shows a PAM authentication failure for a user.

```
<118>Jul 7 15:54:13 kernel: Jul 7 15:54:13 gnu.linuxserver.test sshd[708]: error: PAM:  
authentication error for root from 172.16.197.55
```

```
<118>Jul 7 15:54:13 kernel: Jul 7 15:54:13 gnu.linuxserver.test sshd[708]: error: PAM:  
authentication error for root from 172.16.197.55
```

*Table 727. QRadar field names and highlighted values in the event payload*

| QRadar field name | Highlighted values in the event payload |
|-------------------|-----------------------------------------|
| Event ID          | <b>authentication error</b>             |
| Source IP         | <b>172.16.197.55</b>                    |
| Username          | <b>root</b>                             |

**Sample 2:** The following sample event message show that an incorrect or failed password was received from an invalid user.

```
<38>2015-06-24T14:15:51Z sshd[12239959]: Failed password for invalid user test from 192.168.8.75  
port 57436 ssh2
```

```
<38>2015-06-24T14:15:51Z sshd[12239959]: Failed password for invalid user test from  
192.168.8.75 port 57436 ssh2
```

*Table 728. QRadar field names and highlighted values in the event payload*

| QRadar field name | Highlighted values in the event payload |
|-------------------|-----------------------------------------|
| Event ID          | <b>Failed password</b>                  |
| Source IP         | <b>192.168.8.75</b>                     |
| Source Port       | <b>57436</b>                            |
| Username          | <b>test</b>                             |

# Chapter 96. LOGbinder

Configure your LOGbinder system to send event logs to IBM QRadar.

The following LOGbinder systems are supported:

- [LOGbinder EX event collection from Microsoft Exchange Server.](#)
- [LOGbinder SP event collection from Microsoft SharePoint.](#)
- [LOGbinder SQL event collection from Microsoft SQL Server.](#)

## LOGbinder EX event collection from Microsoft Exchange Server

The IBM QRadar DSM for Microsoft Exchange Server can collect LOGbinder EX V2.0 events.

The following table identifies the specifications for the Microsoft Exchange Server DSM when the log source is configured to collect LOGbinder EX events:

| Table 729. LOGbinder for Microsoft Exchange Server |                                                                                                                                            |
|----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Specification                                      | Value                                                                                                                                      |
| Manufacturer                                       | Microsoft                                                                                                                                  |
| DSM name                                           | Microsoft Exchange Server                                                                                                                  |
| RPM file name                                      | DSM-MicrosoftExchange-QRadar_version-build_number.noarch.rpm                                                                               |
| Supported versions                                 | LOGbinder EX V2.0                                                                                                                          |
| Protocol type                                      | Syslog<br>LEEF                                                                                                                             |
| QRadar recorded event types                        | Admin<br>Mailbox                                                                                                                           |
| Automatically discovered?                          | Yes                                                                                                                                        |
| Included identity?                                 | No                                                                                                                                         |
| More information                                   | <a href="http://www.office.microsoft.com/en-us/exchange/">Microsoft Exchange website (http://www.office.microsoft.com/en-us/exchange/)</a> |

The Microsoft Exchange Server DSM can collect other types of events. For more information on how to configure for other Microsoft Exchange Server event formats, see the Microsoft Exchange Server topic in the *DSM Configuration Guide*.

To collect LOGbinder events from Microsoft Exchange Server, use the following steps:

1. If automatic updates are not enabled, download the most recent version of the following RPMs from the [IBM Support Website](#):
  - DSMCommon RPM
  - Microsoft Exchange Server DSM RPM
2. Configure your LOGbinder EX system to send Microsoft Exchange Server event logs to QRadar.
3. If the log source is not automatically created, add a Microsoft Exchange Server DSM log source on the QRadar Console. The following table describes the parameters that require specific values that are required for LOGbinder EX event collection:

*Table 730. Microsoft Exchange Server log source parameters for LOGbinder event collection*

| Parameter              | Value                     |
|------------------------|---------------------------|
| Log Source type        | Microsoft Exchange Server |
| Protocol Configuration | Syslog                    |

## Configuring your LOGbinder EX system to send Microsoft Exchange event logs to QRadar

To collect Microsoft Exchange LOGbinder events, you must configure your LOGbinder EX system to send events to IBM QRadar.

### Before you begin

Configure LOGbinder EX to collect events from your Microsoft Exchange Server. For more information, see your LOGbinder EX documentation.

### Procedure

1. Open the **LOGbinder EX Control Panel**.
2. Double-click **Output** in the Configure pane.
3. Choose one of the following options:
  - Configure for Syslog-Generic output:
    - a. In the Outputs pane, double-click **Syslog-Generic**.
    - b. Select the **Send output to Syslog-Generic** check box, and then enter the IP address and port of your QRadar Console or Event Collector.
  - Configure for Syslog-LEEF output:
    - a. In the Outputs pane, double-click **Syslog-LEEF**.
    - b. Select the **Send output to Syslog-LEEF** check box, and then enter the IP address and port of your QRadar Console or Event Collector.
4. Click **OK**.
5. To restart the LOGbinder service, click the **Restart** icon.

## LOGbinder SP event collection from Microsoft SharePoint

The IBM QRadar DSM for Microsoft SharePoint can collect LOGbinder SP events.

The following table identifies the specifications for the Microsoft SharePoint DSM when the log source is configured to collect LOGbinder SP events:

*Table 731. LOGbinder for Microsoft SharePoint specifications*

| Specification      | Value                                                          |
|--------------------|----------------------------------------------------------------|
| Manufacturer       | Microsoft                                                      |
| DSM name           | Microsoft SharePoint                                           |
| RPM file name      | DSM-MicrosoftSharePoint-QRadar_version-build_number.noarch.rpm |
| Supported versions | LOGbinder SP V4.0                                              |

*Table 731. LOGbinder for Microsoft SharePoint specifications (continued)*

| Specification               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

The Microsoft SharePoint DSM can collect other types of events. For more information about other Microsoft SharePoint event formats, see the Microsoft SharePoint topic in the *DSM Configuration Guide*.

To collect LOGbinder events from Microsoft SharePoint, use the following steps:

1. If automatic updates are not enabled, download the most recent version of the following RPMs from the [IBM Support Website](#):
  - DSMCommon RPM
  - Microsoft SharePoint DSM RPM
2. Configure your LOGbinder SP system to send Microsoft SharePoint event logs to QRadar.
3. If the log source is not automatically created, add a Microsoft SharePoint DSM log source on the QRadar Console. The following table describes the parameters that require specific values that are required for LOGbinder event collection:

*Table 732. Microsoft SharePoint log source parameters for LOGbinder event collection*

| Parameter              | Value                |
|------------------------|----------------------|
| Log Source type        | Microsoft SharePoint |
| Protocol Configuration | Syslog               |

[Adding a log source](#)

## Configuring your LOGbinder SP system to send Microsoft SharePoint event logs to QRadar

To collect Microsoft SharePoint LOGbinder events, you must configure your LOGbinder SP system to send events to IBM QRadar.

## Procedure

1. Open the **LOGbinder SP Control Panel**.
2. Double-click **Output** in the Configure pane.

3. Choose one of the following options:

- Configure for Syslog-Generic output:
  - a. In the Outputs pane, double-click **Syslog-Generic**.
  - b. Select the **Send output to Syslog-Generic** check box, and then enter the IP address and port of your QRadar Console or Event Collector.
- Configure for Syslog-LEEF output:
  - a. In the Outputs pane, double-click **Syslog-LEEF**.
  - b. Select the **Send output to Syslog-LEEF** check box, and then enter the IP address and port of your QRadar Console or Event Collector.

4. Click **OK**.

5. To restart the LOGbinder service, click the **Restart** icon.

## LOGbinder SQL event collection from Microsoft SQL Server

The IBM QRadar DSM for Microsoft SQL Server can collect LOGbinder SQL events.

The following table identifies the specifications for the Microsoft SQL Server DSM when the log source is configured to collect LOGbinder SQL events:

| Table 733. LOGbinder for Microsoft SQL Server specifications |                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Included identity?                                           | Yes                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| More information                                             | <a href="http://www.logbinder.com/products/logbindersql/">LogBINDER SQL website</a> ( <a href="http://www.logbinder.com/products/logbindersql/">http://www.logbinder.com/products/logbindersql/</a> )<br><a href="http://www.microsoft.com/en-us/server-cloud/products/sql-server/">Microsoft SQL Server website</a> ( <a href="http://www.microsoft.com/en-us/server-cloud/products/sql-server/">http://www.microsoft.com/en-us/server-cloud/products/sql-server/</a> ) |

The Microsoft SQL Server DSM can collect other types of events. For more information about other Microsoft SQL Server event formats, see the Microsoft SQL Server topic in the *DSM Configuration Guide*.

To collect LOGbinder events from Microsoft SQL Server, use the following steps:

1. If automatic updates are not enabled, download the most recent version of the following RPMs from the [IBM Support Website](#):
  - DSMCommon RPM
  - Microsoft SQL Server DSM RPM
2. Configure your LOGbinder SQL system to send Microsoft SQL Server event logs to QRadar.

3. If the log source is not automatically created, add a Microsoft SQL Server DSM log source on the QRadar Console. The following table describes the parameters that require specific values that are required for LOGbinder event collection:

*Table 734. Microsoft SQL Server log source parameters for LOGbinder event collection*

| Parameter              | Value                |
|------------------------|----------------------|
| Log Source type        | Microsoft SQL Server |
| Protocol Configuration | Syslog               |

## Configuring your LOGbinder SQL system to send Microsoft SQL Server event logs to QRadar

To collect Microsoft SQL Server LOGbinder events, you must configure your LOGbinder SQL system to send events to IBM QRadar.

### Before you begin

Configure LOGbinder SQL to collect events from your Microsoft SQL Server. For more information, see your LOGbinder SQL documentation.

### Procedure

1. Open the **LOGbinder SQL Control Panel**.
2. Double-click **Output** in the Configure pane.
3. Choose one of the following options:
  - Configure for Syslog-Generic output:
    - a. In the Outputs pane, double-click **Syslog-Generic**.
    - b. Select the **Send output to Syslog-Generic** check box, and then enter the IP address and port of your QRadar Console or Event Collector.
  - Configure for Syslog-LEEF output:
    - a. In the Outputs pane, double-click **Syslog-LEEF**.
    - b. Select the **Send output to Syslog-LEEF** check box, and then enter the IP address and port of your QRadar Console or Event Collector.
4. Click **OK**.
5. To restart the LOGbinder service, click the **Restart** icon.

# Chapter 97. McAfee

IBM QRadar supports a range of McAfee products.

## JDBC log source parameters for McAfee Application/Change Control

If QRadar does not automatically detect the log source, add a McAfee Application/Change Control log source on the QRadar Console by using the JDBC protocol.

When using the JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from McAfee Application/Change Control:

| Table 735. JDBC log source parameters for the McAfee Application/Change Control DSM |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Includes custom properties?            | No                                                                                                                                                                                                                                                                           |
| More information                       | <a href="http://www.mcafee.com/enterprise/en-us/products/epolicy-orchestrator.html">McAfee website</a> ( <a href="http://www.mcafee.com/enterprise/en-us/products/epolicy-orchestrator.html">http://www.mcafee.com/enterprise/en-us/products/epolicy-orchestrator.html</a> ) |

To integrate McAfee ePolicy Orchestrator with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console.
  - JDBC Protocol RPM
  - SNMP Protocol RPM
  - TLS Syslog Protocol RPM
  - DSMCommon RPM
  - McAfee ePolicy Orchestrator DSM RPM
2. Configure your McAfee ePolicy Orchestrator device to send events to QRadar.
  - a. Add a registered server. If you are using the JDBC protocol, you don't need to add a registered server. For more information about registering servers, see the following procedures:
    - [Register syslog servers](https://docs.trellix.com/bundle/trellix-epolicy-orchestrator-on-prem-5.10.0-product-guide/page/GUID-5C5332B3-837A-4DDA-BE5C-1513A230D90A.html) (<https://docs.trellix.com/bundle/trellix-epolicy-orchestrator-on-prem-5.10.0-product-guide/page/GUID-5C5332B3-837A-4DDA-BE5C-1513A230D90A.html>)
    - [Register SNMP servers](https://docs.trellix.com/bundle/trellix-epolicy-orchestrator-on-prem-5.10.0-product-guide/page/GUID-F37CFF4C-B227-4545-8BC5-2DDC46504F90.html) (<https://docs.trellix.com/bundle/trellix-epolicy-orchestrator-on-prem-5.10.0-product-guide/page/GUID-F37CFF4C-B227-4545-8BC5-2DDC46504F90.html>)

- b. Configure SNMP notifications. If you are using the JDBC protocol or the TLS Syslog protocol, no further configuration is required. For more information about configuring SNMP notifications, see [Configuring SNMP notifications on McAfee ePolicy Orchestrator](#).
- c. Install the Java Cryptography Extension for high-level SNMP decryption algorithms. For more information, see the following procedures:
- [Installing the Java Cryptography Extension on McAfee ePolicy Orchestrator](#)
  - [Installing the Java Cryptography Extension on QRadar](#)

3. Add a McAfee ePolicy Orchestrator log source on the QRadar Console. The following tables describe the SNMPv1, SNMPv2, SNMPv3, JDBC, and TLS syslog protocol log source parameters that require specific values to collect events from McAfee ePolicy Orchestrator.

The following table describes the SNMPv1 protocol log source parameters that require specific values to collect events from McAfee ePolicy Orchestrator.

*Table 737. McAfee ePolicy Orchestrator SNMPv1 log source parameters*

| Parameter                                | Value                                        |
|------------------------------------------|----------------------------------------------|
| <b>Log Source Name</b>                   | Type a unique name for the log source.       |
| <b>Log Source Description (Optional)</b> | Type a description for the log source.       |
| <b>Log Source type</b>                   | <b>McAfee ePolicy Orchestrator</b>           |
| <b>Protocol Configuration</b>            | <b>SNMPv1</b>                                |
| <b>Log Source Identifier</b>             | Type a unique identifier for the log source. |

The following table describes the SNMPv2 protocol log source parameters that require specific values to collect events from McAfee ePolicy Orchestrator.

*Table 738. McAfee ePolicy Orchestrator SNMPv2 log source parameters*

| Parameter                                | Value                                        |
|------------------------------------------|----------------------------------------------|
| <b>Log Source Name</b>                   | Type a unique name for the log source.       |
| <b>Log Source Description (Optional)</b> | Type a description for the log source.       |
| <b>Log Source type</b>                   | <b>McAfee ePolicy Orchestrator</b>           |
| <b>Protocol Configuration</b>            | <b>SNMPv2</b>                                |
| <b>Log Source Identifier</b>             | Type a unique identifier for the log source. |

For a complete list of SNMPv2 protocol log source parameters and their values, see [SNMPv2 protocol configuration options](#).

The following table describes the SNMPv3 protocol log source parameters that require specific values to collect events from McAfee ePolicy Orchestrator.

*Table 739. McAfee ePolicy Orchestrator SNMPv3 log source parameters*

| Parameter                                | Value                                        |
|------------------------------------------|----------------------------------------------|
| <b>Log Source Name</b>                   | Type a unique name for the log source.       |
| <b>Log Source Description (Optional)</b> | Type a description for the log source.       |
| <b>Log Source type</b>                   | <b>McAfee ePolicy Orchestrator</b>           |
| <b>Protocol Configuration</b>            | <b>SNMPv3</b>                                |
| <b>Log Source Identifier</b>             | Type a unique identifier for the log source. |

For a complete list of SNMPv3 protocol log source parameters and their values, see [SNMPv3 protocol configuration options](#).

The following table describes the JDBC protocol log source parameters that require specific values to collect events from McAfee ePolicy Orchestrator.

| Table 740. McAfee ePolicy Orchestrator JDBC log source parameters |                                                                                                                                                                                                                                                                          |
|-------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                         | Value                                                                                                                                                                                                                                                                    |
| <b>Log Source Name</b>                                            | Type a unique name for the log source.                                                                                                                                                                                                                                   |
| <b>Log Source Description (Optional)</b>                          | Type a description for the log source.                                                                                                                                                                                                                                   |
| <b>Log Source type</b>                                            | <b>McAfee ePolicy Orchestrator</b>                                                                                                                                                                                                                                       |
| <b>Protocol Configuration</b>                                     | <b>JDBC</b>                                                                                                                                                                                                                                                              |
| <b>Database Type</b>                                              | Select <b>MSDE</b> from the list.                                                                                                                                                                                                                                        |
| <b>Table Name</b>                                                 | A table or view that includes the event records as follows: <ul style="list-style-type: none"><li>• For ePolicy Orchestrator 3.x, type Events.</li><li>• For ePolicy Orchestrator 4.x, type EP0Events.</li><li>• For ePolicy Orchestrator 5.x, type EP0Events.</li></ul> |

For a complete list of JDBC protocol log source parameters and their values, see [JDBC protocol configuration options](#).

The following table describes the TLS syslog protocol log source parameters that require specific values to collect events from McAfee ePolicy Orchestrator.

| Table 741. McAfee ePolicy Orchestrator TLS syslog log source parameters |                                        |
|-------------------------------------------------------------------------|----------------------------------------|
| Parameter                                                               | Value                                  |
| <b>Log Source Name</b>                                                  | Type a unique name for the log source. |
| <b>Log Source Description (Optional)</b>                                | Type a description for the log source. |
| <b>Log Source type</b>                                                  | <b>McAfee ePolicy Orchestrator</b>     |
| <b>Protocol Configuration</b>                                           | <b>TLS Syslog</b>                      |

For a complete list of TLS syslog log source parameters and their values, see [TLS syslog protocol configuration options](#).

## Related concepts

[“SNMPv2 protocol configuration options” on page 219](#)

You can configure a log source to use the SNMPv2 protocol to receive SNMPv2 events.

[“SNMPv3 protocol configuration options” on page 220](#)

You can configure a log source to use the SNMPv3 protocol to receive SNMPv3 events.

[“TLS Syslog protocol configuration options” on page 231](#)

Configure a TLS Syslog protocol log source to receive encrypted syslog events from network devices that support TLS Syslog event forwarding for each listener port.

## Configuring SNMP notifications on McAfee ePolicy Orchestrator

To send SNMP events from McAfee ePolicy Orchestrator to IBM QRadar, you must configure SNMP notifications on your McAfee ePolicy Orchestrator device.

### Before you begin

You must add a registered server to McAfee ePolicy Orchestrator before you complete the following steps. For more information, see [Register syslog servers](#) (<https://docs.mcafee.com/bundle/epolicy-orchestrator-5.10.0-product-guide/page/GUID-5C5332B3-837A-4DDA-BE5C-1513A230D90A.html>).

### Procedure

1. Select **Menu > Automation > Automatic Responses**.
2. Click **New Responses**, and then configure the following values.
  - a. Type a name and description for the response.
  - b. From the **Event group** list, select **ePO Notification Events**.
  - c. From the **Event type** list, select **Threats**.
  - d. From the **Status** list, select **Enabled**.
3. Click **Next**.
4. From the **Value** column, type a value to use for system selection, or click the ellipsis icon.
5. Optional: From the **Available Properties** list, select more filters to narrow the response results.
6. Click **Next**.
7. Select **Trigger this response for every event** and then click **Next**.

When you configure aggregation for your McAfee ePolicy Orchestrator responses, do not enable throttling.

8. From the **Actions** list, select **Send SNMP Trap**.
9. Configure the following values:
  - a. From the list of SNMP servers, select the SNMP server that you registered when you added a registered server.
  - b. From the **Available Types** list, select **List of All Values**.
  - c. Click **>>** to add the event type that is associated with your McAfee ePolicy Orchestrator version.  
Use the following table as a guide:

| Available Types                | Selected Types       | ePolicy Orchestrator Version |
|--------------------------------|----------------------|------------------------------|
| Detected UTC                   | {listOfDetectedUTC}  | 4.5, 5.9                     |
| Received UTC                   | {listOfReceivedUTC}  | 4.5, 5.9                     |
| Detecting Product IPv4 Address | {listOfAnalyzerIPV4} | 4.5, 5.9                     |
| Detecting Product IPv6 Address | {listOfAnalyzerIPV6} | 4.5, 5.9                     |

| Available Types               | Selected Types         | ePolicy Orchestrator Version |
|-------------------------------|------------------------|------------------------------|
| Detecting Product MAC Address | {listOfAnalyzerMAC}    | 4.5, 5.9                     |
| Source IPv4 Address           | {listOfSourceIPV4}     | 4.5, 5.9                     |
| Source IPv6 Address           | {listOfSourceIPV6}     | 4.5, 5.9                     |
| Source MAC Address            | {listOfSourceMAC}      | 4.5, 5.9                     |
| Source User Name              | {listOfSourceUserName} | 4.5, 5.9                     |
| Target IPv4 Address           | {listOfTargetIPV4}     | 4.5, 5.9                     |
| Target IPv6 Address           | {listOfTargetIPV6}     | 4.5, 5.9                     |
| Target MAC                    | {listOfTargetMAC}      | 4.5, 5.9                     |
| Target Port                   | {listOfTargetPort}     | 4.5, 5.9                     |
| Threat Event ID               | {listOfThreatEventID}  | 4.5, 5.9                     |
| Threat Event ID               | {listOfThreatEventID}  | 4.5, 5.9                     |
| Threat Severity               | {listOfThreatSeverity} | 4.5, 5.9                     |
| SourceComputers               |                        | 4.0                          |
| AffectedComputerIPs           |                        | 4.0                          |
| EventIDs                      |                        | 4.0                          |
| TimeNotificationSent          |                        | 4.0                          |

10. Click **Next**, and then click **Save**.

## What to do next

1. Add a log source in QRadar.
2. Install the Java Cryptography Extension for high-level SNMP decryption algorithms.

### Related tasks

[“Adding a log source” on page 5](#)

The Java™ Cryptography Extension (JCE) is a Java framework that is required for IBM QRadar to decrypt advanced cryptography algorithms for AES192 or AES256. The following information describes how to install Oracle JCE on your McAfee ePolicy Orchestrator (McAfee ePO) device.

[“Installing the Java Cryptography Extension on QRadar” on page 1147](#)

The Java Cryptography Extension (JCE) is a Java framework that is required for IBM QRadar to decrypt advanced cryptography algorithms for AES192 or AES256. The following information describes how to install Oracle JCE on your QRadar appliance.

## Installing the Java Cryptography Extension on McAfee ePolicy Orchestrator

The Java™ Cryptography Extension (JCE) is a Java framework that is required for IBM QRadar to decrypt advanced cryptography algorithms for AES192 or AES256. The following information describes how to install Oracle JCE on your McAfee ePolicy Orchestrator (McAfee ePO) device.

### Procedure

1. Download the latest version of the JavaTM Cryptography Extension from the following website:

<https://www14.software.ibm.com/webapp/iwm/web/preLogin.do?source=jcesdk>

The JavaTM Cryptography Extension version must match the version of the Java™ installed on your McAfee ePO device.

2. Copy the JCE compressed file to the following directory on your McAfee ePO device:

```
<installation path to McAfee ePO>/jre/lib/security
```

## Installing the Java Cryptography Extension on QRadar

The Java Cryptography Extension (JCE) is a Java framework that is required for IBM QRadar to decrypt advanced cryptography algorithms for AES192 or AES256. The following information describes how to install Oracle JCE on your QRadar appliance.

### Procedure

1. Optional: If you are using QRadar 7.2x, 7.3.0, or 7.31, complete the following steps:

- a) Download the latest version of the Java Cryptography Extension from the [IBM website](https://www14.software.ibm.com/webapp/iwm/web/preLogin.do?source=jcesdk) (<https://www14.software.ibm.com/webapp/iwm/web/preLogin.do?source=jcesdk>).

The Java Cryptography Extension version must match the version of the Java that is installed on QRadar.

- b) Extract the JCE file.

The following Java archive (JAR) files are included in the JCE download:

- local\_policy.jar
- US\_export\_policy.jar

- c) Log in to your QRadar Console or QRadar Event Collector as a root user.

- d) Copy the JCE JAR files to the following directory on your QRadar Console or Event Collector:

```
/store/configservices/staging/globalconfig/java_security
```

**Note:** The JCE JAR files are only copied to the system that receives the AES192 or AE256 encrypted files.

- e) Restart the QRadar services by typing one of the following commands:

- If you are using QRadar 7.2.x, type service ecs-ec restart.
- If you are using QRadar 7.3.0, type systemctl restart ecs-ec.service.
- If you are using QRadar 7.3.1, type systemctl restart ecs-ec-ingress.service.

2. Optional: If you are using QRadar 7.4.3 Fix Pack 4 or earlier, complete the [Installing unrestricted SDK JCE policy files](https://www.ibm.com/docs/en/qrip/7.4?topic=authentication-installing-unrestricted-sdk-jce-policy-files) procedure (<https://www.ibm.com/docs/en/qrip/7.4?topic=authentication-installing-unrestricted-sdk-jce-policy-files>).

**Important:** If you are using QRadar 7.4.3 Fix Pack 5 or later, do not install these files.

## McAfee ePolicy Orchestrator sample event messages

Use these sample event messages to verify a successful integration with QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage returns or line feed characters.

## McAfee ePolicy Orchestrator sample event message when you use the JDBC protocol

The following sample event message shows that a host intrusion was detected, but not handled.

## McAfee MVISION Cloud (formerly known as Skyhigh Networks Cloud Security Platform)

The IBM QRadar DSM for McAfee MVISION Cloud collects logs from a McAfee MVISION Cloud Platform.

McAfee MVISION Cloud is formerly known as Skyhigh Networks Cloud Security Platform.

The following table identifies the specifications for the McAfee MVISION Cloud DSM:

| Table 742. McAfee MVISION Cloud DSM specifications |        |
|----------------------------------------------------|--------|
| Specification                                      | Value  |
| Manufacturer                                       | McAfee |

*Table 742. McAfee MVISION Cloud DSM specifications (continued)*

| Specification               | Value                                                                                                                                                                                                                                                            |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DSM name                    | McAfee MVISION Cloud                                                                                                                                                                                                                                             |

| Includes custom properties? | No                                                                                                                                                                                                                                                               |
| More information            | <a href="https://www.mcafee.com/enterprise/en-ca/products/mvision-cloud.html">McAfee MVision Cloud</a> ( <a href="https://www.mcafee.com/enterprise/en-ca/products/mvision-cloud.html">https://www.mcafee.com/enterprise/en-ca/products/mvision-cloud.html</a> ) |

To integrate McAfee MVISION Cloud with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Skyhigh Networks Cloud Security Platform DSM RPM
  - DSMCommon RPM
2. Configure your McAfee MVISION Cloud device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a McAfee MVISION Cloud log source on the QRadar Console. The following table describes the parameters that require specific values for McAfee MVISION Cloud event collection:

*Table 743. McAfee MVISION Cloud log source parameters*

| Parameter                     | Value                                                                                |
|-------------------------------|--------------------------------------------------------------------------------------|
| <b>Log Source type</b>        | McAfee MVISION Cloud                                                                 |
| <b>Protocol Configuration</b> | Syslog                                                                               |
| <b>Log Source Identifier</b>  | The IP address or host name of the McAfee MVISION Cloud that sends events to QRadar. |

## McAfee MVISION Cloud sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### McAfee MVISION Cloud sample message when you use the Syslog protocol

The following sample event message shows that a CAP incident occurred.

```

## McAfee Network Security Platform (formerly known as McAfee Intrushield)

The IBM QRadar McAfee Network Security Platform DSM collects syslog events from a McAfee Network Security Platform device. QRadar records all relevant events.

To integrate McAfee Network Security Platform with QRadar, complete the following steps:

- If automatic updates are not enabled, RPMs are available for download from the IBM support website (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - DSM Common RPM
  - McAfee Network Security Platform, DSM RPM
- To configure your McAfee Network Security Platform device to send events to QRadar, select your McAfee Network Security Platform device version.
  - [“Configuring alert events for McAfee Network Security Platform 2.x - 5.x” on page 1152.](#)
  - [Configuring alert events for McAfee Network Security Platform 6.x - 7.x.](#)
  - [Configuring alert events for McAfee Network Security Platform v8x - 10x.](#)
  - [Configuring fault notification events for McAfee Network Security Platform 6.x - 7.x.](#)
  - [Configuring fault notification events for McAfee Network Security Platform 8.x - 10.x.](#)
- If QRadar does not automatically detect the log source, add a McAfee Network Security Platform log source on the QRadar Console.

## McAfee Network Security Platform DSM specifications

When you configure the McAfee Network Security Platform, understanding the specifications for the McAfee Network Security Platform DSM can help ensure a successful integration. For example, knowing what the supported version of McAfee Network Security Platform is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the McAfee Network Security Platform DSM.

| <i>Table 745. McAfee Network Security Platform DSM specifications</i> |                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Configuring alert events for McAfee Network Security Platform 2.x - 5.x

To collect alert notification events from McAfee Network Security Platform, administrators must configure a syslog forwarder to send events to IBM QRadar.

### Before you begin

To collect alert notification events from McAfee Network Security Platform, you need McAfee Network Security Platform Manager.

### Procedure

1. Log in to the **McAfee Network Security Platform Manager** user interface.
2. On the **Network Security Manager** dashboard, click **Configure**.
3. From the **Resource Tree**, click **root** node (Admin-Domain-Name).
4. Click **Alert Notification > Syslog Forwarder**.
5. Configure the **Syslog Server** details parameters.

| Parameter                      | Value |
|--------------------------------|-------|
| <b>Enable Syslog Forwarder</b> | Yes   |
| <b>Port</b>                    | 514   |

6. Click **Edit**.
7. Select one of the following versions:

*Table 746. McAfee Network Security Platform 2.x - 5.x custom message formats*

| Version                                                                           | Description                                                                                                                                                                                                                                                                                                               |
|-----------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Unpatched McAfee Network Security Platform 2.x systems                            | <code> \$ALERT_ID\$ \$ALERT_TYPE\$ \$ATTACK_TIME\$ "ATTACK_NAME\$" \$ATTACK_ID\$ \$ATTACK_SEVERITY\$ \$ATTACK_SIGNATURE\$ \$ATTACK_CONFIDENCE\$ \$ADMIN_DOMAIN\$ \$SENSOR_NAME\$ \$INTERFACE\$ \$SOURCE_IP\$ \$SOURCE_PORT\$ \$DESTINATION_IP\$ \$DESTINATION_PORT\$ </code>                                              |
| McAfee Network Security Platform that has patches applied to update to 3.x - 5.x. | <code> \$IV_ALERT_ID\$ \$IV_ALERT_TYPE\$ \$IV_ATTACK_TIME\$ "IV_ATTACK_NAME\$" \$IV_ATTACK_ID\$ \$IV_ATTACK_SEVERITY\$ \$IV_ATTACK_SIGNATURE\$ \$IV_ATTACK_CONFIDENCE\$ \$IV_ADMIN_DOMAIN\$ \$IV_SENSOR_NAME\$ \$IV_INTERFACE\$ \$IV_SOURCE_IP\$ \$IV_SOURCE_PORT\$ \$IV_DESTINATION_IP\$ \$IV_DESTINATION_PORT\$ </code> |

**Note:** The custom message string must be entered as a single line without carriage returns or spaces. McAfee Network Security Platform appliances that do not have software patches applied, use different message strings from patched systems. The format of the custom message must contain a dollar sign (\$) as a delimiter before and after each alert element. If you are missing a dollar sign for an element, the alert event might not be formatted properly.

If you are not sure which event message format to use, contact McAfee customer support.

8. Click **Save**.

When alert events are generated by McAfee Network Security Platform, they are forwarded to the syslog destination that you specified. The log source is automatically discovered after enough events are forwarded by the McAfee Network Security Platform appliance. It typically takes a minimum of 25 events to automatically discover a log source.

## What to do next

Administrators can log in to the QRadar Console and verify that the log source is created on the QRadar Console and that the **Log Activity** tab displays events from the McAfee Network Security Platform appliance.

# Configuring alert events for McAfee Network Security Platform 6.x - 7.x

To collect alert notification events from McAfee Network Security Platform, administrators must configure a syslog forwarder to send events to IBM QRadar

## Before you begin

To collect alert notification events from McAfee Network Security Platform, you need McAfee Network Security Platform Manager.

## Procedure

1. Log in to the **McAfee Network Security Platform Manager** user interface.
2. On the **Network Security Manager** dashboard, click **Configure**.
3. Expand the **Resource Tree** and then click **IPS Settings** node.
4. Click the **Alert Notification** tab.
5. On the **Alert Notification** menu, click the **Syslog** tab.
6. Configure the following parameters to forward alert notification events:

*Table 747. McAfee Network Security Platform 6.x - 7.x alert notification parameters*

| Parameter                         | Description                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable Syslog Notification</b> | Select <b>Yes</b> to enable syslog notifications for McAfee Network Security Platform. You must enable this option to forward events to QRadar.                                                                                                                                                                                                                            |
| <b>Admin Domain</b>               | Select any of the following options: <ul style="list-style-type: none"><li>• <b>Current</b> - Select this check box to send syslog notifications for alerts in the current domain. This option is selected by default.</li><li>• <b>Children</b> - Select this check box to send syslog notifications for alerts in any child domains within the current domain.</li></ul> |
| <b>Server Name or IP Address</b>  | The IP address of your QRadar Console or Event Collector. This field supports both IPv4 and IPv6 addresses.                                                                                                                                                                                                                                                                |
| <b>UDP Port</b>                   | Type 514 as the UDP port for syslog events.                                                                                                                                                                                                                                                                                                                                |
| <b>Facility</b>                   | Select a syslog facility value.                                                                                                                                                                                                                                                                                                                                            |

Table 747. McAfee Network Security Platform 6.x - 7.x alert notification parameters (continued)

| Parameter                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Severity Mapping</b>               | Select a value to map the <b>informational</b> , <b>low</b> , <b>medium</b> , and <b>high</b> alert notification levels to a syslog severity.<br>The options include the following levels: <ul style="list-style-type: none"> <li><b>Emergency</b> - The system is down or unusable.</li> <li><b>Alert</b> - The system requires immediate user input or intervention.</li> <li><b>Critical</b> - The system should be corrected for a critical condition.</li> <li><b>Error</b> - The system has non-urgent failures.</li> <li><b>Warning</b> - The system has a warning message that indicates an imminent error.</li> <li><b>Notice</b> - The system has notifications, no immediate action required.</li> <li><b>Informational</b> - Normal operating messages.</li> </ul> |
| <b>Send Notification If</b>           | Select the following check boxes: <ul style="list-style-type: none"> <li><b>The attack definition has this notification option explicitly enabled</b></li> <li><b>The following notification filter is matched</b>, and From the list, select <b>Severity Informational and later</b>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Notify on IPS Quarantine Alert</b> | Select <b>No</b> as the notify on IPS quarantine option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Message Preference</b>             | Select the <b>Customized</b> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

- From the **Message Preference** field, click **Edit** to add a custom message filter.
- To ensure that alert notifications are formatted correctly, type the following message string:

```
|$IV_ALERT_ID|$IV_ALERT_TYPE|$IV_ATTACK_TIME|"$IV_ATTACK_NAME"|$IV_ATTACK_ID|
$IV_ATTACK_SEVERITY|$IV_ATTACK_SIGNATURE|$IV_ATTACK_CONFIDENCE|$IV_ADMIN_DOMAIN$|
$IV_SENSOR_NAME|$IV_INTERFACE|$IV_SOURCE_IP|$IV_SOURCE_PORT|$IV_DESTINATION_IP$|
$IV_DESTINATION_PORT|$IV_DIRECTION|$IV_SUB_CATEGORY$
```

**Note:** The custom message string must be entered as a single line without carriage returns or spaces. McAfee Network Security Platform expects the format of the custom message to contain a dollar sign (\$) as a delimiter before and after each alert element. If you are missing a dollar sign for an element, then the alert event might not be formatted properly.

You might require a text editor to properly format the custom message string as a single line.

- Click **Save**.

As alert events are generated by McAfee Network Security Platform, they are forwarded to the syslog destination you specified. The log source is automatically discovered after enough events are forwarded by the McAfee Network Security Platform appliance. It typically takes a minimum of 25 events to automatically discover a log source.

## What to do next

Administrators can log in to the QRadar Console and verify that the log source is created on the QRadar Console and that the **Log Activity** tab displays events from the McAfee Network Security Platform appliance.

# Configuring alert events for McAfee Network Security Platform 8.x - 10.x

To collect alert notification events from McAfee Network Security Platform, administrators must configure a syslog forwarder to send events to IBM QRadar

## Before you begin

To collect alert notification events from McAfee Network Security Platform, you need McAfee Network Security Platform Manager.

## Procedure

1. Log in to the **McAfee Network Security Platform Manager** user interface.
2. Click the **Manager** tab.
3. From the navigation menu, select **Setup > Notification > IPS Events > Syslog**.
4. In the **Enable Syslog Notification** pane, select **Yes**
5. Click **Save**.
6. On the **Syslog** page, Click **New**. If you are using version 10.x, click the + sign.
7. On the **Add a Syslog Notification Profile** page, configure the following parameters:

Table 748. McAfee Network Security Platform 8.x - 10.x syslog notification profile parameters

| Parameter                        | Description                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Admin Domain</b>              | Select any of the following options: <ul style="list-style-type: none"><li>• <b>Current</b> - Send syslog notifications for alerts in the current domain. This option is selected by default.</li><li>• <b>Children</b> - Include alerts for all child domains within the current domain. (Not applicable to NTBA)</li></ul>                                 |
| <b>Notification Profile Name</b> | The name of the profile where notifications are sent from.                                                                                                                                                                                                                                                                                                   |
| <b>Target Server</b>             | Add a server profile: <ol style="list-style-type: none"><li>a. Click <b>Add</b>.</li><li>b. Type the target server profile name.</li><li>c. Type the IP address of your QRadar Console or Event Collector</li><li>d. From the <b>Protocol</b> list, select <b>UDP</b>.</li><li>e. Type 514 in the <b>Port</b> field.</li><li>f. Click <b>Save</b>.</li></ol> |
| <b>Facility</b>                  | Select a syslog facility value from the list.                                                                                                                                                                                                                                                                                                                |

Table 748. McAfee Network Security Platform 8.x - 10.x syslog notification profile parameters  
(continued)

| Parameter                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Severity Mapping</b>            | Select a value to map the <b>informational</b> , <b>low</b> , <b>medium</b> , and <b>high</b> alert notification levels to a syslog severity. <ul style="list-style-type: none"> <li>• <b>Emergency</b> - The system is down or unusable.</li> <li>• <b>Alert</b> - The system requires immediate user input or intervention.</li> <li>• <b>Critical</b> - The system should be corrected for a critical condition.</li> <li>• <b>Error</b> - The system has non-urgent failures.</li> <li>• <b>Warning</b> - The system has a warning message that indicates an imminent error.</li> <li>• <b>Notice</b> - The system has notifications, no immediate action required.</li> <li>• <b>Informational</b> - Normal operating messages.</li> <li>• <b>Debug</b> - Debug level messages.</li> </ul>                                                                                                                                                                       |
| <b>Notify for All Alerts</b>       | Enable this option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Notify on Quarantine Events</b> | Disable this option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Message</b>                     | To ensure that alert notifications are formatted correctly, type the following message string:<br><br><code> \$IV_ALERT_ID\$ \$IV_ALERT_TYPE\$ \$IV_ATTACK_TIME\$ "\$IV_ATTACK_NAME\$"  \$IV_ATTACK_ID\$ \$IV_ATTACK_SEVERITY\$ \$IV_ATTACK_SIGNATURE\$  \$IV_ATTACK_CONFIDENCE\$ \$IV_ADMIN_DOMAIN\$ \$IV_SENSOR_NAME\$  \$IV_INTERFACE\$ \$IV_SOURCE_IP\$ \$IV_SOURCE_PORT\$ \$IV_DESTINATION_IP\$  \$IV_DESTINATION_PORT\$ \$IV_DIRECTION\$ \$IV_SUB_CATEGORY\$</code><br><br><b>Note:</b> The custom message string must be entered as a single line without carriage returns or spaces. McAfee Network Security Platform expects the format of the custom message to contain a dollar sign (\$) as a delimiter before and after each alert element. If you are missing a dollar sign for an element, then the alert event might not be formatted properly.<br><br>You might require a text editor to properly format the custom message string as a single line. |

8. Click **Save**.

The new notification profile displays on the **Syslog** page. As alert events are generated by McAfee Network Security Platform, they are forwarded to the syslog destination that you specified. The log source is automatically discovered in QRadar after enough events are forwarded by the McAfee Network Security Platform appliance. It typically takes a minimum of 25 events to automatically discover a log source.

## What to do next

Administrators can log in to the QRadar Console and verify that the log source is created on the QRadar Console and that the **Log Activity** tab displays events from the McAfee Network Security Platform appliance.

# Configuring fault notification events for McAfee Network Security Platform 6.x - 7.x

To integrate fault notifications with McAfee Network Security Platform, you must configure your McAfee Network Security Platform to forward fault notification events.

## Procedure

1. Log in to the **McAfee Network Security Platform Manager** user interface.
2. On the **Network Security Manager** dashboard, click **Configure**.
3. Expand the **Resource Tree**, and then click **IPS Settings** node.
4. Click the **Fault Notification** tab.
5. From the **Alert Notification** menu, click the **Syslog** tab.
6. Configure the following parameters to forward fault notification events:

*Table 749. McAfee Network Security Platform 6.x - 7.x fault notification parameters*

| Parameter                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable Syslog Notification</b>         | Select <b>Yes</b> to enable syslog notifications for McAfee Network Security Platform. You must enable this option to forward events to QRadar.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Admin Domain</b>                       | Select any of the following options: <ul style="list-style-type: none"><li>• <b>Current</b> - Select this check box to send syslog notifications for alerts in the current domain. This option is selected by default.</li><li>• <b>Children</b> - Select this check box to send syslog notifications for alerts in any child domains within the current domain.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Server Name or IP Address</b>          | Type the IP address of your QRadar Console or Event Collector. This field supports both IPv4 and IPv6 addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Port</b>                               | Type <b>514</b> as the port for syslog events.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Facilities</b>                         | Select a syslog facility value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Severity Mapping</b>                   | Select a value to map the <b>informational</b> , <b>low</b> , <b>medium</b> , and <b>high</b> alert notification level to a syslog severity.<br>The options include the following levels: <ul style="list-style-type: none"><li>• <b>Emergency</b> - The system is down or unusable.</li><li>• <b>Alert</b> - The system requires immediate user input or intervention.</li><li>• <b>Critical</b> - The system should be corrected for a critical condition.</li><li>• <b>Error</b> - The system has non-urgent failures.</li><li>• <b>Warning</b> - The system has a warning message that indicates an imminent error.</li><li>• <b>Notice</b> - The system has notifications, no immediate action required.</li><li>• <b>Informational</b> - Normal operating messages.</li></ul> |
| <b>Forward Faults with severity level</b> | Select <b>Informational and later</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

7. From the **Message Preference** field, click **Edit** to add a custom message filter.
8. To ensure that fault notifications are formatted correctly, type the following message string:

|%INTRUSHIELD-FAULT|\$IV\_FAULT\_NAME|\$IV\_FAULT\_TIME\$|

**Note:** The custom message string must be entered as a single line with no carriage returns. McAfee Network Security Platform expects the format of the custom message syslog information to contain a dollar sign (\$) delimiter before and after each element. If you are missing a dollar sign for an element, the event might not parse properly.

9. Click **Save**.

As fault events are generated by McAfee Network Security Platform, they are forwarded to the syslog destination that you specified.

### What to do next

You can log in to the QRadar Console and verify that the **Log Activity** tab contains fault events from the McAfee Network Security Platform appliance.

## Configuring fault notification events for McAfee Network Security Platform 8.x - 10.x

To integrate fault notifications with McAfee Network Security Platform, you must configure your McAfee Network Security Platform to forward fault notification events.

### Procedure

1. Log in to the **McAfee Network Security Platform Manager** user interface.
2. Click the **Manager** tab.
3. From the navigation menu, select **Setup > Notification > Faults > Syslog**.
4. On the **Syslog** page, configure the following parameters to forward fault notification events:

Table 750. McAfee Network Security Platform 8.x - 10.x fault notification parameters

| Parameter                         | Description                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable Syslog Notification</b> | Select <b>Yes</b> to enable syslog notifications for McAfee Network Security Platform. You must enable this option to forward events to QRadar.                                                                                                                                                                                                                            |
| <b>Admin Domain</b>               | Select any of the following options: <ul style="list-style-type: none"><li>• <b>Current</b> - Select this check box to send syslog notifications for alerts in the current domain. This option is selected by default.</li><li>• <b>Children</b> - Select this check box to send syslog notifications for alerts in any child domains within the current domain.</li></ul> |
| <b>Server Name or IP Address</b>  | Type the IP address of your QRadar Console or Event Collector. This field supports both IPv4 and IPv6 addresses.                                                                                                                                                                                                                                                           |
| <b>Port</b>                       | Type <b>514</b> as the port for syslog events.                                                                                                                                                                                                                                                                                                                             |
| <b>Facilities</b>                 | Select a syslog facility value.                                                                                                                                                                                                                                                                                                                                            |

Table 750. McAfee Network Security Platform 8.x - 10.x fault notification parameters (continued)

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Severity Mapping</b> | Select a value to map the <b>informational</b> , <b>low</b> , <b>medium</b> , and <b>high</b> alert notification level to a syslog severity.<br>The options include the following levels: <ul style="list-style-type: none"> <li>• <b>Emergency</b> - The system is unusable.</li> <li>• <b>Alert</b> - The system requires immediate user input or intervention.</li> <li>• <b>Critical</b> - The system should be corrected for a critical condition.</li> <li>• <b>Error</b> - The system has non-urgent failures.</li> <li>• <b>Warning</b> - The system displays a warning message that indicates an imminent error.</li> <li>• <b>Notice</b> - The system has notifications, no immediate action required.</li> <li>• <b>Informational</b> - Normal operating messages.</li> <li>• <b>Debug</b> - Debug level messages</li> </ul> |
| <b>Forward Faults</b>   | Select <b>Informational and later</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

- From the **Message Preference** field, click **Edit** to add a custom message filter.
- To ensure that fault notifications are formatted correctly, type the following message string:

|%INTRUSHIELD-FAULT|\$IV\_FAULT\_NAME\$|\$IV\_FAULT\_TIME\$|

**Note:** The custom message string must be entered as a single line with no carriage returns. McAfee Network Security Platform expects the format of the custom message syslog information to contain a dollar sign (\$) delimiter before and after each element. If you are missing a dollar sign for an element, the event might not parse properly.

- Click **Save**.

As fault events are generated by McAfee Network Security Platform, they are forwarded to the syslog destination that you specified.

## What to do next

You can log in to the QRadar Console and verify that the **Log Activity** tab contains fault events from the McAfee Network Security Platform appliance.

## McAfee Network Security Platform sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## McAfee Network Security Platform sample messages when you use the Syslog protocol

**Sample 1:** The following sample event message shows that an HTTP login brute force is detected.

```
<116>Feb 7 11:06:51 SyslogAlertForwarder: |5915530749831189905|Signature|2014-02-07 11:06:49

## McAfee Web Gateway

You can configure McAfee Web Gateway to integrate with IBM QRadar.

Use one of the following methods:

- [“Configuring McAfee Web Gateway to communicate with QRadar \(syslog\)” on page 1161](#)
- [“Configuring McAfee Web Gateway to communicate with IBM QRadar \(log file protocol\)” on page 1162](#)

**Note:** McAfee Web Gateway is formerly known as McAfee WebWasher.

The following table identifies the specifications for the McAfee Web Gateway DSM:

*Table 753. McAfee Web Gateway DSM specifications*

| Specification            | Value                                                 |
|--------------------------|-------------------------------------------------------|
| Manufacturer             | McAfee                                                |
| DSM                      | McAfee Web Gateway                                    |
| RPM file name            | DSM-McAfeeWebGateway-qradarversion-buildnumber.noarch |
| Supported versions       | v6.0.0                                                |
| Protocol                 | Syslog protocol<br>Log file protocol                  |
| Event format             | Log Extended Event Format (LEEF)                      |
| Recorded event types     | All events                                            |
| Automatically discovered | Yes                                                   |
| Includes identity        | No                                                    |

## McAfee Web Gateway DSM integration process

You can integrate McAfee Web Gateway DSM with IBM QRadar.

Use the following procedure:

- Download and install the most recent version of the McAfee Web Gateway DSM RPM from the [IBM Support Website](#) onto your QRadar Console.
- For each instance of McAfee Web Gateway, configure your McAfee Web Gateway VPN system to enable communication with QRadar.
- If QRadar does not automatically discover the log source, for each McAfee Web Gateway server you want to integrate, create a log source on the QRadar Console.
- If you use McAfee Web Gateway v7.0.0 or later, create an event map.

### Related tasks

[“Configuring McAfee Web Gateway to communicate with QRadar \(syslog\)” on page 1161](#)

[“Configuring McAfee Web Gateway to communicate with IBM QRadar \(log file protocol\)” on page 1162](#)

[“Creation of an event map for McAfee Web Gateway events” on page 1164](#)

## Configuring McAfee Web Gateway to communicate with QRadar (syslog)

To collect all events from McAfee Web Gateway, you must specify IBM QRadar as the syslog server and configure the message format.

### Procedure

1. Log in to your McAfee Web Gateway console.
2. On the **Toolbar**, click **Configuration**.
3. Click the **File Editor** tab.
4. Expand the **Appliance Files** and select the file `/etc/rsyslog.conf`.

The file editor displays the `rsyslog.conf` file for editing.

5. Modify the `rsyslog.conf` file to include the following information:

```
# send access log to qradar *.info;
daemon.!={info;
mail.none;authpriv.none;
cron.none -/var/log/messages *.info;mail.none;
authpriv.none;
cron.none
@<IP Address>:<Port>
```

Where:

- `<IP Address>` is the IP address of QRadar.
- `<Port>` is the syslog port number, for example 514.

6. Click **Save Changes**.

You are now ready to import a policy for the syslog handler on your McAfee Web Gateway appliance. For more information, see [“Importing the Syslog Log Handler” on page 1162](#).

# Importing the Syslog Log Handler

## About this task

To Import a policy rule set for the syslog handler:

## Procedure

1. From the support website, download the following compressed file:

`log_handlers-1.1.tar.gz`

2. Extract the file.

The extract file provides XML files that are version dependent to your McAfee Web Gateway appliance.

*Table 754. McAfee Web Gateway required log handler file*

| Version                 | Required XML file                     |
|-------------------------|---------------------------------------|
| McAfee Web Gateway V7.0 | <code>syslog_loghandler_70.xml</code> |
| McAfee Web Gateway V7.3 | <code>syslog_loghandler_73.xml</code> |

3. Log in to your McAfee Web Gateway console.
4. Using the menu toolbar, click **Policy**.
5. Click **Log Handler**.
6. Using the menu tree, select **Default**.
7. From the **Add** list, select **Rule Set from Library**.
8. Click **Import from File** button.
9. Navigate to the directory containing the `syslog_handler` file you downloaded and select `syslog_loghandler.xml` as the file to import.

**Note:** If the McAfee Web Gateway appliance detects any conflicts with the rule set, you must resolve the conflict. For more information, see your *McAfee Web Gateway documentation*.

10. Click **OK**.

11. Click **Save Changes**.

12. You are now ready to configure the log source in QRadar.

QRadar automatically discovers syslog events from a McAfee Web Gateway appliance.

If you want to manually configure QRadar to receive syslog events, select McAfee Web Gateway from the **Log Source Type** list.

## Related tasks

[“Adding a log source” on page 5](#)

# Configuring McAfee Web Gateway to communicate with IBM QRadar (log file protocol)

The McAfee Web Gateway appliance gives the option to forward event log files to an interim file server for retrieval by QRadar.

## Procedure

1. From the support website, download the following file:

`log_handlers-1.1.tar.gz`

2. Extract the file.

This gives you the access handler file that is needed to configure your McAfee Web Gateway appliance.

`access_log_file_loghandler.xml`

3. Log in to your McAfee Web Gateway console.

4. Using the menu toolbar, click **Policy**.

**Note:** If there is an existing access log configuration in your McAfee Web Gateway appliance, you must delete the existing access log from the **Rule Set Library** before you add the `access_log_file_loghandler.xml`.

5. Click **Log Handler**.

6. Using the menu tree, select **Default**.

7. From the **Add** list, select **Rule Set from Library**.

8. Click **Import from File** button.

9. Navigate to the directory that contains the `access_log_file_loghandler.xml` file you downloaded and select `syslog_loghandler.xml` as the file to import.

When the rule set is imported for `access_log_file_loghandler.xml`, a conflict can occur stating the Access Log Configuration exists already in the current configuration and a conflict solution is presented.

10. If the McAfee Web Gateway appliance detects that the Access Log Configuration exists already, select the **Conflict Solution: Change name** option that is presented to resolve the rule set conflict.

For more information on resolving conflicts, see your *McAfee Web Gateway vendor documentation*.

You must configure your `access.log` file to be pushed to an interim server on an auto rotation. It does not matter if you push your files to the interim server based on time or size for your `access.log` file. For more information on auto rotation, see your *McAfee Web Gateway vendor documentation*.

**Note:** Due to the size of `access.log` files that are generated, it is suggested that you select the option GZIP files after rotation in your McAfee Web Gate appliance.

11. Click **OK**.

12. Click **Save Changes**.

**Note:** By default McAfee Web Gateway is configured to write access logs to the `/opt/mwg/log/user-defined-logs/access.log/` directory.

## What to do next

You are now ready to configure QRadar to receive `access.log` files from McAfee Web Gateway. For more information, see [“Pulling data by using the log file protocol” on page 1163](#).

## Pulling data by using the log file protocol

A log file protocol source allows IBM QRadar to retrieve archived log files from a remote host. The McAfee Web Gateway DSM supports the bulk loading of `access.log` files by using the log file protocol source. The default directory for the McAfee Web Gateway access logs is the `/opt/mwg/log/user-defined-logs/access.log/` directory.

## About this task

You can now configure the log source and protocol in QRadar.

## Procedure

1. To configure QRadar to receive events from a McAfee Web Gateway appliance, select **McAfee Web Gateway** from the **Log Source Type** list.
2. To configure the protocol, you must select the **Log File** option from the **Protocol Configuration** list.
3. To configure the **File Pattern** parameter, you must type a regex string for the access.log file, such as access[0-9]+\log.

**Note:** If you selected to **GZIP** your access.log files, you must type access[0-9]+\log\gz for the **File Pattern** field and from the **Processor** list, select **GZIP**.

## Creation of an event map for McAfee Web Gateway events

Event mapping is needed for events that are collected from McAfee Web Gateway v7.0.0 and later, which are identified as Unknown and not covered by the base QID map.

You can individually map each event for your device to an event category in IBM QRadar. Mapping events allows QRadar to identify, coalesce, and track recurring events from your network devices. Until you map an event, some events that are displayed in the **Log Activity** tab for McAfee Web Gateway are categorized as Unknown, and some events might be already assigned to an existing QID map. Unknown events are easily identified as the **Event Name** column and **Low Level Category** columns display Unknown.

## Discovering unknown events

This procedure ensures that you map all event types and that you do not miss events that are not generated frequently, repeat this procedure several times over a period.

## Procedure

1. Log in to QRadar.
2. Click the **Log Activity** tab.
3. Click **Add Filter**.
4. From the first list, select **Log Source**.
5. From the **Log Source Group** list, select the log source group or **Other**.  
Log sources that are not assigned to a group are categorized as **Other**.
6. From the **Log Source** list, select your McAfee Web Gateway log source.
7. Click **Add Filter**.  
The **Log Activity** tab is displayed with a filter for your log source.
8. From the **View** list, select **Last Hour**.

Any events that are generated by the McAfee Web Gateway DSM in the last hour are displayed. Events that are displayed as Unknown in the **Event Name** column or **Low Level Category** column require event mapping.

**Note:** You can save your existing search filter by clicking **Save Criteria**.

You are now ready to modify the event map.

## Modifying the event map

Modify an event map to manually categorize events to a QRadar Identifier (QID) map.

### About this task

Any event that is categorized to a log source can be remapped to a new QRadar Identifier (QID).

**Note:** Events that do not have a defined log source cannot be mapped to an event. Events without a log source display **SIM Generic Log** in the **Log Source** column.

## Procedure

1. On the **Event Name** column, double-click an unknown event for McAfee Web Gateway.  
The detailed event information is displayed.
2. Click **Map Event**.
3. From the Browse for QRadar Identifier pane, select any of the following search options to narrow the event categories for a QRadar Identifier (QID):
  - From the **High-Level Category** list, select a high-level event categorization.
  - From the **Low-Level Category** list, select a low-level event categorization.
  - From the **Log Source Type** list, select a log source type.

The **Log Source Type** list gives the option to search for QIDs from other log sources. Searching for QIDs by log source is useful when events are similar to another existing network device. For example, McAfee Web Gateway provides policy events, you might select another product that likely captures similar events.

To search for a QID by name, type a name in the **QID/Name** field.

The **QID/Name** field gives the option to filter the full list of QIDs for a specific word, for example, policy.

4. Click **Search**.

A list of QIDs are displayed.

5. Select the QID that you want to associate to your unknown event.

6. Click **OK**.

QRadar maps any additional events that are forwarded from your device with the same QID that matches the event payload. The event count increases each time that the event is identified by QRadar.

If you update an event with a new QRadar Identifier (QID) map, past events that are stored in QRadar are not updated. Only new events are categorized with the new QID.

## McAfee Web Gateway sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## McAfee Web Gateway sample message when you use the Syslog protocol

The following sample event message shows that web access is verified.

```

# Chapter 98. Syslog log source parameters for MetaInfo MetaIP

If QRadar does not automatically detect the log source, add a MetaIP log source on the QRadar Console by using the syslog.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Metadata appliances:

| Table 756. Syslog log source parameters for the MetaInfo MetaIP DSM |                                                                                                                       |
|---------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| Parameter                                                           | Value                                                                                                                 |
| <b>Log Source type</b>                                              | MetaInfo MetaIP                                                                                                       |
| <b>Protocol Configuration</b>                                       | Syslog                                                                                                                |
| <b>Log Source Identifier</b>                                        | Type the IP address or host name for the log source as an identifier for events from your MetaInfo MetaIP appliances. |

# Chapter 99. Microsoft

IBM QRadar supports a range of Microsoft products.

## Microsoft 365 Defender

---

The IBM QRadar Microsoft 365 Defender DSM collects events from a Microsoft 365 Defender service by using the Microsoft Azure Event Hubs protocol to collect Streaming API data. You can use the Defender for Endpoint SIEM REST API protocol to collect alerts and device events from a Microsoft 365 Defender service.

The Microsoft 365 Defender DSM also collects alerts from the Microsoft Defender for Endpoint Service Alerts V2 API by using the Microsoft Graph API protocol.

**Important:**

- The Microsoft Windows Defender ATP DSM name is now the Microsoft 365 Defender DSM. The DSM RPM name remains as Microsoft Windows Defender ATP in QRadar.
- Due to a change in the Microsoft Defender API suite as of 25 November 2021, Microsoft no longer allows the onboarding of new integrations with their SIEM API. For more information, see [Deprecating the legacy SIEM API](https://techcommunity.microsoft.com/t5/microsoft-defender-for-endpoint/deprecating-the-legacy-siem-api/ba-p/3139643) (<https://techcommunity.microsoft.com/t5/microsoft-defender-for-endpoint/deprecating-the-legacy-siem-api/ba-p/3139643>).

The Streaming API can be used with the Microsoft Azure Event Hubs protocol to provide event and alert forwarding to QRadar. For more information about the service and its configuration, see [Configure Microsoft 365 Defender to stream Advanced Hunting events to your Azure Event Hub](https://docs.microsoft.com/en-us/microsoft-365/security/defender/streaming-api-event-hub?view=o365-worldwide) (<https://docs.microsoft.com/en-us/microsoft-365/security/defender/streaming-api-event-hub?view=o365-worldwide>)

## Integrate a Microsoft 365 Defender service when you use the Microsoft Azure Event Hubs protocol

If you want to integrate Microsoft 365 Defender service with QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent versions of the RPMs from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>).
  - Protocol Common RPM
  - Microsoft Azure Event Hubs Protocol RPM
  - DSM Common RPM
  - Microsoft 365 Defender DSM RPM
2. Optional: Create a storage account. For more information, see [Create a storage account](#).
- Important:** You must have a storage account to connect to an event hub. For more information, see [Microsoft Azure Event Hubs protocol FAQ](#).
3. Optional: Create an event hub. For more information, see [Quickstart: Create an event hub using Azure portal](#).
4. Configure Microsoft 365 Defender to send advanced hunting events to a Microsoft Azure Event Hub. For more information, see [Configure Microsoft Defender to stream Advanced Hunting events to your Azure Event Hub](#).
5. If QRadar does not automatically detect the log source, add a Microsoft 365 Defender log source that uses the Microsoft Azure Event Hubs protocol on the QRadar Console. For more information about the protocol, see [Microsoft Azure Event Hubs log source parameters for Microsoft 365 Defender](#).

## **Integrate a Microsoft 365 Defender service when you use the Microsoft Defender for Endpoint SIEM REST API protocol**

If you want to integrate a Microsoft 365 Defender service with QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent versions of the RPMs from the [IBM support website](#).
  - Protocol Common RPM
  - Microsoft Defender for Endpoint SIEM REST API Protocol RPM
  - DSMCommon RPM
  - Microsoft 365 Defender DSM RPM
2. Add a Microsoft 365 Defender log source that uses the Microsoft Defender for Endpoint SIEM REST API protocol on the QRadar Console. QRadar does not automatically detect the Microsoft Defender for Endpoint SIEM REST API. For more information, see [Microsoft Defender for Endpoint SIEM REST API log source parameters for Microsoft 365 Defender](#).

## **Integrate a Microsoft Defender for Endpoint service when you use the Microsoft Graph Security API protocol**

If you want to integrate a Microsoft Defender for Endpoint service with QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent versions of the RPMs from the [IBM support website](#).
  - Protocol Common RPM
  - Microsoft Graph Security API Protocol RPM
  - DSMCommon RPM
  - Microsoft 365 Defender DSM RPM
2. Add a Microsoft 365 Defender log source that uses the Microsoft Graph Security API protocol on the QRadar Console. QRadar does not automatically detect the Microsoft Graph Security API. For more information, see [Microsoft Graph Security API log source parameters for Microsoft 365 Defender](#).

### **Related tasks**

## Microsoft Defender for Endpoint SIEM REST API log source parameters for Microsoft 365 Defender

If IBM QRadar does not automatically detect the log source, add a Microsoft 365 Defender log source on the QRadar Console by using Microsoft Defender for Endpoint SIEM REST API protocol.

When you use the Microsoft Defender for Endpoint SIEM REST API protocol, there are specific parameters that you must use.

### Important:

- The Microsoft Windows Defender ATP DSM name is now the Microsoft 365 Defender DSM. The DSM RPM name remains as Microsoft Windows Defender ATP in QRadar.
- Due to a change in the Microsoft Defender API suite as of 25 November 2021, Microsoft no longer allows the onboarding of new integrations with their SIEM API. For more information, see [Deprecating the legacy SIEM API](https://techcommunity.microsoft.com/t5/microsoft-defender-for-endpoint/deprecating-the-legacy-siem-api/ba-p/3139643) (<https://techcommunity.microsoft.com/t5/microsoft-defender-for-endpoint/deprecating-the-legacy-siem-api/ba-p/3139643>).

The Streaming API can be used with the Microsoft Azure Event Hubs protocol to provide event and alert forwarding to QRadar. For more information about the service and its configuration, see [Configure Microsoft 365 Defender to stream Advanced Hunting events to your Azure Event Hub](https://docs.microsoft.com/en-us/microsoft-365/security/defender/streaming-api-event-hub?view=o365-worldwide) (<https://docs.microsoft.com/en-us/microsoft-365/security/defender/streaming-api-event-hub?view=o365-worldwide>)

The following table describes the parameters that require specific values to collect Microsoft Defender for Endpoint SIEM REST API events from Microsoft 365 Defender:

*Table 758. Microsoft Defender for Endpoint SIEM REST API log source parameters for the Microsoft 365 Defender DSM*

| Parameter              | Value                  |
|------------------------|------------------------|
| <b>Log Source type</b> | Microsoft 365 Defender |

*Table 758. Microsoft Defender for Endpoint SIEM REST API log source parameters for the Microsoft 365 Defender DSM (continued)*

| Parameter                     | Value                                         |
|-------------------------------|-----------------------------------------------|
| <b>Protocol Configuration</b> | Microsoft Defender for Endpoint SIEM REST API |

For a complete list of Microsoft Defender for Endpoint SIEM REST API log source protocol parameters and their values, see [Microsoft Defender for Endpoint SIEM REST API protocol configuration options](#).

## Microsoft Azure Event Hubs log source parameters for Microsoft 365 Defender

If IBM QRadar does not automatically detect the log source, add a Microsoft 365 Defender log source on the QRadar Console by using the Microsoft Azure Event Hubs protocol.

When you use the Microsoft Azure Event Hubs protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Microsoft Azure Event Hubs events from Microsoft 365 Defender:

*Table 759. Microsoft Azure Event Hubs log source parameters for the Microsoft 365 Defender DSM*

| Parameter                     | Value                                                                                                                                                                               |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source type</b>        | Microsoft 365 Defender                                                                                                                                                              |
| <b>Protocol Configuration</b> | Microsoft Azure Event Hubs                                                                                                                                                          |
| <b>Log Source Identifier</b>  | Use an identifiable name or IP address for the log source.<br>When the <b>Use as a Gateway Log Source</b> parameter is enabled, the <b>Log Source Identifier</b> value is not used. |

For a complete list of Microsoft Azure Event Hubs protocol parameters and their values, see [Microsoft Azure Event Hubs protocol configuration options](#).

## Microsoft Graph Security API log source parameters for Microsoft 365 Defender

If IBM QRadar does not automatically detect the log source, add a Microsoft 365 Defender log source on the QRadar Console by using the Microsoft Graph Security API protocol.

When you use the Microsoft Graph Security API protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Microsoft Graph Security API events from Microsoft 365 Defender:

*Table 760. Microsoft Graph Security API log source parameters for the Microsoft 365 Defender DSM*

| Parameter                     | Value                        |
|-------------------------------|------------------------------|
| <b>Log Source type</b>        | Microsoft 365 Defender       |
| <b>Protocol Configuration</b> | Microsoft Graph Security API |

Table 760. Microsoft Graph Security API log source parameters for the Microsoft 365 Defender DSM (continued)

| Parameter                    | Value                                 |
|------------------------------|---------------------------------------|
| <b>Log Source Identifier</b> | Use a unique name for the log source. |
| <b>API</b>                   | <b>Alerts V2 (/alerts_v2)</b>         |

For a complete list of Microsoft Graph Security API protocol parameters and their values, see [Microsoft Graph Security API protocol configuration options](#).

## Microsoft 365 Defender sample messages when you use the Microsoft Graph Security API protocol

The following sample event message shows that a lateral movement on another device was observed in close time proximity to a suspicious network event on this device. This could mean that an attacker is attempting to move laterally across devices to gather data or elevate privileges. This alert was triggered based on a Microsoft Defender for Endpoint alert.

```
{
  "id": "da637789431774501659_-1621338217",

## Microsoft Entra ID

The IBM QRadar DSM for Microsoft Entra ID Audit logs collects events such as user creation, role assignment, and group assignment events. The Microsoft Entra ID Sign-in logs collects user sign-in activity events.

**Important:** The **Microsoft Azure Active Directory DSM** name is now the **Microsoft Entra ID DSM**. The DSM RPM name remains as **Microsoft Azure Active Directory** in QRadar.

To integrate Microsoft Entra ID with QRadar, complete the following steps:

- If automatic updates are not enabled, RPMs are available for download from the [IBM support website](#). Download and install the most recent version of the following RPMs on your QRadar Console.
  - Protocol Common RPM
  - DSM Common
  - Microsoft Azure Event Hubs Protocol RPM
  - Microsoft Azure Platform DSM RPM
  - Microsoft Azure Active Directory DSM RPM
- If you do not have an existing storage account, create a storage account. For more information, see [Create a storage account](#).
- Important:** You must have a storage account to connect to an event hub. For more information, see [Microsoft Azure Event Hubs protocol FAQ](#).
- If you do not have an existing event hub, create an event hub. For more information, see [Quickstart: Create an event hub using Azure portal](#).
- Configure Microsoft Entra ID to forward events to an Azure Event Hub by streaming events through diagnostic logs. For more information, see [Tutorial: Stream Azure Active Directory logs to an Azure Event Hub](#).
- If QRadar does not automatically detect the log source, add a Microsoft Entra ID log source on the QRadar Console by using the Microsoft Azure Event Hubs protocol. For more information about configuring the protocol, see [Microsoft Active Directory log source parameters](#).

## Microsoft Entra ID DSM specifications

When you configure the Microsoft Entra ID DSM, understanding the specifications for the Microsoft Entra ID DSM can help ensure a successful integration. For example, knowing what protocol to use before you begin can help reduce frustration during the configuration process.

| Table 766. Microsoft Entra ID DSM specifications |                                                                                                                                                                                                                                                                                                                                                                    |

## Microsoft Entra ID log source parameters

When you add an Entra ID log source on the QRadar Console by using the Microsoft Azure Event Hubs protocol, there are specific parameters you must use.

The following table describes the parameters that require specific values to retrieve Microsoft Entra ID events from Microsoft Entra ID:

| Table 767. Microsoft Azure Event Hubs protocol log source parameters for the Microsoft Entra ID DSM |                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                                                           | Value                                                                                                                                                                                                                                                                                                                                                             |
| <b>Log Source type</b>                                                                              | Microsoft Entra ID                                                                                                                                                                                                                                                                                                                                                |
| <b>Protocol Configuration</b>                                                                       | Microsoft Azure Event Hubs                                                                                                                                                                                                                                                                                                                                        |
| <b>Log Source Identifier</b>                                                                        | The Log Source Identifier can be any valid value, including the same value as the Log Source Name parameter, and doesn't need to reference a specific server. If you configured multiple Microsoft Entra ID log sources, you might want to identify the first log source as EntraID-1, the second log source as EntraID-2, and the third log source as EntraID-3. |

For a complete list of Microsoft Entra ID protocol parameters and their values, see [Microsoft Azure Event Hubs protocol configuration options](#).

## Microsoft Entra ID sample event messages

Use these sample event messages as a way of verifying a successful integration with QRadar.

The following table provides sample event messages for the Microsoft Entra ID DSM:

**Important:** Due to formatting, paste the message formats into a text editor and then remove any carriage return or line feed characters.

*Table 768. Microsoft Entra ID sample event message supported by Microsoft Entra ID*

| Event name                  | Low level category | Sample log message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Microsoft Azure Monitor Agent Linux

The IBM QRadar DSM for Microsoft Azure Monitor Agent (AMA) Linux parses messages and events that are generated by various components within the Linux operating system and applications.

To integrate Microsoft Azure Monitor Agent (AMA) Linux with QRadar, complete the following steps:

- If automatic updates are not enabled, RPMs are available for download from the [IBM support website](#). Download and install the most recent version of the following RPMs on your QRadar Console.
  - MicrosoftAzureMonitorAgentLinux DSM RPM
- Configure the Microsoft Azure Monitor Agent Linux server Logs to send events to QRadar. For more information see, [Microsoft Azure Event Hubs protocol configuration options](#).

*Table 771. Highlighted values in the Microsoft Azure Monitor Agent Linux sample event*

| QRadar field name | Highlighted payload field name |
|-------------------|--------------------------------|
| Event ID          | ProcessName + SeverityLevel    |
| Severity          | SeverityLevel                  |
| Event Time        | EventTime                      |

## Microsoft Azure Platform

The IBM QRadar DSM for Microsoft Azure Platform parses events from the Microsoft Azure Activity log.

The Microsoft Azure Platform DSM collects events that occur at the platform level; such as resource creation, modification, or deletion. For a list of supported event types, see [Microsoft Azure Platform DSM specifications](#).

To integrate Microsoft Azure Platform with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](#). Download and install the most recent version of the following RPMs on your QRadar Console.
  - Protocol Common RPM
  - Protocol Event Hubs RPM
  - DSM Common RPM
  - Microsoft Azure Platform DSM RPM
2. Optional: Create a storage account. For more information, see [Create a storage account](#).  
**Important:** You must have a storage account to connect to an event hub. For more information, see [Microsoft Azure Event Hubs protocol FAQ](#).
3. Optional: Create an event hub. For more information, see [Quickstart: Create an event hub using Azure portal](#).
4. Configure the Microsoft Azure Activity Logs to send events to a Microsoft Azure Event Hub. For more information see, [Export Azure Activity log to storage or Azure Event Hubs](#).
5. Configure QRadar to collect events from Microsoft Azure Event Hubs by using the Microsoft Azure Event Hubs protocol. For more information about the protocol, see [“Microsoft Azure log source parameters for Microsoft Azure Event Hubs” on page 1183](#).

**Note:** Microsoft Azure Log Integration service is no longer used to send events to QRadar. Microsoft Azure Log Integration service is deprecated and no longer supported by Microsoft.

## Microsoft Azure Platform DSM specifications

When you configure the Microsoft Azure Platform DSM, understanding the specifications for the Microsoft Azure Platform DSM can help ensure a successful integration. For example, knowing what event format is supported before you begin can help reduce frustration during the configuration process.

*Table 772. Microsoft Azure Platform DSM specifications*

| Specification | Value                    |
|---------------|--------------------------|
| Manufacturer  | Microsoft                |
| DSM name      | Microsoft Azure Platform |

Table 772. Microsoft Azure Platform DSM specifications (continued)

| Specification               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Microsoft Azure log source parameters for Microsoft Azure Event Hubs

If QRadar does not automatically detect the log source, add a Microsoft Azure Event Hubs log source on the QRadar Console by using the Microsoft Azure protocol.

When using the Microsoft Azure protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Microsoft Azure events from Microsoft Azure Event Hubs:

Table 773. Microsoft Azure log source parameters for the Microsoft Azure Event Hubs DSM

| Parameter                     | Description                                                                                                                                                             |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source type</b>        | Microsoft Azure                                                                                                                                                         |
| <b>Protocol Configuration</b> | Microsoft Azure Event Hubs                                                                                                                                              |
| <b>Log Source Identifier</b>  | An identifiable name or IP address for the log source. When the <b>Use as Gateway Log Source</b> field is selected, the <b>Log Source Identifier</b> value is not used. |

For a complete list of Microsoft Azure Event Hubs protocol parameters and their values, see [“Microsoft Azure Event Hubs protocol configuration options”](#) on page 160.

| Source IP                                 | <code>callerIpAddress</code>   |
| Device Time                               | <code>time</code>              |

**Sample 3:** The following sample event message shows that a specified secret is retrieved from a given key vault.

```
{"eventHubsAzureRecord": {"time": "2016-03-02T 04:31:28.6127743Z", "resourceId": "/SUBSCRIPTIONS//RESOURCEGROUPS//PROVIDERS/MICROSOFT.KEYVAULT/VAULTS/AZLOGTEST", "operationName": "SecretGet", "operationVersion": "2015-06-01", "category": "AuditEvent", "resultType": "Success", "resultSignature": "OK", "resultDescription": "", "durationMs": "187", "callerIpAddress": "", "correlationId": "", "identity": {"claim": {"http://schemas.microsoft.com/identity/claims/objectidentifier": "", "appid": "", "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/upn": ""}}, "properties": {"clientInfo": "", "requestUri": "", "id": "https://.vault.azure.net/secrets/testsecret/", "httpStatusCode": 200}}}}
```

| Table 776. Highlighted fields |                                                                                                                                                  |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>QRadar field name</b>      | <b>Highlighted payload field name</b>                                                                                                            |
| <b>Event ID</b>               | <b>operationName</b>                                                                                                                             |
| <b>Event category</b>         | The <b>Event category</b> is located in the <b>resourceId</b> field after the <b>PROVIDERS</b> keyword. For example, <b>MICROSOFT.KEYVAULT</b> . |
| <b>Device Time</b>            | <b>time</b>                                                                                                                                      |
| <b>Source IP</b>              | <b>callerIpAddress</b>                                                                                                                           |

**Sample 4:** The following sample event message shows that a user successfully logged in to Microsoft SQL Server.

Table 777. Highlighted fields

| QRadar field name | Highlighted payload field name                                                                                                                                                                                                                                                                           |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Event ID          | The <b>Event ID</b> is comprised from the <b>category</b> and <b>action_name</b> field values. For example, " <b>category</b> ":" <b>SQLSecurityAuditEvents</b> " and " <b>action_name</b> ":" <b>LOGIN SUCCEEDED</b> " results in an <b>Event ID</b> value of "sqlsecurityauditevents_login succeeded". |
| Event category    | The <b>Event category</b> is located in the <b>resourceId</b> field after the <b>PROVIDERS</b> keyword. For example, <b>MICROSOFT.SQL</b> .                                                                                                                                                              |
| Device Time       | <b>time</b>                                                                                                                                                                                                                                                                                              |
| Username          | <b>server_principal_name</b>                                                                                                                                                                                                                                                                             |
| Source IP         | <b>client_ip</b>                                                                                                                                                                                                                                                                                         |

## Microsoft Defender for Cloud

The IBM QRadar DSM for Microsoft Defender for Cloud collects JSON events from a Microsoft Defender for Cloud. Events can be collected by using the Microsoft Graph Security API protocol and the Microsoft Azure Event Hubs protocol.

### Important:

The Microsoft Azure Security Center DSM name is now the Microsoft Defender for Cloud DSM. The DSM RPM name remains as Microsoft Azure Security Center in QRadar.

To integrate Microsoft Defender for Cloud with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - Microsoft Defender for Cloud DSM RPM
  - Microsoft Graph Security API Protocol DSM (If you want to add a log source by using the Microsoft Graph Security API protocol, download this RPM.)
  - Microsoft Azure Event Hubs Protocol RPM (If you want to add a log source by using the Microsoft Azure Event Hubs protocol, download this RPM.)
2. Optional: Configure Microsoft Defender for Cloud to send events to QRadar when you use Microsoft Graph Security API. For more information, see [Export security alerts and recommendations](https://docs.microsoft.com/en-us/azure/security-center/continuous-export) <https://docs.microsoft.com/en-us/azure/security-center/continuous-export>.
3. Optional: Configure Microsoft Defender for Cloud to send events to QRadar when you use Microsoft Azure Event Hub. For more information, see [Stream alerts to QRadar](https://learn.microsoft.com/en-us/azure/defender-for-cloud/export-to-siem#stream-alerts-to-qradar) (<https://learn.microsoft.com/en-us/azure/defender-for-cloud/export-to-siem#stream-alerts-to-qradar-and-splunk>)
4. Add a Microsoft Defender for Cloud log source on the QRadar Console.

## Microsoft Defender for Cloud DSM specifications

When you configure Microsoft Defender for Cloud, understanding the specifications for the Microsoft Defender for Cloud DSM can help ensure a successful integration. For example, knowing what event format is supported for Microsoft Defender for Cloud before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Microsoft Defender for Cloud DSM.

*Table 778. Microsoft Defender for Cloud DSM specifications*

| Specification               | Value                                                                                                                                                                                                 |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Manufacturer                | Microsoft                                                                                                                                                                                             |

## Microsoft Graph Security API protocol log source parameters for Microsoft Defender for Cloud

Add a Microsoft Defender for Cloud log source on the QRadar Console by using the Microsoft Graph Security API protocol.

The following table describes the parameters that require specific values to collect Microsoft Graph Security API events from Microsoft Defender for Cloud:

*Table 779. Microsoft Graph Security API log source parameters for the Microsoft Defender for Cloud DSM*

| Parameter                     | Value                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source type</b>        | Microsoft Defender for Cloud                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Protocol Configuration</b> | Microsoft Graph Security API                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Log Source Identifier</b>  | An identifiable name for the log source.<br><br>The Log Source Identifier can be any valid value, including the same value as the Log Source Name parameter, and doesn't need to reference a specific server. If you configured multiple Microsoft Defender for Cloud log sources, you might want to identify the first log source as MASC-1 the second log source as MASC-2, and the third log source as MASC-3. |
| <b>Tenant ID</b>              | To find the <b>Tenant ID</b> parameter value, log in to Microsoft Defender for Cloud, and then select <b>Azure Active Directory &gt; Overview</b> or select <b>Azure Active Directory &gt; App registration &gt; Microsoft Graph Security App &gt; Overview</b> .                                                                                                                                                 |

*Table 779. Microsoft Graph Security API log source parameters for the Microsoft Defender for Cloud DSM (continued)*

| Parameter            | Value                                                                                                                                                                                                                                                                                                     |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Client ID</b>     | To find the <b>Client ID</b> parameter value, log in to Microsoft Defender for Cloud, and then select <b>Azure Active Directory &gt; App registration &gt; Microsoft Graph Security App &gt; Overview</b> .                                                                                               |
| <b>Client Secret</b> | To find the <b>Client Secret</b> parameter value, log in to Microsoft Defender for Cloud, and then select <b>Azure Active Directory &gt; App registration &gt; Microsoft Graph Security App &gt; Certificates and secrets &gt; Client secrets</b> . If no client secret exists, you can create one there. |

## Microsoft DHCP Server

The Microsoft DHCP Server DSM for IBM QRadar accepts DHCP events by using the Microsoft DHCP Server protocol or WinCollect.

### About this task

Before you can integrate your Microsoft DHCP Server with QRadar, you must enable audit logging.

To configure the Microsoft DHCP Server:

### Procedure

1. Log in to the DHCP Server Administration Tool.
2. From the DHCP Administration Tool, right-click on the DHCP server and select **Properties**.  
The **Properties** window is displayed.
3. Click the **General** tab.  
The **General** pane is displayed.
4. Click **Enable DHCP Audit Logging**.

The audit log file is created at midnight and must contain a three-character day of the week abbreviation.

*Table 784. Microsoft DHCP log file examples*

| Log Type | Example              |
|----------|----------------------|
| IPv4     | DhcpSrvLog-Mon.log   |
| IPv6     | DhcpV6SrvLog-Wed.log |

By default Microsoft DHCP is configured to write audit logs to the %WINDIR%\system32\dhcp\ directory.

5. Restart the DHCP service.
6. You can now configure the log source and protocol in QRadar.
  - a) To configure QRadar to receive events from a Microsoft DHCP Server, you must select the Microsoft **DHCP Server** option from the **Log Source Type** list.
  - b) To configure the protocol, you must select the Microsoft DHCP option from the Protocol Configuration list.

**Note:** To integrate Microsoft DHCP Server versions 2000/2003 with QRadar by using WinCollect, see the *IBM QRadar WinCollect User Guide*.

## Related concepts

[“Microsoft DHCP protocol configuration options” on page 179](#)

To receive events from Microsoft DHCP servers, configure a log source to use the Microsoft DHCP protocol.

| Supported versions        | Windows Server 2008 R2<br>Windows Server 2012 R2<br>Windows Server 2016 |
| Protocol                  | WinCollect Microsoft DNS Debug                                          |
| Event format              | LEEF                                                                    |
| Recorded event types      | All operational and configuration network events.                       |
| Automatically discovered? | Yes                                                                     |

Table 786. Microsoft DNS Debug DSM specifications (continued)

| Specification               | Value                                                           |
|-----------------------------|-----------------------------------------------------------------|
| Includes identity?          | Yes                                                             |
| Includes custom properties? | No                                                              |
| More information            | <a href="http://www.microsoft.com">http://www.microsoft.com</a> |

To integrate Microsoft DNS Debug with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following files from the [IBM Support Website](#) in the order that they are listed on your QRadar Console:
  - .sfs file for WinCollect
  - DSMCommon RPM
  - Microsoft DNS Debug RPM
2. Configure WinCollect to forward Microsoft DNS Debug events to QRadar. For more information, go to [Log Sources for WinCollect agents](#) in the *IBM QRadar WinCollect User Guide*. ([https://www.ibm.com/docs/en/SS42VS\\_SHR/com.ibm.wincollect.doc/c\\_ug\\_wincollect\\_log\\_sources.html](https://www.ibm.com/docs/en/SS42VS_SHR/com.ibm.wincollect.doc/c_ug_wincollect_log_sources.html)).
3. If QRadar does not automatically detect the log source, add a Microsoft DNS Debug log source on the QRadar Console.

## Enabling DNS debugging on Windows Server

Enable DNS debugging on Windows Server to collect information that the DNS server sends and receives.

### Before you begin

The DNS role must be installed on the Windows Server.

**Important:** DNS debug logging can affect system performance and disk space because it provides detailed data about information that the DNS server sends and receives. Enable DNS debug logging only when you require this information.

### Procedure

1. Open the **DNS Manager** with the following command:

```
dnsmgmt.msc
```

2. Right-click the DNS server and click **Properties**.
3. Click the **Debug Logging** tab.
4. Select **Log packets for debugging**.
5. Enter the **File path and name**, and **Maximum size**.

**Important:** The **File path and name**, need to align with the **Root Directory** and **File Pattern** you provided when the Microsoft DNS debug log source was created in QRadar .

6. Click **Apply** and **OK**.

## Microsoft DNS Debug sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## Microsoft DNS Debug sample message when you use the Syslog protocol

The following sample event shows a DNS type A query.

```
<13>Aug 01 07:46:17 microsoft.dns.test AgentDevice=WindowsDNS    AgentLogFile=dns.log
PluginVersion=192.168.63.93    Date=1/08/2019    Time=7:46:13    Thread ID=a.m. 0E40
Context=PACKET    Messages=    Internal packet identifier=000000A018724240    UDP/TCP
indicator=UDP    Send/Receive indicator=Snd    Remote IP=192.168.113.142    Xid

## Microsoft Endpoint Protection

The Microsoft Endpoint Protection DSM for IBM QRadar collects malware detection events.

QRadar collects malware detection events by using the JDBC protocol. Adding malware detection events to QRadar gives the capability to monitor and detect malware infected computers in your deployment.

Malware detection events include the following event types:

- Site name and the source from which the malware was detected.
- Threat name, threat ID, and severity.
- User ID associated with the threat.
- Event type, time stamp, and the cleaning action that is taken on the malware.

### Configuration overview

The Microsoft Endpoint Protection DSM uses JDBC to poll an SQL database for malware detection event data. This DSM does not automatically discover. To integrate Microsoft Endpoint Protection with QRadar, take the following steps:

1. If your database is not configured with Predefined Query, create an SQL database view for QRadar with the malware detection event data.
2. Configure a JDBC log source to poll for events from the Microsoft Endpoint Protection database. For information about configuring JDBC log source parameters for Microsoft Endpoint Protection, see “[Microsoft Endpoint Protection JDBC log source parameters for predefined database queries](#)” on page 1196.
3. Ensure that no firewall rules are blocking communication between QRadar and the database that is associated with Microsoft Endpoint Protection.

## Creating a database view

Microsoft EndPoint Protection uses SQL Server Management Studio (SSMS) to manage the EndPoint Protection SQL databases.

### Procedure

1. Log in to the system that hosts your Microsoft EndPoint Protection SQL database.
2. From the **Start** menu, select **Run**.
3. Type the following command:  
`ssms`
4. Click **OK**.
5. Log in to your Microsoft Endpoint Protection database.
6. From the **Object Explorer**, select **Databases**.
7. Select your database and click **Views**.
8. From the navigation menu, click **New Query**.
9. In the **Query** pane, type the following Transact-SQL statement to create the database view:

```
create view dbo.MalwareView as select n.Type , n.RowID , n.Name ,
n.Description , n.Timestamp , n.SchemaVersion , n.ObserverHost , n.ObserverUser ,
n.ObserverProductName , n.ObserverProductversion , n.ObserverProtectionType ,
n.ObserverProtectionVersion , n.ObserverProtectionSignatureVersion , n.ObserverDetection ,
n.ObserverDetectionTime , n.ActorHost , n.ActorUser , n.ActorProcess ,
n.ActorResource , n.ActionType , n.TargetHost , n.TargetUser , n.TargetProcess ,
n.TargetResource , n.ClassificationID , n.ClassificationType , n.ClassificationSeverity ,
n.ClassificationCategory , n.RemediationType , n.RemediationResult ,
n.RemediationErrorCode , n.RemediationPendingAction , n.IsActiveMalware , i.IP_Addresses0
as 'SrcAddress'

from v_AM_NormalizedDetectionHistory n, System_IP_Address_ARR i, v_RA_System_ResourceNames
s, Network_DATA d where n.ObserverHost = s.Resource_Names0 and s.ResourceID = d.MachineID
and d.IPEnabled00 = 1 and d.MachineID = i.ItemKey and i.IP_Addresses0 like '%.%.%.%';
```

10. From the **Query** pane, right-click and select **Execute**.

If the view is created, the following message is displayed in the results pane:

Command(s) completed successfully.

### What to do next

You are now ready to configure a log source in IBM QRadar.

## Microsoft Endpoint Protection JDBC log source parameters for predefined database queries

Administrators who do not have permission to create a database view because of policy restrictions can collect Microsoft Endpoint Protection events with a JDBC log source that uses predefined queries.

Predefined queries are customized statements that can join data from separate tables when the database is polled by the JDBC protocol. To successfully poll for audit data from the Microsoft Endpoint Protection database, create a new user or provide the log source with existing user credentials. For more information about creating a user account, see the [Microsoft website](https://www.microsoft.com) (<https://www.microsoft.com>).

**Restriction:** If you use network segregation to separate networks, using a predefined query might cause duplicate events. Use your own query.

When using the JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from Microsoft Endpoint Protection:

Table 788. Microsoft Endpoint Protection JDBC parameters

| Parameter                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source Name</b>                      | Type a unique name for the log source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Log Source Description</b><br>(Optional) | Type a description for the log source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Log Source Type</b>                      | <b>Microsoft Endpoint Protection</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Protocol Configuration</b>               | <b>JDBC</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Log Source Identifier</b>                | <p>Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.</p> <p>If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2.</p> |
| <b>Database Type</b>                        | <b>MSDE</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Database Name</b>                        | The name of the database to which you want to connect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>IP or Hostname</b>                       | Type the IP address or host name of the Microsoft Endpoint Protection SQL Server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Port</b>                                 | <p>Type the port number that is used by the database server. The default port for MSDE is 1433.</p> <p>The JDBC configuration port must match the listener port of the Microsoft Endpoint Protection database. The Microsoft Endpoint Protection database must have incoming TCP connections that are enabled to communicate with QRadar.</p> <p>If you define a <b>Database Instance</b> when MSDE is used as the database type, you must leave the <b>Port</b> field blank in your configuration.</p>                                                                                                                                                              |
| <b>Username</b>                             | Type the user name the log source can use to access the Microsoft Endpoint Protection database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Password</b>                             | <p>Type the password the log source can use to access the Microsoft Endpoint Protection database.</p> <p>The password can be up to 255 characters in length.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Confirm Password</b>                     | Confirm the password that is used to access the database. The confirmation password must be identical to the password entered in the <b>Password</b> field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Authentication Domain</b>                | <p>If you did not select <b>Use Microsoft JDBC</b>, <b>Authentication Domain</b> is displayed.</p> <p>If you select <b>MSDE</b> as the <b>Database Type</b> and the database is configured for Windows Authentication, you must populate the <b>Authentication Domain</b> field. Otherwise, leave this field blank.</p>                                                                                                                                                                                                                                                                                                                                              |

Table 788. Microsoft Endpoint Protection JDBC parameters (continued)

| Parameter                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Database Instance</b>              | If you have multiple SQL server instances on your database server, type the database instance.<br><br>If you use a non-standard port in your database configuration, or block access to port 1434 for SQL database resolution, you must leave the <b>Database Instance</b> parameter blank in your configuration.                                                                                                                            |
| <b>Predefined Query</b>               | From the list, select <b>Microsoft Endpoint Protection</b> .                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Table Name</b>                     | The name of the table or view that includes the event records. The table name can include the following special characters: dollar sign (\$), number sign (#), underscore (_), en dash (-), and period (.).                                                                                                                                                                                                                                  |
| <b>Select List</b>                    | The list of fields to include when the table is polled for events. You can use a comma-separated list or type an asterisk (*) to select all fields from the table or view. If a comma-separated list is defined, the list must contain the field that is defined in the <b>Compare Field</b> .                                                                                                                                               |
| <b>Compare Field</b>                  | A numeric value or time stamp field from the table or view that identifies new events that are added to the table between queries. Enables the protocol to identify events that were previously polled by the protocol to ensure that duplicate events are not created.                                                                                                                                                                      |
| <b>Use Prepared Statements</b>        | Select the <b>Use Prepared Statements</b> check box.<br><br>Prepared statements allow the JDBC protocol source to set up the SQL statement one time, then run the SQL statement many times with different parameters. For security and performance reasons, it is suggested that you use prepared statements.<br><br>Clearing this checkbox requires you to use an alternative method of querying that does not use pre-compiled statements. |
| <b>Start Date and Time (Optional)</b> | Type the start date and time for database polling.<br><br>The <b>Start Date and Time</b> parameter must be formatted as yyyy-MM-dd HH:mm with HH specified by using a 24-hour clock. If the start date or time is clear, polling begins immediately and repeats at the specified polling interval.                                                                                                                                           |
| <b>Polling Interval</b>               | Type the polling interval, which is the amount of time between queries to the view you created. The default polling interval is 10 seconds.<br><br>You can define a longer polling interval by appending H for hours or M for minutes to the numeric value. The maximum polling interval is 1 week in any time format. Numeric values that are entered without an H or M poll in seconds.                                                    |
| <b>EPS Throttle</b>                   | The maximum number of events per second that QRadar ingests.<br><br>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.<br><br>The valid range is 100 to 20,000.                                                                                                                                                |

Table 788. Microsoft Endpoint Protection JDBC parameters (continued)

| Parameter                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Use Named Pipe Communication</b>  | If you did not select <b>Use Microsoft JDBC</b> , <b>Use Named Pipe Communication</b> is displayed.<br><br>MSDE databases require the username and password field to use a Windows authentication user name and password and not the database user name and password. The log source configuration must use the default that is named pipe on the MSDE database.                                                                                                                        |
| <b>Database Cluster Name</b>         | If you selected the <b>Use Named Pipe Communication</b> , the <b>Database Cluster Name</b> parameter is displayed. If you are running your SQL server in a cluster environment, define the cluster name to ensure Named Pipe communication functions properly.                                                                                                                                                                                                                          |
| <b>Use NTLMv2</b>                    | If you did not select <b>Use Microsoft JDBC</b> , <b>Use NTLMv2</b> is displayed.<br><br>Select the <b>Use NTLMv2</b> check box.<br><br>This option forces MSDE connections to use the NTLMv2 protocol when they communicate with SQL servers that require NTLMv2 authentication. The default value of the check box is selected.<br><br>If the <b>Use NTLMv2</b> check box is selected, it has no effect on MSDE connections to SQL servers that do not require NTLMv2 authentication. |
| <b>Use Microsoft JDBC</b>            | If you want to use the Microsoft JDBC driver, you must enable <b>Use Microsoft JDBC</b> .                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Use SSL</b>                       | If your connection supports SSL communication, select <b>Use SSL</b> . This option requires extra configuration on your Endpoint Protection database and also requires administrators to configure certificates on both appliances.                                                                                                                                                                                                                                                     |
| <b>Microsoft SQL Server Hostname</b> | If you selected <b>Use Microsoft JDBC</b> and <b>Use SSL</b> , the <b>Microsoft SQL Server Hostname</b> parameter is displayed.<br><br>You must type the hostname for the Microsoft SQL server.                                                                                                                                                                                                                                                                                         |

For a complete list of JDBC protocol parameters and their values, see [c\\_logsource\\_JDBCprotocol.dita](#).

## Microsoft Exchange Server

The IBM QRadar DSM for Microsoft Exchange Server collects Exchange events by polling for event log files.

The following table identifies the specifications for the Microsoft Exchange Server DSM:

Table 789. Microsoft Exchange Server

| Specification | Value                                                        |
|---------------|--------------------------------------------------------------|
| Manufacturer  | Microsoft                                                    |
| DSM name      | Exchange Server                                              |
| RPM file name | DSM-MicrosoftExchange-QRadar_version-build_number.noarch.rpm |

*Table 789. Microsoft Exchange Server (continued)*

| Specification               | Value                                                                                                                                                          |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|

To integrate Microsoft Exchange Server with QRadar, use the following steps:

1. If automatic updates are not enabled, download the most recent version of the Microsoft Exchange Server DSM RPM from the [IBM Support Website](#).
2. Configure your Microsoft Exchange Server DSM device to enable communication with QRadar.
3. Create an Microsoft Exchange Server DSM log source on the QRadar Console.

[“Adding a log source” on page 5](#)

## Configuring Microsoft Exchange Server to communicate with QRadar

### Before you begin

Ensure that the firewalls that are located between the Exchange Server and the remote host allow traffic on the following ports:

- TCP port 135 for Microsoft Endpoint Mapper.
- UDP port 137 for NetBIOS name service.
- UDP port 138 for NetBIOS datagram service.
- TCP port 139 for NetBIOS session service.
- TCP port 445 for Microsoft Directory Services to transfer files across a Windows share.

### Procedure

1. Configure OWA logs.
2. Configure SMTP logs.

3. Configure MSGTRK logs.

## Configuring OWA logs on your Microsoft Exchange Server

To prepare your Microsoft Exchange Server to communicate with IBM QRadar, configure Outlook Web Access (OWA) event logs.

### Procedure

1. Log into your Microsoft Internet Information System (IIS) Manager.
2. On the desktop, select **Start > Run**.
3. Type the following command:  
`inetmgr`
4. Click **OK**.
5. In the menu tree, expand **Local Computer**.
6. If you use IIS 6.0 Manager for Microsoft Server 2003, complete the following steps:
  - a) Expand **Web Sites**.
  - b) Right-click **Default Web Site** and select **Properties**.
  - c) From the **Active Log Format** list, select **W3C**.
  - d) Click **Properties**.
  - e) Click the **Advanced** tab.
  - f) From the list of properties, select the **Method (cs-method)** and **Protocol Version (cs-version)** check boxes
  - g) Click **OK**.
7. If you use IIS 7.0 Manager for Microsoft Server 2008 R2, or IIS 8.5 for Microsoft Server 2012 R2, complete the following steps:
  - a) Click **Logging**.
  - b) From the **Format** list, select **W3C**.
  - c) Click **Select Fields**.
  - d) From the list of properties, select the **Method (cs-method)** and **Protocol Version (cs-version)** check boxes
  - e) Click **OK**.

## Enabling SMTP logs on your Microsoft Exchange Server 2003, 2007, and 2010

To prepare your Microsoft Exchange Server 2003, 2007 and 2010 to communicate with IBM QRadar, enable SMTP event logs.

### Procedure

1. Start the Exchange Management Console.
2. To configure your *receive connector*, choose one of the following options:
  - For edge transport servers, select **Edge Transport** in the console tree and click the **Receive Connectors** tab.
  - For hub transport servers, select **Server Configuration > Hub Transport** in the console tree, select the server, and then click the **Receive Connectors** tab.
3. Select your receive connector and click **Properties**.
4. Click the **General** tab.
5. From the **Protocol logging level** list, select **Verbose**.
6. Click **Apply**.

7. Click **OK**.
8. To configure your *send connector*, choose one of the following options:
  - For edge transport servers, select **Edge Transport** in the console tree and click the **Send Connectors** tab.
  - For hub transport servers, select **Organization Configuration > Hub Transport** in the console tree, select your server, and then click the **Send Connectors** tab.
9. Select your send connector and click **Properties**.
10. Click the **General** tab.
11. From the **Protocol logging level** list, select **Verbose**.
12. Click **Apply**.
13. Click **OK**.

## Enabling SMTP logs on your Microsoft Exchange Server 2013, and 2016

To prepare your Microsoft Exchange Server 2013 and 2016 to communicate with IBM QRadar, enable SMTP event logs.

### Procedure

1. Start the Exchange Administration Center.
2. To configure your *receive connector*, select **Mail Flow > Receive Connectors**.
3. Select your receive connector and click **Edit**.
4. Click the **General** tab.
5. From the **Protocol logging level** list, select **Verbose**.
6. Click **Save**.
7. To configure your *send connector*, select **Mail Flow > Send Connectors**
8. Select your send connector and click **Edit**.
9. Click the **General** tab.
10. From the **Protocol logging level** list, select **Verbose**.
11. Click **Save**.

## Configuring MSGTRK logs for Microsoft Exchange 2003, 2007, and 2010

Message Tracking logs created by the Microsoft Exchange Server detail the message activity that takes place on your Microsoft Exchange Server, including the message path information.

### About this task

MSGTRK logs are enabled by default on Microsoft Exchange 2007 or Exchange 2010 installations. The following configuration steps are optional.

To enable MSGTRK event logs:

### Procedure

1. Start the Exchange Management Console.
2. Configure your receive connector based on the server type:
  - For edge transport servers - In the **console tree**, select **Edge Transport** and click **Properties**.
  - For hub transport servers - In the console tree, select **Server Configuration > Hub Transport**, and then select the server and click **Properties**.
3. Click the **Log Settings** tab.
4. Select the **Enable message tracking** check box.

5. Click **Apply**.

6. Click **OK**.

MSGTRK events are now enabled on your Exchange Server.

## Configuring MSGTRK logs for Exchange 2013 and 2016

Message Tracking logs created by the Microsoft Exchange Server detail the message activity that takes place on your Exchange Server, including the message path information.

### Procedure

1. Start the Exchange Administration Center.

2. Click **Servers > Servers**.

3. Select the mailbox server that you want to configure, and then click **Edit**.

4. Click **Transport Logs**.

5. In the **Message tracking log** section, configure the following parameters:

| Parameter                          | Description                                                                                                                               |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable message tracking log</b> | Enable or disable message tracking on the server.                                                                                         |
| <b>Message tracking log path</b>   | The value that you specify must be on the local Exchange server. If the folder does not exist, it is created when you click <b>Save</b> . |

6. Click **Save**.

## Microsoft Exchange Server log source parameters for Microsoft Exchange

If QRadar does not automatically detect the log source, add a Microsoft Exchange log source on the QRadar Console by using the Microsoft Exchange Server protocol.

When using the Microsoft Exchange Server protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Microsoft Exchange Server events from Microsoft Exchange:

Table 790. Microsoft Exchange Server log source parameters for the Microsoft Exchange DSM

| Parameter                     | Value                                                                                                   |
|-------------------------------|---------------------------------------------------------------------------------------------------------|
| <b>Log Source type</b>        | Microsoft Exchange Server                                                                               |
| <b>Protocol Configuration</b> | Microsoft Exchange                                                                                      |
| <b>Log Source Identifier</b>  | The IP address or host name to identify the Windows Exchange event source in the QRadar user interface. |

Table 790. Microsoft Exchange Server log source parameters for the Microsoft Exchange DSM (continued)

| Parameter                   | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SMTP Log Folder Path</b> | <p>The directory path to access the SMTP log files. Use one of the following directory paths:</p> <ul style="list-style-type: none"> <li>• For Microsoft Exchange 2003, use c\$/Program Files/Microsoft/Exchange Server/TransportRoles/Logs/ProtocolLog/ .</li> <li>• For Microsoft Exchange 2007, use c\$/Program Files/Microsoft/Exchange Server/TransportRoles/Logs/ProtocolLog/.</li> <li>• For Microsoft Exchange 2010, use c\$/Program Files/Microsoft/Exchange Server/V14/TransportRoles/Logs/ProtocolLog/.</li> <li>• For Microsoft Exchange 2013, use c\$/Program Files/Microsoft/Exchange Server/V15/TransportRoles/Logs/ProtocolLog/.</li> <li>• For Microsoft Exchange 2016, use c\$/Program Files/Microsoft/Exchange Server/V15/TransportRoles/Logs/ProtocolLog/.</li> </ul> |
| <b>OWA Log Folder Path</b>  | <p>The directory path to access the OWA log files. Use one of the following directory paths:</p> <ul style="list-style-type: none"> <li>• For Microsoft Exchange 2003, use c\$/WINDOWS/system32/LogFiles/W3SVC1/ .</li> <li>• For Microsoft Exchange 2007, use c\$/WINDOWS/system32/LogFiles/W3SVC1/ .</li> <li>• For Microsoft Exchange 2010, use c\$/inetpub/logs/LogFiles/W3SVC1/.</li> <li>• For Microsoft Exchange 2013, use c\$/inetpub/logs/LogFiles/W3SVC1/.</li> <li>• For Microsoft Exchange 2016, use c\$/inetpub/logs/LogFiles/W3SVC1/.</li> <li>• For Microsoft Exchange 2019, use c\$/inetpub/logs/LogFiles/W3SVC1/.</li> </ul>                                                                                                                                             |

Table 790. Microsoft Exchange Server log source parameters for the Microsoft Exchange DSM (continued)

| Parameter                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MSGTRK Log Folder Path</b> | The directory path to access message tracking log files. Message tracking is only available on Microsoft Exchange 2007 servers assigned the Hub Transport, Mailbox, or Edge Transport server role. Use one of the following directory paths: <ul style="list-style-type: none"> <li>For Microsoft Exchange 2007, use c\$/Program Files/Microsoft/Exchange Server/TransportRoles/Logs/MessageTracking/.</li> <li>For Microsoft Exchange 2010, use c\$/Program Files/Microsoft/Exchange Server/V14/TransportRoles/Logs/MessageTracking/.</li> <li>For Microsoft Exchange 2013, use c\$/Program Files/Microsoft/Exchange Server/V15/TransportRoles/Logs/MessageTracking/.</li> <li>For Microsoft Exchange 2016, use c\$/Program Files/Microsoft/Exchange Server/V15/TransportRoles/Logs/MessageTracking/.</li> </ul> |

For a complete list of Microsoft Exchange Server protocol parameters and their values, see [“Microsoft Exchange protocol configuration options” on page 181](#).

## Microsoft Hyper-V DSM integration process

You can integrate Microsoft Hyper-V DSM with IBM QRadar by using WinCollect.

Use the following procedures:

1. Download and install the DSM-MicrosoftHyperV RPM and the WinCollect RPM from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>).
2. Install a WinCollect agent on the Hyper-V system or on another system that has a route to the Hyper-V system. You can also use an existing WinCollect agent. For more information about WinCollect, see the [WinCollect documentation](https://www.ibm.com/docs/en/qcip/7.5?topic=configuring-wincollect-7) (<https://www.ibm.com/docs/en/qcip/7.5?topic=configuring-wincollect-7>).
3. If automatic updates are not enabled, download and install the DSM RPM for Microsoft Hyper-V on your QRadar Console. RPMs need to be installed only one time.
4. For each Microsoft Hyper-V server that you want to integrate, add a log source on the QRadar Console.

## WinCollect log source parameters for Microsoft Hyper-V

If QRadar does not automatically detect the log source, add a Microsoft Hyper-V log source on the QRadar Console by using the WinCollect protocol.

When using the WinCollect protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect WinCollect events from Microsoft Hyper-V:

Table 793. WinCollect log source parameters for the Microsoft Hyper-V DSM

| Parameter                              | Value                                                                   |
|----------------------------------------|-------------------------------------------------------------------------|
| <b>Log Source type</b>                 | Microsoft Hyper-V                                                       |
| <b>Protocol Configuration</b>          | WinCollect                                                              |
| <b>Application or Service Log Type</b> | Microsoft Hyper-V                                                       |
| <b>WinCollect Agent</b>                | Select the WinCollect agent that accesses the Microsoft Hyper-V server. |

For a complete list of WinCollect protocol parameters and their values, see the *WinCollect User Guide*.

## Microsoft IAS Server

The Microsoft IAS Server DSM for IBM QRadar accepts RADIUS events by using syslog.

#### About this task

You can integrate Internet Authentication Service (IAS) or Network Policy Server (NPS<sup>®</sup>) logs with QRadar by using WinCollect. For more information, see the *IBM QRadar WinCollect User Guide*.

You can now configure the log source in QRadar.

To configure QRadar to receive events from a Microsoft Windows IAS Server.

#### Procedure

From the **Log Source Type** list, select the Microsoft **IAS Server** option.

For more information about your server, see your vendor documentation.

## Microsoft IIS Server

The Microsoft Internet Information Services (IIS) Server DSM for IBM QRadar accepts FTP, HTTP, NNTP, and SMTP events using syslog.

You can integrate a Microsoft IIS Server with QRadar by using one of the following methods:

- Configure QRadar to connect to your Microsoft IIS Server by using the IIS Protocol which collects HTTP events from Microsoft IIS servers. For more information, see [“Configuring Microsoft IIS by using the IIS Protocol” on page 1209](#).
- Configure WinCollect to forward IIS events to QRadar. For more information, go to [Log Sources for WinCollect agents](#) in the *IBM QRadar WinCollect User Guide* ([https://www.ibm.com/docs/en/SS42VS\\_SHR/com.ibm.wincollect.doc/c\\_ug\\_wincollect\\_log\\_sources.html](https://www.ibm.com/docs/en/SS42VS_SHR/com.ibm.wincollect.doc/c_ug_wincollect_log_sources.html)).

Table 794. Supported log types for Microsoft IIS 6.0 - IIS 10.0

| Method of Import | Supported Log Type    |
|------------------|-----------------------|
| IIS Protocol     | HTTP                  |
| WinCollect       | SMTP, NNTP, FTP, HTTP |

# Configuring Microsoft IIS by using the IIS Protocol

You can configure Microsoft IIS Protocol to communicate with QRadar by using the IIS Protocol.

## Before you begin

Before you configure IBM QRadar with the Microsoft IIS protocol, you must configure your Microsoft IIS Server to generate the correct log format.

## About this task

The Microsoft IIS Protocol supports only the W3C Extended log file format.

## Procedure

1. Log in to your Microsoft Information Services (IIS) Manager.
2. Expand **IIS Manager > Local Computer > Sites**.
3. Select **Web Site**.
4. Double-click the **Logging** icon.
5. Select **W3C** as the log file format from the **Log File** window.
6. Click **Select Fields**.
7. From the list of properties, select check boxes for the following W3C properties:

*Table 795. Required Properties for IIS event logs*

| IIS 6.0 Required Properties   | IIS 7.0/7.5 Required Properties | IIS 8.0/8.5 Required Properties | IIS 10 Required Properties  |
|-------------------------------|---------------------------------|---------------------------------|-----------------------------|
| Date (date)                   | Date (date)                     | Date (date)                     | Date (date)                 |
| Time (time)                   | Time (time)                     | Time (time)                     | Time (time)                 |
| Client IP Address (c-ip)      | Client IP Address (c-ip)        | Client IP Address (c-ip)        | Client IP Address (c-ip)    |
| User Name (cs-username)       | User Name (cs-username)         | User Name (cs-username)         | User Name (cs-username)     |
| Server IP Address (s-ip)      | Server IP Address (s-ip)        | Server IP Address (s-ip)        | Server IP Address (s-ip)    |
| Server Port (s-port)          | Server Port (s-port)            | Server Port (s-port)            | Server Port (s-port)        |
| Method (cs-method)            | Method (cs-method)              | Method (cs-method)              | Method (cs-method)          |
| URI Stem (cs-uri-stem)        | URI Stem (cs-uri-stem)          | URI Stem (cs-uri-stem)          | URI Stem (cs-uri-stem)      |
| URI Query (cs-uri-query)      | URI Query (cs-uri-query)        | URI Query (cs-uri-query)        | URI Query (cs-uri-query)    |
| Protocol Status (sc-status)   | Protocol Status (sc-status)     | Protocol Status (sc-status)     | Protocol Status (sc-status) |
| Protocol Version (cs-version) | User Agent (cs(User-Agent))     | User Agent (cs(User-Agent))     | User Agent (cs(User-Agent)) |
| User Agent (cs(User-Agent))   |                                 |                                 |                             |

8. Click **OK**, and then click **Apply**.

## What to do next

You are now ready to configure the log source in QRadar.

## Microsoft IIS log source parameters for Microsoft IIS Server

If QRadar does not automatically detect the log source, add a Microsoft IIS Server log source on the QRadar Console by using the Microsoft IIS protocol.

When using the Microsoft IIS protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Microsoft IIS events from a Microsoft IIS Server:

| Table 796. Microsoft IIS log source parameters for the Microsoft IIS Server DSM |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                                       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Log Source type</b>                                                          | Microsoft IIS Server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Protocol Configuration</b>                                                   | Microsoft IIS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Log Source Identifier</b>                                                    | Type the IP address or host name for the log source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>File Pattern</b>                                                             | Type the regular expression (regex) that is needed to filter the file names. All matching files are included in the processing. The default is <code>(?:u_)?ex.*\.(?:log LOG)</code><br><br>For example, to list all files that start with the word log, followed by one or more digits and ending with tar.gz, use the following entry: <code>log[0-9]+\tar\.\gz</code> . Use of this parameter requires knowledge of regular expressions (regex). For more information, see the following website: <a href="http://download.oracle.com/javase/tutorial/essential/regex/">http://download.oracle.com/javase/tutorial/essential/regex/</a> |

For a complete list of Microsoft IIS protocol parameters and their values, see [“Microsoft IIS protocol configuration options” on page 189](#).

## Microsoft ISA

The Microsoft Internet and Acceleration (ISA) DSM for IBM QRadar accepts events by using syslog.

You can integrate Microsoft ISA Server with QRadar by using WinCollect. For more information, see the *IBM QRadar WinCollect User Guide*.

**Note:** The Microsoft ISA DSM also supports events from Microsoft Threat Management Gateway by using WinCollect.

## Microsoft Office 365

The IBM QRadar DSM for Microsoft Office 365 collects events from Microsoft Office 365 online services.

**Important:** The Service Communications API endpoint is no longer available for use because it was deprecated by Microsoft. For more information, see [APAR IJ37562](https://www.ibm.com/support/pages/apar/IJ37562) (<https://www.ibm.com/support/pages/apar/IJ37562>).

The following table describes the specifications for the Microsoft Office 365 DSM:

Table 801. Microsoft Office 365 DSM specifications

| Specification | Value                                                         |
|---------------|---------------------------------------------------------------|
| Manufacturer  | Microsoft                                                     |
| DSM name      | Microsoft Office 365                                          |
| RPM file name | DSM-MicrosoftOffice365-QRadar_version-build_number.noarch.rpm |

*Table 801. Microsoft Office 365 DSM specifications (continued)*

| Specification               | Value                                                                                                                           |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Supported versions          | N/A                                                                                                                             |
| Protocol                    | Office 365 REST API                                                                                                             |
| Event format                | JSON                                                                                                                            |
| Recorded event types        | Exchange Audit, SharePoint Audit, Azure Active Directory Audit                                                                  |
| Automatically discovered?   | No                                                                                                                              |
| Includes identity?          | No                                                                                                                              |
| Includes custom properties? | No                                                                                                                              |

To integrate Microsoft Office 365 with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console.
  - Protocol Common RPM
  - Office 365 REST API Protocol RPM
  - Microsoft Office 365 DSM RPM
2. [Configure a Microsoft Office 365 account in the Microsoft Azure portal.](#)
3. Add a Microsoft Office 365 log source on the QRadar Console. For more information about adding a log source, see the “[Adding a log source](#)” on page 5 topic. The following table describes the log source parameters that require specific values for Microsoft Office 365 event collection:

*Table 802. Microsoft Office 365 log source parameters*

| Parameter              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Log Source type        | Microsoft Office 365                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Protocol Configuration | Office 365 REST API                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Log Source Identifier  | A unique identifier for the log source.<br>The <b>Log Source Identifier</b> can be any valid value and does not need to reference a specific server. The <b>Log Source Identifier</b> can be the same value as the <b>Log Source Name</b> . If you configured multiple Microsoft Office 365 log sources, you might want to identify the first log source as MSOffice365-1, the second log source as MSOffice365-2, and the third log source as MSOffice365-3. |
| Client ID              | In your application configuration of Azure Active Directory, this parameter is under <b>Client ID</b> .                                                                                                                                                                                                                                                                                                                                                       |
| Client Secret          | In your application configuration of Azure Active Directory, this parameter is under <b>Value</b> .                                                                                                                                                                                                                                                                                                                                                           |
| Tenant ID              | Used for Azure AD authentication.                                                                                                                                                                                                                                                                                                                                                                                                                             |

Table 802. Microsoft Office 365 log source parameters (continued)

| Parameter                   | Value                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Event Filter                | The type of audit events to retrieve from Microsoft Office. <ul style="list-style-type: none"><li>• Azure Active Directory</li><li>• Exchange</li><li>• SharePoint</li><li>• General</li><li>• DLP</li></ul>                                                                                                                                                         |
| Use Proxy                   | For QRadar to access the Office 365 Management APIs, all traffic for the log source travels through configured proxies.<br>Configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields.<br>If the proxy does not require authentication, keep the <b>Proxy Username</b> and <b>Proxy Password</b> fields empty. |

# Configuring a Microsoft Office 365 account in Microsoft Azure Active Directory

Before you can add a log source in QRadar, you must run the Azure Active Directory PowerShell cmdlet and then configure Azure Active Directory for Microsoft Office 365.

## Procedure

1. Run the Azure Active Directory PowerShell cmdlet. For more information, see [How to install and configure Azure PowerShell](https://azure.microsoft.com/en-us/documentation/articles/powershell-install-configure/) (<https://azure.microsoft.com/en-us/documentation/articles/powershell-install-configure/>).

2. Identify the **Tenant ID** of the tenant that is subscribed to Microsoft Office 365 by typing the following commands:

```
import-module MSOnline  
$userCredential = Get-Credential  
Connect-MsolService -Credential $userCredential  
Get-MsolAccountSku | % {$_.AccountObjectID}
```

Use the **Tenant ID** value for the **Tenant ID** value when you configure a log source in QRadar.

3. To use Azure Active Directory to register an application, log in to the [Azure Management Portal](https://portal.azure.com) (<https://portal.azure.com>) with the credentials of the tenant that is subscribed to Microsoft Office 365.

- a. From the navigation menu, select **Azure Active Directory**.
- b. From the **Overview** pane, select **App registrations**, and then click **New registration**.
- c. In the **Supported account types** section, select the type of account to use the application or to access the API.
- d. In the **Redirect URI (optional)** section, select **Web**, and type `http://localhost` in the **Web** field.
- e. Click **Register**, and then copy and store the **Application (client) ID** value. Use this value for the **Client ID** value when you configure a log source in QRadar.

4. Generate a client secret for the application.

- a. From the **Manage** pane, select **Certificates & secrets > New client secret**.
- b. Select an expiry period, and then click **Add**.
- c. Copy and store your client secret key value because it can't be retrieved later. Use this value for the **Client Secret** value when you configure a log source in QRadar.

5. Specify the permissions that the Microsoft Azure application must use to access Microsoft Office 365 Management APIs.

- a. From the **Manage** pane, select **API permissions**.
- b. Click **Add a permission >** from the API list, choose **Office 365 Management APIs > Delegated permissions**, and then select the following options:

Table 803. Delegated permissions

| Permission    | Values                                    |
|---------------|-------------------------------------------|
| Activity Feed | ActivityFeed.Read<br>ActivityFeed.ReadDlp |
| ServiceHealth | ServiceHealth.Read                        |

- c. Click **Application permissions**, and then select the following options:

Table 804. Application permissions

| Permission    | Values                                    |
|---------------|-------------------------------------------|
| Activity Feed | ActivityFeed.Read<br>ActivityFeed.ReadDlp |
| ServiceHealth | ServiceHealth.Read                        |

d. Click **Add permissions**.

e. In the **API permissions** window, go to the **Grant consent** section, click **Grant admin consent > Yes**.

## Microsoft Office 365 Message Trace

The IBM QRadar DSM for Microsoft Office 365 Message Trace collects JSON events from a Microsoft Office 365 Message Trace by using the Office 365 Message Trace API protocol.

To integrate Microsoft Office 365 Message Trace with QRadar, complete the following steps:

- If automatic updates are not enabled, download the most recent version of the following RPMs from the IBM support website (<http://www.ibm.com/support>):
  - Microsoft Office 365 Message Trace DSM RPM
  - Protocol Common RPM
  - Office 365 Message Trace API protocol RPM
- Add a Microsoft Office 365 Message Trace log source by using the Office 365 Message Trace REST API protocol on the QRadar Console. The Office 365 Message Trace REST API protocol supports both modern and basic authentication. Modern authentication uses OAuth 2.0 to authenticate and authorize access to the resource, while basic authentication uses a username and password.

**Important:** As of 1 January 2023, Microsoft will no longer support basic authentication. To continue receiving Message Trace events, you must use modern authentication. Modern authentication uses OAuth 2.0 to authenticate and authorize access to the events. For more information

about the deprecation of basic authentication, see [Basic Authentication Deprecation in Exchange Online – September 2022 Update](https://techcommunity.microsoft.com/t5/exchange-team-blog/basic-authentication-deprecation-in-exchange-online-september/ba-p/3609437) (<https://techcommunity.microsoft.com/t5/exchange-team-blog/basic-authentication-deprecation-in-exchange-online-september/ba-p/3609437>).

## Microsoft Office 365 Message Trace DSM specifications

When you configure Microsoft Office 365 Message Trace, understanding the specifications for the Microsoft Office 365 Message Trace DSM can help ensure a successful integration. For example, knowing what the supported version of Microsoft Office 365 Message Trace is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Microsoft Office 365 Message Trace DSM.

| <i>Table 807. Microsoft Office 365 Message Trace DSM specifications</i> |                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Microsoft Office Message Trace REST API log source parameters for Microsoft Office Message Trace

If QRadar does not automatically detect the log source, add a Microsoft Office Message Trace log source on the QRadar Console by using the Office 365 Message Trace REST API protocol.

When using the Microsoft Office 365 Message Trace REST API protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Microsoft Office 365 Message Trace REST API events from Microsoft Office 365 Message Trace:

*Table 808. Microsoft Office 365 Message Trace REST API log source parameters for the Microsoft Office 365 Message Trace DSM*

| Parameter                     | Value                                                                                                                                                                                             |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source type</b>        | Microsoft Office 365 Message Trace                                                                                                                                                                |
| <b>Protocol Configuration</b> | Office 365 Message Trace REST API                                                                                                                                                                 |
| <b>Log Source Identifier</b>  | A unique name for the log source.<br>The name can't include spaces and must be unique among all log sources of this type that are configured with the Office 365 Message Trace REST API protocol. |

For a complete list of Office 365 Message Trace REST API protocol parameters and their values, see [Office 365 Message Trace REST API protocol configuration options](#).

## Microsoft Office 365 Message Trace sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Microsoft Office 365 Message Trace sample message when you use the Office 365 Message Trace REST API protocol

The following sample event message shows that a message was successfully delivered to the intended destination.

```
{"Organization": "test.oncompany.test", "MessageId": "<32A2AAA5SAA4.AAAA00A6A2AA@AA00155AA5A4A6>", "Received": "2020-06-02T01:29:06.3627033", "SenderAddress": "username@domain.test", "RecipientAddress": "testRecep@test.oncompany.test", "Subject": "Azure AD Identity Protection Weekly Digest", "Status": "Delivered", "ToIP": null, "FromIP": "10.10.10.12", "Size": 76047, "MessageTraceId": "66f62cca-c8ce-4436-f519-08d80694575d", "StartDate": "2020-05-31T16:34:00Z", "EndDate": "2020-06-02T16:34:00Z", "Index": 0}
```

## JDBC log source parameters for Microsoft Operations Manager

If QRadar does not automatically detect the log source, add a Microsoft Operations Manager log source on the QRadar Console by using the JDBC protocol.

When using the JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from Microsoft Operations Manager:

| Table 810. JDBC log source parameters for the Microsoft Operations Manager DSM |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Log Source type</b>                                                         | Microsoft Operations Manager                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Protocol Configuration</b>                                                  | JDBC                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Log Source Identifier</b>                                                   | Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.<br><br>If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2. |
| <b>Database Type</b>                                                           | From the list, select <b>MSDE</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Database Name</b>                                                           | Type OnePoint as the name of the Microsoft Operations Manager database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>IP or Hostname</b>                                                          | Type the IP address or host name of the Microsoft Operations Manager SQL Server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Port</b>                                                                    | Type the port number that is used by the database server. The default port for MSDE is 1433.<br><br>The JDBC configuration port must match the listener port of the Microsoft Operations Manager database. The Microsoft Operations Manager database must have incoming TCP connections that are enabled to communicate with QRadar.<br><br>If you define a <b>Database Instance</b> when MSDE is used as the database type, you must leave the <b>Port</b> parameter blank in your configuration.                                                                                                                                                            |
| <b>Table Name</b>                                                              | Type SDKEventView as the name of the table or view that includes the event records.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Compare Field</b>                                                           | Type TimeStored as the compare field. The compare field is used to identify new events that are added between queries to the table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

For a complete list of JDBC protocol parameters and their values, see “[JDBC protocol configuration options](#)” on page 147.

## Microsoft SharePoint

---

The Microsoft SharePoint DSM for IBM QRadar collects audit events from the SharePoint database by using JDBC to poll an SQL database for audit events.

Audit events can track changes that are made to sites, files, and content that is managed by Microsoft SharePoint.

Microsoft SharePoint audit events include the following elements:

- Site name and the source from which the event originated
- Item ID, item name, and event location
- User ID associated with the event
- Event type, time stamp, and event action

Two log source configurations can be used to collect Microsoft SharePoint database events.

1. Create a database view in your SharePoint database to poll for events with the JDBC protocol. See [Creating a database view for Microsoft SharePoint](#).
2. Create a JDBC log source and use predefined database queries to collect SharePoint events. This option does not require an administrator to create database view. See “[JDBC log source parameters for Microsoft Share Point](#)” on page 1223.

**Note:** The collection of Microsoft Sharepoint events now uses a predefined query, instead of requiring an administrator to create a database view. If you are an administrator, you might want to update existing Microsoft Sharepoint log sources so that they use the Microsoft Sharepoint predefined query.

## Configuring Microsoft SharePoint audit events

The audit settings for Microsoft SharePoint give you the option to define what events are tracked for each site that is managed by Microsoft SharePoint.

#### Procedure

1. Log in to your Microsoft SharePoint site.
2. From the **Site Actions** list, select **Site Settings**.
3. From the **Site Collection Administration** list, click **Site collection audit settings**.
4. From the **Documents and Items** section, select a check box for each document and item audit event you want to audit.
5. From the **Lists, Libraries, and Sites** section, select a check box for each content audit event you want to enable.
6. Click **OK**.

#### What to do next

Create a database view for IBM QRadar to poll Microsoft SharePoint events.

#### Related tasks

[“Creating a database view for Microsoft SharePoint” on page 1222](#)

Microsoft SharePoint uses SQL Server Management Studio (SSMS) to manage the SharePoint SQL databases. To collect audit event data, you must create a database view on your Microsoft SharePoint server that is accessible to IBM QRadar.

## Creating a database view for Microsoft SharePoint

Microsoft SharePoint uses SQL Server Management Studio (SSMS) to manage the SharePoint SQL databases. To collect audit event data, you must create a database view on your Microsoft SharePoint server that is accessible to IBM QRadar.

### Before you begin

Do not use a period (.) in the name of your view, or in any of the table names. If you use a period in your view or table name, JDBC cannot access the data within the view and access is denied. Anything after a (.) is treated as a child object.

### Procedure

1. Log in to the system that hosts your Microsoft SharePoint SQL database.
  2. From the **Start** menu, select **Run**.
  3. Type the following command:  
`ssms`
  4. Click **OK**.
- The Microsoft SQL Server 2008 displays the **Connect to Server** window.
5. Log in to your Microsoft SharePoint database.
  6. Click **Connect**.
  7. From the **Object Explorer** for your SharePoint database, click **Databases > WSS\_Logging > Views**.
  8. From the navigation menu, click **New Query**.
  9. In the **Query** pane, type the following Transact-SQL statement to create the AuditEvent database view:

```
create view dbo.AuditEvent as select a.siteID  
  
,a.ItemId ,a.ItemType ,u.tp_Title as  
"User" ,a.MachineName ,a.MachineIp ,a.DocLocation ,a.LocationType ,a.Occurred as  
"EventTime" ,a.Event as "EventID" ,a.EventName ,a.EventSource ,a.SourceName ,a.EventData  
  
from WSS_Content.dbo.AuditData a, WSS_Content.dbo.UserInfo u where a.UserId = u.tp_ID and  
a.SiteId = u.tp_SiteID;
```

10. From the **Query** pane, right-click and select **Execute**.

If the view is created, the following message is displayed in the results pane:

`Command(s) completed successfully.`

The `dbo.AuditEvent` view is created. You are now ready to configure the log source in QRadar to poll the view for audit events.

## Creating read-only permissions for Microsoft SharePoint database users

Restrict user access on the SharePoint database by granting read-only permissions on objects.

### Procedure

1. From the **Object Explorer** in your SharePoint database, click **Security**. Expand the **Security** folder tree.
2. Right-click **Logins** and select **New Login**.

3. For Windows authentication, complete the following steps:
  - a) On the **General** page, click **Search**.
  - b) Click **Locations**. From the **Locations** page, select a location that the user belongs to and click **OK**.
  - c) Enter the object name in the text-box, and click **Check Names** to validate the user.

**Note:** Set the **Default database** to **WSS\_Logging**.

  - d) On the **Server Roles** page, select **public**.
  - e) On the **User Mapping** page, select the **WSS\_Content** and **WSS\_Logging**. In the **Default Schema** column, click ... > **Browse...** and select **db\_datareader** as the default schema.
  - f) On the **Status** page, select **Grant** permission to connect to the database engine and select **Enabled** login.
4. From the **Object Explorer** in your SharePoint database, click **Databases** > **WSS\_Logging** > **Security** > **Users**.
  - a) Double-click the Windows user that was created in step 3.
  - b) On the **Securables** page, click **Search**.
  - c) On the **Add Objects** page, select **Specific objects...** and click **OK**.
  - d) Click **Object Types...** and select **Views**.
  - e) For object names, click **Browse** and select the database view that you created. For example, **[dbo].[AuditEvent]**.
  - f) For the permissions of the database view you select, grant **Select**.
  - g) Click **OK**.
5. From the **Object Explorer** in your SharePoint database, click **Databases** > **WSS\_Content** > **Security** > **Users**.
  - a) Double-click the Windows user that was created in step 3.
  - b) On the **Securables** page, click **Search**.
  - c) On the **Add Objects** page, select **Specific objects...** and click **OK**.
  - d) Click **Object Types...** and select **Tables**.
  - e) For object names, click **Browse**. Select **[dbo].[AuditData]** and **[dbo].[UserInfo]**.
  - f) For the permissions of the **AuditData** table, grant **Select**.
  - g) For the permissions of the **UserInfo** table, grant **Select**.
  - h) Click **OK**.

## JDBC log source parameters for Microsoft Share Point

If QRadar does not automatically detect the log source, add a Microsoft SharePoint log source on the QRadar Console by using the JDBC protocol.

**Tip:** Ensure that firewall rules are not blocking the communication between QRadar and the database that is associated with Microsoft SharePoint.

The following table describes the parameters that require specific values to collect JDBC events from Microsoft SharePoint:

| Table 811. JDBC log source parameters for the Microsoft SharePoint DSM |                      |
|------------------------------------------------------------------------|----------------------|
| Parameter                                                              | Value                |
| <b>Log Source type</b>                                                 | Microsoft SharePoint |
| <b>Protocol Configuration</b>                                          | JDBC                 |

Table 811. JDBC log source parameters for the Microsoft SharePoint DSM (continued)

| Parameter                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source Identifier</b> | Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.<br><br>If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2. |
| <b>Database Type</b>         | From the list, select <b>MSDE</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Database Name</b>         | Type WSS_Logging as the name of the Microsoft SharePoint database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>IP or Hostname</b>        | Type the IP address or host name of the Microsoft SharePoint SQL Server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Port</b>                  | Type the port number that is used by the database server. The default port for MSDE is 1433.<br><br>The JDBC configuration port must match the listener port of the Microsoft SharePoint database. The Microsoft SharePoint database must have incoming TCP connections that are enabled to communicate with QRadar.<br><br>If you define a <b>Database Instance</b> when you use <b>MSDE</b> as the database type, you must leave the <b>Port</b> parameter blank in your configuration.                                                                                                                                                                     |
| <b>Table Name</b>            | Type AuditEvent as the name of the table or view that includes the event records.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Compare Field</b>         | Type EventTime as the compare field. The compare field is used to identify new events added between queries to the table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## JDBC log source parameters for Microsoft SharePoint with predefined database queries

Administrators who do not have permission to create a database view because of policy restrictions can collect Microsoft SharePoint events with a log source that uses predefined queries. If QRadar does not

automatically detect the log source, add a Microsoft SharePoint log source on the QRadar Console by using the JDBC protocol.

Predefined queries are customized statements that can join data from separate tables when the database is polled by the JDBC protocol.

**Tip:** Ensure that firewall rules are not blocking the communication between QRadar and the database that is associated with Microsoft SharePoint.

The following table describes the parameters that require specific values to collect JDBC events from Microsoft SharePoint:

| Table 812. JDBC log source parameters for the Microsoft SharePoint DSM |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Database Type</b>                                                   | From the list, select <b>MSDE</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Database Name</b>                                                   | Type WSS_Logging as the name of the Microsoft SharePoint database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>IP or Hostname</b>                                                  | Type the IP address or host name of the Microsoft SharePoint SQL Server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Port</b>                                                            | <p>Type the port number that is used by the database server. The default port for MSDE is 1433.</p> <p>The JDBC configuration port must match the listener port of the Microsoft SharePoint database. The Microsoft SharePoint database must have incoming TCP connections that are enabled to communicate with IBM QRadar.</p> <p>If you define a <b>Database Instance</b> when you use <b>MSDE</b> as the database type, you must leave the <b>Port</b> parameter blank in your configuration.</p>                                                  |
| <b>Predefined Query</b>                                                | From the list, select <b>Microsoft SharePoint</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

*Table 812. JDBC log source parameters for the Microsoft SharePoint DSM (continued)*

| Parameter                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Use Prepared Statements</b> | Select the <b>Use Prepared Statements</b> check box.<br>Prepared statements allow the JDBC protocol source to set up the SQL statement one time, then run the SQL statement many times with different parameters. For security and performance reasons, it is suggested that you use prepared statements.<br>Clearing this check box requires you to use an alternative method of querying that does not use pre-compiled statements. |
| <b>Use NTLMv2</b>              | Select the <b>Use NTLMv2</b> check box.<br>This option forces MSDE connections to use the NTLMv2 protocol when they communicate with SQL servers that require NTLMv2 authentication. The default value of the check box is selected.<br>If the <b>Use NTLMv2</b> check box is selected, it has no effect on MSDE connections to SQL servers that do not require NTLMv2 authentication.                                                |

For a complete list of JDBC protocol parameters and their values, see “[JDBC protocol configuration options](#)” on page 147.

## Microsoft SQL Server

The IBM QRadar DSM for Microsoft SQL Server collect SQL events by using the syslog, WinCollect Microsoft SQL, or JDBC protocol.

The following table identifies the specifications for the Microsoft SQL Server DSM:

*Table 813. Microsoft SQL Server DSM*

| Specification               | Value                                                                                                                                                                                                                                                |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Manufacturer                | Microsoft                                                                                                                                                                                                                                            |
| DSM name                    | SQL Server                                                                                                                                                                                                                                           |
| RPM file name               | DSM-MicrosoftSQL-QRadar-version- <i>Build_number</i> .noarch.rpm                                                                                                                                                                                     |
| Supported versions          | 2012, 2014 (Enterprise editions only), 2016, 2017, and 2019                                                                                                                                                                                          |
| Event format                | Syslog, JDBC, WinCollect                                                                                                                                                                                                                             |
| QRadar recorded event types | SQL error log events                                                                                                                                                                                                                                 |
| Automatically discovered?   | Yes                                                                                                                                                                                                                                                  |
| Includes identity?          | Yes                                                                                                                                                                                                                                                  |

You can integrate Microsoft SQL Server with QRadar by using one of the following methods:

### Syslog

The IBM QRadar DSM for Microsoft SQL Server can collect LOGbinder SQL events. For information about configuring LOGbinder SQL to collect events from your Microsoft SQL Server, see “[LOGbinder SQL event collection from Microsoft SQL Server](#)” on page 1138

### JDBC

Microsoft SQL Server Enterprise can capture audit events by using the JDBC protocol. The audit events are stored in a table view. Audit events are only available in Microsoft SQL Server 2012, 2014 Enterprise, and 2016.

### WinCollect

You can integrate Microsoft SQL Server 2012, 2014, 2016, 2017, and 2019 with QRadar by using WinCollect to collect ERRORLOG messages from the databases that are managed by your Microsoft SQL Server. For more information about WinCollect, go to the [WinCollect documentation](#) (<https://www.ibm.com/docs/en/qrip/7.5?topic=7-wincollect-overview>).

To integrate the Microsoft SQL Server DSM with QRadar, use the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the Microsoft SQL Server RPM from the [IBM Support Website](#) onto your QRadar Console.
2. For each instance of Microsoft SQL Server, configure your Microsoft SQL Server appliance to enable communication with QRadar.
3. If QRadar does not automatically discover the Microsoft SQL Server log source, create a log source for each instance of Microsoft SQL Server on your network.

### Related concepts

“[LOGbinder SQL event collection from Microsoft SQL Server](#)” on page 1138

The IBM QRadar DSM for Microsoft SQL Server can collect LOGbinder SQL events.

### Related tasks

“[Configuring your LOGbinder SQL system to send Microsoft SQL Server event logs to QRadar](#)” on page 1139

To collect Microsoft SQL Server LOGbinder events, you must configure your LOGbinder SQL system to send events to IBM QRadar.

“[Adding a DSM](#)” on page 4

“[Adding a log source](#)” on page 5

## Microsoft SQL Server preparation for communication with QRadar

To prepare Microsoft SQL Server for communication with QRadar, you must create an audit object, audit specification, and database view.

### Creating a Microsoft SQL Server auditing object

Create an auditing object to store audit events.

### Procedure

1. Log in to your Microsoft SQL Server Management Studio.
2. From the navigation menu, select **Security > Audits**.
3. Right-click **Audits** and select **New Audit**.
4. In the **Audit name** field, type a name for the new audit file.
5. From the **Audit destination** list, select **File**.
6. From the **File path** field, type the directory path for your Microsoft SQL Server audit file.
7. Click **OK**.

8. Right-click your audit object and select **Enable Audit**.

## Creating a Microsoft SQL Server audit specification

Create an audit specification to define the level of auditing events that are written to an audit file.

### Before you begin

You must create an audit object. For more information, see [“Creating a Microsoft SQL Server auditing object” on page 1227](#).

### About this task

You can create an audit specification at the server level or at the database level. Depending on your requirements, you might require both a server and database audit specification.

### Procedure

1. From the Microsoft SQL Server Management Studio navigation menu, select one of the following options:
  - **Security > Server Audit Specifications**
  - **<Database> > Security > Database Audit Specifications**
2. To enable Server or Database Audit, select one of the following options:
  - Right-click **Server Audit Specification**, then select **New Server Audit Specifications**
  - Right-click **Database Audit Specification**, then select **New Database Audit Specifications**
3. In the **Name** field, type a name for the new audit file.
4. From the **Audit** list, select the audit object that you created.
5. In the **Actions** pane, add actions and objects to the server audit.
6. Click **OK**.
7. Right-click your server audit specification and select one of the following options:
  - **Enable Server Audit Specification**
  - **Enable Database Audit Specification**

### What to do next

[Create a SQL Server database view.](#)

## Creating a Microsoft SQL Server database view

Create the dbo.AuditData database view to allow QRadar to poll for audit events from a database table by using the JDBC protocol. The database view contains the audit events from your server audit specification and database audit specification.

### Procedure

1. From the Microsoft SQL Server Management Studio toolbar, click **New Query**.
2. Type the following Transact-SQL statement:

```
create view dbo.AuditData as      SELECT * FROM sys.fn_get_audit_file      ('<Audit File Path  
and Name>',default,default);      GOa
```

For example:

```
create view dbo.AuditData as      SELECT * FROM sys.fn_get_audit_file  
('C:\inetpub\logs\SQLAudits*',default,default);      GO
```

3. From the Standard toolbar, click **Execute**.

## JDBC log source parameters for Microsoft SQL Server

If QRadar does not automatically detect the log source, add a Microsoft SQL Server log source on the QRadar Console by using the JDBC protocol.

When using the JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from Microsoft SQL Server:

| Table 814. JDBC log source parameters for the Microsoft SQL Server DSM |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Log Source type</b>                                                 | Microsoft SQL Server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Protocol Configuration</b>                                          | JDBC                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Log Source Identifier</b>                                           | Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.<br><br>If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2. |
| <b>Database Type</b>                                                   | From the list, select <b>MSDE</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Database Name</b>                                                   | Type <b>Master</b> as the name of the Microsoft SQL database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>IP or Hostname</b>                                                  | Type the IP address or host name of the Microsoft SQL server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Port</b>                                                            | Type the port number that is used by the database server. The default port for MSDE is 1433.<br><br>The JDBC configuration port must match the listener port of the Microsoft SQL database. The Microsoft SQL database must have incoming TCP connections that are enabled to communicate with QRadar.<br><br><b>Important:</b> If you define a <b>Database Instance</b> when you are using MSDE as the <b>Database Type</b> , you must leave the <b>Port</b> parameter blank in your configuration.                                                                                                                                                          |
| <b>Table Name</b>                                                      | Type <b>dbo . AuditData</b> as the name of the table or view that includes the audit event records.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Compare Field</b>                                                   | Type <b>event_time</b> in the <b>Compare Field</b> parameter. The <b>Compare Field</b> identifies new events that are added between queries, in the table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Microsoft SQL Server sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Microsoft SQL Server sample message when you use the Syslog protocol

The following sample event message shows a Microsoft SQL Server Drop Login event.

```

Table 815. Highlighted values in the Microsoft SQL Server sample event

| QRadar field name | Highlighted values in the event payload                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Event ID          | action_id + class_type                                                                                                           |
| Category          | When the Microsoft SQL Server DSM parses this type of event, the <b>Category</b> value in QRadar is always <b>MicrosoftSQL</b> . |
| Username          | session_server_principal_name                                                                                                    |
| Log Source Time   | event_time                                                                                                                       |

## JDBC log source parameters for Microsoft System Center Operations Manager

If QRadar does not automatically detect the log source, add a Microsoft System Center Operations Manager (SCOM) log source on the QRadar Console by using the JDBC protocol.

When using the JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from the Microsoft System Center Operations Manager:

| Table 816. JDBC log source parameters for the Microsoft System Center Operations Manager DSM |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Log Source type</b>                                                                       | Microsoft SCOM                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Protocol Configuration</b>                                                                | JDBC                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Log Source Identifier</b>                                                                 | <p>Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.</p> <p>If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2.</p> |
| <b>Database Type</b>                                                                         | From the list, select <b>MSDE</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Database Name</b>                                                                         | The name of the Microsoft SCOM database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>IP or Hostname</b>                                                                        | Type the IP address or host name of the Microsoft SCOM SQL Server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Port</b>                                                                                  | <p>Type the port number that is used by the database server. The default port for MSDE is 1433.</p> <p>The JDBC configuration port must match the listener port of the Microsoft SCOM database. The Microsoft SCOM database must have incoming TCP connections that are enabled to communicate with QRadar.</p> <p>If you define a <b>Database Instance</b> when MSDE is used as the database type, you must leave the <b>Port</b> parameter blank in your configuration.</p>                                                                                                                                                                                        |
| <b>Table Name</b>                                                                            | Type EventView as the name of the table or view that includes the event records.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Compare Field</b>                                                                         | Type <b>TimeAdded</b> as the compare field. The compare field is used to identify new events added between queries to the table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

For a complete list of JDBC protocol parameters and their values, see [JDBC protocol configuration options](#).

# Microsoft Windows Security Event Log

---

The IBM QRadar DSM for Microsoft Windows Security Event Log accepts syslog events from Microsoft Windows systems. All events, including Sysmon and winlogbeats.json, are supported.

**Important:** Support for the Windows Event Log protocols ended on 31 October 2022. To continue collecting Windows Event Log events, you must select a new protocol type from the list of supported protocols. For more information about the end of support, see [QRadar: End of life announcement for WMI-based Microsoft Windows Security Event Log protocols \(31 Oct 2022\)](#) (<https://www.ibm.com/support/pages/node/6616223>).

For event collection from Microsoft operating systems, QRadar supports the following protocols:

- Syslog (Intended for Snare, BalaBit, and other third-party Windows solutions).
- Forwarded. For more information, see [“Forwarded protocol configuration options” on page 117](#).
- TLS Syslog. For more information, see [“TLS Syslog protocol configuration options” on page 231](#).
- TCP Multiline Syslog. For more information, see [“TCP Multiline Syslog protocol configuration options” on page 226](#).
- MSRPC (Microsoft Security Event Log over MSRPC). For more information, see [“Microsoft Security Event Log over MSRPC protocol” on page 191](#).
- WinCollect. See the [IBM QRadar WinCollect User Guide](#).
- WinCollect NetApp Data ONTAP. See the [IBM QRadar WinCollect User Guide](#).
- Amazon Web Services protocol from AWS CloudWatch. For more information, see [“Amazon Web Services protocol configuration options” on page 83](#) and [How do I upload my Windows logs to CloudWatch?](#) (<https://aws.amazon.com/premiumsupport/knowledge-center/cloudwatch-upload-windows-logs/>).
- Microsoft Azure Event Hubs. For more information, see [Microsoft Azure Event Hubs protocol configuration options](#) and [Install and configure Windows Azure diagnostics extension \(WAD\) - Azure Monitor](#) (<https://docs.microsoft.com/en-us/azure/azure-monitor/platform/diagnostics-extension-windows-install>).

Ensure that you have an Azure storage account and an Azure event hub.

1. Optional: Create a storage account. For more information, see [Create a storage account](#) (<https://docs.microsoft.com/en-us/azure/storage/common/storage-account-create?tabs=azure-portal>).

**Important:** You must have a storage account to connect to an event hub. For more information, see [Microsoft Azure Event Hubs protocol FAQ](#).

2. Optional: Create an event hub. For more information, see [Quickstart: Create an event hub using Azure portal](#) (<https://docs.microsoft.com/en-us/azure/event-hubs/event-hubs-create>).

[MSRPC parameters on Windows hosts](#)

To enable communication between your Windows host and IBM QRadar over MSRPC, configure the Remote Procedure Calls (RPC) settings on the Windows host for the Microsoft Remote Procedure Calls (MSRPC) protocol.

[WMI parameters on Windows hosts](#)

Support for the Windows Event Log protocols ended on 31 October 2022.

## Installing the MSRPC protocol on the QRadar Console

You must install the MSRPC protocol RPM on the QRadar Console before events can be collected from a Windows host.

### Before you begin

Ensure that you download the MSRPC protocol RPM from the [IBM Support Website](#) onto your QRadar Console.

## Procedure

1. Log in to the QRadar Console as a root user.
2. Copy the MSRPC protocol RPM to a directory on the QRadar Console.
3. Go to the directory where you copied the MSRPC protocol RPM by typing the following command:

```
cd <path_to_directory>
```

4. Install the MSRPC protocol RPM by typing the following command:

```
yum -y install PROTOCOL-WindowsEventRPC-<version_number>.noarch.rpm
```

5. From the **Admin** tab of the QRadar Console, select **Advanced > Deploy Full Configuration**.
6. After you deploy the configuration, select **Advanced > Restart Web Server**.

## MSRPC parameters on Windows hosts

To enable communication between your Windows host and IBM QRadar over MSRPC, configure the Remote Procedure Calls (RPC) settings on the Windows host for the Microsoft Remote Procedure Calls (MSRPC) protocol.

You must be a member of the administrators group to enable communication over MSRPC between your Windows host and the QRadar appliance.

Based on performance tests on an IBM QRadar QRadar Event Processor 1628 appliance with 128 GB of RAM and 40 cores (Intel(R) Xeon(R) CPU E5-2680 v2 @ 2.80 GHz), a rate of 8500 events per second (eps) was achieved successfully, while simultaneously receiving and processing logs from other non-Windows systems. The log source limit is 500.

[Microsoft Windows Security Event Log](#)

The IBM QRadar DSM for Microsoft Windows Security Event Log accepts syslog events from Microsoft Windows systems. All events, including Sysmon and winlogbeats.json, are supported.

## Microsoft Security Event Log over MSRPC log source parameters for Microsoft Windows Security Event Log

If QRadar does not automatically detect the log source, add a Microsoft Windows Security Event Log log source on the QRadar Console by using the Microsoft Security Event Log over MSRPC protocol.

When using the Microsoft Security Event Log over MSRPC protocol, you must use some specific parameters.

The following table describes the parameters that require specific values to collect Microsoft Security Event Log over MSRPC events from Microsoft Windows Security Event Log:

*Table 817. Microsoft Security Event Log over MSRPC log source parameters for the Microsoft Windows Security Event Log DSM*

| Parameter                     | Value                                                                                                                                  |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source type</b>        | <b>Microsoft Windows Security Event Log</b>                                                                                            |
| <b>Protocol Configuration</b> | <b>Microsoft Security Event Log over MSRPC</b>                                                                                         |
| <b>Log Source Identifier</b>  | Type the IP address or hostname for the log source as an identifier for events from your Microsoft Windows Security Event Log devices. |

The following table lists the configuration options of the MSRPC protocol.

*Table 818. Configuration options for MSRPC protocol*

| Features               | Configuration options for MSRPC protocol                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Protocol type          | <p>The protocol type for collecting events through the remote procedure. The protocol type depends on your operating system.</p> <p>Select one of the following options from the <b>Protocol Type</b> list:</p> <p><b>MS-EVEN6</b><br/> The default protocol type for new log sources.<br/> The protocol type that is used by QRadar to communicate with Windows Vista and Windows Server 2012 and later.</p> <p><b>Important:</b> The <b>MS-EVEN (for Windows XP/2003)</b> option is no longer supported. However, it still appears in the <b>Protocol Type</b> list.</p> <p><b>auto-detect (for legacy configurations)</b><br/> Previous log source configurations for the Microsoft Windows Security Event Log DSM use the <b>auto-detect (for legacy configurations)</b> protocol type.<br/> Upgrade to the <b>MS_EVEN6</b> protocol type.</p> |
| Log Source Identifier  | An identifier string for this log source. It must not include spaces and must be unique among all log sources of the protocol type that is configured with the Windows Security Event Log over MSRPC protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Domain                 | If your username requires you to specify the domain, include it separately in this field rather than using <DOMAIN\USERNAME> as the username.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Username               | Username required to access the Windows host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Password               | Password required to access the Windows host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Polling Interval (sec) | The frequency at which the log source attempts to obtain data. The default value is 5000, but the upper limit of the protocol is around 100 EPS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

# Installing Winlogbeat and Logstash on a Windows host

To retrieve Winlogbeat JSON formatted events in QRadar, you must install Winlogbeat and Logstash on your Microsoft Windows host.

## Before you begin

Ensure that you are using the Oracle Java Development Kit V8 for Windows x64 and later.

## Procedure

1. Install Winlogbeat 7.7 by using the default values. For more information, see [Getting Started With Winlogbeat](https://www.elastic.co/guide/en/beats/winlogbeat/7.7/winlogbeat-getting-started.html) (<https://www.elastic.co/guide/en/beats/winlogbeat/7.7/winlogbeat-getting-started.html>).
2. Start the Winlogbeat service.

**Note:** For Windows services, the service name is Winlogbeat. After installation, the service is set to STOPPED, and then must be started for the first time. Any configuration changes beyond this point require a service restart.

3. Optional. For more flexibility when you configure Winlogbeat, see [Set up Winlogbeat](https://www.elastic.co/guide/en/beats/winlogbeat/7.7/configuration-winlogbeat-options.html) (<https://www.elastic.co/guide/en/beats/winlogbeat/7.7/configuration-winlogbeat-options.html>).
4. Install Logstash by downloading the package and saving it to a file location of your choice.
5. To ensure that Winlogbeat communicates properly with QRadar, see [Configure Winlogbeat to use Logstash](https://www.elastic.co/guide/en/beats/winlogbeat/7.7/config-winlogbeat-logstash.html) (<https://www.elastic.co/guide/en/beats/winlogbeat/7.7/config-winlogbeat-logstash.html>).

The following basic sample configuration file can be used in the <logstash\_install\_directory>/config file.

```
    input {      beats {          port => 5044      }      }      output {      tcp {          codec => host      }      }      host      beats {          port => 514          mode => "client"      }      stdio {          codec => rubydebug      }
```

### Notes:

- If you are using rubydebug, debugging must be enabled in the logstash.yml file. Uncomment the line `# log.level: info`, and replace info with debug. Restarting the service is required after any configuration changes.
  - The codec in output must be set to json\_lines to ensure that each event is sent separately to QRadar.
  - If you want to send Kafka output to an existing Kafka server, see [Configure the Kafka output](https://www.elastic.co/guide/en/beats/winlogbeat/7.7/kafka-output.html) (<https://www.elastic.co/guide/en/beats/winlogbeat/7.7/kafka-output.html>).
6. Ensure that Logstash is set up correctly by verifying that the config file for Logstash is working. Run the following command from the Logstash bin directory:

```
logstash --config.test_and_exit -f <path_to_config_file>
```

7. Ensure that Winlogbeat is configured correctly.

- a) Verify that the config file is working by running the following command from the winlogbeat directory:

```
./winlogbeat test config
```

- b) Verify that Winlogbeat can access the Logstash server by running the following command from the winlogbeat directory:

```
./winlogbeat test output
```

If the output of the ./winlogbeat test output command is successful, it might break any existing connection to Logstash. If the connection breaks, restart the Logstash service.

## What to do next

Add a log source in QRadar and use the parameters that are listed in “[Microsoft Windows Security Event Log log source parameters](#)” on page 1239.

## Microsoft Windows Security Event Log log source parameters

When you add a Microsoft Windows Security Event Log log source on the QRadar Console by using the Syslog protocol, there are specific parameters you must use.

The following table describes the parameters that require specific values to collect Syslog events from Microsoft Windows Security Event Log:

| Table 819. Microsoft Windows Security Event Log Syslog log source parameters for the Microsoft Windows Security Event Log DSM |                                      |
|-------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| Parameter                                                                                                                     | Value                                |
| <b>Log Source type</b>                                                                                                        | Microsoft Windows Security Event Log |
| <b>Protocol Configuration</b>                                                                                                 | Syslog                               |
| <b>Log Source Identifier</b>                                                                                                  | The host ID of the logstash server.  |

For a complete list of Syslog protocol parameters and their values, see [“Adding a log source” on page 5](#).

## Configuring which usernames QRadar considers to be system users in events that are collected from Microsoft Windows Security Event Log

By default, all user names in Microsoft Windows Security Event Log events that end with a dollar sign (\$) are considered as system users and are excluded from event parsing. If you want to change the way that IBM QRadar parses events, you can use the DSM Editor to include system users.

### Procedure

1. Click the **Admin** tab.
2. In the **Data Sources** section, click **DSM Editor**.
3. From the **Select Log Source Type** window, select **Windows Security Event Log** from the list, and click **Select**.
4. On the **Configuration** tab, set **Display DSM Parameters Configuration** to on.
5. From the **Event Collector** list, select the event collector for the log source.
6. If you want usernames that end with a dollar sign (\$) to *always* be considered as system users, set the **System User Criteria** parameter value to **Usernames Ending With A Dollar Sign Are Considered As System Users**.
7. If you want usernames that end with a dollar sign (\$) as system users *only when they match with the computer name*, set the **System User Criteria** parameter value to **Usernames Ending With a Dollar Sign If It Matches Computer Name Are Considered As System Users**.

**Tip:** A username is considered to match the computer name when the username (excluding the dollar sign) is equal to the computer name or, if the computer name is a fully-qualified domain name, the host component of the computer name. Letter case is ignored. For example, if the username is **HOST\$** and the computer name is **host** or **host.example.com**, then the username is considered to match the computer name.

8. If you want usernames that end with a dollar sign (\$) to *never* be considered as system users, set the **System User Criteria** parameter value to **Usernames Ending With a Dollar Sign Are Not Considered As System Users**.
9. Click **Save** and close out the DSM Editor.

**Tip:** If the **Include System User With (No) Identity** parameter value is set to **Include System User With No Identity** or **Include System User With Identity**, all system users are included in parsing, regardless of the **System User Criteria** parameter value.

## Configuring QRadar to parse the XML Level tag for application events that are collected from Microsoft Windows Security Event Log

By default, Microsoft Windows Security Event Log does not parse the level tag when it determines the QID for XML formatted application events. If you want to enable parsing of the Level tag for the Microsoft Windows Security Event Log DSM, use the DSM Editor to enable mapping.

### Procedure

1. Click the **Admin** tab.
2. In the **Data Sources** section, click **DSM Editor**.
3. From the **Select Log Source Type** window, select **Microsoft Windows Security Event Log** from the list, and click **Select**.
4. On the **Configuration** tab, set **Display DSM Parameters Configuration** to **on**.
5. From the **Event Collector** list, select the event collector for the log source.
6. Set **Enable XML Tag For XML Application events** to **on**.
7. Click **Save** and close out the DSM Editor.

## Microsoft Windows Security Event Log sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Microsoft Windows Security Event Log sample messages when you use WinCollect

The following sample has an event ID of 4624 that shows a successful login for the `<account_name>` user that has a source IP address of 10.0.0.1 and a destination IP of 10.0.0.2.

workstation_name Source Network Address: 10.0.0.1 Source Port: 0 Detailed Authentication
Information: Logon Process: User32 Authentication Package: Negotiate Transited Services:
- Package Name (NTLM only): - Key Length: 0 This event is generated when a logon session is
created. It is generated on the computer that was accessed. The subject fields indicate the
account on the local system which requested the logon. This is most commonly a service such as
the Server service, or a local process such as Winlogon.exe or Services.exe. The logon type
field indicates the kind of logon that occurred. The most common types are 2 (interactive) and
3 (network). The New Logon fields indicate the account for whom the new logon was created,
i.e. the account that was logged on. The network fields indicate where a remote logon request
originated. Workstation name is not always available and may be left blank in some cases. The
impersonation level field indicates the extent to which a process in the logon session can
impersonate. The authentication information fields provide detailed information about this
specific logon request. - Logon GUID is a unique identifier that can be used to correlate this
event with a KDC event. - Transited services indicate which intermediate services have
participated in this logon request. - Package name indicates which sub-protocol was used among
```

the NTLM protocols. - Key length indicates the length of the generated session key. This will be 0 if no session key was requested.

The following sample has an event ID of 4624 that shows a successful login for the <target\_user\_name> user that has a source IP address of 10.0.0.1.

## **Microsoft Windows Security Event Log sample message when you use Syslog to collect logs in Snare format**

The following sample has an event ID of 4724 that shows that an attempt was made to reset an account's password, and that the attempt was made by the account name Administrator.

**Important:** The logs that you send to QRadar must be tab-delimited. If you cut and paste the code from this sample, make sure that you press the tab key where indicated by the `<tab>` variables, then remove the variables.

```

## Azure Monitor Agent Support for Microsoft Windows Security Events Logs from Sentinel

Azure Monitor Agent (AMA) supports Microsoft Windows Security Event logs by using Microsoft Sentinel. Also, logs from AMA that arrives by using Event Hub, including Application and System logs, are also supported.

The following sample logs are supported.

### 1. Windows Security Event log (by using Sentinel from Event Hub)

```
{"TimeGenerated": "2025-02-12T11:13:35.1159672Z", "SourceSystem": "OpsManager", "Computer": "amawintestvm", "EventSourceName": "Microsoft-Windows-Security-Auditing", "Channel": "Security", "Task": 13571, "Level": "0", "EventLevelName": "LogAlways", "EventData": "<EventData xmlns='http://schemas.microsoft.com/win/2004/08/events/event'><Data

# Chapter 100. Motorola Symbol AP

The Motorola Symbol AP DSM for IBM QRadar records all relevant events forwarded from Motorola Symbol AP devices using syslog.

## Syslog log source parameters for Motorola SymbolAP

If QRadar does not automatically detect the log source, add a Motorola SymbolAP log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Motorola SymbolAP:

| Table 820. Syslog log source parameters for the Motorola SymbolAP DSM |                                                                                                                   |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| Parameter                                                             | Value                                                                                                             |
| <b>Log Source type</b>                                                | Motorola SymbolAP                                                                                                 |
| <b>Protocol Configuration</b>                                         | Syslog                                                                                                            |
| <b>Log Source Identifier</b>                                          | The IP address or host name for the log source as an identifier for events from your Motorola SymbolAP appliance. |

### Related tasks

[Adding a log source](#)

## Configure syslog events for Motorola Symbol AP

You can configure the device to forward syslog events to IBM QRadar.

### Procedure

1. Log in to your Symbol AP device user interface.
2. From the menu, select **System Configuration > Logging Configuration**.  
The Access Point window is displayed.
3. Using the **Logging Level** list, select the desired log level for tracking system events. The options are:
  - 0 - Emergency
  - 1 - Alert
  - 2 - Critical
  - 3 - Errors
  - 4 - Warning
  - 5 - Notice
  - 6 - Info. This is the default.
  - 7 - Debug
4. Select the Enable logging to an external syslog server check box.
5. In the **Syslog Server IP Address** field, type the IP address of an external syslog server, such as QRadar.

This is required to route the syslog events to QRadar.

6. Click **Apply**.

7. Click **Logout**.

A confirmation window is displayed.

8. Click **OK** to exit the application.

The configuration is complete. Events forwarded to QRadar are displayed on the **Log Activity** tab.

# Chapter 101. Name Value Pair

The Name Value Pair DSM gives you the option to integrate IBM QRadar with devices that might not normally send syslog logs.

The Name Value Pair DSM provides a log format that gives you the option to send logs to QRadar. For example, for a device that does not export logs natively with syslog, you can create a script to export the logs from a device that QRadar does not support, format the logs in the Name Value Pair log format, and send the logs to QRadar using syslog.

The Name Value Pair DSM log source that is configured in QRadar then receives the logs and is able to parse the data since the logs are received in the Name Value Pair log format.

**Tip:** Events for the Name Value Pair DSM are not automatically discovered by QRadar.

The Name Value Pair DSM accepts events by using syslog. QRadar records all relevant events. The log format for the Name Value Pair DSM must be a tab-separated single-line list of Name=Parameter. The Name Value Pair DSM does not require a valid syslog header.

**Note:** The Name Value Pair DSM assumes an ability to create custom scripts or thorough knowledge of your device capabilities to send logs to QRadar using syslog in Name Value Pair format.

The Name Value Pair DSM is able to parse the following tags:

| Table 821. Name Value Pair log format tags |                                                                                                                                                                                                                                                    |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Tag                                        | Description                                                                                                                                                                                                                                        |
| <b>DeviceType</b>                          | Type NVP as the <b>DeviceType</b> . This identifies the log formats as a Name Value Pair log message.<br><br>This is a required parameter and DeviceType=NVP must be the first pair in the list.                                                   |
| <b>EventName</b>                           | Type the event name that you want to use to identify the event in the Events interface when using the Event Mapping functions. For more information on mapping events, see the <i>IBM QRadar User Guide</i> .<br><br>This is a required parameter. |
| <b>EventCategory</b>                       | Type the event category that you want to use to identify the event in the Events interface. If this value is not included in the log message, the value NameValuePair value is used.                                                               |
| <b>SourceIp</b>                            | Type the source IP address for the message.                                                                                                                                                                                                        |
| <b>SourcePort</b>                          | Type the source port for the message.                                                                                                                                                                                                              |
| <b>SourceIpPreNAT</b>                      | Type the source IP address for the message before Network Address Translation (NAT) occurred.                                                                                                                                                      |
| <b>SourceIpPostNAT</b>                     | Type the source IP address for the message after NAT occurs.                                                                                                                                                                                       |
| <b>SourceMAC</b>                           | Type the source MAC address for the message.                                                                                                                                                                                                       |
| <b>SourcePortPreNAT</b>                    | Type the source port for the message before NAT occurs.                                                                                                                                                                                            |

Table 821. Name Value Pair log format tags (continued)

| Tag                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SourcePortPostNAT</b>      | Type the source port for the message after NAT occurs.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DestinationIp</b>          | Type the destination IP address for the message.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DestinationPort</b>        | Type the destination port for the message.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DestinationIpPreNAT</b>    | Type the destination IP address for the message before NAT occurs.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DestinationIpPostNAT</b>   | Type the IP address for the message after NAT occurs.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DestinationPortPreNAT</b>  | Type the destination port for the message before NAT occurs.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DestinationPortPostNAT</b> | Type the destination port for the message after NAT occurs.                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DestinationMAC</b>         | Type the destination MAC address for the message.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DeviceTime</b>             | Type the time that the event was sent, according to the device. The format is: YY/MM/DD hh:mm:ss. If no specific time is provided, the syslog header or <b>DeviceType</b> parameter is applied.                                                                                                                                                                                                                                                                       |
| <b>UserName</b>               | Type the user name that is associated with the event.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>HostName</b>               | Type the host name that is associated with the event. Typically, this parameter is only associated with identity events.                                                                                                                                                                                                                                                                                                                                              |
| <b>GroupName</b>              | Type the group name that is associated with the event. Typically, this parameter is only associated with identity events.                                                                                                                                                                                                                                                                                                                                             |
| <b>NetBIOSName</b>            | Type the NetBIOS name that is associated with the event. Typically, this parameter is only associated with identity events.                                                                                                                                                                                                                                                                                                                                           |
| <b>Identity</b>               | <p>Type TRUE or FALSE to indicate whether you want this event to generate an identity event.</p> <p>An identity event is generated if the log message contains the <b>SourceIp</b> (if the <b>IdentityUseSrcIp</b> parameter is set to TRUE) or <b>DestinationIp</b> (if the <b>IdentityUseSrcIp</b> parameter is set to FALSE) and one of the following parameters: <b>UserName</b>, <b>SourceMAC</b>, <b>HostName</b>, <b>NetBIOSName</b>, or <b>GroupName</b>.</p> |
| <b>IdentityUseSrcIp</b>       | <p>Type TRUE or FALSE (default).</p> <p>TRUE indicates that you want to use the source IP address for identity. FALSE indicates that you want to use the destination IP address for identity. This parameter is used only if the Identity parameter is set to TRUE.</p>                                                                                                                                                                                               |

Use these sample event messages to verify a successful integration with QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## Example 1

The following example parses all fields:

```
DeviceType=NVP EventName=Test
DestinationIpPostNAT=<IP_address>
DeviceTime=2007/12/14 09:53:49
SourcePort=1111 Identity=FALSE SourcePortPostNAT=3333
DestinationPortPostNAT=6666 HostName=testhost
DestinationIpPreNAT=<IP_address> SourcePortPreNAT=2222
DestinationPortPreNAT=5555 SourceMAC=<MAC_address>
SourceIp=<IP_address> SourceIpPostNAT=<IP_address>
NetBIOSName=<BIOS_name> DestinationMAC=<MAC_address>
EventCategory=Accept DestinationPort=4444
GroupName=testgroup SourceIpPreNAT=<IP_address>
UserName=<Username> DestinationIp=<IP_address>
```

```
DeviceType=NVP EventName=Test DestinationIpPostNAT=<IP_address> DeviceTime=2007/12/14
09:53:49 SourcePort=1111 Identity=FALSE SourcePortPostNAT=3333
DestinationPortPostNAT=6666 HostName=testhost DestinationIpPreNAT=<IP_address>
SourcePortPreNAT=2222 DestinationPortPreNAT=5555 SourceMAC=<MAC_address> SourceIp=<IP_address>
SourceIpPostNAT=<IP_address> NetBIOSName=<BIOS_name> DestinationMAC=<MAC_address>
EventCategory=Accept DestinationPort=4444 GroupName=testgroup SourceIpPreNAT=<IP_address>
UserName=<Username> DestinationIp=<IP_address>
```

## Example 2

The following example provides identity by using the destination IP address:

```
<133>Apr 16 12:41:00 192.0.2.1 namevaluepair:
DeviceType=NVP EventName=Test EventCategory=Accept
Identity=TRUE SourceMAC=<MAC_address>
SourceIp=<Source_IP_address> DestinationIp=<Destination_IP_address>
UserName=<Username>
```

```
<133>Apr 16 12:41:00 192.0.2.1 namevaluepair: DeviceType=NVP EventName=Test
EventCategory=Accept Identity=TRUE SourceMAC=<MAC_address> SourceIp=<Source_IP_address>
DestinationIp=<Destination_IP_address> UserName=<Username>
```

## Example 3

The following example provides identity by using the source IP address:

```
DeviceType=NVP EventName=Test
EventCategory=Accept DeviceTime=2007/12/14 09:53:49
SourcePort=5014 Identity=TRUE IdentityUseSrcIp=TRUE
SourceMAC=<MAC_address> SourceIp=<Source_IP_address>
DestinationIp=<Destination_IP_address>
DestinationMAC=<MAC_address> UserName=<Username>

DeviceType=NVP EventName=Test EventCategory=Accept DeviceTime=2007/12/14
09:53:49 SourcePort=5014 Identity=TRUE IdentityUseSrcIp=TRUE
SourceMAC=<MAC_address> SourceIp=<Source_IP_address> DestinationIp=<Destination_IP_address>
DestinationMAC=<MAC_address> UserName=<Username>
```

## Example 4

The following example provides an entry with no identity:

```
DeviceType=NVP EventName=Test
EventCategory=Accept DeviceTime=2007/12/14 09:53:49
SourcePort=5014 Identity=FALSE
SourceMAC=<MAC_address>
SourceIp=<Source_IP_address>
DestinationIp=<Destination_IP_address>
DestinationMAC=<MAC_address>
UserName=<Username>
```

```
DeviceType=NVP EventName=Test
EventCategory=Accept DeviceTime=2007/12/14 09:53:49
SourcePort=5014 Identity=FALSE
SourceMAC=<MAC_address>
SourceIp=<Source_IP_address>
DestinationIp=<Destination_IP_address>
```

```
DestinationMAC=<MAC_address>
UserName=<Username>
```

# Chapter 102. NCC Group DDoS Secure

The IBM QRadar DSM for NCC Group DDoS Secure collects events from NCC Group DDoS Secure devices.

The following table describes the specifications for the NCC Group DDoS Secure DSM:

| Table 822. NCC Group DDoS Secure DSM specifications |                                                                                                 |
|-----------------------------------------------------|-------------------------------------------------------------------------------------------------|
| Specification                                       | Value                                                                                           |
| Manufacturer                                        | NCC Group                                                                                       |
| DSM name                                            | NCC Group DDoS Secure                                                                           |
| RPM file name                                       | DSM-NCCGroupDDoS-Secure-QRadar_version-build_number.noarch.rpm                                  |
| Supported versions                                  | 5.13.1-2s to 5.16.1-0                                                                           |
| Protocol                                            | Syslog                                                                                          |
| Event format                                        | LEEF                                                                                            |
| Recorded event types                                | All events                                                                                      |
| Automatically discovered?                           | Yes                                                                                             |
| Includes identity?                                  | No                                                                                              |
| Includes custom properties?                         | No                                                                                              |
| More information                                    | <a href="https://www.nccgroup.trust/uk/">NCC Group website (https://www.nccgroup.trust/uk/)</a> |

To integrate NCC Group DDoS Secure with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM
  - NCC Group DDoS Secure DSM RPM
2. Configure your NCC Group DDoS Secure device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add an NCC Group DDoS Secure log source on the QRadar Console. The following table describes the parameters that require specific values to collect event from NCC Group DDoS Secure:

Table 823. NCC Group DDoS Secure log source parameters

| Parameter              | Value                 |
|------------------------|-----------------------|
| Log Source type        | NCC Group DDoS Secure |
| Protocol Configuration | Syslog                |

4. To verify that QRadar is configured correctly, review the following table to see an example of a normalized event message.

The following table shows a sample event message from NCC Group DDoS Secure:

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

Table 824. NCC Group DDoS Secure sample message

| Event name                   | Low level category | Sample log message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Configuring NCC Group DDoS Secure to communicate with QRadar

The NCC Group DDoS Secure DSM for IBM QRadar receives events from NCC Group DDoS Secure devices by using syslog in Log Event Extended Format (LEEF) format. QRadar records all relevant status and network condition events.

### Procedure

1. Log in to NCC Group DDoS Secure.
2. Go to the **Structured Syslog Server** window.
3. In the **Server IP Address(es)** field, type the IP address of the QRadar Console.
4. From the **Format** list, select **LEEF**.
5. Optional: If you do not want to use the default of `local0` in the **Facility** field, type a syslog facility value.
6. From the **Priority** list, select the syslog priority level that you want to include. Events that meet or exceed the syslog priority level that you select are forwarded to QRadar.
7. In the **Log Refresh (Secs)** field, specify a refresh update time for structured logs. The refresh update time is specified in seconds.
8. In the **Normal Peak Bandwidth** field, specify the expected normal peak bandwidth of the appliance.

---

## Chapter 103. NetApp Data ONTAP

IBM QRadar accepts events from a Windows host by using the WinCollect NetApp Data ONTAP plug-in.

For more information about NetApp Data ONTAP source parameters in WinCollect 10, see [Netapp Data ONTAP source](#).

For more information about configuring the WinCollect 7 plug-in for NetApp ONTAP, see [NetApp Data ONTAP configuration options](#).

# Chapter 104. Netgate pfSense

The IBM QRadar DSM for Netgate pfSense collects syslog events from a pfSense device.

To integrate Netgate pfSense with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:

- DSM Common RPM
- Netgate pfSense DSM RPM
- Linux DHCP DSM RPM (only if DHCP event logging is enabled)
- Sourcefire Snort DSM RPM (only if the Snort package for Netgate pfSense is installed and event logging is enabled)

Suricata events are not officially supported by the Sourcefire Snort DSM. However, they might be parsed by the Snort DSM.

2. Configure your Netgate pfSense device to send events to QRadar. For more information, see [Configuring Netgate pfSense to communicate with QRadar](#).

If you send Snort or Suricata events to QRadar, and the log source is not automatically detected, add a Snort log source on the QRadar Console. For more information, see [Syslog log source parameters for Open Source SNORT](#).

3. If QRadar does not automatically detect the log source, add a Netgate pfSense Syslog log source on the QRadar Console. For more information, see [Syslog log source parameters for Netgate pfSense](#).

If you send Snort or Suricata events to QRadar and QRadar does not automatically detect the log source, add a Snort log source on the QRadar Console. For more information, see [Syslog log source parameters for Open Source SNORT](#).

## Netgate pfSense DSM specifications

When you configure Netgate pfSense, understanding the specifications for the Netgate pfSense DSM can help ensure a successful integration. For example, knowing what the supported version of Netgate pfSense is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Netgate pfSense DSM.

| Table 825. Netgate pfSense DSM specifications |                                                           |
|-----------------------------------------------|-----------------------------------------------------------|
| Specification                                 | Value                                                     |
| Manufacturer                                  | Netgate                                                   |
| DSM name                                      | Netgate pfSense                                           |
| RPM file name                                 | DSM-NetgatePfSense-QRadar_version-build_number.noarch.rpm |
| Supported version                             | 2.4.4                                                     |
| Protocol                                      | Syslog                                                    |
| Event format                                  | CSV, Syslog                                               |

Table 825. Netgate pfSense DSM specifications (continued)

| Specification               | Value                                                                                                                                                                                                                                                                                                                |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Recorded event types        | System<br>Firewall<br>DNS<br>DHCP (when you use the Linux DHCP DSM)                                                                                                                                                                                                                                                  |
| Automatically discovered?   | Yes                                                                                                                                                                                                                                                                                                                  |
| Includes identity?          | Yes                                                                                                                                                                                                                                                                                                                  |
| Includes custom properties? | No                                                                                                                                                                                                                                                                                                                   |

## Configuring Netgate pfSense to communicate with QRadar

To send syslog messages to IBM QRadar, the Netgate pfSense remote logging options must be configured to specify a remote log server.

### Before you begin

If you want to send Snort IDS events to QRadar, ensure that the Snort package for Netgate pfSense is installed and configured. Snort is an open source network intrusion detection and prevention system.

### Procedure

1. Log in to your Netgate pfSense device.
2. Configure remote logging options for Netgate pfSense.
  - a) Select **Status > System Logs**.
  - b) Click the **Settings** tab and then go to the **Remote Logging Options** section.
  - c) Select a **Source Address**, or use the default.
  - d) Select an **IP Protocol** or use the default.
  - e) In the **Remote log servers** options section, enable **System Events**, **Firewall Events**, **DNS Events**, and **DHCP Events**.

**Important:** If the **System Events** logging option is enabled, **Unknown** or **Stored** events might occur because extra services that are installed by packages for Netgate pfSense can output log messages to the system log. Due to the large number of packages available for Netgate pfSense, the DSM was developed to support the base installation of the device. The DSM Editor can be used in this case to create custom parsing for any **Unknown** or **Stored** events that result from user installed packages. For more information about the DSM Editor, see the *IBM QRadar Administration Guide*.

**Important:** If DHCP events are enabled, you must create a Linux DHCP log source in QRadar to normalize the DHCP events. The Linux DHCP log source must be placed after Netgate pfSense log source in the parsing order. For more information, see [Syslog log source parameters for Linux DHCP](#) and [Adding a log source parsing order](#).

**Important:** If you send Snort or Suricata events to QRadar and the log source is not automatically detected, add a Snort log source on the QRadar Console For more information, see [Syslog log source parameters for Open Source SNORT](#).

**Important:** For DNS logs to be properly send to QRadar, complete the following steps. These steps apply only for the Unbound DNS Resolver, the default DNS service configured on Netgate pfSense. If you're running BIND instead of Unbound, these steps do not apply.

- a. Go to **Services > DNS Resolver**.
- b. On the General Settings tab, scroll down to Custom Options.
- c. Add the following lines in custom options.

```
server:  
log-replies:yes
```

- d. Click **Save**.
  - e. To confirm that Netgate pfSense is generating DNS logs, go to **Status > System logs**.
3. Optional: Configure the Snort service to output logs to the Netgate pfSense system log.
- a) Select **Service > Snort**.
  - b) On the **Snort Interface** tab, click **Edit this Snort interface mapping** (pencil icon).
  - c) In the **Alert Settings** section, enable **Send Alerts to System Log**.
  - d) Click **Save**.
  - e) On the **Snort Interface** tab, click **Restart Snort on this interface**.

## Syslog log source parameters for Netgate pfSense

If QRadar does not automatically detect the log source, add a Netgate pfSense log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Netgate pfSense:

| Table 826. Syslog log source parameters for the Netgate pfSense DSM |                 |
|---------------------------------------------------------------------|-----------------|
| Parameter                                                           | Value           |
| <b>Log Source type</b>                                              | Netgate pfSense |
| <b>Protocol Configuration</b>                                       | Syslog          |

For a list of common protocol parameters and their values, see [Adding a log source..](#)

## Netgate pfSense sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage returns or line feed characters.

### Netgate pfSense sample message when you use the Syslog protocol: name server DNS query

The following sample event message shows that the event indicates that a name server DNS query was made.

```
<30>Mar 17 00:35:02 unbound: [33068:6] info: 192.168.1.222 hostname.test. NS IN
```

```
<30>Mar 17 00:35:02 unbound: [33068:6] info: 192.168.1.222 hostname.test. NS IN
```

*Table 827. Highlighted fields in the Netgate pfSense sample event*

| QRadar field name | Highlighted payload field name |
|-------------------|--------------------------------|
| Event Name        | NS                             |
| Source IP         | <b>192.168.1.222</b>           |

### Netgate pfSense sample message when you use the Syslog protocol: firewall permit event

The following sample event message shows a firewall permit event.

```
<134>Mar 10 08:43:23 filterlog: 100,,,1581299744,hn0,match,pass,out,4,0x0,,127,46462,0,DF,6,tcp,52,192.168.0.10,192.168.2.3,10945,443,0,S,1283715954,,64240,,mss;nop;wscale;nop;nop;sackOK
```

```
<134>Mar 10 08:43:23 filterlog:  
100,,,1581299744,hn0,match,pass,out,4,0x0,,127,46462,0,DF,6,tcp,52,192.168.0.10,192.168.2.3,10945,443,0,S,1283715954,,64240,,mss;nop;wscale;nop;nop;sackOK
```

*Table 828. Highlighted fields in the Netgate pfSense sample event*

| QRadar field name | Highlighted payload field name |
|-------------------|--------------------------------|
| Event Name        | <b>pass</b>                    |
| Protocol          | <b>6</b> (TCP)                 |
| Source IP         | <b>192.168.0.10</b>            |
| Destination IP    | <b>192.168.2.3</b>             |
| Source Port       | <b>10945</b>                   |
| Destination Port  | <b>443</b>                     |

# Chapter 105. Netskope Active

The IBM QRadar DSM for Netskope Active collects events from your Netskope Active servers.

**Important:** The IBM QRadar DSM for Netskope Active is deprecated.

To continue taking advantage of this integration, please download the Netskope Security Cloud DSM from the [IBM Security App Exchange website](https://exchange.xforce.ibmcloud.com/hub/extension/ff97aaadc10ed96b0e05d1a1f24af2f7) (<https://exchange.xforce.ibmcloud.com/hub/extension/ff97aaadc10ed96b0e05d1a1f24af2f7>).

The following table identifies the specifications for the Netskope Active DSM:

| <i>Table 829. Netskope Active DSM specifications</i> |                                                                                                                          |
|------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Specification</b>                                 | <b>Value</b>                                                                                                             |
| Manufacturer                                         | Netskope                                                                                                                 |
| DSM name                                             | Netskope Active                                                                                                          |
| RPM file name                                        | DSM-NetskopeActive-Qradar_version-build_number.noarch.rpm                                                                |
| Protocol                                             | Netskope Active REST API                                                                                                 |
| Recorded event types                                 | Alert, All                                                                                                               |
| Automatically discovered?                            | No                                                                                                                       |
| Includes identity?                                   | Yes                                                                                                                      |
| More information                                     | <a href="http://www.netskope.com">Netskope Active website</a> ( <a href="http://www.netskope.com">www.netskope.com</a> ) |

To integrate Netskope Active DSM with QRadar complete the following steps:

**Note:** If multiple DSM RPMs are required, the integration sequence must reflect the DSM RPM dependency.

1. If automatic updates are not enabled, download and install the most recent version of the following DSMs from the [IBM Support Website](#) onto your QRadar Console.
  - Netskope Active DSM RPM
  - Netskope Active REST API Protocol RPM
  - PROTOCOL-Common RPM
2. Configure the required parameters, and use the following table for the Netskope Active log source specific parameters:

*Table 830. Netskope Active log source parameters*

| <b>Parameter</b>       | <b>Value</b>             |
|------------------------|--------------------------|
| Log Source type        | Netskope Active          |
| Protocol Configuration | Netskope Active REST API |

## Netskope Active REST API log source parameters for Netskope Active

---

If QRadar does not automatically detect the log source, add a Netskope Active log source on the QRadar Console by using the Netskope Active REST API protocol.

**Important:** The IBM QRadar DSM for Netskope Active is deprecated.

To continue taking advantage of this integration, please download the Netskope Security Cloud DSM from the [IBM Security App Exchange](https://exchange.xforce.ibmcloud.com/hub/extension/ff97aaadc10ed96b0e05d1a1f24af2f7) website (<https://exchange.xforce.ibmcloud.com/hub/extension/ff97aaadc10ed96b0e05d1a1f24af2f7>).

When using the Netskope Active REST API protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Netskope Active REST API events from Netskope Active:

| <i>Table 831. Netskope Active REST API log source parameters for the Netskope Active DSM</i> |                                                                                                                                                                                                                                                        |
|----------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                                                    | Value                                                                                                                                                                                                                                                  |
| <b>Log Source type</b>                                                                       | Netskope Active                                                                                                                                                                                                                                        |
| <b>Protocol Configuration</b>                                                                | Netskope Active REST API                                                                                                                                                                                                                               |
| <b>IP or Hostname</b>                                                                        | <customer_tenant_name>.goskope.com                                                                                                                                                                                                                     |
| <b>Authentication Token</b>                                                                  | The authentication token is generated in the Netskope WebUI and is the only credential that is required for <b>Netskope Active REST API</b> usage. To access the token generation option in the Netskope WebUI, select <b>Settings &gt; REST API</b> . |
| <b>Automatically Acquire Server Certificates</b>                                             | If you choose <b>Yes</b> from the list, QRadar automatically downloads the certificate and begins trusting the target server. The correct server must be entered in the <b>IP or Hostname</b> field.                                                   |
| <b>Throttle</b>                                                                              | The maximum number of events per second. The default is 5000.                                                                                                                                                                                          |
| <b>Recurrence</b>                                                                            | You can specify when the log source attempts to obtain data. The format is M/H/D for Minutes/Hours/Days. The default is 1 M.                                                                                                                           |
| <b>Collection Type</b>                                                                       | <b>All Events</b><br>Select to collect all events.<br><b>Alerts Only</b><br>Select to collect only alerts.                                                                                                                                             |

**Sample 2:** The following sample event message shows a successful user login audit event.

```
{"supporting_data":{"data_values":["XXX","XXXX"],"data_type":"user"},"severity_level":2,"time_stamp":1419922155,"organization_unit":"","ccl":unknown,"user":XXXXXX,"audit_log_event":"Login Successful","_id":XXXXXX,"type":admin_audit_logs,"appcategory":n/a}}
```

# Chapter 106. NGINX HTTP Server

The IBM QRadar DSM for NGINX HTTP Server collects Syslog events from an NGINX HTTP Server device.

To integrate NGINX HTTP Server with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - Apache HTTP Server DSM RPM
  - NGINX HTTP Server DSM RPM
2. Configure your NGINX HTTP Server device to send events to QRadar.
3. If QRadar does not automatically detect the log source, add an NGINX HTTP Server log source on the QRadar Console. The following table describes the parameters that require specific values to collect Syslog events from NGINX HTTP Server:

*Table 832. NGINX HTTP Server Syslog log source parameters*

| Parameter                     | Value                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source type</b>        | NGINX HTTP Server                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Protocol Configuration</b> | Syslog                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Log Source Identifier</b>  | The IPv4 address or host name that identifies the log source. If your network contains multiple devices that are attached to a single management console, specify the IP address of the individual device that created the event. A unique identifier, such as an IP address, prevents event searches from identifying the management console as the source for all of the events. |

## Configuring NGINX HTTP Server to communicate with QRadar

To collect events from NGINX HTTP Server, configure your NGINX HTTP Server device to forward Syslog events to QRadar.

### Procedure

1. Log in to your NGINX HTTP Server device.
2. Open the `nginx.conf` file.
3. Add the following LEEF format string under `http` block. For more information about configuring logging, see <https://docs.nginx.com/nginx/admin-guide/monitoring/logging/>.

```
LEEF:1.0|NGINX|NGINX|$nginx_version|$status|devTime=$time_local\tdevTimeFormat=dd/MMM/
yyyy:HH:mm:ss
Z|tsrc=$remote_addr\tdst=$server_addr\tdstPort=$server_port\tproto=$server_protocol\tusrName=
$remote_user\trequest=$request\tbody_bytes_sent=$body_bytes_sent\thttp_referer=$http_referer\
$http_true_client_ip=$http_true_client_ip\thttp_user_agent=$http_user_agent\thttt_x_header=$h
ttt_x_header\thttt_x_forwarded_for=$http_x_forwarded_for\trquest_time=$request_time\tpipea
m_response_time=$upstream_response_time\tpipe=$pipe\truri_query=$query_string\truri_path=$uri\t
cookie=$http_cookie
```

4. Add the following syslog server configuration under `http` block.

```
access_log syslog:server=QRadar_Server_IP:514,facility=Facility_Parameter qradar;
```

5. Save the configuration.
6. To verify the configuration, type the following command:

```
nginx -t
```

7. If NGINX is running, reload the configuration by typing the following command:

```
nginx -s reload
```

## NGINX HTTP Server sample event messages

Use these sample event messages as a way of verifying a successful integration with QRadar.

The following table provides sample event messages when you use the Syslog protocol for the NGINX HTTP Server DSM:

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

Table 834. NGINX HTTP Server sample message supported by NGINX HTTP Server.

| Event name         | Low-level category | Sample log message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

# Chapter 107. Niksun

The Niksun DSM for IBM QRadar records all relevant Niksun events by using the syslog protocol.

You can integrate NetDetector/NetVCR2005, version 3.2.1sp1\_2 with QRadar. Before you configure QRadar to integrate with a Niksun device, you must configure a log source and then enable syslog forwarding on your Niksun appliance. For more information about configuring Niksun, see your *Niksun appliance documentation*.

## Syslog log source parameters for Niksun

If QRadar does not automatically detect the log source, add a Niksun log source on the QRadar Console by using the syslog protocol.

The following table describes the parameters that require specific values to collect syslog events from Niksun:

| Table 835. Syslog log source parameters for the Niksun DSM |                                                                                                             |
|------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| Parameter                                                  | Value                                                                                                       |
| <b>Log Source type</b>                                     | Niksun 2005 v3.5                                                                                            |
| <b>Protocol Configuration</b>                              | Syslog                                                                                                      |
| <b>Log Source Identifier</b>                               | Type the IP address or host name for the log source as an identifier for events from your Niksun appliance. |

### Related tasks

[Adding a log source](#)

# Chapter 108. Nokia Firewall

The Check Point Firewall-1 DSM allows IBM QRadar to accept Check Point-based Firewall events sent from Nokia Firewall appliances by using syslog or OPSEC protocols.

## Integration with a Nokia Firewall by using syslog

This method gives you the option to configure your Nokia Firewall to accept Check Point syslog events that are forwarded from your Nokia Firewall appliance.

To configure IBM QRadar to integrate with a Nokia Firewall device, take the following steps:

1. Configure iptables on your QRadar Console or Event Collector to receive syslog events from Nokia Firewall.
2. Configure your Nokia Firewall to forward syslog event data.
3. Configure the events that are logged by the Nokia Firewall.
4. Optional. Configure a log source in QRadar.

### Configuring IPtables

Nokia Firewalls require a TCP reset (rst) or a TCP acknowledge (ack) from IBM QRadar on port 256 before they forward syslog events.

#### About this task

The Nokia Firewall TCP request is an online status request that is designed to ensure that QRadar is online and able to receive syslog events. If a valid reset or acknowledge is received from QRadar, then Nokia Firewall begins forwarding events to QRadar on UDP port 514. By default, QRadar does not respond to any online status requests from TCP port 256.

You must configure IPtables on your QRadar Console or any Event Collector that receives Check Point events from a Nokia Firewall to respond to an online status request.

#### Procedure

1. Using SSH, log in to QRadar as the root user.

Login: root

Password: <password>

2. Type the following command to edit the IPtables file:

`vi /opt/qradar/conf/iptables.pre`

The IPtables configuration file is displayed.

3. Type the following command to instruct QRadar to respond to your Nokia Firewall with a TCP reset on port 256:

`-A INPUT -s <IP address> -p tcp --dport 256 -j REJECT --reject-with tcp-reset`

Where <IP address> is the IP address of your Nokia Firewall. You must include a TCP reset for each Nokia Firewall IP address that sends events to your QRadar Console or Event Collector, for example,

- `-A INPUT -s <IP_address1>/32 -p tcp --dport 256 -j REJECT --reject-with tcp-reset`
- `-A INPUT -s <IP_address2>/32 -p tcp --dport 256 -j REJECT --reject-with tcp-reset`
- `-A INPUT -s <IP_address3>/32 -p tcp --dport 256 -j REJECT --reject-with tcp-reset`

4. Save your IPtables configuration.

- Type the following command to update IPTables in QRadar:  

```
./opt/qradar/bin/iptables_update.pl
```
- Repeat steps 1 - 5 to configure any additional QRadar Event Collectors that receive syslog events from a Nokia Firewall.

You are now ready to configure your Nokia Firewall to forward events to QRadar.

## Configuring syslog

To configure your Nokia Firewall to forward syslog events to IBM QRadar:

### Procedure

- Log in to the Nokia Voyager.
- Click **Config**.
- In the **System Configuration** pane, click **System Logging**.
- In the **Add new remote IP address to log to** field, type the IP address of your QRadar Console or Event Collector.
- Click **Apply**.
- Click **Save**.

You are now ready to configure which events are logged by your Nokia Firewall to the logger.

## Configuring the logged events custom script

To configure which events are logged by your Nokia Firewall and forwarded to IBM QRadar, you must configure a custom script for your Nokia Firewall.

### Procedure

- Using SSH, log in to Nokia Firewall as an administrative user.  

If you cannot connect to your Nokia Firewall, check that SSH is enabled. You must enable the command-line by using the Nokia Voyager web interface or connect directly by using a serial connection. For more information, see your *Nokia Voyager documentation*.
- Type the following command to edit your Nokia Firewall `rc.local` file:  

```
vi /var/etc/rc.local
```
- Add the following command to your `rc.local` file:  

```
$FWDIR/bin/fw log -ftn | /bin/logger -p local1.info &
```
- Save the changes to your `rc.local` file.  

The **terminal** is displayed.
- To begin logging immediately, type the following command:  

```
nohup $FWDIR/bin/fw log -ftn | /bin/logger -p local1.info &
```

You can now configure the log source in QRadar.

## Syslog log source parameters for Nokia Firewall

If QRadar does not automatically detect the log source, add a Nokia Firewall log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Nokia Firewall:

Table 836. Syslog log source parameters for the Nokia Firewall DSM

| Parameter                     | Value                                                                                                            |
|-------------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>Log Source type</b>        | Check Point                                                                                                      |
| <b>Protocol Configuration</b> | Syslog                                                                                                           |
| <b>Log Source Identifier</b>  | Use the IP address or host name for the log source as an identifier for events from your Nokia Firewall devices. |

#### Related tasks

[Adding a log source](#)

## Integration with a Nokia Firewall by using OPSEC

IBM QRadar can accept Check Point FireWall-1 events from Nokia Firewalls using the Check Point FireWall-1 DSM configured using the OPSEC/LEA protocol.

Before you configure QRadar to integrate with a Nokia Firewall device, you must:

1. Configure Nokia Firewall using OPSEC, see [“Configuring a Nokia Firewall for OPSEC” on page 1271](#).
2. Configure a log source in QRadar for your Nokia Firewall using the OPSEC LEA protocol, see [“OPSEC/LEA log source parameters for Nokia FireWall” on page 1272](#).

## Configuring a Nokia Firewall for OPSEC

You can configure Nokia Firewall by using OPSEC.

### Procedure

1. To create a host object for your IBM QRadar, open up the **Check Point SmartDashboard** GUI, and select **Manage > Network Objects > New > Node > Host**.
2. Type the Name, IP address, and an optional comment for your QRadar.
3. Click **OK**.
4. Select **Close**.
5. To create the OPSEC connection, select **Manage > Servers and OPSEC Applications > New > OPSEC Application Properties**.
6. Type the Name and an optional comment.  
The name that you type must be different from the name in [“Configuring a Nokia Firewall for OPSEC” on page 1271](#).
7. From the **Host drop-down** menu, select the QRadar host object that you created.
8. From **Application Properties**, select **User Defined as the Vendor Type**.
9. From **Client Entries**, select **LEA**.
10. Select **Communication** and enter an activation key to configure the Secure Internal Communication (SIC) certificate.
11. Select **OK** and then select **Close**.
12. To install the policy on your firewall, select **Policy > Install > OK**.

For more information on policies, see your vendor documentation. You can now configure a log source for your Nokia Firewall in QRadar.

## OPSEC/LEA log source parameters for Nokia FireWall

If QRadar does not automatically detect the log source, add a Nokia FireWall log source on the QRadar Console by using the OPSEC/LEA protocol.

When using the OPSEC/LEA protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect OPSEC/LEA events from a Nokia FireWall:

| Table 837. OPSEC/LEA log source parameters for the Nokia FireWall DSM |                                                                                                                                                                                     |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                             | Value                                                                                                                                                                               |
| <b>Log Source type</b>                                                | Check Point FireWall-1                                                                                                                                                              |
| <b>Protocol Configuration</b>                                         | OPSEC/LEA                                                                                                                                                                           |
| <b>Log Source Identifier</b>                                          | Type an IP address, host name, or name to identify the event source. IP addresses or host names are better because they enable QRadar to match a log file to a unique event source. |

For a complete list of OPSEC/LEA protocol parameters and their values, see “[OPSEC/LEA protocol configuration options](#)” on page 203.

## Chapter 109. Nominum Vantio

**Note:** The Nominum Vantio DSM for QRadar is deprecated.

---

# Chapter 110. Nortel Networks

Several Nortel Networks DSMs can be integrated with IBM QRadar.

## Nortel Multiprotocol Router

---

The Nortel Multiprotocol Router DSM for IBM QRadar records all relevant Nortel Multiprotocol Router events by using syslog.

### About this task

Before you configure QRadar to integrate with a Nortel Multiprotocol Router device, you must:

### Procedure

1. Log in to your Nortel Multiprotocol Router device.
2. At the prompt, type the following command:

```
bcc
```

The Bay Command Console prompt is displayed.

```
Welcome to the Bay Command Console!
```

- \* To enter configuration mode, type config
- \* To list all system commands, type ?
- \* To exit the BCC, type exit

```
bcc>
```

3. Type the following command to access configuration mode:

```
config
```

4. Type the following command to access syslog configuration:

```
syslog
```

5. Type the following commands:

```
log-host address <IP address>
```

Where <IP address> is the IP address of your QRadar.

6. View current default settings for your QRadar:

```
info
```

For example:

```
log-host/<IP_address># info
```

```
address <IP_address>
```

```
log-facility local0
```

```
state enabled
```

7. If the output of the command entered in “[Nortel Multiprotocol Router](#)” on page 1275 indicates that the state is not enabled, type the following command to enable forwarding for the syslog host:

```
state enable
```

8. Configure the log facility parameter:

```
log-facility local0
```

9. Create a filter for the hardware slots to enable them to forward the syslog events. Type the following command to create a filter with the name WILDCARD:

```
filter name WILDCARD entity all
```

10. Configure the slot-upper bound parameter:

```
slot-upper bound <number of slots>
```

Where *<number of slots>* is the number of slots available on your device. This parameter can require different configuration which depends on your version of Nortel Multiprotocol Router device, which determines the maximum number of slots available on the device.

11. Configure the level of syslog messages you want to send to your QRadar.

```
severity-mask all
```

12. View the current settings for this filter:

```
info
```

For example:

```
filter/<IP_address>/WILDCARD# info
debug-map debug
entity all
event-lower-bound 0
event-upper-bound 255
fault-map critical
info-map info
name WILDCARD
severity-mask {fault warning info trace debug}
slot-lower-bound 0
slot-upper-bound 1
state enabled
trace-map debug
warning-map warning
```

13. View the currently configured settings for the syslog filters:

```
show syslog filters
```

When the syslog and filter parameters are correctly configured, the Operational State indicates up.

For example:

```
syslog# show syslog filters
show syslog filters Sep 15, 2008 18:21:25 [GMT+8]
```

Table 838. Syslog filters

| Host IP address | Filter Name | Entity Name | Entity Code | Configured State | Operational State |
|-----------------|-------------|-------------|-------------|------------------|-------------------|
| <IP_address1>   | WILDCARD    | all         | 255         | enabled          | up                |
| <IP_address2>   | WILDCARD    | all         | 255         | enabled          | up                |

14. View the currently configured syslog host information:

```
show syslog log-host
```

The host log displays the number of packets that are going to the various syslog hosts.

For example:

```
syslog# show syslog log-host
```

```
show syslog log-host Sep 15, 2008 18:21:32 [GMT+8]
```

*Table 839. Syslog host log*

| Host IP address | Configured State | Operational State | Time Sequencing | UDP Port | Facility Code | #Messages Sent |
|-----------------|------------------|-------------------|-----------------|----------|---------------|----------------|
| <IP_address 1>  | enabled          | up                | disabled        | 514      | local0        | 1402           |
| <IP_address 2>  | enabled          | up                | disabled        | 514      | local0        | 131            |

15. Exit the command line interface:

a) Exit the current command line to return to the bcc command line:

```
exit
```

16. Exit the bcc command line:

```
exit
```

17. Exit the command-line session:

```
logout
```

18. You can now configure the log source in QRadar.

To configure QRadar to receive events from a Nortel Multiprotocol Router device:

a) From the **Log Source Type** list, select the **Nortel Multiprotocol Router** option.

## Nortel Application Switch

Nortel Application Switches integrate routing and switching by forwarding traffic at layer 2 speed by using layer 4-7 information.

### About this task

The Nortel Application Switch DSM for IBM QRadar accepts events by using syslog. QRadar records all relevant status and network condition events. Before you configure a Nortel Application Switch device in QRadar, you must configure your device to send syslog events to QRadar.

To configure the device to send syslog events to QRadar:

### Procedure

1. Log in to the Nortel Application Switch command-line interface (CLI).

2. Type the following command:

```
/cfg/sys/syslog/host
```

3. At the prompt, type the IP address of your QRadar:

Enter new syslog host: <IP address>

Where <IP address> is the IP address of your QRadar.

4. Apply the configuration:

apply

5. After the new configuration is applied, save your configuration:

save

6. Type y at the prompt to confirm that you want to save the configuration to flash.

See the following example:

```
Confirm saving to FLASH [y/n]: y
```

```
New config successfully saved to FLASH
```

Next you will need to configure QRadar to receive events from a Nortel Application Switch:

7. Configure the log source in QRadar. From the **Log Source Type** list, select the **Nortel Application Switch** option.

For more information about the Nortel Application Switch, see your vendor documentation.

## Nortel Contivity

---

A QRadar Nortel Contivity DSM records all relevant Nortel Contivity events by using syslog.

### About this task

Before you configure QRadar to integrate with a Nortel Contivity device, take the following steps:

### Procedure

1. Log in to the Nortel Contivity command-line interface (CLI).

2. Type the following command:

```
enable <password>
```

Where <password> is the Nortel Contivity device administrative password.

3. Type the following command:

```
config t
```

4. Configure the logging information:

```
logging <IP address> facility-filter all level all
```

Where <IP address> is the IP address of the QRadar.

5. Type the following command to exit the command-line:

```
exit
```

Next you will need to configure QRadar to receive events from a Nortel Contivity device.

6. You can now configure the log source in QRadar. From the **Log Source Type** list, select the **Nortel Contivity VPN Switch**

For more information about your Nortel Contivity device, see your vendor documentation.

## Nortel Ethernet Routing Switch 2500/4500/5500

---

The IBM QRadar Nortel Ethernet Routing Switch (ERS) 2500/4500/5500 DSM records all relevant routing switch events by using syslog.

### About this task

Before configuring a Nortel ERS 2500/4500/5500 device in QRadar, you must configure your device to send syslog events to QRadar.

To configure the device to send syslog events to QRadar:

### Procedure

1. Log in to the Nortel ERS 2500/4500/5500 user interface.
2. Type the following commands to access global configuration mode:

```
ena
```

```
config term
```

3. Type informational as the severity level for the logs you want to send to the remote server.

```
For example, logging remote level {critical|informational|serious|none}
```

```
logging remote level informational
```

Where a severity level of informational sends all logs to the syslog server.

4. Enable the host:

```
host enable
```

5. Type the remote logging address:

```
logging remote address <IP address>
```

Where <IP address> is the IP address of the QRadar system.

6. Ensure that remote logging is enabled:

```
logging remote enable
```

You can now configure the log source in QRadar.

7. To configure to receive events from a Nortel ERS 2500/4500/5500 device: From the **Log Source Type** list, select the **Nortel Ethernet Routing Switch 2500/4500/5500** option.

## Nortel Ethernet Routing Switch 8300/8600

---

The IBM QRadar Nortel Ethernet Routing Switch (ERS) 8300/8600 DSM records all relevant events by using syslog.

### About this task

Before you configure a Nortel ERS 8600 device in QRadar, you must configure your device to send syslog events to QRadar.

To configure the device to send syslog events to QRadar:

### Procedure

1. Log in to the Nortel ERS 8300/8600 command-line interface (CLI).

2. Type the following command:

```
config sys syslog host <ID>
```

Where <ID> is the ID of the host you wish to configure to send syslog events to QRadar.

For the syslog host ID, the valid range is 1 - 10.

3. Type the IP address of your QRadar system:

```
address <IP address>
```

Where <IP address> is the IP address of your QRadar system.

4. Type the facility for accessing the syslog host.

```
host <ID> facility local0
```

Where <ID> is the ID specified in “[Nortel Ethernet Routing Switch 8300/8600](#)” on page 1279.

5. Enable the host:

```
host enable
```

6. Type the severity level for which syslog messages are sent:

```
host <ID> severity info
```

Where <ID> is the ID specified in “[Nortel Ethernet Routing Switch 8300/8600](#)” on page 1279.

7. Enable the ability to send syslog messages:

```
state enable
```

8. Verify the syslog configuration for the host:

```
sylog host <ID> info
```

For example, the output might resemble the following:

```
ERS-8606:5/config/sys/syslog/host/1# info Sub-Context: Current Context:  
address : 192.0.2.1 create : 1 delete : N/A facility : local6 host : enable  
mapinfo : info mapwarning : warning maperror : error mapfatal : emergency  
severity : info|warning|error|fatal udp-port : 514 ERS-8606:5/config/sys/  
syslog/host/1#
```

You can now configure the log source in QRadar.

9. To configure QRadar to receive events from a Nortel ERS 8300/8600 device: From the **Log Source Type** list, select the **Nortel Ethernet Routing Switch 8300/8600** option.

## Nortel Secure Router

---

The IBM QRadar Nortel Secure Router DSM records all relevant router events by using syslog.

### About this task

Before you configure a Nortel Secure Router device in QRadar, you must configure your device to send syslog events to QRadar.

To configure the device to send syslog events to QRadar:

### Procedure

1. Log in to the Nortel Secure Router command line interface (CLI).

2. Type the following to access global configuration mode:

```
config term
```

3. Type the following command:

```
system logging syslog
```

4. Type the IP address of the syslog server (QRadar system):

```
host_ipaddr <IP address>
```

Where *<IP address>* is the IP address of the QRadar system.

5. Ensure that remote logging is enabled:

```
enable
```

6. Verify that the logging levels are configured correctly:

```
show system logging syslog
```

The following code is an example of the output:

```
----- Syslog Setting
----- Syslog:
Enabled Host IP Address: <IP_address> Host UDP Port: 514
Facility Priority Setting:
facility priority
=====
auth: info
bootp: warning
daemon: warning
domainname: warning
gated: warning
kern: info
mail: warning
ntp: warning
system: info
fr: warning
ppp: warning
ipmux: warning
bundle: warning
qos: warning
hdlc: warning
local7: warning
vpn: warning
firewall: warning
```

You can now configure the log source in QRadar.

7. To configure QRadar to receive events from a Nortel Secure Router device: From the **Log Source Type** list, select the **Nortel Secure Router** option.

#### Related tasks

## Nortel Secure Network Access Switch

---

The IBM QRadar Nortel Secure Network Access Switch (SNAS) DSM records all relevant switch events by using syslog.

### About this task

Before you configure a Nortel SNAS device in QRadar, take the following steps:

### Procedure

1. Log in to the Nortel SNAS user interface.
2. Select the **Config** tab.
3. Select **Secure Access Domain and Syslog** from the **Navigation** pane.

The **Secure Access Domain** window is displayed.

4. From the **Secure Access Domain** list, select the **secure access domain**. Click **Refresh**.
5. Click **Add**.

The **Add New Remote Server** window is displayed.

6. Click **Update**.

The server is displayed in the secure access domain table.

7. Using the toolbar, click **Apply** to send the current changes to the Nortel SNAS.

You are now ready to configure the log source in QRadar.

8. To configure QRadar to receive events from a Nortel SNAS device: From the **Log Source Type** list, select the **Nortel Secure Network Access Switch (SNAS)** option.

## Nortel Switched Firewall 5100

---

A IBM QRadar Nortel Switched Firewall 5100 DSM records all relevant firewall events by using either syslog or OPSEC.

Before you configure a Nortel Switched Firewall device in QRadar, you must configure your device to send events to QRadar.

See information about configuring a Nortel Switched Firewall by using one the following methods:

- [“Integrating Nortel Switched Firewall by using syslog” on page 1282](#)
- [“Integrate Nortel Switched Firewall by using OPSEC” on page 1283](#)

## Integrating Nortel Switched Firewall by using syslog

This method ensures the IBM QRadar Nortel Switched Firewall 5100 DSM accepts events by using syslog.

### About this task

To configure your Nortel Switched Firewall 5100:

### Procedure

1. Log into your Nortel Switched Firewall device command-line interface (CLI).
2. Type the following command:

/cfg/sys/log/syslog/add

3. Type the IP address of your QRadar system at the following prompt:

Enter IP address of syslog server:

A prompt is displayed to configure the severity level.

4. Configure **info** as the severity level.

For example, Enter minimum logging severity

(emerg | alert | crit | err | warning | notice | info | debug): info

A prompt is displayed to configure the facility.

5. Configure **auto** as the local facility.

For example, Enter the local facility (auto | local0-local17): auto

6. Apply the configuration:

apply

7. Repeat for each firewall in your cluster.

You are now ready to configure the log source in QRadar.

8. To configure QRadar to receive events from a Nortel Switched Firewall 5100 device by using syslog:

From the **Log Source Type** list, select the **Nortel Switched Firewall 5100** option.

# Nortel Switched Firewall 6000

---

A IBM QRadar Nortel Switched Firewall 6000 DSM records all relevant firewall events by using either syslog or OPSEC.

Before you configure a Nortel Switched Firewall device in QRadar, you must configure your device to send events to QRadar.

The following information is about configuring a Nortel Switched Firewall 6000 device with QRadar by using one of the following methods:

- [“Configuring syslog for Nortel Switched Firewalls” on page 1284](#)
- [“Configuring OPSEC for Nortel Switched Firewalls ” on page 1285](#)

## Configuring syslog for Nortel Switched Firewalls

This method ensures the IBM QRadar Nortel Switched Firewall 6000 DSM accepts events by using syslog.

### About this task

To configure your Nortel Switched Firewall 6000:

### Procedure

1. Log into your Nortel Switched Firewall device command-line interface (CLI).
2. Type the following command:

```
/cfg/sys/log/syslog/add
```

3. Type the IP address of your QRadar system at the following prompt:

```
Enter IP address of syslog server:
```

A prompt is displayed to configure the severity level.

4. Configure **info** as the severity level.

```
For example, Enter minimum logging severity
```

```
(emerg | alert | crit | err | warning | notice | info | debug): info
```

A prompt is displayed to configure the facility.

5. Configure **auto** as the local facility.

```
For example, Enter the local facility (auto | local0-local17): auto
```

6. Apply the configuration:

```
apply
```

You can now configure the log source in QRadar.

7. To configure QRadar to receive events from a Nortel Switched Firewall 6000 using syslog: From the Log Source Type list, select the **Nortel Switched Firewall 6000** option.

# Configuring OPSEC for Nortel Switched Firewalls

This method ensures the IBM QRadar Nortel Switched Firewall 6000 DSM accepts Check Point FireWall-1 events by using OPSEC.

## About this task

Depending on your Operating System, the procedures for the Check Point SmartCenter Server can vary. The following procedures are based on the Check Point SecurePlatform Operating system.

To enable Nortel Switched Firewall and QRadar integration, take the following steps:

## Procedure

1. Reconfigure Check Point SmartCenter Server. See [“Reconfiguring the Check Point SmartCenter Server” on page 1285](#).

2. Configure the OPSEC LEA protocol in QRadar.

To configure QRadar to receive events from a Check Point SmartCenter Server that uses OPSEC LEA, you must select the **LEA** option from the **Protocol Configuration** list when you configure LEA.

3. Configure the log source in QRadar.

To configure QRadar to receive events from a Nortel Switched Firewall 6000 device using OPSEC you must select the **Nortel Switched Firewall 6000** option from the **Log Source Type** list.

## Related concepts

# Reconfiguring the Check Point SmartCenter Server

In the Check Point SmartCenter Server, you can create a host object that represents the IBM QRadar system. The *lepipe* is the connection between the Check Point SmartCenter Server and QRadar.

## About this task

To reconfigure the Check Point SmartCenter Server:

## Procedure

1. To create a host object, open the Check Point SmartDashboard user interface and select **Manage > Network Objects > New > Node > Host**.
2. Type the Name, IP address, and type a comment for your host if you want.
3. Click **OK**.
4. Select **Close**.
5. To create the OPSEC connection, select **Manage > Servers and OPSEC applications > New > OPSEC Application Properties**.
6. Type the Name, and type a comment if you want.

The name that you type must be different from the name in [“Reconfiguring the Check Point SmartCenter Server” on page 1285](#).

7. From the **Host** drop-down menu, select the host object that you have created in [“Reconfiguring the Check Point SmartCenter Server” on page 1285](#).
8. From **Application Properties**, select **User Defined** as the vendor.
9. From **Client Entries**, select **LEA**.

10. Click **Communication** to generate a Secure Internal Communication (SIC) certificate and enter an activation key.
11. Click **OK** and then click **Close**.
12. To install the Security Policy on your firewall, select **Policy > Install > OK**.

The configuration is complete.

## Nortel Threat Protection System (TPS)

---

The IBM QRadar Nortel Threat Protection System (TPS) DSM records all relevant threat and system events by using syslog.

### About this task

Before you configure a Nortel TPS device in QRadar, take the following steps:

### Procedure

1. Log in to the Nortel TPS user interface.
2. Select **Policy & Response > Intrusion Sensor > Detection & Prevention**.  
The **Detection & Prevention** window is displayed.
3. Click **Edit** next to the intrusion policy you want to configure alerting option.  
The **Edit Policy** window is displayed.
4. Click **Alerting**.  
The **Alerting** window is displayed.
5. Under **Syslog Configuration**, select **on next to State** to enable *syslog alerting*.
6. From the list, select the facility and priority levels.
7. Optional: In the **Logging Host** field, type the IP address of your QRadar system. This configures your QRadar system to be your logging host. Separate multiple hosts with commas.
8. Click **Save**.  
The *syslog alerting* configuration is saved.
9. Apply the policy to your appropriate detection engines.  
You can now configure the log source in QRadar.

10. To configure QRadar to receive events from a Nortel TPS device: From the **Log Source Type** list, select the **Nortel Threat Protection System (TPS) Intrusion Sensor** option.

## Nortel VPN Gateway

---

The IBM QRadar Nortel VPN Gateway DSM accepts events by using syslog.

### About this task

QRadar records all relevant operating system (OS), system control, traffic processing, startup, configuration reload, AAA, and IPsec events. Before you configure a Nortel VPN Gateway device in QRadar, you must configure your device to send syslog events to QRadar.

To configure the device to send syslog events to QRadar:

## Procedure

1. Log in to the Nortel VPN Gateway command-line interface (CLI).
2. Type the following command:

```
/cfg/sys/syslog/add
```

3. At the prompt, type the IP address of your QRadar system:

```
Enter new syslog host: <IP address>
```

Where *<IP address>* is the IP address of your QRadar system.

4. Apply the configuration:

```
apply
```

5. View all syslog servers currently added to your system configuration:

```
/cfg/sys/syslog/list
```

You can now configure the log source in QRadar.

6. To configure QRadar to receive events from a Nortel VPN Gateway device: From the **Log Source Type** list, select the **Nortel VPN Gateway** option.

# Chapter 111. Novell eDirectory

The Novell eDirectory DSM for IBM QRadar accepts audit events from Novell eDirectory using syslog.

To use the Novell eDirectory DSM, you must have the following components installed:

- Novell eDirectory v8.8 with service pack 6 (sp6)
- Novell Audit Plug-in
- Novell iManager v2.7
- XDASv2

To configure Novell eDirectory with QRadar, you must:

1. Configure the XDASv2 property file to forward events to QRadar.
2. Load the XDASv2 module on your Linux or Windows Operating System.
3. Install the Novell Audit Plug-in on the Novell iManager.
4. Configure auditing using Novell iManager.
5. Configure QRadar.

## Configuring XDASv2 to forward events

By default, XDASv2 is configured to log events to a file. To forward events from XDASv2 to QRadar, you must edit the `xdasconfig.properties.template` and configure the file for syslog forwarding.

### About this task

Audit events must be forwarded by syslog to QRadar, instead of being logged to a file.

To configure XDASv2 to forward syslog events:

### Procedure

1. Log in to the server hosting Novell eDirectory.
2. Open the following file for editing:
  - Windows - `C:\Novell\NDS\xdasconfig.properties.template`
  - Linux or Solaris - `/etc/opt/novell/eDirectory/conf/xdasconfig.properties.template`
3. To set the root logger, remove the comment marker (#) from the following line:  
`log4j.rootLogger=debug, S, R`
4. To set the appender, remove the comment marker (#) from the following line:  
`log4j.appenders.S=org.apache.log4j.net.SyslogAppender`
5. To configure the IP address for the syslog destination, remove the comment marker (#) and edit the following lines:  
`log4j.appenders.S.Host=<IP address> log4j.appenders.S.Port=<Port>`  
Where,  
`<IP address>` is the IP address or hostname of QRadar.  
`<Port>` is the port number for the UDP or TCP protocol. The default port for syslog communication is port **514** for QRadar or Event Collectors.

6. To configure the syslog protocol, remove the comment marker (#) and type the protocol (UDP, TCP, or SSL) use in the following line:

```
log4j.appenders.S.Protocol=TCP
```

The encrypted protocol SSL is not supported by QRadar.

7. To set the severity level for logging events, remove the comment marker (#) from the following line:

```
log4j.appenders.S.Threshold=INFO
```

The default value of INFO is the correct severity level for events.

8. To set the facility for logging events, remove the comment marker (#) from the following line:

```
log4j.appenders.S.Facility=USER
```

The default value of USER is the correct facility value for events.

9. To set the facility for logging events, remove the comment marker (#) from the following line:

```
log4j.appenders.R.MaxBackupIndex=10
```

10. Save the `xdasconfig.properties.template` file.

After you configure the syslog properties for XDASv2 events, you are ready to load the XDASv2 module.

## Loading the XDASv2 Module

---

Before you can configure events in Novell iManager, you must load the changes that you made to the XDASv2 module.

### About this task

To load the XDASv2 module, select your operating system:

- To load the XDASv2 in Linux, see [“Loading the XDASv2 on a Linux Operating System” on page 1290](#).
- To load the XDASv2 in Windows, see [“Loading the XDASv2 on a Windows Operating System” on page 1291](#).

**Important:** If your Novell eDirectory has Novell Module Authentication Service (NMAS) installed with NMAS auditing enabled, the changes made to XDASv2 modules are loaded automatically. If you have NMAS installed, you should configure event auditing. For information on configuring event auditing, see [“Configuring event auditing using Novell iManager” on page 1291](#).

## Loading the XDASv2 on a Linux Operating System

---

You can load XDASv2 on a Linux Operating System.

### Procedure

1. Log in to your Linux server hosting Novell eDirectory, as a root user.
2. Type the following command:

```
ndstrace -c "load xdasauditds"
```

### What to do next

You are now ready to configure event auditing in Novell eDirectory. For more information, see [“Configuring event auditing using Novell iManager” on page 1291](#).

## Loading the XDASv2 on a Windows Operating System

---

You can load XDASv2 on a Windows Operating System.

### Procedure

1. Log in to your Windows server hosting Novell eDirectory.
2. On your desktop, click **Start > Run**.

The Run window is displayed.

3. Type the following:

C:\Novell\NDS\ndscons.exe

This is the default installation path for the Windows Operating System. If you installed Novell eDirectory to a different directory, then the correct path is required.

4. Click **OK**.

The Novell Directory Service console displays a list of available modules.

5. From the **Services** tab, select **xdasauditds**.

6. Click **Start**.

The xdasauditds service is started for Novell eDirectory.

7. Click **Startup**.

The Service window is displayed.

8. In the **Startup Type** panel, select the **Automatic** check box.

9. Click **OK**.

10. Close the Novell eDirectory Services window.

### What to do next

You are now ready to configure event auditing in Novell eDirectory. For more information, see [“Configuring event auditing using Novell iManager” on page 1291](#).

## Configuring event auditing using Novell iManager

---

You can configure event auditing for XDASv2 in Novell iManager.

### Procedure

1. Log in to your Novell iManager console user interface.
2. From the navigation bar, click **Roles and Tasks**.
3. In the left-hand navigation, click **eDirectory Auditing > Audit Configuration**.

The Audit Configuration panel is displayed.

4. In the **NPC Server name** field, type the name of your NPC Server.
5. Click **OK**.

The Audit Configuration for the NPC Server is displayed.

6. Configure the following parameters:

- a) On the **Components** panel, select one or both of the following:

**DS** - Select this check box to audit XDASv2 events for an eDirectory object.

**LDAP** - Select this check box to audit XDASv2 events for a Lightweight Directory Access Protocol (LDAP) object.

7. On the **Log Event's Large Values** panel, select one of the following:

**Log Large Values** - Select this option to log events that are larger than 768 bytes.

**Don't Log Large Values** - Select this option to log events less than 768 bytes. If a value exceeds 768 bytes, then the event is truncated.

8. On the **XDAS Events Configuration**, select the check boxes of the events you want XDAS to capture and forward to IBM QRadar.

9. Click **Apply**.

10. On the **XDAS** tab, click **XDASRoles**.

The XDAS Roles Configuration panel is displayed.

11. Configure the following role parameters:

a) Select a check box for each object class to support event collection.

12. From the **Available Attribute(s)** list, select any attributes and click the **arrow** to add these to the **Selected Attribute(s)** list.

13. Click **OK** after you have added the object attributes.

14. Click **Apply**.

15. On the **XDAS** tab, click **XDASAccounts**.

The XDAS Accounts Configuration panel is displayed.

16. Configure the following account parameters:

a) From the **Available Classes** list, select any classes and click the **arrow** to add these to the **Selected Attribute(s)** list.

17. Click **OK** after you have added the object attributes.

18. Click **Apply**.

## What to do next

You are now ready to add a log source in QRadar.

### Related tasks

[“Adding a log source” on page 5](#)

## Configuring a log source

---

IBM QRadar automatically detects syslog events from Novell eDirectory. If the log source is not automatically detected, add a log source in QRadar.

### Procedure

From the Log Source Type list, select Novell eDirectory.

For more information about Novell eDirectory, Novell iManager, or XDASv2, see your vendor documentation.

| Includes identity?                           | Yes                                                                                                                                                                                                                                                                                            |
| Includes custom properties?                  | No                                                                                                                                                                                                                                                                                             |
| More information                             | <a href="http://www.observeit-sys.com">ObserveIT website</a> ( <a href="http://www.observeit-sys.com">http://www.observeit-sys.com</a> )                                                                                                                                                       |

To collect ObserveIT JDBC events, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent versions of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - ObserveIT JDBC DSM RPM
  - DSMCommon DSM RPM
  - ObserveIT JDBC PROTOCOL RPM
  - JDBC PROTOCOL RPM
2. Make sure that your ObserveIT system is installed and the SQL Server database is accessible over the network.
3. For each ObserveIT server that you want to integrate, create a log source on the QRadar Console. Configure all the required parameters. Use these tables to configure ObserveIT specific parameters:

*Table 842. ObserveIT JDBC log source parameters*

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Protocol Configuration | ObserveIT JDBC                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Log Source Identifier  | <p>Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.</p> <p>If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2.</p> |
| Database name          | ObserveIT                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| IP or Hostname         | The IP address or host name of the ObserveIT system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Port                   | The port on the ObserveIT host. The default is 1433.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Username               | The user name that is required to connect to the ObserveIT MS SQL database                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Password               | The password that is required to connect to the ObserveIT MS SQL database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Start Date and Time    | Use the yyyy-MM-dd HH: mm format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Polling Interval       | The frequency by which to poll the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| EPS Throttle           | <p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p>                                                                                                                                                                                                                                                                                                                                                                                                          |

*Table 843. Log file protocol parameters*

| Parameter              | Description                                                                                                                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Protocol Configuration | Log file                                                                                                                                                                                                                   |
| Log Source Identifier  | <p>The IP address for the log source. This value must match the value that is configured in the <b>Remote IP or Hostname</b> parameter. The <b>Log Source Identifier</b> value must be unique for the log source type.</p> |

Table 843. Log file protocol parameters (continued)

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Service Type          | <p>From the list, select the protocol that you want to use when retrieving log files from a remote server. The default is SFTP.</p> <p>SFTP - SSH File Transfer Protocol</p> <p>FTP - File Transfer Protocol</p> <p>SCP - Secure Copy</p> <p>The underlying protocol that retrieves log files for the SCP and SFTP service type requires that the server specified in the <b>Remote IP or Hostname</b> field has the SFTP subsystem enabled.</p> |
| Remote IP or Hostname | The IP address or host name of the device that stores your event log files.                                                                                                                                                                                                                                                                                                                                                                      |
| Remote Port           | If the remote host uses a non-standard port number, you must adjust the port value to retrieve events.                                                                                                                                                                                                                                                                                                                                           |
| Remote User           | The user name necessary to log in to the host that contains your event files. The user name can be up to 255 characters in Length.                                                                                                                                                                                                                                                                                                               |
| Remote Password       | The password that is necessary to log in to the host.                                                                                                                                                                                                                                                                                                                                                                                            |
| Confirm Password      | Confirmation of the password that is necessary to log in to the host.                                                                                                                                                                                                                                                                                                                                                                            |
| SSH Key File          | The path to the SSH key, if the system is configured to use key authentication. When an SSH key file is used, the <b>Remote Password</b> field is ignored.                                                                                                                                                                                                                                                                                       |
| Remote Directory      | For FTP, if the log files are in the remote user's home directory, you can leave the remote directory blank. A blank <b>remote directory</b> field supports systems where a change in the working directory (CWD) command is restricted.                                                                                                                                                                                                         |
| SCP Remote File       | If you selected <b>SCP</b> as the <b>Service Type</b> , you must type the file name of the remote file.                                                                                                                                                                                                                                                                                                                                          |
| Recursive             | This option is ignored for SCP file transfers.                                                                                                                                                                                                                                                                                                                                                                                                   |
| FTP File Pattern      | The regular expression (regex) required to identify the files to download from the remote host.                                                                                                                                                                                                                                                                                                                                                  |
| FTP Transfer Mode     | For ASCII transfers over FTP, you must select <b>NONE</b> in the <b>Processor</b> field and <b>LINEBYLINE</b> in the <b>Event Generator</b> field.                                                                                                                                                                                                                                                                                               |

Table 843. Log file protocol parameters (continued)

| Parameter                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Start Time                          | The time of day when you want the processing to begin. For example, type 12:00 AM to schedule the log file protocol to collect event files at midnight. This parameter functions with the <b>Recurrence value</b> to establish when and how often the <b>Remote Directory</b> is scanned for files. Type the <b>start time</b> , based on a 12-hour clock, in the following format: HH:MM <AM/PM>.                                            |
| Recurrence                          | The time interval to determine how frequently the remote directory is scanned for new event log files. The time interval can include values in hours (H), minutes (M), or days (D). For example, a recurrence of 2H scans the remote directory every 2 hours.                                                                                                                                                                                 |
| Run On Save                         | Starts the log file import immediately after you save the log source configuration. When selected, this check box clears the list of previously downloaded and processed files. After the first file import, the log file protocol follows the start time and recurrence schedule that is defined by the administrator.                                                                                                                       |
| EPS Throttle                        | The maximum number of events per second that QRadar ingests.<br><br>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.                                                                                                                                                                                          |
| Processor                           | Processors allow QRadar to expand event file archives, and to process contents for events. QRadar processes files only after they are downloaded. QRadar can process files in zip, gzip, tar, or tar+gzip archive format.                                                                                                                                                                                                                     |
| Ignore Previously Processed File(s) | Tracks and ignores files that were processed by the log file protocol. QRadar examines the log files in the remote directory to determine whether a file was processed previously by the log file protocol. If a previously processed file is detected, the log file protocol does not download the file for processing. All files that were not processed previously are downloaded. This option applies only to FTP and SFTP Service Types. |
| Change Local Directory?             | Changes the local directory on the Target Event Collector to store event logs before they are processed.                                                                                                                                                                                                                                                                                                                                      |
| Local Directory                     | The local directory on the Target Event Collector. The directory must exist before the log file protocol attempts to retrieve events.                                                                                                                                                                                                                                                                                                         |

*Table 843. Log file protocol parameters (continued)*

| Parameter        | Description                                                                                                                                                                                                                                                                                                                        |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| File Encoding    | The character encoding that is used by the events in your log file.                                                                                                                                                                                                                                                                |
| Folder Separator | The character that is used to separate folders for your operating system. Most configurations can use the default value in <b>Folder Separator</b> field. This field is intended for operating systems that use a different character to define separate folders. For example, periods that separate folders on mainframe systems. |

# Chapter 113. Okta

The IBM QRadar DSM for Okta collects Okta REST API events from an Okta device.

The following table identifies the specifications for the Okta DSM:

| Table 844. Okta DSM specifications |                                                                          |
|------------------------------------|--------------------------------------------------------------------------|
| Specification                      | Value                                                                    |
| Manufacturer                       | Okta                                                                     |
| DSM name                           | Okta                                                                     |
| RPM file name                      | DSM-OktaIdentityManagement-QRadar_version-build_number.noarch.rpm        |
| Protocol                           | Okta REST API                                                            |
| Event format                       | JSON                                                                     |
| Recorded event types               | All                                                                      |
| Automatically discovered?          | No                                                                       |
| Includes identity?                 | Yes                                                                      |
| Includes custom properties?        | No                                                                       |
| More information                   | <a href="https://www.okta.com/">Okta website (https://www.okta.com/)</a> |

To integrate Okta with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the IBM support website (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - Protocol Common
  - Okta REST API Protocol RPM
  - Okta DSM RPM

If multiple DSM RPMs are required, the integration sequence must reflect the DSM RPM dependency.

2. Add an Okta log source on the QRadar Console:

| Table 845. Okta DSM log source parameters |                                  |
|-------------------------------------------|----------------------------------|
| Parameter                                 | Value                            |
| <b>Log Source type</b>                    | Okta                             |
| <b>Protocol type</b>                      | Okta REST API                    |
| <b>Name</b>                               | A name for the log source        |
| <b>Description (optional)</b>             | A description for the log source |

For a list of Okta REST API protocol parameters and their values, see [Okta REST API protocol configuration options](#).

The following table provides a sample event message for the Okta DSM:

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

Table 846. Okta sample message supported by the Okta device

| Event name                   | Low level category | Sample log message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Includes identity?                                      | No                                                                              |
| Includes custom properties?                             | No                                                                              |
| More information                                        | <a href="https://www.onapsis.com">Onapsis website (https://www.onapsis.com)</a> |

To integrate Onapsis Security Platform with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Onapsis Security Platform DSM RPM
  - DSM Common RPM
2. Configure your Onapsis Security Platform device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add an Onapsis Security Platform log source on the QRadar Console. The following table describes the parameters that require specific values for Onapsis Security Platform event collection:

Table 848. Onapsis Security Platform log source parameters

| Parameter              | Value                     |
|------------------------|---------------------------|
| Log Source type        | Onapsis Security Platform |
| Protocol Configuration | Syslog                    |

# Configuring Onapsis Security Platform to communicate with QRadar

---

To collect events from Onapsis Security Platform, you must add a connector and an alarm profile.

## About this task

Alarm profiles configure the Onapsis Security Platform to automatically take action when an incident is observed.

## Procedure

1. Log in to Onapsis Security Platform.
2. Click the **Gear** icon.
3. Click **Settings**.
4. From **Connectors Settings**, click **Add** to include a new connector.
5. Click **Respond > Alarm Profiles**.
6. Add new alarm profile.
  - a) Select **Alarm Type** and **Severity**.
  - b) Type the name and the description.
  - c) Select the target from the **Assets List** or **Tags List**.  
The lists are mutually exclusive.
  - d) Add a condition for when the alarm is triggered
  - e) To add an action that runs when the alarm is triggered, click **Action**.
  - f) Select the QRadar connector that was created in step 4.

# Chapter 115. OpenBSD

The OpenBSD DSM for IBM QRadar accepts events by using syslog.

QRadar records all relevant informational, authentication, and system level events that are forwarded from OpenBSD operating systems.

## Syslog log source parameters for OpenBSD

If QRadar does not automatically detect the log source, add a OpenBSD log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from OpenBSD:

| Table 849. Syslog log source parameters for the OpenBSD DSM |                                                                                                              |
|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| Parameter                                                   | Value                                                                                                        |
| <b>Log Source type</b>                                      | Open BSD OS                                                                                                  |
| <b>Protocol Configuration</b>                               | Syslog                                                                                                       |
| <b>Log Source Identifier</b>                                | Type the IP address or host name for the log source as an identifier for events from your OpenBSD appliance. |

### Related tasks

[Adding a log source](#)

## Configuring syslog for OpenBSD

You can configure OpenBSD to forward syslog events.

### Procedure

1. Use SSH, to log in to your OpenBSD device, as a root user.
2. Open the /etc/syslog.conf file.
3. Add the following line to the top of the file. Make sure that all other lines remain intact:

`*.* @<IP address>`

Where <IP address> is the IP address of your IBM QRadar.

4. Save and exit the file.
5. Send a hang-up signal to the syslog daemon to ensure that all changes are applied:

```
kill -HUP `cat /var/run/syslog.pid`
```

**Note:** This command line uses the back quotation mark character (`), which is located to the left of the number one on most keyboard layouts.

The configuration is complete. Events that are forwarded to QRadar by OpenBSD are displayed on the **Log Activity** tab.

# Chapter 116. Open LDAP

The Open LDAP DSM for IBM QRadar accepts UDP Multiline syslog events from Open LDAP installations that are configured to log stats events by using logging level 256.

Open LDAP events are forwarded to QRadar by using port 514. The events must be redirected to the port that is configured for the UDP Multiline syslog protocol. QRadar does not support UDP Multiline syslog on the standard listen port 514.

**Note:** UDP Multiline Syslog events can be assigned to any available port that is not in use, other than port 514. The default port that is assigned to the UDP Multiline Syslog protocol is port 517. If port 517 is already being used in your network, see the *QRadar port usage* topic in the *IBM QRadar Administration Guide* or the [IBM Knowledge Center](https://www.ibm.com/support/knowledgecenter/SS42VS_7.3.0/com.ibm.qradar.doc/c_qradar_adm_common_ports.html?pos=2) ([https://www.ibm.com/support/knowledgecenter/SS42VS\\_7.3.0/com.ibm.qradar.doc/c\\_qradar\\_adm\\_common\\_ports.html?pos=2](https://www.ibm.com/support/knowledgecenter/SS42VS_7.3.0/com.ibm.qradar.doc/c_qradar_adm_common_ports.html?pos=2)) for a list of ports that are used by QRadar.

**Important:** Forward the UDP Multiline syslog events directly to the chosen port (default 517) from your Open LDAP device. If you can't send events to this port directly, you can use the backup method of configuring IPtables for UDP Multiline Syslog events.

## Related concepts

[“UDP multiline syslog protocol configuration options” on page 237](#)

To create a single-line syslog event from a multiline event, configure a log source to use the UDP multiline protocol. The UDP multiline syslog protocol uses a regular expression to identify and reassemble the multiline syslog messages into single event payload.

## Related tasks

[“Adding a DSM” on page 4](#)

## UDP Multiline Syslog log source parameters for Open LDAP

If QRadar does not automatically detect the log source, add a Open LDAP log source on the QRadar Console by using the UDP Multiline Syslog protocol.

When using the UDP Multiline Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect UDP Multiline Syslog events from Open LDAP:

| Table 850. UDP Multiline Syslog log source parameters for the Open LDAP DSM |                      |
|-----------------------------------------------------------------------------|----------------------|
| Parameter                                                                   | Value                |
| <b>Log Source type</b>                                                      | Open LDAP Software   |
| <b>Protocol Configuration</b>                                               | UDP Multiline Syslog |
| <b>Log Source Identifier</b>                                                |                      |

Table 850. UDP Multiline Syslog log source parameters for the Open LDAP DSM (continued)

| Parameter                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Listen Port</b>        | <p>Type the port number that is used by QRadar to accept incoming UDP Multiline Syslog events. The valid port range is 1 - 65536.</p> <p>The default UDP Multiline Syslog listen port is 517.</p> <p>If you do not see the <b>Listen Port</b> field, you must restart Tomcat on QRadar.</p> <p>To edit the <b>Listen Port</b> number:</p> <p>Update IPtables on your QRadar Console or Event Collector with the new UDP Multiline Syslog port number. For more information, see “<a href="#">Configuring IPtables for UDP Multiline Syslog events</a>” on page 1310.</p> <ol style="list-style-type: none"> <li>1. In the <b>Listen Port</b> field, type the new port number for receiving UDP Multiline Syslog events.</li> <li>2. Click <b>Save</b>.</li> </ol> <p>The port update is complete and event collection starts on the new port number.</p> |
| <b>Message ID Pattern</b> | <p>Type the regular expression (regex) that is needed to filter the event payload messages. All matching events are included when processing Open LDAP events.</p> <p>The following regular expression is suggested for Open LDAP events:</p> <p><code>conn=(\d+)</code></p> <p>For example, Open LDAP starts connection messages with the word <code>conn</code>, followed by the rest of the event payload. Use of this parameter requires knowledge of regular expressions (regex). For more information, see the following website: <a href="http://download.oracle.com/javase/tutorial/essential/regex/">http://download.oracle.com/javase/tutorial/essential/regex/</a></p>                                                                                                                                                                        |

For a complete list of UDP Multiline Syslog protocol parameters and their values, see “[UDP multiline syslog protocol configuration options](#)” on page 237.

[Adding a log source](#)

## Configuring IPtables for UDP Multiline Syslog events

To collect UDP Multiline Syslog events in IBM QRadar, if you are unable to send the events directly to the standard UDP Multiline port of 517 or any other available port that is not already in use by QRadar, then you must redirect events from port 514 to the default port 517 or your chosen alternate port by using IPTables as outlined below. You must configure IPtables on your QRadar Console or for each QRadar Event Collector that receives UDP Multiline Syslog events from an Open LDAP server, and then complete the configuration for each Open LDAP server IP address that you want to receive logs from.

## Before you begin

**Important:** Complete this configuration method only if you can't send UDP Multiline Syslog events directly to the chosen UDP Multiline port on QRadar from your Open LDAP server, and you are restricted to only sending to the standard syslog port 514.

## Procedure

1. Using SSH, log in to QRadar as the root user.

Login: <root>

Password: <password>

2. Type the following command to edit the IPtables file:

```
vi /opt/qradar/conf/iptables-nat.post
```

The IPtables NAT configuration file is displayed.

3. Type the following command to instruct QRadar to redirect syslog events from UDP port 514 to UDP port 517:

```
-A PREROUTING -p udp --dport 514 -j REDIRECT --to-port <new-port> -s <IP address>
```

Where:

<IP address> is the IP address of your Open LDAP server.

<New port> is the port number that is configured in the UDP Multiline protocol for Open LDAP.

You must include a redirect for each Open LDAP IP address that sends events to your QRadar Console or Event Collector. Example:

```
-A PREROUTING -p udp --dport 514 -j REDIRECT --to-port 517 -s <IP_address>
```

4. Save your IPtables NAT configuration.

You are now ready to configure IPtables on your QRadar Console or Event Collector to accept events from your Open LDAP servers.

5. Type the following command to edit the IPtables file:

```
vi /opt/qradar/conf/iptables.post
```

The IPtables configuration file is displayed.

6. Type the following command to instruct QRadar to allow communication from your Open LDAP servers:

```
-I QChain 1 -m udp -p udp --src <IP_address> --dport <New port> -j ACCEPT
```

Where:

<IP address> is the IP address of your Open LDAP server.

<New port> is the port number that is configured in the UDP Multiline protocol for Open LDAP.

You must include a redirect for each Open LDAP IP address that sends events to your QRadar Console or Event Collector. Example:

```
-I QChain 1 -m udp -p udp --src <IP_address> --dport 517 -j ACCEPT
```

7. Type the following command to update IPtables in QRadar:

```
./opt/qradar/bin/iptables_update.pl
```

## Example

If you need to configure another QRadar Console or Event Collector that receives syslog events from an Open LDAP server, repeat these steps.

## What to do next

Configure your Open LDAP server to forward events to QRadar.

# Configuring event forwarding for Open LDAP

---

Configure syslog event forwarding for Open LDAP:

## Procedure

1. Log in to the command line interface for your Open LDAP server.
2. Edit the following file:

/etc/syslog.conf

3. Add the following information to the syslog configuration file:

<facility>@<IP address>

Where:

<facility> is the syslog facility, for example local4.

<IP address> is the IP address of your QRadar Console or Event Collector.

For example,

```
#Logging for SLAPD local4.debug /var/log/messages local4.debug @<IP_address>
```

**Note:** If your Open LDAP server stores event messages in a directory other than /var/log/messages, you must edit the directory path.

4. Save the syslog configuration file.
5. Type the following command to restart the syslog service:

/etc/init.d/syslog restart

The configuration for Open LDAP is complete. UDP Multiline Syslog events that are forwarded to QRadar are displayed on the **Log Activity** tab.

# Configuring QRadar for users to use OP code instead of connection number

---

By default, Open LDAP events are combined on the operation code. If you want to change the way that IBM QRadar maps events, you can use the DSM Editor to combine events on connection number.

## Procedure

1. Click the **Admin** tab.
2. In the **Data Sources** section, click **DSM Editor**.
3. From the **Select Log Source Type** window, select **Open LDAP Software** from the list, and click **Select**.
4. On the **Configuration** tab, set **Display DSM Parameters Configuration** to **on**.
5. From the **Event Collector** list, select the event collector for the log source.
6. Set **Allow User to use OP code rather than Connection number** to **on**.
7. Click **Save** and close out the DSM Editor.

# Chapter 117. Open Source SNORT

The Open Source SNORT DSM for IBM QRadar records all relevant SNORT events using syslog.

The SourceFire VRT certified rules for registered SNORT users are supported. Rule sets for Bleeding Edge, Emerging Threat, and other vendor rule sets might not be fully supported by the Open Source SNORT DSM.

## Configuring Open Source SNORT

To configure syslog on an Open Source SNORT device:

### About this task

The following procedure applies to a system that runs Red Hat Enterprise. The following procedures can vary for other operating systems.

### Procedure

1. Configure SNORT on a remote system.
2. Open the `snort.conf` file.
3. Uncomment the following line:

```
output alert_syslog:LOG_AUTH LOG_INFO
```

4. Save and exit the file.
5. Open the following file:  
`/etc/init.d/snortd`
6. Add a `-s` to the following lines, as shown in the example:

```
daemon /usr/sbin/snort $ALERTMODE  
$BINARY_LOG $NO_PACKET_LOG $DUMP_APP -D  
$PRINT_INTERFACE -i $i -s -u $USER -g  
$GROUP $CONF -i $LOGIR/$i $PASS_FIRST
```

```
daemon /usr/sbin/snort $ALERTMODE  
$BINARY_LOG $NO_PACKET_LOG $DUMP_APP -D  
$PRINT_INTERFACE $INTERFACE -s -u $USER -g  
$GROUP $CONF -i $LOGDIR
```

7. Save and exit the file.
8. Restart SNORT by typing the following command:  
`/etc/init.d/snortd restart`
9. Open the `syslog.conf` file.
10. Update the file to reflect the following code:

```
auth.info@<IP Address>
```

Where `<IP Address>` is the system to which you want logs sent.

11. Save and exit the file.
12. Restart syslog:  
`/etc/init.d/syslog restart`

### What to do next

You can now configure the log source in QRadar.

## Syslog log source parameters for Open Source SNORT

---

If QRadar does not automatically detect the log source, add a Open Source SNORT log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Open Source SNORT:

| <i>Table 851. Syslog log source parameters for the Open Source SNORT DSM</i> |                                                                                                         |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <b>Parameter</b>                                                             | <b>Value</b>                                                                                            |
| <b>Log Source type</b>                                                       | Open Source IDS                                                                                         |
| <b>Protocol Configuration</b>                                                | Syslog                                                                                                  |
| <b>Log Source Identifier</b>                                                 | Type the IP address or host name for the log source as an identifier for your Open Source SNORT events. |

To send events from OpenStack to QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - PROTOCOL-HTTPReceiver RPM
  - OpenStack DSM RPM
2. Add an OpenStack log source on the QRadar Console. The following table describes the parameters that are required to collect OpenStack events:

Table 853. OpenStack log source parameters

| Parameter              | Value                                                                                                                                                       |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Log Source type        | <b>OpenStack</b>                                                                                                                                            |
| Log Source Identifier  | The IP address of the OpenStack server, and not the host name.                                                                                              |
| Protocol Configuration | <b>HTTPReceiver</b>                                                                                                                                         |
| Communication Type     | <b>HTTP</b>                                                                                                                                                 |
| Listen Port            | The port number that OpenStack uses to communicate with QRadar.<br><b>Important:</b> Do not use Port 514. Port 514 is used by the standard Syslog listener. |
| Message Pattern        | <code>^\\{ "typeURI</code>                                                                                                                                  |

3. Configure your OpenStack device to communicate with QRadar.

The following table provides a sample event message for the OpenStack DSM:

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

Table 854. OpenStack sample message supported by the OpenStack device

| Event name                    | Low level category      | Sample log message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Configuring OpenStack to communicate with QRadar

To collect OpenStack events, you must configure your OpenStack device to allow connections from QRadar.

**Important:** OpenStack is an open source product with many different distributions that can be set up on many different operating systems. This procedure might vary in your environment.

### Procedure

1. Log in to your OpenStack device.
2. Edit the `/etc/nova/api-paste.ini` file.
3. At the end of the file, add the following text:

```
[filter:audit] paste.filter_factory = pycadf.middleware.audit:AuditMiddleware.factory  
audit_map_file = /etc/nova/api_audit_map.conf
```

4. Review the `[composite:openstack_compute_api_v2]` settings and verify that the values match the following sample:

```
[composite:openstack_compute_api_v2] use = call:nova.api.auth:pipeline_factory noauth =  
faultwrap sizelimit noauth ratelimit osapi_compute_app_v2 keystone = faultwrap sizelimit  
authtoken keystonecontext ratelimit audit osapi_compute_app_v2 keystone_nolimit = faultwrap  
sizelimit authtoken keystonecontext audit osapi_compute_app_v2
```

5. Copy the `api_audit_map.conf` file to the `/etc/nova/` directory.
6. Restart the api service.

The command to restart the API service depends on what operating system your OpenStack node is hosted on. On Redhat Enterprise Linux systems, the command is `service openstack-nova-api restart`.

7. Open the `entry_points.txt` file in the `egg-info` subdirectory of your OpenStack installation directory.

For PackStack installations, the file path resembles the following path: `/usr/lib/python2.7/site-packages/ceilometer-2014.2-py2.7.egg-info/entry_points.txt`.

8. Add the http dispatcher to the `[ceilometer.dispatcher]` section.

```
[ceilometer.dispatcher] file = ceilometer.dispatcher.file:FileDispatcher  
database = ceilometer.dispatcher.database:DatabaseDispatcher http =  
ceilometer.dispatcher.http:HttpDispatcher
```

9. Copy the supplied `http.py` script to the dispatcher subdirectory of the Ceilometer installation directory.

The exact location depends on your operating system and OpenStack distribution. On the Redhat Enterprise Linux Distribution of OpenStack, the directory is `/usr/lib/python2.7/site-packages/ceilometer/dispatcher/`.

10. Edit the `/etc/ceilometer/ceilometer.conf` file.
11. Under the `[default]` section, add `dispatcher=http`.
12. At the bottom of the file, add this section:

```
[dispatcher_http] target = http://<QRadar-IP>:<QRadar-Port> cadf_only = True
```

Use the port that you configured for OpenStack when you created the log source on your QRadar system.

13. Restart the ceilometer collector and notification services.

The command to restart the ceilometer collector and notification services depends on what operating system your OpenStack device is hosted on. On devices that use the Redhat Enterprise Linux operating system, use the following commands:

```
service openstack-ceilometer-collector restart
```

```
service openstack-ceilometer-notification restart
```

# Chapter 119. Oracle

IBM QRadar supports a number of Oracle DSMs.

## Oracle Acme Packet Session Border Controller

You can use IBM QRadar to collect events from Oracle Acme Packet Session Border Controller (SBC) installations in your network.

The Oracle Acme Packet SBC installations generate events from syslog and SNMP traps. SNMP trap events are converted to syslog and all events are forwarded to QRadar over syslog. QRadar does not automatically discover syslog events that are forwarded from Oracle Communications SBC. QRadar supports syslog events from Oracle Acme Packet SBC V6.2 and later.

To collect Oracle Acme Packet SBC events, you must complete the following tasks:

1. On your QRadar system, configure a log source with the Oracle Acme Packet Session Border Controller DSM.
2. On your Oracle Acme Packet SBC installation, enable SNMP and configure the destination IP address for syslog events.
3. On your Oracle Acme Packet SBC installation, enable syslog settings on the media-manager object.
4. Restart your Oracle Acme Packet SBC installation.
5. Optional. Ensure that firewall rules do not block syslog communication between your Oracle Acme Packet SBC installation and the QRadar Console or managed host that collects syslog events.

## Supported Oracle Acme Packet event types that are logged by IBM QRadar

The Oracle Acme Packet SBC DSM for QRadar can collect syslog events from the authorization and the system monitor event categories.

Each event category can contain low-level events that describe the action that is taken within the event category. For example, authorization events can have low-level categories of login success or login failed.

## Syslog log source parameters for Oracle Acme Packet SBC

If QRadar does not automatically detect the log source, add a Oracle Acme Packet SBC log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Oracle Acme Packet SBC:

| Table 855. Syslog log source parameters for the Oracle Acme Packet SBC DSM |                                                                                                                                                                    |
|----------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameter</b>                                                           | <b>Value</b>                                                                                                                                                       |
| <b>Log Source type</b>                                                     | Oracle Acme Packet SBC                                                                                                                                             |

# Configuring SNMP to syslog conversion on Oracle Acme Packet SBC

To collect events in a format compatible with IBM QRadar, you must enable SNMP to syslog conversion and configure a syslog destination.

## Procedure

1. Use SSH to log in to the command-line interface of your Oracle Acme Packet SBC installation, as an administrator.

2. Type the following command to start the configuration mode:

```
config t
```

3. Type the following commands to start the system configuration:

```
(configure)# system (system)# (system)# system-config (system-config)# sel
```

The **sel** command is required to select a single-instance of the system configuration object.

4. Type the following commands to configure your QRadar system as a syslog destination:

```
(system-config)# syslog-servers (syslog-config)# address <QRadar IP address>
(syslog-config)# done
```

5. Type the following commands to enable SNMP traps and syslog conversion for SNMP trap notifications:

```
(system-config)# enable-snmp-auth-traps enabled (system-config)# enable-snmp-syslog-notify
enabled (system-config)# enable-snmp-monitor-traps enabled (system-config)# ids-syslog-
facility 4 (system-config)# done
```

6. Type the following commands to return to configuration mode:

```
(system-config)# exit (system)# exit (configure)#
```

# Enabling syslog settings on the media manager object

The media-manager object configuration enables syslog notifications when the Intrusion Detection System (IDS) completes an action on an IP address. The available action for the event might depend on your firmware version.

## Procedure

1. Type the following command to list the firmware version for your Oracle Acme Packet SBC installation:

```
(configure)# show ver
```

```
ACME Net-Net OSVM Firmware SCZ 6.3.9 MR-2 Patch 2 (Build 465) Build
Date=03/12/13
```

You may see underlined text which shows the major and minor version number for the firmware.

2. Type the following commands to configure the media-manager object:

```
(configure)# media-manager (media-manager)# (media-manager)# media-manager
(media-manager)# sel (media-manager-config)#
```

The **sel** command is used to select a single-instance of the media-manager object.

3. Type the following command to enable syslog messages when an IP is demoted by the Intrusion Detection System (IDS) to the denied queue.

```
(media-manager-config)# syslog-on-demote-to-deny enabled
```

4. For firmware version C6.3.0 and later, type the following command to enable syslog message when sessions are rejected.

- ```
(media-manager-config)# syslog-on-call-reject enabled
```
5. For firmware version C6.4.0 and later, type the following command to enable syslog messages when an IP is demoted to the untrusted queue
- ```
(media-manager-config)# syslog-on-demote-to-untrusted enabled
```
6. Type the following commands to return to configuration mode:
- ```
(media-manager-config)# done (media-manager-config)# exit (media-manager)# exit (configure)# exit
```
7. Type the following commands to save and activate the configuration:
- ```
# save Save complete # activate
```
8. Type `reboot` to restart your Oracle Acme Packet SBC installation.

After the system restarts, events are forwarded to IBM QRadar and displayed on the **Log Activity** tab.

## Oracle Audit Vault

The IBM QRadar DSM for Oracle Audit Vault collects events from an Oracle Audit Vault server.

The following table describes the specifications for the Oracle Audit Vault DSM:

| Table 856. Oracle Audit Vault DSM specifications |                                                                                                                                                                                                                                                              |

To integrate Oracle Audit Vault with QRadar, complete the following steps:

- If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - JDBC Protocol RPM
  - DSMCommon RPM

- Oracle Audit Vault DSM RPM
2. Obtain the database information for your Oracle Audit Vault server and then configure your Oracle Audit Vault database to allow incoming TCP connections.
  3. For each instance of Oracle Audit Vault, add an Oracle Audit Vault log source on the QRadar Event Collector. The following table describes the parameters that require specific values to collect events from Oracle Audit Vault:

*Table 857. Oracle Audit Vault JDBC log source parameters*

| Parameter                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Protocol Configuration</b> | <b>JDBC</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Log Source Identifier</b>  | Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.<br><br>If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2. |
| <b>Database Type</b>          | <b>Oracle</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Database Name</b>          | The name of the Oracle Audit Vault database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>IP or Hostname</b>         | The IP address or host name of the Oracle Audit Vault server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Port</b>                   | The port from where the Oracle Audit Vault database is listening.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Username</b>               | Any user with the AV_AUDITOR permission. For example, AVAUDITOR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Password</b>               | The password for the database user.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Predefined Query</b>       | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Table Name</b>             | For Oracle Audit Vault Version 10.3, the <b>Table Name</b> value is AVSYS.AV\$ALERT_STORE.<br><br>For Oracle Audit Vault Version 12.2, the <b>Table Name</b> value is AVSYS.AV_ALERT_STORE_V.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Select List</b>            | The list of fields to include when the table is polled for events. You can use a comma-separated list or type an asterisk (*) to select all fields from the table or view. If a comma-separated list is defined, the list must contain the field that is defined in the <b>Compare Field</b> .                                                                                                                                                                                                                                                                                                                                                                |

Table 857. Oracle Audit Vault JDBC log source parameters (continued)

| Parameter                             | Value                                                                                                                                                                                                                                |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Compare Field</b>                  | For Oracle Audit Vault Version 10.3, the <b>Compare Field</b> value is ALERT_SEQUENCE<br>For Oracle Audit Vault Version 12.2, the <b>Compare Field</b> value is RECORD_ID.                                                           |
| <b>Use Prepared Statements</b>        | You must select the <b>Use Prepared Statements</b> option.                                                                                                                                                                           |
| <b>Start Date and Time</b> (Optional) | The initial date and time for the JDBC retrieval.                                                                                                                                                                                    |
| <b>Use Oracle Encryption</b>          | <i>Oracle Encryption and Data Integrity settings</i> is also known as <i>Oracle Advanced Security</i> .<br>If selected, Oracle JDBC connections require the server to support similar Oracle Data Encryption settings as the client. |

For more information about configuring JDBC protocol parameters, see [c\\_logsource\\_JDBCprotocol.dita](#).

- Verify that QRadar is configured correctly.

The following table shows a sample parsed audit event message from Oracle Audit Vault:

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

Table 858. Oracle Audit Vault sample message

| Event name    | Low level category | Sample log message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

["Configuring Oracle Audit Vault to communicate with QRadar" on page 1325](#)

If you are using Oracle Audit Vault V12.2, you must create a database view. If you are using Oracle Audit Vault V10.3, no further configuration is required.

## Configuring Oracle Audit Vault to communicate with QRadar

If you are using Oracle Audit Vault V12.2, you must create a database view. If you are using Oracle Audit Vault V10.3, no further configuration is required.

### Procedure

1. Log in to your Oracle Audit Vault V12.2 database as the AVSYS user.
2. To create the database view, type the following query:

```
create or replace view AVSYS.AV_ALERT_STORE_V as select
RECORD_ID, USER_NAME, SECURED_TARGET_ID, SECURED_TARGET_NAME,
SECURED_TARGET_TYPE, EVENT_TIME, OSUSER_NAME, COMMAND_CLASS,
nvl(to_number(decode(EVENT_STATUS,'SUCCESS','0','FAILURE','1','1')),1)
EVENT_STATUS, EVENT_NAME EVENT_ID, nvl(ERROR_CODE,0) ERROR_CODE,
ERROR_MESSAGE, AV_TIME, TARGET_TYPE, TARGET_OBJECT, TARGET_OWNER,
CLIENT_HOST_NAME, CLIENT_IP, AUDIT_TRAIL_ID, MONITORING_POINT_ID, MARKER,
ALERT_RAISED, ACTION_TAKEN, NETWORK_CONNECTION, LOGFILE_ID, SERVICE_NAME,
POLICY_NAME, THREAT_SEVERITY, LOG_CAUSE, CLUSTER_ID, CLUSTER_TYPE,
GRAMMAR_VERSION, CLIENT_PROGRAM, COMMAND_TEXT, COMMAND_PARAM, EXTENSION,
SECURED_TARGET_CLASS, LOCATION, TERMINAL, CLIENT_ID from avsys.EVENT_LOG el
where el.alert_raised = 1;
```

3. To allow a user that has AV\_AUDITOR permission to read the view that you created, type the following query:

```
grant select on AVSYS.AV_ALERT_STORE_V to AV_AUDITOR;
```

## Oracle BEA WebLogic

The Oracle BEA WebLogic DSM allows IBM QRadar to retrieve archived server logs and audit logs from any remote host, such as your Oracle BEA WebLogic server.

### About this task

QRadar uses the log file protocol to retrieve events from your Oracle BEA WebLogic server and provides information on application events that occur in your domain or on a single server.

QRadar supports Oracle events by using the Log File protocol from Oracle BEA Weblogic v12.2.1.3.0.

To integrate Oracle BEA WebLogic events, take the following steps:

1. Enable auditing on your Oracle BEA WebLogic server.
2. Configure *domain logging* on your Oracle BEA WebLogic server.
3. Configure *application logging* on your Oracle BEA WebLogic server.
4. Configure an audit provider for Oracle BEA WebLogic.
5. Configure QRadar to retrieve log files from Oracle BEA WebLogic.

## Enabling event logs

By default, Oracle BEA WebLogic does not enable event logging.

### About this task

To enable event logging on your Oracle WebLogic console:

## Procedure

1. Log in to your Oracle WebLogic console user interface.
2. Select **Domain > Configuration > General**.
3. Click **Advanced**.
4. From the **Configuration Audit Type** list, select **Change Log and Audit**.
5. Click **Save**.

## What to do next

You can now configure the collection of domain logs for Oracle BEA WebLogic.

## Configuring domain logging

Oracle BEA WebLogic supports multiple instances. Event messages from instances are collected in a single domain-wide log for the Oracle BEA WebLogic server.

### About this task

To configure the log file for the domain:

## Procedure

1. From your Oracle WebLogic console, select **Domain > Configuration > Logging**.
2. From the **Log file name** parameter, type the directory path and file name for the domain log.  
For example, `OracleDomain.log`.
3. Optional: Configure any additional domain log file rotation parameters.
4. Click **Save**.

## What to do next

You can now configure *application logging* for the server.

## Configuring application logging

You can configure application logging for Oracle BEA WebLogic:

## Procedure

1. From your Oracle WebLogic console, select **Server > Logging > General**.
2. From the **Log file name** parameter, type the directory path and file name for the application log.  
For example, `OracleDomain.log`.
3. Optional: Configure any additional application log file rotation parameters.
4. Click **Save**.

## What to do next

You can now configure an audit provider for Oracle BEA WebLogic.

## Configuring an audit provider

You can configure an audit provider:

## Procedure

1. Select **Security Realms > Realm Name > Providers > Auditing**.

2. Click **New**.
  3. Configure an audit provider by typing a name for the audit provider that you are creating.
  4. From the **Type** list, select **DefaultAuditor**.
  5. Click **OK**.
- The **Settings** window is displayed.
6. Click the auditing provider that you created in “Configuring an audit provider” on page 1326.
  7. Click the **Provider Specific** tab.
  8. Add any **Active Context Handler Entries** that are needed.
  9. From the **Severity** list, select **Information**.
  10. Click **Save**.

## What to do next

You can now configure IBM QRadar to pull log files from Oracle BEA WebLogic.

## Log file log source parameters for Oracle BEA WebLogic

If QRadar does not automatically detect the log source, add a Oracle BEA WebLogic log source on the QRadar Console by using the Log file protocol.

When using the Log file protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect log file events from Oracle BEA WebLogic:

| Table 859. Log file log source parameters for the Oracle BEA WebLogic DSM |                                                                                                                                                                                                                                             |
|---------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                                 | Value                                                                                                                                                                                                                                       |
| <b>Log Source type</b>                                                    | Oracle BEA WebLogic                                                                                                                                                                                                                         |
| <b>Protocol Configuration</b>                                             | Log file                                                                                                                                                                                                                                    |
| <b>Log Source Identifier</b>                                              | <p>Type the IP address or host name for the log source. This value must match the value that is configured in the <b>Remote Host IP or Hostname</b> parameter.</p> <p>The log source identifier must be unique for the log source type.</p> |
| <b>Event Generator</b>                                                    | From the <b>Event Generator</b> list, select <b>Oracle BEA WebLogic</b> .                                                                                                                                                                   |

For a complete list of Log file protocol parameters and their values, see “[Log File protocol configuration options](#)” on page 155.

## Oracle Cloud Infrastructure

The IBM QRadar DSM for Oracle Cloud Infrastructure (OCI) parses messages and events that are generated by OCI services to provide security insights and threat detection.

To integrate OCI with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](#). Download and install the most recent version of the following RPM on your QRadar Console:
  - a. OracleCloudInfrastructure DSM RPM
2. Configure your OCI account to send events to QRadar by selecting **Log Source Type** as **Oracle Cloud Infrastructure** instead of **Universal DSM** in Task 5.3.
3. Configure the Apache Kafka Protocol to forward OCI logs and then add an OCI log source on the QRadar Console for proper parsing. For more information, see [Apache Kafka protocol configuration options](#).

## Oracle RDBMS Audit Record

The IBM QRadar DSM for Oracle RDBMS Audit Record collects logs from an Oracle database.

The following table describes the specifications for the Oracle RDBMS Audit Record DSM:

*Table 866. Oracle RDBMS Audit Record DSM specifications*

| Specification               | Value                                                                                                               |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------|
| Manufacturer                | Oracle                                                                                                              |
| DSM name                    | Oracle RDBMS Audit Record                                                                                           |
| RPM file name               | DSM-OracleDbAudit-QRadar_version-build_number.noarch.rpm                                                            |
| Supported versions          | 9i, 10g, 11g, 12c (includes unified auditing)                                                                       |
| Protocol                    | JDBC, Syslog                                                                                                        |
| Event format                | Name-Value Pair                                                                                                     |
| Recorded event types        | Audit records                                                                                                       |
| Automatically discovered?   | Yes                                                                                                                 |
| Includes identity?          | Yes                                                                                                                 |
| Includes custom properties? | No                                                                                                                  |
| More information            | <a href="https://www.oracle.com">Oracle website</a> ( <a href="https://www.oracle.com">https://www.oracle.com</a> ) |

To integrate Oracle RDBMS Audit Record with QRadar, complete the following steps:

- If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Protocol JDBC RPM
  - DSMCommon RPM
  - Oracle RDBMS Audit Record DSM RPM
- Configure your Oracle RDBMS Audit Record device to write audit logs.
- If QRadar does not automatically detect the log source, add an Oracle RDBMS Audit Record log source on the QRadar Console. The following tables describe the parameters that require specific values to collect audit events from Oracle RDBMS Audit Record:

*Table 867. Oracle RDBMS Audit Record Syslog log source parameters*

| Parameter                     | Value                                        |
|-------------------------------|----------------------------------------------|
| <b>Log Source type</b>        | Oracle RDBMS Audit Record                    |
| <b>Protocol Configuration</b> | Syslog                                       |
| <b>Log Source Identifier</b>  | Type a unique identifier for the log source. |

*Table 868. Oracle RDBMS Audit Record JDBC log source parameters*

| Parameter                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Log Source type</b>        | <b>Oracle RDBMS Audit Record</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Protocol Configuration</b> | <b>JDBC</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Log Source Identifier</b>  | Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.<br><br>If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2. |
| <b>Database Type</b>          | <b>Oracle</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Database Name</b>          | The name of the database from where you collect audit logs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>IP or Hostname</b>         | The IP or host name of the Oracle database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Table 868. Oracle RDBMS Audit Record JDBC log source parameters (continued)

| Parameter               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Port</b>             | <p>Enter the JDBC port. The JDBC port must match the listener port that is configured on the remote database. The database must permit incoming TCP connections. The valid range is 1 - 65535.</p> <p>The defaults are:</p> <ul style="list-style-type: none"> <li>• MSDE - 1433</li> <li>• Postgres - 5432</li> <li>• MySQL - 3306</li> <li>• Sybase - 1521</li> <li>• Oracle - 1521</li> <li>• Informix - 9088</li> <li>• DB2 - 50000</li> </ul> <p>If a database instance is used with the MSDE database type, you must leave the <b>Port</b> field blank.</p> |
| <b>Username</b>         | A user account to connect to the database. The user must have <b>AUDIT_ADMIN</b> or <b>AUDIT_VIEWER</b> permissions.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Password</b>         | The password that is required to connect to the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Predefined Query</b> | Select a predefined database query for the log source. If a predefined query is not available for the log source type, administrators can select the <b>none</b> option.                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Table Name</b>       | The name of the table or view that includes the event records. The table name can include the following special characters: dollar sign (\$), number sign (#), underscore (_), en dash (-), and period (.)                                                                                                                                                                                                                                                                                                                                                        |
| <b>Select List</b>      | The list of fields to include when the table is polled for events. You can use a comma-separated list or type an asterisk (*) to select all fields from the table or view. If a comma-separated list is defined, the list must contain the field that is defined in the <b>Compare Field</b> .                                                                                                                                                                                                                                                                    |
| <b>Compare Field</b>    | <p>For Oracle 9i or Oracle 10g Release 1, type <code>Qradar_time</code>.</p> <p>For Oracle 10g Release 2, Oracle 11g, or Oracle 12c (non-unified auditing), type <code>extended_timestamp</code>.</p> <p>For Oracle 12c (unified auditing), type <code>event_timestamp</code>.</p>                                                                                                                                                                                                                                                                                |

Table 868. Oracle RDBMS Audit Record JDBC log source parameters (continued)

| Parameter                    | Value                                                                                                                                                                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Use Oracle Encryption</b> | <i>Oracle Encryption and Data Integrity settings</i> is also known as <i>Oracle Advanced Security</i> .<br>If selected, Oracle JDBC connections require the server to support similar Oracle Data Encryption settings as the client. |

For more information about configuring JDBC parameters, see [JDBC protocol configuration options](#).

#### 4. Verify that QRadar is configured correctly.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

The following table shows a sample normalized event message from Oracle RDBMS Audit Record:

Table 869. Oracle RDBMS Audit Record sample message

| Event name       | Low level category  | Sample log message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Enabling Unified Auditing in Oracle 12c

To enable Unified Auditing in Oracle 12c, you must shut down the Oracle database, stop the Oracle listener service and then restart the Oracle database and Oracle Listener service.

### Before you begin

You must have the AUDIT\_SYSTEM system privilege or the AUDIT\_ADMIN role to complete the following steps.

### Procedure

1. Shut down the Oracle database by connecting to the database with SQLplus, and then type the following command:

```
shutdown immediate
```

2. Stop the Oracle listener service by typing the following command:

```
lsnrctl stop
```

3. If applicable, stop the Enterprise Manager by typing the following commands:

```
cd /u01/app/oracle/product/middleware/oms
```

```
export OMS_HOME=/u01/app/oracle/product/middleware/oms
```

```
$OMS_HOME/bin/emctl stop oms
```

4. Relink Oracle DB with the *uniaud* option by typing the following commands:

```
cd $ORACLE_HOME/rdbms/lib
```

```
make -f ins_rdbms.mk uniaud_on ioracle
```

5. Restart the Oracle database by connecting to the database with SQLplus, and then type the following command:

```
startup
```

6. Restart the Oracle *listener* service by typing the following command:

```
lsnrctl start
```

7. If applicable, restart the Enterprise Manager by typing the following commands:

```
cd /u01/app/oracle/product/middleware/oms
```

```
export OMS_HOME=/u01/app/oracle/product/middleware/oms
```

```
$OMS_HOME/bin/emctl start oms
```

8. To verify that unified auditing is enabled, connect to the Oracle database with SQLplus, and then type the following command:

```
select * from v$option where PARAMETER = 'Unified Auditing';
```

Verify that the command returns one row with **VALUE equal to "TRUE"**.

## Configuring an Oracle database server to send audit logs to QRadar

Configure your Oracle device to send audit logs to IBM QRadar.

### Procedure

1. Log in to the Oracle host as an Oracle user.
2. Ensure that the *ORACLE\_HOME* and *ORACLE\_SID* environment variables are configured properly for your deployment.
3. Open the following file:

```
 ${ORACLE_HOME}/dbs/init${ORACLE_SID}.ora
```

4. Choose one of the following options:

a) For database audit trails, type the following command:

```
*.audit_trail='DB'
```

b) For syslog, type the following commands:

```
*.audit_trail='os'
```

```
*.audit_syslog_level='local0.info'
```

You must ensure that the syslog daemon on the Oracle host is configured to forward the audit log to QRadar. For systems that run Red Hat Enterprise, the following line in the /etc/syslog.conf file affects the forwarding:

```
local0.info @ qradar.domain.tld
```

Where *qradar.domain.tld* is the hostname of QRadar that receives the events. The syslog configuration must be reloaded for the command to be recognized. On a system that runs Red Hat Enterprise, type the following line to reload the syslog configuration:

```
kill -HUP /var/run/syslogd.pid
```

5. Save and exit the file.

6. To restart the database, connect to SQLplus and log in as sysdba:

**Example:** Enter user-name: sys as sysdba

7. Shut down the database by typing the following line:

```
shutdown immediate
```

8. Restart the database by typing the following line:

```
startup
```

9. If you are using Oracle v9i or Oracle v10g Release 1, you must create a view that uses SQLplus to enable the QRadar integration. If you are using Oracle 10g Release 2 or later, you can skip this step:

```
CREATE VIEW qradar_audit_view AS SELECT CAST(dba_audit_trail.timestamp AS TIMESTAMP) AS qradar_time, dba_audit_trail.* FROM dba_audit_trail;
```

If you are using the JDBC protocol, when you configure the JDBC protocol within QRadar, use the following specific parameters:

Table 870. Configuring log source parameters

| Parameter Name | Oracle v9i or 10g Release 1 Values                                                                                                                                                                                                                             | Oracle v10g Release 2 and v11g Values |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
| Table Name     | QRadar_audit_view                                                                                                                                                                                                                                              | dba_audit_trail                       |
| Select List    | *                                                                                                                                                                                                                                                              | *                                     |
| Compare Field  | QRadar_time                                                                                                                                                                                                                                                    | extended_timestamp                    |
| Database Name  | For all supported versions of Oracle, the <b>Database Name</b> must be the exact service name that is used by the Oracle <i>listener</i> . You can view the available service names by running the following command on the Oracle host: <b>lsnrctl status</b> |                                       |

**Note:** Ensure that the database user that QRadar uses to query events from the audit log table has the appropriate permissions for the Table Name object.

10. You can now configure QRadar to receive events from an Oracle database: From the **Log Source Type** list, select the **Oracle RDBMS Audit Record** option.

## Oracle Database Listener log source parameters

If QRadar does not automatically detect the log source, add a Oracle Database Listener log source on the QRadar Console by using the Oracle Database Listener protocol.

When using the Oracle Database Listener protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect events from Oracle Database Listener:

*Table 871. Oracle Database Listener log source parameters for the Oracle Database Listener DSM*

| Parameter                     | Value                                                                         |
|-------------------------------|-------------------------------------------------------------------------------|
| <b>Log Source type</b>        | Oracle Database Listener                                                      |
| <b>Protocol Configuration</b> | Oracle Database Listener                                                      |
| <b>Log Source Identifier</b>  | Type the IP address or host name for the Oracle Database Listener log source. |

For a complete list of Oracle Database Listener protocol parameters and their values, see [“Oracle Database Listener protocol configuration options” on page 205](#).

## Related tasks

[Adding a log source](#)

## Collecting Oracle database events by using Perl

The Oracle Database Listener application stores logs on the database server. To forward these logs from the Oracle server to IBM QRadar, you must configure a Perl script on the Oracle server. The Perl script monitors the listener log file, combines any multi-line log entries in to a single log entry, and sends the logs, by using syslog (UDP), to QRadar.

## About this task

Before the logs are sent to QRadar, they are processed and reformatted so that they are not forwarded line-by-line, as they are in the log file. All of the relevant information is retained.

**Note:** Perl scripts that are written for Oracle DB listener work on Linux/UNIX servers only. Windows Perl script is not supported. You must make sure Perl 5.8 is installed on the device that hosts the Oracle server.

To install and configure the Perl script:

## Procedure

1. Go to the following website to download the files that you need:  
<http://www.ibm.com/support>
2. From the **Downloads** list, click **Fix Central**.
3. Click **Select product** tab.
4. Select **IBM Security** from the **Product Group** list.
5. Select **IBM Security QRadar SIEM** from the **Select from IBM Security** list.
6. Select the **Installed Version** of QRadar.
7. Select **Linux** from the **Platform** list and click **Continue**.
8. Select **Browse for fixes** and click **Continue**.
9. Select **Script**.
10. Click `<QRadar_version>-oracle_dblistener-fwdr-<version_number>.pl.tar.gz` to download the Oracle DB Listener Script.
11. Copy the Oracle DB Listener Script to the server that hosts the Oracle server.
12. Log in to the Oracle server by using an account that has read/write permissions for the `listener.log` file and the `/var/run` directory.
13. Extract the Oracle DB Listener Script file by typing the following command:  
`tar -xvzf oracle_dblistener-fwdr-<version_number>.pl.tar.gz`
14. Type the following command and include any additional command parameters to start monitoring the Oracle DB Listener log file:  
`oracle_dblistener-fwdr.pl -h <IP address> -t "tail -F <absolute_path_to_listener_log>/listener.log"`  
where `<IP address>` is the IP address of your QRadar Console or Event Collector, and `<absolute_path_to_listener_log>` is the absolute path of the listener log file on the Oracle server.

Table 872. Command parameters

| Parameters | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-D</b>  | The <b>-D</b> parameter defines that the script is to run in the foreground. Default is to run as a daemon and log all internal messages to the local syslog service.                                                                                                                                                                                                                                                                                                                                                                        |
| <b>-t</b>  | The <b>-t</b> parameter defines that the command-line is used to tail the log file (monitors any new output from the listener). The location of the log file might be different across versions of the Oracle database. For examples,<br>Oracle 9i: <code>&lt;install_directory&gt;/product/9.2/network/log/listener.log</code><br>Oracle 10g: <code>&lt;install_directory&gt;/product/10.2.0/db_1/network/log/listener.log</code><br>Oracle 11g: <code>&lt;install_directory&gt;/diag/tnslsnr/qaoracle11/listener/trace/listener.log</code> |
| <b>-f</b>  | The <b>-f</b> parameter defines the <b>syslog facility.priority</b> to be included at the beginning of the log.<br>If nothing is specified, <code>user.info</code> is used.                                                                                                                                                                                                                                                                                                                                                                  |

Table 872. Command parameters (continued)

| Parameters | Description                                                                                                                                                                                                                                                         |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-g</b>  | The <b>-g</b> parameter defines the language pack file. For example,<br><br>./oracle_dblistener-fwdr.pl -h <IP_address> -g /root/OracleDBListener/languagepacks/localization.french -t "tail -f /root/smbtest/listener_vali.log"<br><br>This parameter is optional. |
| <b>-H</b>  | The <b>-H</b> parameter defines the host name or IP address for the syslog header. It is suggested that is the IP address of the Oracle server on which the script is running.                                                                                      |
| <b>-h</b>  | The <b>-h</b> parameter defines the receiving syslog host (the Event Collector host name or IP address that is used to receive the logs).                                                                                                                           |
| <b>-p</b>  | The <b>-p</b> parameter defines the receiving UDP syslog port.<br><br>If a port is not specified, 514 is used.                                                                                                                                                      |
| <b>-r</b>  | The <b>-r</b> parameter defines the directory name where you want to create the .pid file. The default is /var/run. This parameter is ignored if <b>-D</b> is specified.                                                                                            |
| <b>-l</b>  | The <b>-l</b> parameter defines the directory name where you want to create the lock file. The default is /var/lock. This parameter is ignored if <b>-D</b> is specified.                                                                                           |

For example, to monitor the listener log on an Oracle 9i server with an IP address of 192.0.2.10 and forward events to QRadar with the IP address of 192.0.2.20, type the following code:

```
oracle_dblistener-fwdr.pl -t "tail -f <install_directory>/product/9.2/network/log/listener.log" -f user.info -H 192.0.2.10 -h 192.0.2.20 -p 514
```

A sample log from this setup would appear as follows:

```
<14>Apr 14 13:23:37 192.0.2.10 AgentDevice=OracleDBListener
Command=SERVICE_UPDATE DeviceTime=18-AUG-2006 16:51:43 Status=0 SID=qora9
```

**Note:** The **kill** command can be used to stop the script if you need to reconfigure a script parameter or stop the script from sending events to QRadar. For example,

```
kill -QUIT `cat /var/run/oracle_dblistener-fwdr.pid`
```

The example command uses the *backquote* character (`), which is located to the left of the number one on most keyboard layouts.

## What to do next

You can now configure the Oracle Database Listener within QRadar.

## Configuring the Oracle Database Listener within QRadar.

You can configure the Oracle Database Listener within IBM QRadar.

### Procedure

- From the **Log Source Type** list, select **Oracle Database Listener**.
- From the **Protocol Configuration** list, select **syslog**.
- In the **Log Source Identifier** field, type the IP address of the Oracle Database you specified using the **-H** option in “[Collecting Oracle database events by using Perl](#)” on page 1340.

The configuration of the Oracle Database Listener protocol is complete. For more information on Oracle Database Listener, see your vendor documentation.

## Oracle Directory Server overview

---

Oracle Directory Server is formerly known as Sun ONE LDAP.

## Oracle Enterprise Manager

---

The IBM QRadar DSM for Oracle Enterprise Manager collects events from an Oracle Enterprise Manager device. The Real-time Monitoring Compliance feature of Oracle Enterprise Manager generates the events.

The following table lists the specifications for the Oracle Enterprise Manager DSM:

| Table 873. Oracle Enterprise Manager DSM specifications |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| More information                                        | <a href="https://www.oracle.com/enterprise-manager/">Oracle Enterprise Manager</a> ( <a href="https://www.oracle.com/enterprise-manager/">https://www.oracle.com/enterprise-manager/</a> ).<br>The original format of the events are rows in an Oracle Enterprise Manager database view (sysman.mgmt\$ccc_all_observations). QRadar polls this view for new rows and uses them to generate events. For more information, see <a href="http://docs.oracle.com/cd/E24628_01/doc.121/e57277/ch5_complianceviews.htm#BABBIJAA">Compliance Views</a> ( <a href="http://docs.oracle.com/cd/E24628_01/doc.121/e57277/ch5_complianceviews.htm#BABBIJAA">http://docs.oracle.com/cd/E24628_01/doc.121/e57277/ch5_complianceviews.htm#BABBIJAA</a> ) |

To collect events from Oracle Enterprise Manager, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the Oracle Enterprise Manager DSM RPM from the [IBM Support Website](#) onto your QRadar Console.
2. Ensure that the Oracle Enterprise Manager system is configured to accept connections from external devices.
3. Add an Oracle Enterprise Manager log source on the QRadar Console. The following table describes the parameters that require specific values for Oracle Enterprise Manager event collection:

Table 874. Oracle Enterprise Manager JDBC log source parameters

| Parameter                                | Description                                                                                                                                                                                                                                                                                   |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source Name</b>                   | Type a unique name for the log source.                                                                                                                                                                                                                                                        |
| <b>Log Source Description (Optional)</b> | Type a description for the log source.                                                                                                                                                                                                                                                        |

## Oracle Fine Grained Auditing

The Oracle Fine Grained Auditing DSM can poll for database audit events from Oracle 9i and later by using the Java Database Connectivity (JDBC) protocol.

To collect events, administrators must enable fine grained auditing on their Oracle databases. Fine grained auditing provides events on select, update, delete, and insert actions that occur in the source database and the records that the data changed. The database table `dba_fga_audit_trail` is updated with a new row each time a change occurs on a database table where the administrator enabled an audit policy.

To configure Oracle fine grained auditing, administrators can complete the following tasks:

1. Configure an audit on any tables that require policy monitoring in the Oracle database.
2. Configure a log source for the Oracle Fine Grained Auditing DSM to poll the Oracle database for events.
3. Verify that the events polled are collected and displayed on the **Log Activity** tab of IBM QRadar.

## JDBC log source parameters for Oracle Fine Grained Auditing

If QRadar does not automatically detect the log source, add a Oracle Fine Grained Auditing log source on the QRadar Console by using the JDBC protocol.

When using the JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from Oracle Fine Grained Auditing:

Table 875. JDBC log source parameters for the Oracle Fine Grained Auditing DSM

| Parameter                     | Value                        |
|-------------------------------|------------------------------|
| <b>Log Source type</b>        | Oracle Fine Grained Auditing |
| <b>Protocol Configuration</b> | JDBC                         |

Table 875. JDBC log source parameters for the Oracle Fine Grained Auditing DSM (continued)

| Parameter                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source Identifier</b>   | Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.<br><br>If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2. |
| <b>Database Type</b>           | Oracle                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Predefined Query</b>        | From the list, select <b>None</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Table Name</b>              | Type dba_fga_audit_trail as the name of the table that includes the event records. If you change the value of this field from the default, events cannot be properly collected by the JDBC protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Compare Field</b>           | Type extended_timestamp to identify new events added between queries to the table by their time stamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Use Prepared Statements</b> | Select the <b>Use Prepared Statements</b> check box. Prepared statements allow the JDBC protocol source to set up the SQL statement one time, then run the SQL statement many times with different parameters. For security and performance reasons, it is suggested that you use prepared statements. Clearing this check box requires you to use an alternative method of querying that does not use pre-compiled statements.                                                                                                                                                                                                                               |

For a complete list of JDBC protocol parameters and their values, see “[JDBC protocol configuration options](#)” on page 147.

## Oracle RDBMS OS Audit Record

The IBM QRadar DSM for Oracle RDBMS OS Audit Record collects events from an Oracle device.

To integrate Oracle RDBMS OS Audit Record with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](#) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:

- DSM Common RPM
  - OracleOSAudit DSM RPM
2. Configure your Oracle RDBMS OS Audit Record device to send events to QRadar. For more information, see [Configuring Oracle RDBMS OS Audit Record to communicate with QRadar](#).
  3. If QRadar does not automatically detect the log source, add an Oracle RDBMS OS Audit Record log source on the QRadar Console by using the Syslog or Log File protocol. For more information, see [Syslog log source parameters for Oracle RDBMS OS Audit Record](#) or [Log File log source parameters for Oracle RDBMS OS Audit Record](#).

## Oracle RDBMS OS Audit Record DSM specifications

When you configure the Oracle RDBMS OS Audit Record DSM, understanding the specifications for the Oracle RDBMS OS Audit Record DSM can help ensure a successful integration. For example, knowing what the supported version of Oracle RDBMS OS Audit Record is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Oracle RDBMS OS Audit Record DSM.

| Table 876. Oracle RDBMS OS Audit Record DSM specifications |                                                                                                                        |

| Includes identity?                                         | Yes                                                                                                                    |
| Includes custom properties?                                | No                                                                                                                     |
| More information                                           | <a href="https://docs.oracle.com">Oracle website</a> ( <a href="https://docs.oracle.com">https://docs.oracle.com</a> ) |

## Configuring Oracle RDBMS OS Audit Record to communicate with QRadar

When using the Oracle RDBMS OS Audit Record DSM for IBM QRadar, you can monitor the audit records that are stored in the local operating system file.

### About this task

When audit event files are created or updated in the local operating system directory, a Perl script detects the change and then forwards the data to QRadar. The Perl script monitors the Audit log file, and combines any multi-line log entries into a single log entry to make sure that the logs are not forwarded line-by-line. This format matches the format in the log file. The logs are then sent by using Syslog to

QRadar. Perl scripts that are written for Oracle RDBMS OS Audit Record work only on Linux or UNIX servers. Windows - based Perl installations are not supported.

## Procedure

1. Go to the [IBM Support website](https://www.ibm.com/support/fixcentral) (<https://www.ibm.com/support/fixcentral>) and download the following script:  
QRadar 7.4.0 - 7.4.0-QRADAR-SCRIPT-oracle\_osauditlog\_fwdr\_5.3.tar.gz ([https://www.ibm.com/support/fixcentral/swg/selectFixes?parent=IBM%20Security&product=ibm/Other+software/IBM+Security+QRadar+SIEM&release>All&platform>All&function=fixId&fixids=7.4.0-QRADAR-SCRIPT-oracle\\_osauditlog\\_fwdr\\_5.3.tar.gz&includeSupersedes=0](https://www.ibm.com/support/fixcentral/swg/selectFixes?parent=IBM%20Security&product=ibm/Other+software/IBM+Security+QRadar+SIEM&release>All&platform>All&function=fixId&fixids=7.4.0-QRADAR-SCRIPT-oracle_osauditlog_fwdr_5.3.tar.gz&includeSupersedes=0))

2. Type the following command to extract the file:

```
tar -zvxf oracle_osauditlog_fwdr_5.3.tar.gz
```

3. Copy the Perl script to the server that hosts the Oracle server.

**Note:** Perl 5.8 must be installed on the device that hosts the Oracle server. If you don't have Perl 5.8 installed, you might be prompted that library files are missing when you attempt to start the Oracle OS Audit script. Verify that Perl 5.8 is installed before you continue.

4. Log in to the Oracle host as an Oracle user that has SYS or root privilege.
5. Make sure the *ORACLE\_HOME* and *ORACLE\_SID* environment variables are configured properly for your deployment.
6. Open the following file:

```
 ${ORACLE_HOME}/dbs/init${ORACLE_SID}.ora
```

7. For syslog, add the following lines to the file:

```
*.audit_trail=os *.audit_syslog_level=local0.info
```

8. Verify that account has read/write permissions for the following directory:

```
/var/lock/ /var/run/
```

9. Restart the Oracle database instance.

10. Start the OS Audit DSM script:

```
oracle_osauditlog_fwdr_5.3.pl -t target_host -d logs_directory
```

If you restart your Oracle server, you must restart the script:

```
oracle_osauditlog_fwdr.pl -t target_host -d logs_directory
```

For more information about Oracle OS Audit command parameters, see [Oracle RDBMS OS Audit Record command parameters](#).

## What to do next

Configure a log source in QRadar. For more information about Oracle OS Audit log source parameters, see [Syslog log source parameters for Oracle RDBMS OS Audit Record](#) or [Log File log source parameters for Oracle RDBMS OS Audit Record](#).

## Oracle RDBMS OS Audit Record command parameters

When you use Oracle RDBMS OS Audit Record commands, there are specific parameters that you must use.

The following table describes the Oracle RDBMS OS Audit Record command parameters for Oracle RDBMS OS Audit Record:

*Table 877. Oracle RDBMS OS Audit Record command parameters*

| Parameter | Description                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-t</b> | Defines the remote host that receives the audit log files.                                                                                                                                       |
| <b>-d</b> | Defines directory location of the DDL and DML log files.<br>The directory location that you specify must be the absolute path from the root directory.                                           |
| <b>-H</b> | Defines the host name or IP address for the syslog header. It is suggested that is the IP address of the Oracle server on which the script is running.                                           |
| <b>-D</b> | The <b>-D</b> parameter defines that the script is to run in the foreground.<br>The default is to run as a daemon (in the background) and log all internal messages to the local syslog service. |
| <b>-n</b> | Processes new logs, and monitors existing log files for changes to be processed.<br>If the <b>-n</b> option string is absent, all existing log files are processed during script execution.      |
| <b>-u</b> | Defines UDP.                                                                                                                                                                                     |
| <b>-f</b> | Defines the <b>syslog facility.priority</b> to be included at the beginning of the log.<br>If you do not type a value, <b>user.info</b> is used.                                                 |
| <b>-r</b> | Defines the directory name where you want to create the .pid file. The default is /var/run. This parameter is ignored if <b>-D</b> is specified.                                                 |
| <b>-l</b> | Defines the directory name where you want to create the lock file. The default is /var/lock. This parameter is ignored if <b>-D</b> is specified.                                                |
| <b>-h</b> | Displays the help message.                                                                                                                                                                       |
| <b>-v</b> | Displays the version information for the script.                                                                                                                                                 |

#### Related tasks

[“Configuring Oracle RDBMS OS Audit Record to communicate with QRadar” on page 1347](#)

When using the Oracle RDBMS OS Audit Record DSM for IBM QRadar, you can monitor the audit records that are stored in the local operating system file.

## Syslog log source parameters for Oracle RDBMS OS Audit Record

When you add an Oracle RDBMS OS Audit Record log source on the QRadar Console by using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Oracle RDBMS OS Audit Record:

*Table 878. Syslog log source parameters for the Oracle RDBMS OS Audit Record DSM*

| Parameter                     | Value                               |
|-------------------------------|-------------------------------------|
| <b>Log Source type</b>        | <b>Oracle RDBMS OS Audit Record</b> |
| <b>Protocol Configuration</b> | Syslog                              |

*Table 878. Syslog log source parameters for the Oracle RDBMS OS Audit Record DSM (continued)*

| Parameter                    | Value                                                                                                                                     |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source Identifier</b> | Type the address that is specified when you use the <b>-H</b> option in <a href="#">Oracle RDBMS OS Audit Record command parameters</a> . |

For more common log source parameters and their values, see [Adding a log source..](#)

## Log File log source parameters for Oracle RDBMS OS Audit Record

If QRadar does not automatically detect the log source, add an Oracle RDBMS OS Audit Record log source on the QRadar Console by using the Log File protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from Oracle RDBMS OS Audit Record:

*Table 879. Log File log source parameters for the Oracle RDBMS OS Audit Record DSM*

| Parameter                     | Value                                                                                                                                     |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Log Source type</b>        | Oracle RDBMS OS Audit Record                                                                                                              |
| <b>Protocol Configuration</b> | Log File                                                                                                                                  |
| <b>Log Source Identifier</b>  | Type the address that is specified when you use the <b>-H</b> option in <a href="#">Oracle RDBMS OS Audit Record command parameters</a> . |

For a complete list of Log File protocol parameters and their values, see [Log File protocol configuration options](#).

---

# Chapter 120. osquery

The IBM QRadar DSM for osquery receives JSON formatted events from devices that use a Linux operating system. The osquery DSM is available for QRadar V7.3.0 and later.

The osquery DSM supports rsyslog and the following queries that are included in the `qradar.pack.conf` file for osquery V3.3.2:

- container\_processes
- docker\_container\_mounts
- docker\_containers
- listening\_ports
- process\_open\_sockets
- sudoers
- users
- file\_events

**Important:** The supported osquery queries run on a 10 second interval, and only capture data that is available at that moment. For example, if a new process starts and finishes between queries of `container_processes`, that information is not captured by osquery. For information about osquery differential logs, see the [osquery documentation](https://osquery.readthedocs.io/en/stable/deployment/logging/#results-logs) (<https://osquery.readthedocs.io/en/stable/deployment/logging/#results-logs>).

The following supported queries only capture data that is available at the 10 second querying interval:

- container\_processes
- docker\_container\_mounts
- docker\_containers
- listening\_ports
- process\_open\_sockets
- sudoers
- users

To integrate osquery with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - DSM Common RPM
  - osquery DSM RPM
  - TCP Multiline Syslog protocol RPM
  - Protocol Common RPM
2. Ensure that the TCP port you want to use on your QRadar Console to receive events is open. For more information, see [QRadar: Managing IPtables firewall ports using the User Interface](https://www.ibm.com/support/pages/qradar-managing-iptables-firewall-ports-using-user-interface). (<https://www.ibm.com/support/pages/qradar-managing-iptables-firewall-ports-using-user-interface>)
3. Configure rsyslog on your Linux system. For more information about configuring rsyslog, see [“Configuring rsyslog on your Linux system” on page 1354](#).
4. Configure osquery on your Linux system. For more information about configuring osquery, see [“Configuring osquery on your Linux system” on page 1355](#).
5. Add an osquery log source on the QRadar Console to use the TCP multiline syslog protocol. For information about osquery log source parameters, see [“osquery log source parameters” on page 1356](#).

## osquery DSM specifications

When you configure osquery, understanding the specifications for the osquery DSM can help ensure a successful integration. For example, knowing what the supported version of osquery is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the osquery DSM

| Table 881. osquery DSM specifications |                                                                                                          |
|---------------------------------------|----------------------------------------------------------------------------------------------------------|
| Specification                         | Value                                                                                                    |
| DSM name                              | osquery                                                                                                  |
| RPM file name                         | DSM-osquery-QRadar_version-build_number.noarch.rpm                                                       |
| Supported versions                    | 3.3.2                                                                                                    |
| Protocol                              | Syslog<br>TCP Multiline Syslog                                                                           |
| Event format                          | JSON                                                                                                     |
| Recorded event types                  | Access Audit Authentication System                                                                       |
| Automatically discovered?             | No                                                                                                       |
| Includes identity?                    | No                                                                                                       |
| Includes custom properties?           | Yes                                                                                                      |
| More information                      | <a href="https://osquery.io">osquery website</a> ( <a href="https://osquery.io">https://osquery.io</a> ) |

## Configuring rsyslog on your Linux system

Before you can add a log source in QRadar, you need to configure rsyslog on your Linux system.

### Before you begin

Rsyslog must be installed on your Linux system. For more information, go to the [rsyslog website](https://www.rsyslog.com) (<https://www.rsyslog.com>).

### Procedure

1. On your Linux system, open the /etc/rsyslog.conf file, and then add the following entry at the end of the file:

```
local3.info @@<QRadar_IP_address>:12468
```

where <QRadar\_IP\_address> is the IP address of the QRadar Event Collector that you want to send events to.

2. You must be able to send rsyslog on a non-traditional TCP port. A potential challenge is that SELinux might block TCP port 12468. For more information, see [Configuring rsyslog on](#)

a logging server ([https://access.redhat.com/documentation/en-us/red\\_hat\\_enterprise\\_linux/7/html/system\\_administrators\\_guide/s1-configuring\\_rsyslog\\_on\\_a\\_logging\\_server](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/7/html/system_administrators_guide/s1-configuring_rsyslog_on_a_logging_server)).

3. Restart the rsyslog service.

## What to do next

Configure osquery on your Linux system. For more information, see [“Configuring osquery on your Linux system” on page 1355](#).

### Related concepts

[“osquery” on page 1353](#)

## Configuring osquery on your Linux system

---

Before you can add a log source in QRadar, you must configure osquery on your Linux device.

### Before you begin

Osquery V3.3.2 must be installed and running on your Linux system. For more information about installing osquery for Linux, see [Downloading and Installing Osquery](#) (<https://osquery.io/downloads/official/3.3.2>).

### Procedure

1. Download the `qradar.pack.conf` file from [IBM Fix Central](#) (<https://www.ibm.com/support/fixcentral>).
2. Copy the `qradar.pack.conf` file to your osquery host. For example, `<location_of_pack_file>/qradar.pack.conf`
3. Edit the `osquery.conf` file. The default file location is `/etc/osquery/osquery.conf`.
  - a) Ensure the following options are included in the `osquery.conf` file.

```
"disable_logging": "false"  
"disable_events" : "false"  
"logger_plugin": "filesystem,syslog"
```

- b) Add `qradar.pack.conf` to the `osquery.conf` file.

```
"qradar": "<path_to_packs>/qradar.pack.conf"
```

### Example `<osquery>.conf` file:

```
{ // Configure the daemon below: "options": { "disable_logging": "false",  
"disable_events" : "false", "logger_plugin": "filesystem,syslog", "utc": "true" },  
"packs": { "qradar": "<location_of_pack_file>/qradar.pack.conf" }}
```

**Note:** The `qradar.pack.conf` file contains a “file\_paths” section that defines default file integrity monitoring for the QRadar pack. “file\_paths” that are defined inside customer `<osquery>.conf` files take precedent over the `qradar.pack.conf` file.

4. Restart the osquery daemon.

## What to do next

To get the parameter values that you need to add a log source in QRadar, see [“osquery log source parameters” on page 1356](#).

### Related concepts

[“osquery” on page 1353](#)

## osquery log source parameters

When you add an osquery log source on the QRadar Console by using the TCP multiline syslog protocol, there are specific parameters you must use.

**Note:** You might need to restart rsyslog after you add the log source in QRadar.

The following table describes the parameters that require specific values to collect TCP multiline syslog events from osquery:

| Table 882. TCP multiline syslog log source parameters for the osquery DSM |                                                                                                                                                                                                                     |
|---------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameter                                                                 | Value                                                                                                                                                                                                               |
| <b>Log Source type</b>                                                    | osquery                                                                                                                                                                                                             |

# Chapter 121. OSSEC

The OSSEC DSM for IBM QRadar accepts events that are forwarded from OSSEC installations by using syslog.

OSSEC is an open source Host-based Intrusion Detection System (HIDS) that can provide intrusion events to QRadar. If you have OSSEC agents that are installed, you must configure syslog on the OSSEC management server. If you have local or stand-alone installations of OSSEC, then you must configure syslog on each stand-alone OSSEC to forward syslog events to QRadar.

## Configuring OSSEC

---

You can configure syslog for OSSEC on a stand-alone installation or management server:

### Procedure

1. Use SSH to log in to your OSSEC device.
2. Edit the OSSEC configuration `ossec.conf` file.

```
<installation directory>/ossec/etc/ossec.conf
```

3. Add the following syslog configuration:

**Note:** Add the syslog configuration after the `alerts` entry and before the `localfile` entry.

```
</alerts>  
<syslog_output> <server>(QRadar IP Address)</server> <port>514</port> </  
syslog_output>  
<localfile>
```

For example,

```
<syslog_output> <server><IP_address></server> <port>514</port> </  
syslog_output>
```

4. Save the OSSEC configuration file.
5. Type the following command to enable the syslog daemon:

```
<installation directory>/ossec/bin/ossec-control enable client-syslog
```

6. Type the following command to restart the syslog daemon:

```
<installation directory>/ossec/bin/ossec-control restart
```

The configuration is complete. The log source is added to IBM QRadar as OSSEC events are automatically discovered. Events that are forwarded to QRadar by OSSEC are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for OSSEC

---

If QRadar does not automatically detect the log source, add an OSSEC log source on the QRadar Console by using the Syslog protocol.

When you use the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from OSSEC:

*Table 884. Syslog parameters log source parameters for the OSSEC DSM*

<b>Parameter</b>	<b>Description</b>
<b>Log Source type</b>	OSSEC
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or hostname for the log source as an identifier for events from your OSSEC installation.

# Chapter 122. Palo Alto Networks

IBM QRadar supports a range of Palo Alto Network devices.

## Palo Alto Endpoint Security Manager

The IBM QRadar DSM for Palo Alto Endpoint Security Manager (Traps) collects events from a Palo Alto Endpoint Security Manager (Traps) device.

The following table describes the specifications for the Palo Alto Endpoint Security Manager DSM:

Table 885. Palo Alto Endpoint Security Manager DSM specifications	
Specification	Value
Manufacturer	Palo Alto Networks
DSM name	Palo Alto Endpoint Security Manager
RPM file name	DSM-PaloAltoEndpointSecurityManager-QRadar_version-build_number.noarch.rpm
Supported versions	3.4.2.17401
Protocol	Syslog
Event format	Log Event Extended Format (LEEF) Common Event Format (CEF). CEF:0 is supported.
Recorded event types	Agent Config Policy System Threat
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.paloaltonetworks.com">Palo Alto Networks website</a> ( <a href="https://www.paloaltonetworks.com">https://www.paloaltonetworks.com</a> )

To integrate Palo Alto Endpoint Security Manager with QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent versions of the RPMs from the IBM support website (<http://www.ibm.com/support>).
  - DSMCommon RPM
  - Palo Alto Endpoint Security Manager DSM RPM
2. Configure your Palo Alto Endpoint Security Manager device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a Palo Alto Endpoint Security Manager log source on the QRadar Console. The following table describes the parameters that require specific values for Palo Alto Endpoint Security Manager event collection:

*Table 886. Palo Alto Endpoint Security Manager log source parameters*

Parameter	Value
<b>Log Source type</b>	Palo Alto Endpoint Security Manager
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	A unique identifier for the log source.

- To verify that QRadar is configured correctly, review the following table to see an example of a parsed event message.

The following table shows a sample event message for Palo Alto Endpoint Security Manager:

*Table 887. Palo Alto Endpoint Security Manager sample message*

## Configuring Palo Alto Endpoint Security Manager to communicate with QRadar

Before IBM QRadar can collect events from Palo Alto Endpoint Security Manager, you must configure Palo Alto Endpoint Security Manager to send events to QRadar.

### Procedure

- Log in to the Endpoint Security Manager (ESM) Console.
- Click **Settings > ESM**.
- Click **Syslog**, and then select **Enable Syslog**.
- Configure the syslog parameters:

Parameter	Value
<b>Syslog Server</b>	Host name or IP address of the QRadar server.
<b>Syslog Port</b>	514

Parameter	Value
<b>Syslog Protocol</b>	LEEF
<b>Keep-alive-timeout</b>	0
<b>Send reports interval</b>	Frequency (in minutes), in which Traps sends logs from the endpoint. The default is 10. The range is 1 - 2,147,483,647.
<b>Syslog Communication Protocol</b>	Transport layer protocol that the ESM Console uses to send syslog reports by using UDP, TCP, or TCP with SSL.

5. In the **Logging Events** area, select the types of events that you want to send to QRadar.
6. Click **Check Connectivity**. The ESM Console sends a test communication to the syslog server by using the information on the **Syslog** page. If the test message is not received, verify that the settings are correct, and then try again.

## Palo Alto Networks PA Series

Use the IBM QRadar DSM for Palo Alto PA Series to collect events from Palo Alto PA Series, Next Generation Firewall logs, and Prisma Access logs, by using Cortex Data Lake.

To send events from Palo Alto PA Series to QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent version of the following RPMs from the [IBM support website](https://www.ibm.com/support) (<https://www.ibm.com/support>).
  - DSMCommon RPM
  - TLS Syslog Protocol RPM
  - Palo Alto PA Series DSM RPM
2. Configure your Palo Alto PA Series device to send events to QRadar.
3. If QRadar does not automatically detect the log source, add a Palo Alto PA Series log source on the QRadar Console.

# Configuring Syslog or LEEF formatted events on your Palo Alto PA Series device

To send Palo Alto PA Series events to IBM QRadar, create a Syslog destination (Syslog or LEEF event format) on your Palo Alto PA Series device.

## About this task

Palo Alto can send only one format to all Syslog devices. By modifying the Syslog format, any other device that requires Syslog must support the modified format.

## Procedure

1. Log in to Palo Alto Networks.
2. On the **Device** tab, click **Server Profiles > Syslog**, and then click **Add**.
3. Create a Syslog destination by following these steps:
  - a) In the **Syslog Server Profile** dialog box, click **Add**.
  - b) Specify the name, server IP address, port, and facility of the QRadar system that you want to use as a Syslog server.
  - c) If you are using Syslog, set the **Custom Format** column to **Default** for all log types.
4. Configure LEEF events by following these steps:

**Important:** Due to formatting issues, copy the text into a text editor, remove any carriage return or line feed characters, and then paste it into the appropriate field.

- a) Click the **Custom Log Format** tab in the **Syslog Server Profile** dialog.
- b) Click **Config**, copy one of the following texts applicable to the version you are using, and paste it in the **Config Log Format** field for the **Config** log type. If your version is not listed, omit this step.

### PAN-OS 3.0 - 6.1

```
LEEF:2.0|Palo Alto Networks|PAN-OS
Syslog Integration|4.0|$result|x7C|cat=$type|usrName=$admin|src=$host|devTime=$cef-

```

- s) If you are using **PAN-OS 11.0.4**, copy the following text, and paste it in the Custom Format column for the DNS log type.

#### PAN-OS 11.0.4

```

LEEF:2.0|Palo Alto Networks|Prisma Access|
$sender_sw_version|$verdict|x7C|ProfileToken=$actionflags|DeviceSN=$log_source_id|
TimeReceived=$time_generated|cat=$log_type|DNSResponseCode=$dns_response_code|
UsrName=$source_user|LogSource=$log_source|url=$fqdn|SubType=$subtype|
devTime=$time_generated|RecordType=$record_type|DNSResolverIP=$dest_ip|ThreatID=$gtid|
ThreatName=$threat_name|src=$source_ip|FromZone=$from_zone|Action=$action|
DNSResponse=$dns_response|ToZone=$dst_zone|DestinationUser=$dst_user

```

5. Click **OK**.

6. To specify the severity of events that are contained in the Syslog messages, click **Log Settings**.

- a) For each severity that you want to include in the Syslog message, click the **Severity** name and select the Syslog destination from the **Syslog** menu.

- b) Click **OK**.
7. Click **Commit**.

## What to do next

To enable communication between your Palo Alto Networks device and QRadar create a forwarding policy. For more information, see [Creating a forwarding policy on your Palo Alto PA Series device](#).

# Forwarding Palo Alto Cortex Data Lake (Next Generation Firewall) LEEF events to IBM QRadar

To send Palo Alto Cortex Data Lake events to QRadar, you must add a TLS Syslog log source in QRadar and configure Cortex Data Lake to forward logs to a Syslog server.

## Procedure

1. Add a log source in QRadar by using the TLS Syslog protocol. For more information, see [TLS Syslog log source parameters for Palo Alto PA Series](#).

**Important:** If your log source is dedicated only to Cortex Data Lake events, then you must disable **Use as a Gateway Log Source** and set the DSM type to **Palo Alto PA Series**. If the log source is shared with multiple integrations, and you already enabled **Use as a Gateway Log Source**, then the **Log Source Identifier** must use the following regex structure:

```
<Log Source Identifier>=stream-logfwd.*?logforwarder
```

2. Forward logs from Cortex Data Lake to QRadar. For more information, see your [Palo Alto documentation](#) (<https://docs.paloaltonetworks.com/cortex/cortex-data-lake/cortex-data-lake-getting-started/get-started-with-log-forwarding-app/forward-logs-from-logging-service-to-syslog-server.html>).

**Important:**

- When forwarding logs from Cortex Data Lake, choose the LEEF log format.
- You must enable the **cat** and **EventStatus/Status** fields in Palo Alto. The **EventStatus/Status** field is required to parse **Global Protect** events in QRadar.

# Creating a forwarding policy on your Palo Alto PA Series device

If your IBMQRadar Console or Event Collector is in a different security zone than your Palo Alto PA Series device, create a forwarding policy rule.

## Procedure

1. Log in to Palo Alto Networks.
2. Click **Policies > Policy Based Forwarding**.
3. Click **Add**.
4. Configure the parameters. For descriptions of the policy-based forwarding values, see your *Palo Alto Networks Administrator's Guide*.

# Configuring ArcSight CEF formatted Syslog events on your Palo Alto PA Series Networks Firewall device

Configure your Palo Alto Networks firewall to send ArcSight CEF formatted Syslog events to IBM QRadar.

## Procedure

1. Log in to the Palo Alto Networks interface.
2. Click the **Device** tab.

3. Select **Server Profiles > Syslog**.
4. Click **Add**.
5. Specify the name, server IP address, port, and facility of the QRadar system that you want to use as a Syslog server:
  - a) The **Name** is the Syslog server name.
  - b) The **Syslog Server** is the IP address for the Syslog server.
  - c) The **Transport** default is **UDP**.
  - d) The **Port** default is **514**.
  - e) The **Facility** default is **LOG\_USER**.
6. To select any of the listed log types that define a custom format, based on the ArcSight CEF for that log type, complete the following steps:
  - a) Click the **Custom Log Format** tab and select any of the listed log types to define a custom format based on the ArcSight CEF for that log type. The listed log types are **Config, System, Threat, Traffic, and HIP Match**.
  - b) Click **OK** twice to save your entries, then click **Commit**.
7. To define your own CEF-style formats that use the event mapping table that is provided in the ArcSight document, *Implementing ArcSight CEF*, you can use the following information about defining CEF style formats:
  - a) The **Custom Log Format** tab supports escaping any characters that are defined in the CEF as special characters. For example, to use a backslash to escape the backslash and equal characters, enable the **Escaping** check box, specify \= as the **Escaped Characters** and \ as the **Escape Character**.
  - b) The following list displays the CEF-style format that was used during the certification process for each log type. These custom formats include all of the fields, in a similar order, that the default format of the Syslogs display.

**Important:** Due to PDF formatting, do not copy and paste the message formats directly into the PAN-OS web interface. Instead, paste into a text editor, remove any carriage return or line feed characters, and then copy and paste into the web interface.

### Traffic

## What to do next

For more information about Syslog configuration, see the [PAN-OS Administrator's Guide](#) on the [Palo Alto Networks website](#) (<https://www.paloaltonetworks.com>).

## TLS Syslog log source parameters for Palo Alto PA Series

If IBM QRadar does not automatically detect the log source, add a Palo Alto PA Series log source on the QRadar Console by using the TLS Syslog protocol.

When you use the TLS Syslog protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect TLS Syslog events from Palo Alto PA Series:

Table 889. TLS Syslog log source parameters for the Palo Alto PA Series DSM	
Parameter	Value
<b>Log Source type</b>	Palo Alto PA Series
<b>Protocol Configuration</b>	TLS Syslog
<b>Log Source Identifier</b>	An IP address or hostname to identify the log source.

For a complete list of TLS Syslog protocol parameters and their values, see [TLS Syslog protocol configuration options](#).

# Chapter 123. PingFederate

The IBM QRadar DSM for PingFederate collects CEF events from a PingFederate server.

To integrate PingFederate with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from [IBM support](#). Download and install the most recent version of the PingFederateRPM on your QRadar Console.
2. Configure your PingFederate device to send events to QRadar. For more information, see [Configuring PingFederate to communicate with IBM QRadar](#).
3. If QRadar does not automatically detect the log source, add a PingFederate log source on the QRadar Console. For more information, see [Syslog log source parameters for PingFederate](#).

## Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## PingFederate DSM specifications

The IBM QRadar DSM for PingFederate supports events that are collected from PingFederate with the help of the Syslog protocol.

The following table lists the specifications for the PingFederate DSM.

Table 893. PingFederate DSM specifications	
Specification	Value
Manufacturer	Ping Identity
DSM name	PingFederate
RPM file name	<i>DSM-PingFederate-QRadar_version-Build_number.noarch.rpm</i>
Supported protocols	Syslog
Event format	CEF
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="#">PingFederate Server</a>

## Configuring PingFederate to communicate with IBM QRadar

To collect PingFederate events, configure your PingFederate to send CEF events to QRadar.

The IBM QRadar DSM for PingFederate supports events that are collected from PingFederate with the help of the Syslog protocol.

### Procedure

1. Configure PingFederate to communicate with QRadar by following the configuration steps in the [PingFederate writing audit log](#).
2. Edit `log4j2.xml` file present at the location - `<pf_install>/pingfederate/server/default/conf/log4j2.xml`.

3. Add the below details to log4j2.xml.

```

<Socket name="SecurityAuditToCEFSyslog" host="" port="514" protocol="TCP"
ignoreExceptions="false"> <PingSyslogLayout>
  <PatternLayout>
    <pattern>%escape{CEF}{CEF:0|Ping_Identity|PingFederate|%X{pfversion}|%X{event}|
%X{event}|0|rt=%d{MMM dd yyyy HH:mm:ss.SSS} duid=%X{subject} src=%X{ip} msg=%X{status}

cs3Label=Protocol cs3=%X{protocol} dvchost=%X{host} cs4Label=Role cs4=%X{role}
externalId=%X{trackingid} cs5Label=SP Local User ID cs5=%X{localuserid} cs6Label=Attributes
cs6=%X{attributes} %n}</pattern>
  </PatternLayout>
</PingSyslogLayout>
</Socket>

```

## What to do next

Add a PingFederate - Syslog log source in QRadar. For more information, see [Syslog log source parameters for PingFederate](#).

## Syslog log source parameters for PingFederate

The IBM QRadar DSM for PingFederate collects security audit logging events from a PingFederate server.

If QRadar does not automatically detect the log source, add a PingFederate log source on the QRadar Console by using the Syslog protocol.

Configure specific parameters when you are using the Syslog protocol.

The following table describes the parameters that require specific values to collect the security audit logging events from PingFederate:

Table 894. PingFederate log source parameters	
Parameter	Value
<b>Log Source type</b>	PingFederate
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type a unique name for the log source.

For more information about the protocol parameters and their values, see [Adding a log source](#).

## PingFederate sample event message

Use these sample event messages to verify a successful integration with IBM QRadar.

### PingFederate sample message when you use the Syslog protocol: Authentication Attempt

The following sample event message shows that the event indicates an authentication attempt against an identity provider (IdP) adapter instance, and also an authentication request sent to another identity provider instance through an identity provider connection.

```

CEF:0|Ping_Identity|PingFederate|12.0|AUTHN_ATTEMPT|AUTHN_ATTEMPT|0|rt=Feb 02 2024 15:49:12.139

# Chapter 124. Pirean Access: One

The Pirean Access: One DSM for IBM QRadar collects events by polling the DB2 audit database for access management, and authentication events.

QRadar supports Pirean Access: One software installations at v2.2 that use a DB2 v9.7 database to store *access management* and *authentication* events.

## Before you begin

Before you configure QRadar to integrate with Pirean Access: One, you can create a database user account and password for QRadar. Creating a QRadar account is not required, but is beneficial as it secures your *access management* and *authentication* event table data for the QRadar user.

Your QRadar user needs read permission access for the database table that contains your events. The JDBC protocol allows QRadar to log in and poll for events from the database based on the time stamp to ensure that the most recent data is retrieved.

**Note:** Ensure that firewall rules do not block communication between your Pirean Access: One installation and the QRadar Console or managed host responsible for event polling with JDBC.

## JDBC log source parameters for Pirean Access: One

If QRadar does not automatically detect the log source, add a Pirean Access: One log source on the QRadar Console by using the JDBC protocol.

When using the JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from Pirean Access: One:

Parameter	Description
<b>Log Source Name</b>	Type a unique name for the log source.
<b>Log Source Description (Optional)</b>	Type a description for the log source.
<b>Log Source Type</b>	<b>Pirean Access: One</b>
<b>Protocol Configuration</b>	<b>JDBC</b>
<b>Log Source Identifier</b>	Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.  If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2.
<b>Database Type</b>	<b>DB2</b>
<b>Database Name</b>	Type the name of the database to which you want to connect. The default database name is LOGINAUD.

Parameter	Description
<b>IP or Hostname</b>	Type the IP address or host name of the database server.
<b>Port</b>	<p>Enter the JDBC port. The JDBC port must match the listener port that is configured on the remote database. The database must permit incoming TCP connections. The valid range is 1 - 65535.</p> <p>The defaults are:</p> <ul style="list-style-type: none"> <li>• MSDE - 1433</li> <li>• Postgres - 5432</li> <li>• MySQL - 3306</li> <li>• Sybase - 1521</li> <li>• Oracle - 1521</li> <li>• Informix - 9088</li> <li>• DB2 - 50000</li> </ul> <p>If a database instance is used with the MSDE database type, you must leave the <b>Port</b> field blank.</p>
<b>Username</b>	A user account for QRadar in the database.
<b>Password</b>	The password that is required to connect to the database.
<b>Confirm Password</b>	The password that is required to connect to the database.
<b>Table Name</b>	<p>Type AUDITDATA as the name of the table or view that includes the event records.</p> <p>The table name can be up to 255 alphanumeric characters in length. The table name can include the following special characters: dollar sign (\$), number sign (#), underscore (_), en dash (-), and period(.) .</p>
<b>Select List</b>	<p>Type * to include all fields from the table or view.</p> <p>You can use a comma-separated list to define specific fields from tables or views, if it is needed for your configuration. The list must contain the field that is defined in the <b>Compare Field</b> parameter. The comma-separated list can be up to 255 alphanumeric characters in length. The list can include the following special characters: dollar sign (\$), number sign (#), underscore (_), en dash (-), and period(.) .</p>
<b>Compare Field</b>	<p>Type <b>TIMESTAMP</b> to identify new events added between queries to the table.</p> <p>The compare field can be up to 255 alphanumeric characters in length. The list can include the special characters: dollar sign (\$), number sign (#), underscore (_), en dash (-), and period(.) .</p>
<b>Use Prepared Statements</b>	<p>Select this check box to use prepared statements, which allows the JDBC protocol source to set up the SQL statement one time, then run the SQL statement many times with different parameters. For security and performance reasons, it is suggested that you use prepared statements.</p> <p>Clear this check box to use an alternative method of querying that does not use pre-compiled statements.</p>

Parameter	Description
<b>Start Date and Time</b> (Optional)	<p>Optional. Configure the start date and time for database polling.</p> <p>The <b>Start Date and Time</b> parameter must be formatted as yyyy-MM-dd HH: mm with HH specified by using a 24-hour clock. If the start date or time is clear, polling begins immediately and repeats at the specified polling interval.</p>
<b>Polling Interval</b>	<p>Type the polling interval, which is the amount of time between queries to the event table. The default polling interval is 10 seconds.</p> <p>You can define a longer polling interval by appending H for hours or M for minutes to the numeric value. The maximum polling interval is 1 week in any time format. Numeric values without an H or M designator poll in seconds.</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The default is 20,000 EPS.</p>
<b>Security Mechanism</b>	<p>From the list, select the security mechanism that is supported by your DB2 server. If you don't want to select a security mechanism, select <b>None</b>.</p> <p>The default is <b>None</b>.</p> <p>For more information about security mechanisms that are supported by DB2 environments, see the <a href="https://www.ibm.com/support/knowledgecenter/en/SSEPGG_11.1.0/com.ibm.db2.luw.apdv.java.doc/src/tpc/imjcc_cjvcsec.html">IBM Support website</a> (<a href="https://www.ibm.com/support/knowledgecenter/en/SSEPGG_11.1.0/com.ibm.db2.luw.apdv.java.doc/src/tpc/imjcc_cjvcsec.html">https://www.ibm.com/support/knowledgecenter/en/SSEPGG_11.1.0/com.ibm.db2.luw.apdv.java.doc/src/tpc/imjcc_cjvcsec.html</a>)</p>
<b>Enabled</b>	<p>Select this check box to enable the Pirean Access: One log source.</p>

For a complete list of JDBC protocol parameters and their values, see “[JDBC protocol configuration options](#)” on page 147.

# Chapter 125. PostFix Mail Transfer Agent

IBM QRadar can collect and categorize syslog mail events from PostFix Mail Transfer Agents (MTA) installed in your network.

To collect syslog events, you must configure PostFix MTA installation to forward syslog events to QRadar. QRadar does not automatically discover syslog events that are forwarded from PostFix MTA installations as they are multiline events. QRadar supports syslog events from PostFix MTA V2.6.6.

To configure PostFix MTA, complete the following tasks:

1. On your PostFix MTA system, configure `syslog.conf` to forward mail events to QRadar.
2. On your QRadar system, create a log source for PostFix MTA to use the UDP multiline syslog protocol.
3. On your QRadar system, configure IPtables to redirect events to the port defined for UDP multiline syslog events.
4. On your QRadar system, verify that your PostFix MTA events are displayed on the **Log Activity** tab.

If you have multiple PostFix MTA installations where events go to different QRadar systems, you must configure a log source and IPtables for each QRadar system that receives PostFix MTA multiline UDP syslog events.

## Configuring syslog for PostFix Mail Transfer Agent

To collect events, you must configure syslog on your PostFix MTA installation to forward mail events to IBM QRadar.

### Procedure

1. Use SSH to log in to your PostFix MTA installation as a root user.
2. Edit the following file:

`/etc/syslog.conf`

3. To forward all mail events, type the following command to change `- /var/log/maillog/` to an IP address. Make sure that all other lines remain intact:

`mail.*@<IP address>`

Where `<IP address>` is the IP address of the QRadar Console, Event Processor, or Event Collector, or all-in-one system.

4. Save and exit the file.
5. Restart your syslog daemon to save the changes.

## UDP Multiline Syslog log source parameters for PostFix MTA

If QRadar does not automatically detect the log source, add a PostFix MTA log source on the QRadar Console by using the UDP Multiline Syslog protocol.

When using the UDP Multiline Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect UDP Multiline Syslog events from PostFix MTA:

Table 897. UDP Multiline Syslog log source parameters for the PostFix MTA DSM

Parameter	Description
<b>Log Source Identifier</b>	Type the IP address, host name, or name to identify your PostFix MTA installation.
<b>Listen Port</b>	<p>Type <b>517</b> as the port number used by QRadar to accept incoming UDP Multiline Syslog events. The valid port range is 1 - 65535.</p> <p>To edit a saved configuration to use a new port number:</p> <ol style="list-style-type: none"> <li>1. In the <b>Listen Port</b> field, type the new port number for receiving UDP Multiline Syslog events.</li> <li>2. Click <b>Save</b>.</li> <li>3. On the <b>Admin</b> tab toolbar, click <b>Deploy Changes</b> to make this change effective.</li> </ol> <p>The port update is complete and event collection starts on the new port number.</p>
<b>Message ID Pattern</b>	<p>Type the following regular expression (regex) needed to filter the event payload messages.</p> <pre>postfix/.*?[ \[]\d+[ \]](?:- -  : )([A-Z0-9]{8,})</pre>
<b>Enabled</b>	Select this check box to enable the log source.
<b>Credibility</b>	<p>Select the credibility of the log source. The range is 0 - 10.</p> <p>The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.</p>
<b>Target Event Collector</b>	Select the <b>Target Event Collector</b> to use as the target for the log source.
<b>Coalescing Events</b>	<p>Select this check box to enable the log source to coalesce (bundle) events.</p> <p>By default, automatically discovered log sources inherit the value of the <b>Coalescing Events</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.</p>
<b>Store Event Payload</b>	<p>Select this check box to enable the log source to store event payload information.</p> <p>By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.</p>

For a complete list of UDP Multiline Syslog protocol parameters and their values, see “[UDP multiline syslog protocol configuration options](#)” on page 237.

[“Adding a log source” on page 5](#)

## Configuring IPTables for multiline UDP syslog events

To collect events, you must redirect events from the standard PostFix MTA port to port 517 for the UDP multiline protocol.

### Procedure

1. Use SSH to log in to IBM QRadar as the root user.
2. To edit the IPTables file, type the following command:

```
vi /opt/qradar/conf/iptables-nat.post
```

3. To instruct QRadar to redirect syslog events from UDP port 514 to UDP port 517, type the following command:

```
-A PREROUTING -p udp --dport 514 -j REDIRECT --to-port <new-port> -s <IP address>
```

Where:

- <IP address> is the IP address of your PostFix MTA installation.
- <New port> is the port number that is configured in the UDP Multiline protocol for PostFix MTA.

For example, if you had three PostFix MTA installations that communicate to QRadar, you can type the following code:

```
-A PREROUTING -p udp --dport 514 -j  
REDIRECT --to-port 517 -s <IP_address1> -A PREROUTING -p udp --dport 514 -j  
REDIRECT --to-port 517 -s <IP_address2> -A PREROUTING -p udp --dport 514 -j  
REDIRECT --to-port 517 -s <IP_address3>
```

4. Save your IPTables NAT configuration.

You are now ready to configure IPTables on your QRadar Console or Event Collector to accept events from your PostFix MTA installation.

5. Type the following command to edit the IPTables file:

```
vi /opt/qradar/conf/iptables.post
```

6. Type the following command to instruct QRadar to allow communication from your PostFix MTA installations:

```
-I QChain 1 -m udp -p udp --src <IP address> --dport <New port> -j ACCEPT
```

Where:

- <IP address> is the IP address of your PostFix MTA installation.
- <New port> is the port number that is configured in the UDP Multiline protocol.

For example, if you had three PostFix MTA installations that communicate with an Event Collector, you can type the following code:

```
-I QChain 1 -m udp -p udp --src <IP_address1>  
--dport 517 -j ACCEPT -I QChain 1 -m udp -p udp  
--src <IP_address2> --dport 517 -j ACCEPT -I QChain 1 -m udp -p udp  
--src <IP_address3> --dport 517 -j ACCEPT
```

7. To save the changes and update IPTables, type the following command:

```
./opt/qradar/bin/iptables_update.pl
```

## PostFix Mail Transfer Agent sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## PostFix Mail Transfer Agent sample messages when you use the Syslog protocol

**Sample 1:** The following sample event message shows that an email is sent successfully.

```
<22>Mar 5 13:09:45 postfix.mailtransferagent.test postfix/smtpd[7609]: B83C6210AB:

Destination Port	<b>25</b>

**Sample 2:** The following sample event message shows that an email is received.

```
<22>Jun 19 15:41:12 postfix.mailtransferagent.test postfix/qmgr[12345]: FFFFFFFFFF:  
from=<User.Name@domain1.test>, size=3806, nrcpt=1 (queue active)
```

```
<22>Jun 19 15:41:12 postfix.mailtransferagent.test postfix/qmgr[12345]: FFFFFFFFFF:  
from=<User.Name@domain1.test>, size=3806, nrcpt=1 (queue active)
```

Table 899. QRadar field names and highlighted values in the event payload

QRadar field name	Highlighted values in the event payload
Event ID	<b>qmgr</b>
Username	<b>User.Name@domain1.test</b>
Message Size (custom property)	<b>3806</b>
MessageID (custom property)	<b>FFFFFFFFFF</b>

**Tip:**

Use the *IBM® QRadar® Custom Properties for Postfix* to closely monitor your Custom Properties for Postfix deployment. The Postfix custom event properties expand your QRadar searches and reports by normalizing specific event data from a log source. If the *IBM QRadar Custom Properties for Postfix* content pack is not installed on your system, download it from the IBM X-Force Exchange website (<https://exchange.xforce.ibmcloud.com/hub>).

# Chapter 126. ProFTPD

IBM QRadar can collect events from a ProFTP server through syslog.

By default, ProFTPD logs authentication related messages to the local syslog using the **auth** (or **authpriv**) facility. All other logging is done using the daemon facility. To log ProFTPD messages to QRadar, use the SyslogFacility directive to change the default facility.

## Configuring ProFTPD

You can configure syslog on a ProFTPD device:

### Procedure

1. Open the `/etc/proftpd.conf` file.
2. Below the LogFormat directives add the following line:

```
SyslogFacility <facility>
```

Where `<facility>` is one of the following options: **AUTH** (or **AUTHPRIV**), **CRON**, **DAEMON**, **KERN**, **LPR**, **MAIL**, **NEWS**, **USER**, **UUCP**, **LOCAL0**, **LOCAL1**, **LOCAL2**, **LOCAL3**, **LOCAL4**, **LOCAL5**, **LOCAL6**, or **LOCAL7**.

3. Save the file and exit.
4. Open the `/etc/syslog.conf` file
5. Add the following line at the end of the file:

```
<facility> @<QRadar host>
```

Where:

`<facility>` matches the facility that is chosen in [“Configuring ProFTPD” on page 1397](#). The facility must be typed in lowercase.

`<QRadar host>` is the IP address of your QRadar Console or Event Collector.

6. Restart syslog and ProFTPD:

```
/etc/init.d/syslog restart  
/etc/init.d/proftpd restart
```

### What to do next

You can now configure the log source in QRadar.

## Syslog log source parameters for ProFTPD

If QRadar does not automatically detect the log source, add a ProFTPD log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from ProFTPD:

Table 900. Syslog log source parameters for the ProFTPD DSM	
Parameter	Value
<b>Log Source type</b>	ProFTPD Server
<b>Protocol Configuration</b>	Syslog

*Table 900. Syslog log source parameters for the ProFTPD DSM (continued)*

Parameter	Value
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your ProFTPD installation.

# Chapter 127. Proofpoint Enterprise Protection and Enterprise Privacy

The IBM QRadar DSM for Proofpoint Enterprise Protection and Enterprise privacy can collect events from your Proofpoint Enterprise Protection and Enterprise Privacy DSM servers.

The following table identifies the specifications for the Proofpoint Enterprise Protection and Enterprise Privacy DSM:

Table 901. Proofpoint Enterprise Protection and Enterprise Privacy DSM specifications	
Specification	Value
Manufacturer	Proofpoint
DSM name	Proofpoint Enterprise Protection/Enterprise Privacy
RPM file name	DSM-Proofpoint_Enterprise_Protection/_Enterprise_Privacy-QRadar_version-build_number.noarch.rpm
Supported versions	V7.02 V7.1 V7.2 V7.5 V8.0
Protocol	Syslog Log File
Recorded event types	System Email security threat classification Email audit and encryption
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.proofpoint.com/us/solutions/products/enterprise-protection">Proofpoint website</a> ( <a href="https://www.proofpoint.com/us/solutions/products/enterprise-protection">https://www.proofpoint.com/us/solutions/products/enterprise-protection</a> )

To integrate the Proofpoint Enterprise Protection and Enterprise Privacy DSM with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the Proofpoint Enterprise Protection and Enterprise Privacy DSM RPM from the [IBM Support Website](#) onto your QRadar Console.
2. For each instance of Proofpoint Enterprise Protection and Enterprise Privacy, configure your Proofpoint Enterprise Protection and Enterprise Privacy DSM appliance to enable communication with QRadar.
3. Add a Proofpoint Enterprise Protection and Enterprise Privacy log source on your QRadar Console.

# Configuring Proofpoint Enterprise Protection and Enterprise Privacy DSM to communicate with IBM QRadar

To collect all audit logs and system events from your Proofpoint Enterprise Protection and Enterprise Privacy DSM, you must add a destination that specifies IBM QRadar as the Syslog server.

## Procedure

1. Log in to the Proofpoint Enterprise interface.
2. Click **Logs and Reports**.
3. Click **Log Settings**.
4. From the **Remote Log Settings** pane, configure the following options to enable Syslog communication:
  - a) Select **Syslog** as the communication protocol.
5. Type the IP address of the QRadar Console or Event Collector.
6. In the **Port** field, type 514 as the port number for Syslog communication.
7. From the **Syslog Filter Enable** list, select **On**.
8. From the **Facility** list, select **local1**.
9. From the **Level** list, select **Information**.
10. From the **Syslog MTA Enable** list, select **On**.
11. Click **Save**

## Syslog log source parameters for Proofpoint Enterprise Protection and Enterprise Privacy

If QRadar does not automatically detect the log source, add a Proofpoint Enterprise Protection and Enterprise Privacy log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Proofpoint Enterprise Protection and Enterprise Privacy:

Table 902. Syslog log source parameters for the Proofpoint Enterprise Protection and Enterprise Privacy DSM	
Parameter	Value
<b>Log Source type</b>	Proofpoint Enterprise Protection/Enterprise Privacy
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	<p>The IP address or host name for the log source as an identifier for events from Proofpoint Enterprise Protection and Enterprise Privacy installations.</p> <p>For each additional log source that you create when you have multiple installations, include a unique identifier, such as an IP address or host name</p>

# Chapter 128. Pulse Secure

IBM QRadar supports a range of Pulse Secure DSMs.

## Pulse Secure Infranet Controller

The Pulse Secure Infranet Controller DSM for IBM QRadar accepts DHCP events by using syslog. QRadar records all relevant events from a Pulse Secure Infranet Controller.

Before you configure QRadar to integrate with a Pulse Secure Infranet Controller, you must configure syslog in the server. For more information on configuring your Pulse Secure Infranet Controller, consult your vendor documentation.

### Syslog log source parameters for Pulse Secure Infranet Controller

If QRadar does not automatically detect the log source, add a Pulse Secure Infranet Controller log source on the QRadar Console by using the syslog protocol.

When using the syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect syslog events from Pulse Secure Infranet Controller:

*Table 905. Syslog log source parameters for the Pulse Secure Infranet Controller DSM*

Parameter	Value
<b>Log Source type</b>	Juniper Networks Infranet Controller
<b>Protocol Configuration</b>	Syslog

After you configure syslog for your Pulse Secure Infranet Controller, you are now ready to configure the log source in QRadar.

## Pulse Secure Pulse Connect Secure

The IBM QRadar DSM for Pulse Secure Pulse Connect Secure collects syslog and WebTrends Enhanced Log File (WELF) formatted events from Pulse Secure Pulse Connect Secure mobile VPN devices.

The following table describes the specifications for the Pulse Secure Pulse Connect Secure DSM:

*Table 906. Pulse Secure Pulse Connect Secure DSM specifications*

Specification	Value
Manufacturer	Pulse Secure
DSM name	Pulse Secure Pulse Connect Secure
RPM file name	DSM-PulseSecurePulseConnectSecure-QRadar_version-build_number.noarch.rpm
Supported versions	8.2R5
Protocol	Syslog, TLS Syslog

*Table 906. Pulse Secure Pulse Connect Secure DSM specifications (continued)*

Specification	Value
Recorded event types	Admin Authentication System Network Error
Automatically discovered?	Yes
Includes identity?	Yes
Includes custom properties?	Yes
More information	<a href="https://www.pulsesecure.net">Pulse Secure website (https://www.pulsesecure.net)</a>

To integrate Pulse Secure Pulse Connect Secure with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the Pulse Secure Pulse Connect Secure DSM RPM on your QRadar Console.
2. Configure your Pulse Secure Pulse Connect Secure device to send WebTrends Enhanced Log File (WELF) formatted events to QRadar.
3. Configure your Pulse Secure Pulse Connect Secure device to send syslog events to QRadar.
4. If QRadar does not automatically detect the log source, add a Pulse Secure Pulse Connect Secure log source on the QRadar Console. The following tables describe the parameters that require specific values to collect Syslog events from Pulse Secure Pulse Connect Secure:

*Table 907. Pulse Secure Pulse Connect Secure Syslog log source parameters*

Parameter	Value
Log Source type	Pulse Secure Pulse Connect Secure
Protocol Configuration	Syslog
Log Source Identifier	Type a unique identifier for the log source.

5. Optional. To add a Pulse Secure Pulse Connect Secure log source to receive syslog events from network devices that support TLS Syslog event forwarding, configure the log source on the QRadar Console to use the TLS Syslog protocol.

The following table describes the parameters that require specific values to collect TLS Syslog events from Pulse Secure Pulse Connect Secure:

*Table 908. Pulse Secure Pulse Connect Secure TLS Syslog log source parameters*

Parameter	Value
Log Source type	Pulse Secure Pulse Connect Secure
Protocol Configuration	TLS Syslog
Log Source Identifier	Type a unique identifier for the log source.
TLS Protocols	Select the version of TLS that is installed on the client.

## Related concepts

# Configuring a Pulse Secure Pulse Connect Secure device to send WebTrends Enhanced Log File (WELF) events to IBM QRadar

Before you can send WebTrends Enhanced Log File (WELF) formatted events to QRadar, you must configure syslog server information for events, user access, administrator access and client logs on your Pulse Secure Pulse Connect Secure device.

## Procedure

1. Log in to your Pulse Secure Pulse Connect Secure device administration user interface on the web:  
`https://<IP_address>/admin`
2. Configure syslog server information for events.
  - a) Click **System > Log/Monitoring > Events > Settings**.
  - b) From the **Select Events to Log pane**, select the events that you want to log.
  - c) In the **Server name/IP** field, type the name or IP address of the syslog server.
  - d) From the **Facility list**, select a syslog server facility level.
  - e) From the **Filter** list, select **WELF:WELF**.
  - f) Click **Add**, and then click **Save Changes**.
3. Configure syslog server information for user access.
  - a) Click **System > Log/Monitoring > User Access > Settings**.
  - b) From the **Select Events to Log pane**, select the events that you want to log.
  - c) In the **Server name/IP** field, type the name or IP address of the syslog server.
  - d) From the **Facility** list, select the facility.
4. Configure syslog server information for Administrator access.
  - a) Click **System > Log/Monitoring > Admin Access > Settings**.
  - b) From the **Select Events to Log pane**, select the events that you want to log.
  - c) In the **Server name/IP** field, type the name or IP address of the syslog server.
  - d) From the **Facility** list, select the facility.
  - e) From the **Filter** list, select **WELF:WELF**.
  - f) Click **Add**, then click **Save Changes**.
5. Configure syslog server information for client logs.
  - a) Click **System > Log/Monitoring > Client Logs > Settings**.
  - b) From the **Select Events to Log pane**, select the events that you want to log.
  - c) In the **Server name/IP** field, type the name or IP address of the syslog server.
  - d) From the **Facility** list, select the facility.
  - e) From the **Filter** list, select **WELF:WELF**.
  - f) Click **Add**, then click **Save Changes**.

## Results

You are now ready to configure a log source in QRadar.

# Configuring a Pulse Secure Pulse Connect Secure device to send syslog events to QRadar

To forward syslog events to QRadar, you need to configure syslog server information for events, user access, administrator access and client logs on your Pulse Secure Pulse Connect Secure device.

## Procedure

1. Log in to your Pulse Secure Pulse Connect Secure device administration user interface on the web:  
`https://<IP_address>/admin`
2. Configure syslog server information for events.
  - a) Click **System > Log/Monitoring > Events > Settings**.
  - b) From the **Select Events to Log** section, select the events that you want to log.
  - c) In the **Server name/IP** field, type the name or IP address of the syslog server.
  - d) Click **Add**, and then click **Save Changes**.
3. Configure syslog server information for user access.
  - a) Click **System > Log/Monitoring > User Access > Settings**.
  - b) From the **Select Events to Log** section, select the events that you want to log.
  - c) In the **Server name/IP** field, type the name or IP address of the syslog server.
  - d) Click **Add**, and then click **Save Changes**.
4. Configure syslog server information for Administrator access.
  - a) Click **System > Log/Monitoring > Admin Access > Settings**.
  - b) From the **Select Events to Log** section, select the events that you want to log.
  - c) In the **Server name/IP** field, type the name or IP address of the syslog server.
  - d) Click **Add**, and then click **Save Changes**.
5. Configure syslog server information for client logs.
  - a) Click **System > Log/Monitoring > Client Logs > Settings**.
  - b) From the **Select Events to Log** section, select the events that you want to log.
  - c) In the **Server name/IP** field, type the name or IP address of the syslog server.
  - d) Click **Add**, and then click **Save**.

## Results

You are now ready to configure a log source in QRadar.

# Pulse Secure Pulse Connect Secure sample event message

Use this sample event message as a way of verifying a successful integration with QRadar.

The following table provides a sample event message for the Pulse Secure Pulse Connect Secure DSM:

*Table 909. Pulse Secure Pulse Connect Secure sample message*

<b>Event name</b>	<b>Low level category</b>	<b>Sample log message</b>
VlanAssigned	Information	<pre>id=firewall time="2009-10-01 22:26:39" pri=6 fw=&lt;IP_address&gt; vpn=ic user=user realm="&lt;Domain&gt;" roles="Employee, Remediation" proto= src=&lt;Source_IP_address&gt; dst= dstname= type=vpn op= arg="" result= sent= rcvd= agent="" duration= msg="EAM24459: User assigned to vlan (VLAN='16')"</pre>

# Chapter 129. Radware

IBM QRadar supports a range of Radware devices.

## Radware AppWall

The IBM QRadar DSM for Radware AppWall collects logs from a Radware AppWall appliance.

The following table describes the specifications for the Radware AppWall DSM:

Table 910. Radware AppWall DSM specifications	
Specification	Value
Manufacturer	Radware
DSM name	Radware AppWall
RPM file name	DSM-RadwareAppWall-QRadar_version-build_number.noarch.rpm
Supported versions	6.5.2 8.2
Protocol	Syslog
Recorded event types	Administration Audit Learning Security System
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	For more information, see the Radware link to public site website ( <a href="https://www.radware.com">https://www.radware.com</a> ).

To integrate Radware AppWall with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the Radware AppWall DSM RPM from the [IBM Support Website](#) onto your QRadar Console:
2. Configure your Radware AppWall device to send logs to QRadar.
3. If QRadar does not automatically detect the log source, add a Radware AppWall log source on the QRadar Console. The following table describes the parameters that require specific values for Radware AppWall event collection:

Table 911. Radware AppWall log source parameters

Parameter	Value
Log Source type	Radware AppWall
Protocol Configuration	Syslog

**Important:** Your RadWare AppWall device might have event payloads that are longer than the default maximum TCP Syslog payload length of 4096 bytes. This overage can result in the event payload being split into multiple events by QRadar. To avoid this behavior, increase the maximum TCP Syslog payload length. To optimize performance, start by configuring the value to 8192 bytes. The maximum length for RadWare AppWall events is 14,019 bytes.

The maximum QRadar syslog payload size is 32,000 bytes. For more information about increasing the QRadar maximum payload size, see [QRadar: TCP and UDP Syslog Maximum Payload Message Length for QRadar Appliances](https://www.ibm.com/support/pages/qradar-tcp-and-udp-syslog-maximum-payload-message-length-qradar-appliances) (<https://www.ibm.com/support/pages/qradar-tcp-and-udp-syslog-maximum-payload-message-length-qradar-appliances>).

You can verify that QRadar is configured to receive events from your Radware AppWall device when you complete Step 6 of the [Configuring Radware AppWall to communicate with QRadar](#) procedure.

#### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

[“Configuring Radware AppWall to communicate with QRadar” on page 1410](#)

Configure your Radware AppWall device to send logs to IBM QRadar. You integrate AppWall logs with QRadar by using the Vision Log event format.

[“Increasing the maximum TCP Syslog payload length for Radware AppWall” on page 1411](#)

Increase the maximum TCP Syslog payload length for your RadWare AppWall appliance in IBM QRadar for payloads that are longer than the default maximum TCP Syslog payload length.

## Configuring Radware AppWall to communicate with QRadar

Configure your Radware AppWall device to send logs to IBM QRadar. You integrate AppWall logs with QRadar by using the Vision Log event format.

#### Procedure

1. Log in to your Radware AppWall Console.
2. Select **Configuration View** from the menu bar.
3. In the Tree View pane on the left side of the window, click **appwall Gateway > Services > Vision Support**.
4. From the **Server List** tab on the right side of the window, click the add icon (+) in the Server List pane.
5. In the **Add Vision Server** window, configure the following parameters:

Parameter	Value
<b>Address</b>	The IP address for the QRadar Console.
<b>Port</b>	514
<b>Version</b>	Select the most recent version from the list. It is the last item in the list.

6. Click **Check** to verify that the AppWall can successfully connect to QRadar.
7. Click **Submit** and **Save**.
8. Click **Apply > OK**.

# Increasing the maximum TCP Syslog payload length for Radware AppWall

Increase the maximum TCP Syslog payload length for your RadWare AppWall appliance in IBM QRadar for payloads that are longer than the default maximum TCP Syslog payload length.

## Before you begin

**Important:** Your RadWare AppWall device might have event payloads that are longer than the default maximum TCP Syslog payload length of 4096 bytes. This overage can result in the event payload being split into multiple events by QRadar. To avoid this behavior, increase the maximum TCP Syslog payload length. To optimize performance, start by configuring the value to 8192 bytes. The maximum length for RadWare AppWall events is 14,019 bytes.

The maximum QRadar syslog payload size is 32,000 bytes. For more information about increasing the QRadar maximum payload size, see [QRadar: TCP and UDP Syslog Maximum Payload Message Length for QRadar Appliances](https://www.ibm.com/support/pages/qradar-tcp-and-udp-syslog-maximum-payload-message-length-qradar-appliances) (<https://www.ibm.com/support/pages/qradar-tcp-and-udp-syslog-maximum-payload-message-length-qradar-appliances>).

## Procedure

1. Login to the QRadar Console as an administrator.
2. From the **Admin** tab, click **System Settings > Advanced**.
3. In the **Max TCP Syslog Payload Length** field, type 8192, and then click **Save**.
4. From the **Admin** tab, click **Deploy Changes**.

## Radware AppWall sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Radware AppWall sample messages when you use the Syslog protocol

**Sample 1:** The following sample event message shows that a service is stopped.

```
OLF6 appwall 2.1 date="05/27/2019 06:01:24 +00" milli.1=92
et=Initialization sev=notice subj="Subsystem stopped" evtid=1558936884-109
hostname=testHostName hostip=10.22.126.18 module=SystemType devtype="Stand Alone
Gateway" cmip=10.22.126.18 msg="The subsystem was stopped."
```

Table 912. Highlighted values in the Radware AppWall sample event

QRadar field name	Highlighted values in the event payload
Event ID	<b>1558936884-109</b>
Source IP	<b>10.22.126.18</b>
Device Time	<b>05/27/2019 06:01:24 +00</b>

**Sample 2:** The following sample event message shows a reverse DNS lookup failure.

```
OLF6 appwall 2.1 date="05/27/2019 09:00:33 +00" milli.1=244 et=Initialization
sev=warning subj="Reverse DNS Lookup Initialization Error" evtid=1558947633-294
hostname=testHostName hostip=10.22.126.18 module=WebApp_SubSys devtype="Stand Alone
Gateway" cmip=10.22.126.18 msg="Reverse DNS Lookup operation failed to initialize.Dig
Init Check failed: ;; connection timed out; no servers could be reached\n\nPrimary DNS Server:
10.22.14.135:53"
```

*Table 913. Highlighted values in the Radware AppWall sample event*

QRadar field name	Highlighted values in the event payload
Event ID	<b>1558947633-294</b>
Source IP	<b>10.22.126.18</b>
Device Time	<b>05/27/2019 09:00:33 +00</b>

## Radware DefensePro

The Radware DefensePro DSM for IBM QRadar accepts events by using syslog. Event traps can also be mirrored to a syslog server.

Before you configure QRadar to integrate with a Radware DefensePro device, you must configure your Radware DefensePro device to forward syslog events to QRadar. You must configure the appropriate information by using the **Device > Trap and SMTP option**.

Any traps that are generated by the Radware device are mirrored to the specified syslog server. The current Radware Syslog server gives you the option to define the status and the event log server address.

You can also define more notification criteria, such as Facility and Severity, which are expressed by numerical values:

- **Facility** is a user-defined value that indicates the type of device that is used by the sender. This criteria is applied when the device sends syslog messages. The default value is 21, meaning Local Use 6.
- Severity indicates the importance or impact of the reported event. The Severity is determined dynamically by the device for each message sent.

In the **Security Settings** window, you must enable security reporting by using the **connect** and **protect/security** settings. You must enable security reports to syslog and configure the severity (syslog risk).

You are now ready to configure the log source in QRadar.

**Tip:** If you have custom events that display as unknown in QRadar, see the IBM Support article about [QRadar: Custom events for Radware DefensePro display 'parsed, but not mapped'](https://www.ibm.com/support/pages/node/6960301) (<https://www.ibm.com/support/pages/node/6960301>).

## Syslog log source parameters for Radware DefensePro

If QRadar does not automatically detect the log source, add a Radware DefensePro log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Radware DefensePro:

*Table 914. Syslog log source parameters for the Radware DefensePro DSM*

Parameter	Value
Log Source type	Radware DefensePro
Protocol Configuration	Syslog
Log Source Identifier	Type the IP address or host name for the log source as an identifier for events from your Radware DefensePro installation.

### Related tasks

# Chapter 130. Raz-Lee iSecurity

IBM QRadar collects and parses Log Event Extended Format (LEEF) events that are forwarded from Raz-Lee iSecurity installations on IBM i. The events are parsed and categorized by the IBM i DSM.

QRadar supports events from Raz-Lee iSecurity installations for iSecurity Firewall V15.7 and iSecurity Audit V11.7.

The following table describes the specifications for the IBM i DSM for Raz-Lee iSecurity installations:

Table 915. IBM i DSM specifications for Raz-Lee iSecurity	
Specification	Value
Manufacturer	IBM
DSM name	IBM i
RPM file name	DSM-IBMi-QRadar_version-build_number.noarch.rpm
Supported versions	iSecurity Firewall V15.7 iSecurity Audit V11.7
Protocol	Syslog
Event format	LEEF
Recorded event types	All security, compliance, firewall, and audit events.
Automatically discovered?	Yes
Includes identity?	Yes
Includes custom properties?	No
More information	<a href="http://www.ibm.com">IBM website (http://www.ibm.com)</a>

## Configuring Raz-Lee iSecurity to communicate with QRadar

To collect security, compliance, and audit events, configure your Raz-Lee iSecurity installation to forward Log Event Extended Format (LEEF) syslog events to IBM QRadar.

### Procedure

1. Log in to the IBM i command-line interface.
2. From the command line, type STRAUD to access the **Audit** menu options.
3. From the **Audit** menu, select **81. System Configuration**.
4. From the **iSecurity/Base System Configuration** menu, select **32. SIEM 1**.
5. Configure the **32.SIEM 1** parameter values.

**Learn more about 32. SIEM 1 parameter values:**

Table 916. 32.SIEM 1 parameter values

Parameter	Value
SIEM 1 name	Type QRadar.

*Table 916. 32.SIEM 1 parameter values (continued)*

Parameter	Value
Port	Type the port that is used to send syslog messages. The default port is 514, which is the syslog standard.
SYSLOG type	Type 1 for UDP.
Destination address	Type the IP address for QRadar.
Severity range to auto send	Type a severity message level in the range of 0 - 7. For example, type <b>7</b> to send all syslog messages.
Facility to use	Type a syslog facility level in the range of 0 - 23.
Message structure	Type *LEEF.
Convert data to CCSID	Type 0 in the <b>Convert data to CCSID</b> field. This is the default character conversion.
Maximum length	Type 1024.

6. From the **iSecurity/Base System Configuration** menu, select **31. Main Control**.

7. Configure the **31. Main Control** parameter values.

**Learn more about 31. Main Control parameter values:**

*Table 917. 31. Main Control parameter values*

Parameter	Value
Run rules before sending	To process the events that you want to send, type Y. To send all events, type N.
SIEM 1: QRadar	Type Y.
Send JSON messages (for DAM)	Type N.
As only operation	Type N.

8. From the command line, to configure the **Firewall** options, type STRFW to access the menu options.

9. From the **Firewall** menu, select **81. System Configuration**.

10. From the **iSecurity (part 1) Global Parameters:** menu, select **72. SIEM 1**.

11. Configure the **72.SIEM 1** parameter values.

**Learn more about 72. SIEM 1 parameter values:**

*Table 918. 72.SIEM 1 parameter values*

Parameter	Value
SIEM 1 name	Type QRadar.
Port	Type the port that is used to send syslog messages. The default port is 514, which is the Syslog standard.
SYSLOG type	Type 1 for UDP syslog type.
Send in FYI mode	Type N.

*Table 918. 72.SIEM 1 parameter values (continued)*

Parameter	Value
Destination address	Type the IP address for the QRadar console.
Severity range to auto send	Type a severity level in the range 0 - 7.
Facility to use	Type a facility level.
Message structure	Type *LEEF.
Convert data to CCSID	Type 0.
Maximum length	Type 1024.

12. From the **iSecurity (part 1) Global Parameters:** menu, select **71. Main Control**.

13. Configure the **71. Main Control** parameter values.

**Learn more about 71. Main Control parameter values:**

*Table 919. 71. Main Control parameter values*

Parameter	Value
SIEM 1: QRadar	Type 2.
Send JSON messages (for DAM)	Type 0.

## Results

Syslog LEEF events that are forwarded by Raz-Lee iSecurity are automatically discovered by the QRadar DSM for IBM i. In most cases, the log source is automatically created in QRadar after a few events are detected.

If the event rate is low, you can manually configure a log source for Raz-Lee iSecurity in QRadar. Until the log source is automatically discovered and identified, the event type displays as Unknown on the **Log Activity** tab.

## Syslog log source parameters for Raz-Lee iSecurity

If QRadar does not automatically detect the log source, add a Raz-Lee iSecurity log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Raz-Lee iSecurity:

*Table 920. Syslog log source parameters for the Raz-Lee iSecurity DSM*

Parameter	Value
<b>Log Source type</b>	Raz-Lee iSecurity
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	The IP address or host name of the log source that sends events from the Raz-Lee iSecurity device.
<b>Enabled</b>	By default, the check box is selected.

Table 920. Syslog log source parameters for the Raz-Lee iSecurity DSM (continued)

Parameter	Value
<b>Credibility</b>	The <b>Credibility</b> of the log source. The range is 0 - 10. The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.
<b>Coalescing Events</b>	By default, automatically discovered log sources inherit the value of the <b>Coalescing Events</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.
<b>Incoming Payload Encoding</b>	Select <b>Incoming Payload Encoder</b> for parsing and storing the logs.
<b>Store Event Payload</b>	By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the <b>System Settings</b> in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.

# Chapter 131. Redback ASE

The Redback ASE DSM for IBM QRadar accepts events by using syslog.

The Redback ASE device can send log messages to the Redback device console or to a log server that is integrated with QRadar to generate deployment-specific reports. Before you configure a Redback ASE device in QRadar, you must configure your device to forward syslog events.

## Configuring Redback ASE

You can configure the device to send syslog events to IBM QRadar.

### Procedure

1. Log in to your Redback ASE device user interface.

2. Start the CLI configuration mode.

3. In global configuration mode, configure the default settings for the security service:

```
asp security default
```

4. In ASP security default configuration mode, configure the IP address of the log server and the optional transport protocol:

```
log server <IP address> transport udp port 9345
```

Where *<IP address>* is the IP address of the QRadar.

5. Configure the IP address that you want to use as the source IP address in the log messages:

```
log source <source IP address>
```

Where *<source IP address>* is the IP address of the loopback interface in context local.

6. Commit the transaction.

For more information about Redback ASE device configuration, see your vendor documentation.

For example, if you want to configure:

- Log source server IP address *<IP\_address>*
- Default transport protocol: UDP
- Default server port: 514

The source IP address that is used for log messages is *<IP\_address>*. This address must be an IP address of a *loopback* interface in context local.

```
asp security default log server <IP_address1> log source <IP_address2>
```

### What to do next

You can now configure the log sources in QRadar.

## Syslog log source parameters for Redback ASE

If QRadar does not automatically detect the log source, add a Redback ASE log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Redback ASE:

*Table 921. Syslog log source parameters for the Redback ASE DSM*

<b>Parameter</b>	<b>Value</b>
<b>Log Source type</b>	Redback ASE
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Redback ASE appliance.

## Red Hat Advanced Cluster Security for Kubernetes DSM specifications

When you configure Red Hat Advanced Cluster Security for Kubernetes, understanding the specifications for the DSM can help ensure a successful integration. For example, knowing what the supported protocol for Red Hat Advanced Cluster Security for Kubernetes is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Red Hat Advanced Cluster Security for Kubernetes DSM.

<i>Table 922. Red Hat Advanced Cluster Security for Kubernetes DSM specifications</i>	
Specification	Value
Manufacturer	Red Hat
DSM name	Red Hat Advanced Cluster Security for Kubernetes
RPM file name	DSM-RedhatKubernetes-QRadar_version-build_number.noarch.rpm
Protocol	HTTP Receiver
Event format	JSON
Recorded event types	audit and alert events
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No

# Configuring Red Hat Advanced Cluster Security for Kubernetes to communicate with QRadar

---

To send events to IBM QRadar, you must add a new Generic Webhook integration.

## Before you begin

You must have permission to access Generic Webhook Integrations in the Red Hat Advanced Cluster for Kubernetes application.

## Procedure

1. Log in to the Red Hat Advanced Cluster Security for Kubernetes application.
2. From the navigation menu, select **Platform Configuration > Integrations**.
3. In the **Integrations** window, click **StackRox Generic Webhook**.
4. In the **CONFIGURE GENERIC WEBHOOK NOTIFIER INTEGRATIONS** window, click **+ NEW INTEGRATION**.
5. Type your integration name and endpoint in the **Integration Name** field.

Use the following example as a guide:

<URL to QRadar Box:<Port of Integration>

6. Click **Create**.

## What to do next

[HTTP Receiver log source parameters for Red Hat Advanced Cluster Security for Kubernetes](#)

## HTTP Receiver log source parameters for Red Hat Advanced Cluster Security for Kubernetes

---

If QRadar does not automatically detect the log source, add a Red Hat Advanced Cluster Security for Kubernetes log source on the QRadar Console by using the HTTP Receiver.

When using the HTTP Receiver protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect HTTP Receiver events from Red Hat Advanced Cluster Security for Kubernetes:

Table 923. HTTP Receiver log source parameters for the Red Hat Advanced Cluster Security for Kubernetes DSM	
Parameter	Value
<b>Log Source type</b>	Red Hat Advanced Cluster Security for Kubernetes
<b>Protocol Configuration</b>	HTTP Receiver
<b>Log Source Identifier</b>	The IP address, hostname, or any name to identify the source of the payloads. Must be unique for the log source type.
<b>Communication Type</b>	HTTP or HTTPS - The value is determined by the open port and the StackRox Generic Webhook integration that you completed.
<b>Listen Port</b>	The port that you specified when you completed the StackRox Generic Webhook integration.

For a complete list of HTTP Receiver protocol parameters and their values, see [HTTP Receiver protocol configuration options](#).

# Chapter 133. Resolution1 CyberSecurity

Resolution1 CyberSecurity is formerly known as AccessData InSight. The Resolution1 CyberSecurity DSM for IBM QRadar collects event logs from your Resolution1 CyberSecurity device.

The following table identifies the specifications for the Resolution1 CyberSecurity DSM:

Table 926. Resolution1 CyberSecurity DSM specifications	
Specification	Value
Manufacturer	Resolution1
DSM name	Resolution1 CyberSecurity
RPM file name	DSM-Resolution1CyberSecurity-Qradar_version-build_number.noarch.rpm
Supported versions	V2
Event format	Log file
QRadar recorded event types	Volatile Data Memory Analysis Data Memory Acquisition Data Collection Data Software Inventory Process Dump Data Threat Scan Data Agent Remediation Data
Automatically discovered?	No
Included identity?	No

To send events from Resolution1 CyberSecurity to QRadar, use the following steps:

1. If automatic updates are not enabled, download the most recent versions of the following RPMs from the [IBM Support Website](#).
  - LogFileProtocol
  - DSMCommon
  - Resolution1 CyberSecurity DSM
2. Configure your Resolution1 CyberSecurity device to communicate with QRadar.
3. Create a Resolution1 CyberSecurity log source on the QRadar Console.

## Related concepts

[Log file log source parameters for Resolution1 CyberSecurity](#)

## Related tasks

[Adding a DSM](#)

[Configuring your Resolution1 CyberSecurity device to communicate with QRadar](#)

To collect Resolution1 CyberSecurity events, you must configure your third-party device to generate event logs in LEEF format. You must also create an FTP site for Resolution1 CyberSecurity to transfer the LEEF files. QRadar can then pull the logs from the FTP server.

## Configuring your Resolution1 CyberSecurity device to communicate with QRadar

To collect Resolution1 CyberSecurity events, you must configure your third-party device to generate event logs in LEEF format. You must also create an FTP site for Resolution1 CyberSecurity to transfer the LEEF files. QRadar can then pull the logs from the FTP server.

### Procedure

1. Log in to your Resolution1 CyberSecurity device.
2. Open the `ADGIntegrationServiceHost.exe.config` file, which is in the `C:\Program Files\AccessData\eDiscovery\Integration Services` directory.
3. Change the text in the file to match the following lines:

```
<Option Name="Version" Value="2.0" />
<Option Name="Version" Value="2.0" />
<Option Name="OutputFormat" Value="LEEF" />
<Option Name="LogOnly" Value="1" />
<Option Name="OutputPath" Value="C:\CIRT\logs" />
```

4. Restart the Resolution1 Third-Party Integration service.
5. Create an FTP site for the `C:\CIRT\logs` output folder:
  - a) Open Internet Information Services Manager (IIS).
  - b) Right-click the **Sites** tab and click **Add FTP Site**.
  - c) Name the FTP site, and enter `C:\CIRT\logs` as the location for the generated LEEF files.
  - d) Restart the web service.

## Log file log source parameters for Resolution1 CyberSecurity

If QRadar does not automatically detect the log source, add a Resolution1 CyberSecurity log source on the QRadar Console by using the Log file.

When using the Log file protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log file events from Resolution1 CyberSecurity:

Table 927. Log file log source parameters for the Resolution1 CyberSecurity DSM	
Parameter	Value
<b>Log Source type</b>	Resolution1 CyberSecurity
<b>Protocol Configuration</b>	Log file
<b>Log Source Identifier</b>	Type the IP address or host name of the Resolution1 CyberSecurity device

For a complete list of Log File protocol parameters and their values, see [“Log File protocol configuration options” on page 155](#).

# Chapter 134. Riverbed

IBM QRadar supports a number of Riverbed DSMs:

## Riverbed SteelCentral NetProfiler (Cascade Profiler) Audit

The IBM QRadar DSM for Riverbed SteelCentral NetProfiler Audit collects audit logs from your Riverbed SteelCentral NetProfiler system. This product is also known as *Cascade Profiler*.

The following table identifies the specifications for the Riverbed SteelCentral NetProfiler DSM:

Table 928. Riverbed SteelCentral NetProfiler specifications	
Specification	Value
Manufacturer	Riverbed
DSM name	SteelCentral NetProfiler Audit
RPM file name	DSM-RiverbedSteelCentralNetProfilerAudit-Qradar_version-build_number.noarch.rpm
Protocol	Log file
Recorded event types	Audit Events
Automatically discovered?	No
Includes identity?	Yes
Includes custom properties?	No
More information	Riverbed website ( <a href="http://www.riverbed.com/">http://www.riverbed.com/</a> )

To integrate Riverbed SteelCentral NetProfiler Audit with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent versions of the following RPMs from the [IBM Support Website](#) onto your QRadar Console.
  - Protocol-LogFile RPM
  - Riverbed SteelCentral NetProfiler Audit RPM
2. Create an audit report template on your Riverbed host and then configure a third-party host to use the template to generate the audit file. See “[Creating a Riverbed SteelCentral NetProfiler report template and generating an audit file](#)” on page 1426.
3. Create a log source on the QRadar Console. The log source allows QRadar to access the third-party host to retrieve the audit file. Use the following table to define the Riverbed-specific parameters:

Table 929. Riverbed SteelCentral NetProfiler log source parameters

Parameter	Description
Log Source Type	Riverbed SteelCentral NetProfiler Audit
Protocol Configuration	LogFile
Remote IP or Hostname	The IP address or host name of the third-party host that stores the generated audit file
Remote User	The user name for the account that can access the host.
Remote Password	The password for the user account.
Remote Directory	The absolute file path on the third-party host that contains the generated audit file.
FTP File Pattern	A regex pattern that matches the name of the audit file.

Table 929. Riverbed SteelCentral NetProfiler log source parameters (continued)

Parameter	Description
Recurrence	Ensure that recurrence matches the frequency at which the SteelScript for Python SDK script is run on the remote host.
Event Generator	Line Matcher
Line Matcher RegEx	<code>^\d+/\d+/\d+ \d+:\d+,</code>

### Related tasks

[“Adding a DSM” on page 4](#)

## Creating a Riverbed SteelCentral NetProfiler report template and generating an audit file

To prepare for Riverbed SteelCentral NetProfiler integration with QRadar, create a report template on the Riverbed SteelCentral NetProfiler and then use a third-party host to generate an audit file. The third-party host must be a system other than the host you use for Riverbed SteelCentral NetProfiler or QRadar.

### Before you begin

Ensure that the following items are installed on a third-party host that you use to run the audit report:

#### Python

Download and install Python from the Python website (<https://www.python.org/download/>).

#### SteelScript for Python

Download and install the SteelScript for Python SDK from the [Riverbed SteelScript for Python website](#) (<https://support.riverbed.com/apis/steelscript/index.html>). The script generates and downloads an audit file in CSV format. You must periodically run this script.

### Procedure

1. Define the audit file report template.
  - a) Log in to your Riverbed SteelCentral NetProfiler host user interface.
  - b) Select **System > Audit Trail**.
  - c) Select the criteria that you want to include in the audit file.
  - d) Select a time frame.
  - e) On the right side of the window, click **Template**.
  - f) Select **Save As/Schedule**.
  - g) Type a name for the report template.
2. To run the report template and generate an audit file, complete the following steps
  - a) Log in to the third-party host on which you installed Python.
  - b) Type the following command:

```
$ python ./get_template_as_csv.py <riverbed_host_name> -u admin -p admin -t "  
<report_template_name>" -o <absolute_path_to_target_file>
```

**Tip:** Record the report template name and file path. You need to use the name to run the report template and when you configure a log source in the QRadar interface.

## Riverbed SteelCentral NetProfiler (Cascade Profiler) Alert

The IBM QRadar DSM for Riverbed SteelCentral NetProfiler collects alert logs from your Riverbed SteelCentral NetProfiler system. This product is also known as *Cascade Profiler*.

The following table identifies the specifications for the Riverbed SteelCentral NetProfiler DSM:

Table 930. Riverbed SteelCentral NetProfiler specifications	
Specification	Value
Manufacturer	Riverbed
DSM name	SteelCentral NetProfiler
RPM file name	DSM-RiverbedSteelCentralNetProfiler-QRadar_version-build_number.noarch.rpm
Protocol	JDBC
Recorded event types	Alert Events
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://www.riverbed.com/">Riverbed website</a> ( <a href="http://www.riverbed.com/">http://www.riverbed.com/</a> )

To integrate Riverbed SteelCentral NetProfiler with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent versions of the following RPMs from the [IBM Support Website](#) onto your QRadar Console.
  - Protocol-JDBC RPM
  - Riverbed SteelCentral NetProfiler RPM
2. Configure your Riverbed SteelCentral NetProfiler system to enable communication with QRadar.
3. Create a log source on the QRadar Console. Use the following table to define the Riverbed-specific JDBC parameters:

Table 931. Riverbed SteelCentral NetProfiler JDBC log source parameters	
Parameter	Description
Log Source Type	Riverbed SteelCentral NetProfiler
Protocol Configuration	JDBC
Log Source Identifier	Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.  If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2.
Database Type	Postgres
Database Name	You can type the actual name of the Riverbed database. For most configurations, the database name is mazu.  <b>Tip:</b> Confirm the actual name of the Riverbed database.
IP or Hostname	The IP address or host name of the database server.

Table 931. Riverbed SteelCentral NetProfiler JDBC log source parameters (continued)

Parameter	Description
<b>Port</b>	<p>Enter the JDBC port. The JDBC port must match the listener port that is configured on the remote database. The database must permit incoming TCP connections. The valid range is 1 - 65535.</p> <p>The defaults are:</p> <ul style="list-style-type: none"> <li>• MSDE - 1433</li> <li>• Postgres - 5432</li> <li>• MySQL - 3306</li> <li>• Sybase - 1521</li> <li>• Oracle - 1521</li> <li>• Informix - 9088</li> <li>• DB2 - 50000</li> </ul> <p>If a database instance is used with the MSDE database type, you must leave the <b>Port</b> field blank.</p>
<b>Table Name</b>	events.export_csv_view
<b>Select List</b>	The list of fields to include when the table is polled for events. You can use a comma-separated list or type an asterisk (*) to select all fields from the table or view. If a comma-separated list is defined, the list must contain the field that is defined in the <b>Compare Field</b> .
<b>Username</b>	The user name for the account that is configured to access the PostgreSQL database on the Riverbed SteelCentral NetProfiler system.
<b>Password</b>	The password that is required to connect to the database.
<b>Compare Field</b>	start_time
<b>Use Prepared Statements</b>	Prepared statements enable the JDBC protocol source to set up the SQL statement, and then run the SQL statement numerous times with different parameters. For security and performance reasons, most JDBC protocol configurations can use prepared statements.
<b>Start Date and Time (Optional)</b>	Type the start date and time for database polling in the following format: yyyy-MM-dd HH:mm with HH specified by using a 24-hour clock. If the start date or time is clear, polling begins immediately and repeats at the specified polling interval.
<b>Polling Interval</b>	<b>5M</b>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests.</p> <p>If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The valid range is 100 to 20,000.</p>

For more information about configuring JDBC protocol parameters, see [c\\_logsource\\_JDBCprotocol.dita](#)

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## **Configuring your Riverbed SteelCentral NetProfiler system to enable communication with QRadar**

To collect Riverbed SteelCentral NetProfiler alert events, you must configure your Riverbed SteelCentral NetProfiler system to allow QRadar to retrieve events from the PostgreSQL database.

### **Procedure**

1. Log in to your Riverbed SteelCentral NetProfiler host user interface.
2. Select **Configuration > Appliance Security > Security Compliance**.
3. Check the **Enable ODBC Access** check box.
4. Select **Configuration > Account Management > User Accounts**.
5. Add an account that QRadar can use to access to the PostgreSQL database.

# Chapter 135. RSA Authentication Manager

You can use an RSA Authentication Manager DSM to integrate IBM QRadar with an RSA Authentication Manager 6.x or 7.x by using syslog or the log file protocol. RSA Authentication Manager 8.x uses syslog only.

Before you configure QRadar to integrate with RSA Authentication Manager, select your configuration preference:

- [“Configuration of syslog for RSA Authentication Manager 6.x, 7.x and 8.x” on page 1431](#)
- [“Configuring the log file protocol for RSA Authentication Manager 6.x and 7.x” on page 1432](#)

**Note:** You must apply the most recent hot fix on RSA Authentication Manager 7.1 primary, replica, node, database, and radius installations before you configure syslog.

## Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Configuration of syslog for RSA Authentication Manager 6.x, 7.x and 8.x

The procedure to configure your RSA Authentication Manager 6.x, 7.x and 8.x using syslog depends on the operating system version for your RSA Authentication Manager or SecureID 3.0 appliance.

If you are using RSA Authentication Manager on Linux, see [“Configuring Linux” on page 1431](#).

If you are using RSA Authentication Manager on Windows, see [“Configuring Windows” on page 1432](#).

## Configuring Linux

You can configure RSA Authentication Manager for syslog on Linux based operating systems.

### Procedure

1. Using SSH, log in to the RSA Security Console as root user.
2. Open one of the following files for editing based on your version of RSA Authentication Manager:

#### Versions earlier than version 8

```
/usr/local/RSAsecurity/RSAAuthenticationManager/utils/resources/  
ims.properties
```

#### Version 8

```
/opt/rsa/am/utils/resources/ims.properties
```

3. Add the following entries to the ims.properties file:

```
ims.logging.audit.admin.syslog_host = <IP address>  
ims.logging.audit.admin.use_os_logger = true  
ims.logging.audit.runtime.syslog_host = <IP address>  
ims.logging.audit.runtime.use_os_logger = true  
ims.logging.system.syslog_host = <IP address>  
ims.logging.system.use_os_logger = true
```

Where <IP address> is the IP address or host name of IBM QRadar.

4. Save the ims.properties file.
5. Open the following file for editing:  
`/etc/syslog.conf`
6. Type the following command to add QRadar as a syslog entry:

\*.\* @<IP address>

Where <IP address> is the IP address or host name of QRadar.

7. Type the following command to restart the syslog services for Linux.

```
service syslog restart
```

For more information on configuring syslog forwarding, see your *RSA Authentication Manager documentation*.

## What to do next

Configure the log source and protocol in QRadar. To receive events from RSA Authentication Manager, from the **Log Source Type** list, select the **RSA Authentication Manager** option.

## Configuring Windows

---

To configure RSA Authentication Manager for syslog using Microsoft Windows.

### Procedure

1. Log in to the system that hosts your RSA Security Console.
2. Open the following file for editing based on your operating system:  
`/Program Files/RSA Security/RSA Authentication Manager/utils/resources/ims.properties`
3. Add the following entries to the ims.properties file:

```
ims.logging.audit.admin.syslog_host = <IP address>
ims.logging.audit.admin.use_os_logger = true
ims.logging.audit.runtime.syslog_host = <IP address>
ims.logging.audit.runtime.use_os_logger = true
ims.logging.system.syslog_host = <IP address>
ims.logging.system.use_os_logger = true
```

Where <IP address> is the IP address or host name of QRadar.

4. Save the ims.properties files.
5. Restart RSA services.

You are now ready to configure the log source in QRadar.

6. To configure QRadar to receive events from your RSA Authentication Manager: From the **Log Source Type** list, select the **RSA Authentication Manager** option.

For more information on configuring syslog forwarding, see your *RSA Authentication Manager documentation*.

### Related concepts

[“Log File log source parameters for RSA Authentication Manager” on page 1433](#)

## Configuring the log file protocol for RSA Authentication Manager 6.x and 7.x

---

The log file protocol allows IBM QRadar to retrieve archived log files from a remote host. The RSA Authentication Manager DSM supports the bulk loading of log files using the log file protocol source.

The procedure to configure your RSA Authentication Manager using the log file protocol depends on the version of RSA Authentication Manager:

- If you are using RSA Authentication Manager v6.x, see [“Configuring RSA Authentication Manager 6.x” on page 1433](#).

- If you are using RSA Authentication Manager v7.x, see “Configuring RSA Authentication Manager 7.x” on page 1434.

## Log File log source parameters for RSA Authentication Manager

If QRadar does not automatically detect the log source, add a RSA Authentication Manager log source on the QRadar Console by using Log File protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from RSA Authentication Manager:

Table 932. Log File log source parameters for the RSA Authentication Manager DSM	
Parameter	Value
<b>Log Source type</b>	RSA Authentication Manager
<b>Protocol Configuration</b>	Log File

For a complete list of Log File protocol parameters and their values, see “Log File protocol configuration options” on page 155.

### Related tasks

[“Adding a log source” on page 5](#)

## Configuring RSA Authentication Manager 6.x

---

You can configure your RSA Authentication Manager 6.x device.

### Procedure

1. Log in to the RSA Security Console.
2. Log in to the RSA Database Administration tool:
3. Click the **Advanced** tool.  
The system prompts you to log in again.
4. Click **Database Administration**.  
For complete information on using **SecurID**, see your vendor documentation.
5. From the **Log** list, select **Automate Log Maintenance**.  
The **Automatic Log Maintenance** window is displayed.
6. Select the **Enable Automatic Audit Log Maintenance** check box.
7. Select **Delete and Archive**.
8. Select **Replace files**.
9. Type an archive file name.
10. In the **Cycle Through Version(s)** field, type a value.
11. For example 1, Select **Select all Logs**.
12. Select a frequency.
13. Click **OK**.

### Related concepts

[“Log File log source parameters for RSA Authentication Manager” on page 1433](#)

### Related tasks

[“Adding a log source” on page 5](#)

# Configuring RSA Authentication Manager 7.x

---

You can configure your RSA Authentication Manager 7.x device.

## Procedure

1. Log in to the RSA Security Console.
2. Click **Administration > Log Management > Recurring Log Archive Jobs**.
3. In the Schedule section, configure values for the **Job Starts, Frequency, Run Time**, and **Job Expires** parameters.
4. For the **Operations** field, select **Export Only** or **Export and Purge** for the following settings: **Administration Log Settings**, **Runtime Log Settings**, and **System Log Settings**.

**Note:** The **Export and Purge** operation exports log records from the database to the archive and then purges the logs from the database. The **Export Only** operation exports log records from the database to the archive and the records remain in the database.

5. For **Administration, Runtime, and System**, configure an Export Directory to which you want to export your archive files.  
Ensure that you can access the Administration Log, Runtime Log, and System Log by using FTP before you continue.
6. For Administration, Runtime, and System parameters, set the Days Kept Online parameter to 1. Logs older than 1 day are exported. If you selected **Export and Purge**, the logs are also purged from the database.
7. Click **Save**.

## Related concepts

# Chapter 136. SafeNet DataSecure

The IBM QRadar DSM for SafeNet DataSecure collects syslog events from a SafeNet DataSecure device. DataSecure maintains activity, such as, record administrative actions, network activity, and cryptography requests. QRadar supports SafeNet DataSecure V6.3.0.

SafeNet DataSecure creates the following event logs:

## **Activity Log**

Contains a record of each request that is received by the key server.

## **Audit Log**

Contains a record of all configuration changes and user input errors that are made to SafeNet KeySecure, whether through the management console or the command-line interface.

## **Client Event Log**

Contains a record of all client requests that have the <RecordEventRequest> element.

## **System Log**

Contains a record of all system events, such as the following events:

- Service starts, stops, and restarts
- SNMP traps
- Hardware failures
- Successful or failed cluster replication and synchronization
- Failed log transfers

To integrate SafeNet DataSecure with QRadar, complete the following steps:

1. Enable syslog on the SafeNet DataSecure device.
2. QRadar automatically detects SafeNet DataSecure after your system receives 25 events and configures a log source. If QRadar does not automatically discover SafeNet DataSecure, add a log source.

## **Related tasks**

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Configuring SafeNet DataSecure to communicate with QRadar

Before you can add the DSM for SafeNet DataSecure, enable syslog on your SafeNet DataSecure device.

### **Procedure**

1. Log in to the SafeNet DataSecure management console as an administrator with logging access control.
2. Select **Device > Log Configuration**.
3. Select the **Rotation & Syslog** tab.
4. Select a log in the **Syslog Settings** section and click **Edit**.
5. Select **Enable Syslog**.
6. Configure the following parameters:

Parameter	Description
Syslog Server #1 IP	The IP address or host name of the target QRadar Event Collector.

<b>Parameter</b>	<b>Description</b>
Syslog Server #1 Port	The listening port for QRadar. Use Port 514.
Syslog Server #1 Proto	QRadar can receive syslog messages by using either UDP or TCP.

7. Optional. Type an IP address port, and protocol for a Syslog Server #2. When two servers are configured, SafeNet DataSecure sends messages to both servers.
8. Type the Syslog Facility or accept the default value of local1.
9. Click **Save**.

# Chapter 137. Salesforce

IBM QRadar supports a range of Salesforce DSMs for the Salesforce Service type.

## Salesforce Security

The IBM QRadar DSM for Salesforce Security collects Salesforce Security Auditing audit logs and Salesforce Security Monitoring event logs from your Salesforce console by using a RESTful API.

The following table identifies the specifications for the Salesforce Security DSM:

Table 933. Salesforce Security DSM specifications	
Specification	Value
Manufacturer	Salesforce
DSM	Salesforce Security
RPM file name	DSM-SalesforceSecurity-QRadar_Version-Build_Number.noarch.rpm
Protocol	Salesforce REST API Protocol
QRadar recorded events	Login History, Account History, Case History, Entitlement History, Service Contract History, Contract Line Item History, Contract History, Contact History, Lead History, Opportunity History, Solution History, Salesforce Security Auditing audit trail
Automatically discovered	No
Includes identity	Yes
More information	<a href="http://www.salesforce.com/">Salesforce website (http://www.salesforce.com/)</a>

### Salesforce Security DSM integration process

To integrate Salesforce Security DSM with QRadar, use the following procedures:

1. If automatic updates are not enabled, download and install the most recent versions of the following RPMs from the [IBM Support Website](#) onto your QRadar Console.
  - Protocol Common RPM
  - SalesforceRESTAPI Protocol RPM
  - DSMCommon RPM
  - Salesforce Security Auditing RPM
  - Salesforce Security RPM
2. Configure the Salesforce Security server to communicate with QRadar.
3. Obtain and install a certificate to enable communication between Salesforce Security and QRadar. The certificate must be in the /opt/QRadar/conf/trusted\_certificates folder and be in .DER format.
4. For each instance of Salesforce Security, create a log source on the QRadar Console.

# Configuring the Salesforce Security Monitoring server to communicate with QRadar

To allow QRadar communication, you need to configure Connected App on the Salesforce console and collect information that the Connected App generates. This information is required for when you configure the QRadar log source.

## Before you begin

If the RESTful API isn't enabled on your Salesforce server, contact Salesforce support.

## Procedure

1. Configure and collect information that is generated by the Connected App.
  - a) Log in to your Salesforce Security Monitoring server.
  - b) Click the **Setup** button.
  - c) In the navigation pane, click **Create > Apps > New**.
  - d) Type the name of your application.
  - e) Type the contact email information.
  - f) Select **Enable OAuth Settings**.
  - g) From the **Selected OAuth Scopes** list, select **Access and manage your data (api)**.
  - h) In the **Info URL** field, type a URL where the user can go for more information about your application.
  - i) Configure the remaining optional parameters.
  - j) Click **Save**.
2. Turn on **Entitlement History**.
  - a) Click the **Setup** button.
  - b) In the navigation pane, select **Build > Customize > Entitlement Management > Enablement Settings**.
  - c) From the **Entitlement Management Settings** window, select the **Enable Entitlement Management** check box.
  - d) Click **Save**.

## What to do next

The Connected App generates the information that is required for when you to configure a log source on QRadar. Record the following information:

### Consumer Key

Use the **Consumer Key** value to configure the **Client ID** parameter for the QRadar log source.

### Consumer Secret

You can click the link to reveal the consumer secret. Use the **Consumer Secret** value to configure the **Secret ID** parameter for the QRadar log source.

**Important:** The **Consumer Secret** value is confidential. Don't store the consumer secret as plain text.

### Security token

A security token is sent by email to the email address that you configured as the contact email.

## Salesforce REST API log source parameters for Salesforce Security

If QRadar does not automatically detect the log source, add a Salesforce Security log source on the QRadar Console by using the Salesforce REST API protocol.

When you use the Salesforce REST API protocol, you must configure specific parameters.

The following table describes the parameters that require specific values to collect Salesforce REST API events from Salesforce Security:

Table 934. Salesforce REST API log source parameters for the Salesforce Security DSM	
Parameter	Value
<b>Log Source type</b>	Salesforce Security
<b>Protocol Configuration</b>	Salesforce REST API
<b>Login URL</b>	The URL of the Salesforce security console. For example, <a href="https://test.my.salesforce.com">https://test.my.salesforce.com</a> .
<b>Username</b>	The user name of the Salesforce security console.
<b>Security Token</b>	The security token that was sent to the email address configured as the contact email for the Connected App on the Salesforce security console. Security tokens are required when: <ul style="list-style-type: none"> <li>Accessing Salesforce from outside trusted IP ranges.</li> <li>Integrating with Salesforce by using third-party tools that do not support OAuth authentication.</li> </ul>
<b>Client ID</b>	The Consumer Key that was generated when you configured the Connected App on the Salesforce security console.
<b>Secret ID</b>	The Consumer Secret that was generated when you configured the Connected App on the Salesforce security console.
<b>Use Proxy</b>	When a proxy is configured, all traffic for the log source travels through the proxy for QRadar to access the Salesforce Security buckets. Configure the <b>Proxy Server</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy Password</b> fields. If the proxy does not require authentication, you can leave the <b>Proxy Username</b> and <b>Proxy Password</b> fields blank.
<b>Advanced Options</b>	By default the Salesforce REST API collects Audit Trail and Security Monitoring events. Configure the available options as required.

**Note:** Salesforce credentials that are used by QRadar must have admin permission with query API (<https://<>/services/data/v53.0/query?q=<query>>) access.

[“Adding a log source” on page 5](#)

## Salesforce Security Auditing

The IBM QRadar DSM for Salesforce Security Auditing can collect Salesforce Security Auditing audit trail logs that you copy from the cloud to a location that QRadar can access.

The following table identifies the specifications for the Salesforce Security Auditing DSM:

Table 935. Salesforce Security Auditing DSM specifications

Specification	Value
Manufacturer	Salesforce
DSM	Salesforce Security Auditing
RPM file name	DSM-SalesforceSecurityAuditing-QRadar_Version-Build_Number.noarch.rpm
Protocol	Log File
QRadar recorded events	Setup Audit Records
Automatically discovered	No
Includes identity	No
More information	<a href="http://www.salesforce.com/">Salesforce web site (http://www.salesforce.com/)</a>

## Salesforce Security Auditing DSM integration process

To integrate Salesforce Security Auditing DSM with QRadar, use the following procedures:

1. If automatic updates are not enabled, download and install the most recent versions of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Log File Protocol RPM
  - Salesforce Security Auditing RPM
2. Download the Salesforce audit trail file to a remote host that QRadar can access.
3. For each instance of Salesforce Security Auditing, create a log source on the QRadar Console.

## Downloading the Salesforce audit trail file

To collect Salesforce Security Auditing events, you must download the Salesforce audit trail file to a remote host that QRadar can access.

### About this task

You must use this procedure each time that you want to import an updated set of audit data into QRadar. When you download the audit trail file, you can overwrite the previous audit trail CSV file. When QRadar retrieves data from the audit trail file, QRadar processes only audit records that were not imported before.

### Procedure

1. Log in to your Salesforce Security Auditing server.
2. Go to the **Setup** section.
3. Click **Security Controls**.
4. Click **View Setup Audit Trail**.
5. Click **Download setup audit trail for last six months (Excel.csv file)**.
6. Copy the downloaded file to a location that QRadar can reach by using Log File Protocol.

## Log File log source parameters for Salesforce Security Auditing

If QRadar does not automatically detect the log source, add a Salesforce Security Auditing log source on the QRadar Console by using the Log File protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from Salesforce Security Auditing:

Table 936. Log File log source parameters for the Salesforce Security Auditing DSM	
Parameter	Value
<b>Log Source type</b>	Salesforce Security Auditing
<b>Protocol Configuration</b>	Log File
<b>Event Generator</b>	RegEx Based Multiline
<b>Start Pattern</b>	(\d{1,2}/\d{1,2}/\d{4} \d{1,2}:\d{2}:\d{2} \w+)
<b>End Pattern</b>	Ensure that this parameter remains empty.
<b>Date Time RegEx</b>	(\d{1,2}/\d{1,2}/\d{4} \d{1,2}:\d{2}:\d{2} \w+)
<b>Date Time Format</b>	dd/MM/yyyy hh:mm:ss z

For a complete list of Log File protocol parameters and their values, see [“Log File protocol configuration options” on page 155](#).

#### Related tasks

[“Adding a log source” on page 5](#)

# Chapter 138. Samhain Labs

The Samhain Labs Host-Based Intrusion Detection System (HIDS) monitors changes to files on the system.

The Samhain HIDS DSM for IBM QRadar supports Samhain version 2.4 when used for File Integrity Monitoring (FIM).

You can configure the Samhain HIDS DSM to collect events by using syslog or JDBC.

## Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Configuring syslog to collect Samhain events

Before you configure IBM QRadar to integrate with Samhain HIDS using syslog, you must configure the Samhain HIDS system to forward logs to your QRadar system.

### About this task

The following procedure is based on the default samhainrc file. If the samhainrc file is modified, some values might be different, such as the syslog facility,

### Procedure

1. Log in to Samhain HIDS from the command-line interface.

2. Open the following file:

`/etc/samhainrc`

3. Remove the comment marker (#) from the following line:

`SetLogServer=info`

4. Save and exit the file.

Alerts are sent to the local system by using syslog.

5. Open the following file:

`/etc/syslog.conf`

6. Add the following line:

`local2.* @<IP Address>`

Where <IP Address> is the IP address of your QRadar.

7. Save and exit the file.

8. Restart syslog:

`/etc/init.d/syslog restart`

Samhain sends logs by using syslog to QRadar.

You are now ready to configure Samhain HIDS DSM in QRadar. To configure QRadar to receive events from Samhain:

9. From the **Log Source Type** list, select the **Samhain HIDS** option.

## Related tasks

[“Adding a log source” on page 5](#)

## JDBC log source parameters for Samhain

If QRadar does not automatically detect the log source, add a Samhain log source on the QRadar Console by using the JDBC protocol.

When using the JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from Samhain:

Table 937. JDBC log source parameters for the Samhain DSM	
Parameter	Value
<b>Log Source type</b>	Samhain HIDS
<b>Protocol Configuration</b>	JDBC
<b>Log Source Identifier</b>	Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.  If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2.
<b>Database Type</b>	Select <b>Oracle</b> , <b>PostgresSQL</b> , or <b>MySQL</b>
<b>Database Name</b>	< <i>Samhain SetDBName</i> >
<b>IP or Hostname</b>	< <i>Samhain SetDBHost</i> >
<b>Username</b>	< <i>Samhain SetDBUser</i> >
<b>Password</b>	< <i>Samhain SetDBPassword</i> >
<b>Table Name</b>	< <i>Samhain SetDBTable</i> >

For a complete list of JDBC protocol parameters and their values, see “[JDBC protocol configuration options](#)” on page 147.

### Related tasks

[“Adding a log source” on page 5](#)

## JDBC protocol configuration options

QRadar uses the JDBC protocol to collect information from tables or views that contain event data from several database types.

The JDBC protocol is an outbound/active protocol. QRadar does not include a MySQL driver for JDBC. If you are using a DSM or protocol that requires a MySQL JDBC driver, you must download and install the *platform-independent MySQL Connector/J* from <http://dev.mysql.com/downloads/connector/j/>.

1. Copy the Java archive (JAR) file to /opt/qradar/jars and /opt/ibm/si/services/ecs-ec-ingress/eventgnosis/lib/q1labs/.
2. Restart Tomcat service by typing the following command:

```
systemctl restart tomcat
```

3. Restart event collection services by typing the following command:

```
systemctl restart ecs-ec-ingress
```

The following table describes the protocol-specific parameters for the JDBC protocol:

Table 938. JDBC protocol parameters	
Parameter	Description
<b>Log Source Name</b>	Type a unique name for the log source.
<b>Log Source Description (Optional)</b>	Type a description for the log source.
<b>Log Source Type</b>	Select your Device Support Module (DSM) that uses the JDBC protocol from the <b>Log Source Type</b> list.
<b>Protocol Configuration</b>	<b>JDBC</b>
<b>Log Source Identifier</b>	Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.  If the log source collects events from a single appliance that has a static IP address or hostname, use the IP address or hostname of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or hostname, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2.
<b>Database Type</b>	Select the type of database that contains the events.
<b>Database Name</b>	The name of the database to which you want to connect.
<b>Schema (Snowflake only)</b>	This parameter specifies either the default schema to be used for the specified database post connection, or an empty string.  The specified schema must be an existing schema for which the specified default role has privileges.
<b>IP or Hostname</b>	The IP address or hostname of the database server.
<b>Warehouse (Snowflake only)</b>	This parameter specifies the virtual warehouse to use post connection, or an empty string.  The specified warehouse must be an existing warehouse for which the specified default role has privileges.

Table 938. JDBC protocol parameters (continued)

Parameter	Description
<b>Role (Snowflake only)</b>	<p>This parameter specifies the default access control role to be used in the Snowflake session initiated by the driver.</p> <p>The specified role must be an existing role that is already assigned to the specified user for the driver.</p> <p>If the specified role is not assigned to the user, then the role is not used during the session initiation by the driver.</p>
<b>Port</b>	<p>Enter the JDBC port. The JDBC port must match the listener port that is configured on the remote database. The database must permit incoming TCP connections. The valid range is 1 - 65535.</p> <p>The defaults are:</p> <ul style="list-style-type: none"> <li>• Db2 - 50000</li> <li>• Informix - 9088</li> <li>• MSDE - 1433</li> <li>• MySQL - 3306</li> <li>• Oracle - 1521</li> <li>• Postgres - 5432</li> <li>• Sybase - 5000</li> <li>• Snowflake - 443</li> </ul> <p>If you configure the <b>Database Instance</b> parameter and have an MSDE database type, leave the <b>Port</b> parameter blank.</p>
<b>Username</b>	A user account for QRadar in the database.
<b>Password</b>	The password that is required to connect to the database.
<b>Confirm Password</b>	The password that is required to connect to the database.
<b>Authentication Domain</b> (MSDE only)	<p>If you disable <b>Use Microsoft JDBC</b>, the <b>Authentication Domain</b> parameter is displayed.</p> <p>The domain for MSDE that is a Windows domain. If your network does not use a domain, leave this field blank.</p>
<b>Database Instance</b> (MSDE or Informix only)	<p>The database instance, if required. MSDE databases can include multiple SQL server instances on one server.</p> <p>When you use a different port number from the default for SQL database resolution, leave this parameter blank.</p>
<b>Predefined Query</b> (Optional)	<p>Select a predefined database query for the log source. If a predefined query is not available for the log source type, you can select the <b>None</b> option.</p> <p>If the configuration guide for a specific integration states to use a predefined query, choose it from the list. Otherwise, select <b>None</b> and populate the remaining required values.</p>
<b>Table Name</b>	The name of the table or view that includes the event records. The table name can include the following special characters: dollar sign (\$), number sign (#), underscore (_), en dash (-), and period (.)

Table 938. JDBC protocol parameters (continued)

Parameter	Description
<b>Select List</b>	The list of fields to include when the table is polled for events. You can use a comma-separated list or type an asterisk (*) to select all fields from the table or view. If you defined a comma-separated list, the list must contain the field that is defined in the <b>Compare Field</b> parameter.
<b>Compare Field</b>	A numeric value or time stamp field from the table or view that identifies new events that are added to the table between queries. When you set this parameter value, the protocol identifies events that were previously pulled by the protocol to ensure that duplicate events are not created.
<b>Use Prepared Statements</b>	Prepared statements enable the JDBC protocol source to set up the SQL statement, and then run the SQL statement numerous times with different parameters. For security and performance reasons, most JDBC protocol configurations can use prepared statements.
<b>Start Date and Time</b> (Optional)	<p>Select or enter the start date and time for database polling. The format is yyyy-mm-dd HH:mm, where HH is specified by using a 24-hour clock.</p> <p>If this parameter is empty, polling begins immediately and repeats at the specified polling interval.</p> <p>This parameter is used to set the time and date at which the protocol connects to the target database to initialize event collection. It can be used along with the <b>Polling Interval</b> parameter to configure specific schedules for the database polls. For example, use these parameters to ensure that the poll happens at five minutes past the hour, every hour, or to ensure that the poll happens at exactly 1:00 AM each day.</p> <p>This parameter cannot be used to retrieve older table rows from the target database. For example, if you set the parameter to <b>Last Week</b>, the protocol does not retrieve all table rows from the previous week. The protocol retrieves rows that are newer than the maximum value of the <b>Compare Field</b> on initial connection.</p>
<b>Polling Interval</b>	<p>Enter the amount of time between queries to the event table. To define a longer polling interval, append H for hours or M for minutes to the numeric value.</p> <p>The maximum polling interval is one week.</p>
<b>EPS Throttle</b>	<p>The maximum number of events per second that QRadar ingests. If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.</p> <p>The valid range is 100 to 20,000.</p>

Table 938. JDBC protocol parameters (continued)

Parameter	Description
<b>Security Mechanism</b> (Db2 only)	<p>From the list, select the security mechanism that is supported by your Db2 server. If you don't want to select a security mechanism, select <b>None</b>.</p> <p>The default is <b>None</b>.</p> <p>For more information about security mechanisms that are supported by Db2 environments, see the <a href="https://www.ibm.com/support/knowledgecenter/en/SSEPGG_11.1.0/com.ibm.db2.luw.apdv.java.doc/src/tpc/imjcc_cjvcsec.html">IBM Support website</a> (<a href="https://www.ibm.com/support/knowledgecenter/en/SSEPGG_11.1.0/com.ibm.db2.luw.apdv.java.doc/src/tpc/imjcc_cjvcsec.html">https://www.ibm.com/support/knowledgecenter/en/SSEPGG_11.1.0/com.ibm.db2.luw.apdv.java.doc/src/tpc/imjcc_cjvcsec.html</a>)</p>
<b>Use Named Pipe Communication</b> (MSDE only)	<p>If you disable <b>Use Microsoft JDBC</b>, the <b>Use Named Pipe Communication</b> parameter is displayed.</p> <p>MSDE databases require the user name and password field to use a Windows authentication user name and password and not the database user name and password. The log source configuration must use the default that is named pipe on the MSDE database.</p>
<b>Database Cluster Name</b>	<p>If you are running your SQL server in a cluster environment, define the cluster name to ensure named pipe communication functions properly.</p> <p>This parameter is required if you enable <b>Use Named Pipe Communication</b> and select the MSDE database type option.</p>
<b>Use NTLMv2</b> (MSDE only)	<p>If you disable <b>Use Microsoft JDBC</b>, the <b>Use NTLMv2</b> parameter is displayed.</p> <p>Select this option if you want MSDE connections to use the NTLMv2 protocol when they are communicating with SQL servers that require NTLMv2 authentication. This option does not interrupt communications for MSDE connections that do not require NTLMv2 authentication.</p> <p>Does not interrupt communications for MSDE connections that do not require NTLMv2 authentication.</p>
<b>Use Microsoft JDBC</b> (MSDE only)	<p>If you want to use the Microsoft JDBC driver, you must enable <b>Use Microsoft JDBC</b>.</p> <p>This parameter is enabled by default.</p>
<b>Use SSL</b> (MSDE only)	Enable this option if your MSDE connection supports SSL.
<b>SSL Certificate Hostname</b>	<p>This field is required when both <b>Use Microsoft JDBC</b> and <b>Use SSL</b> are enabled.</p> <p>This value must be the fully qualified domain name (FQDN) for the host. The IP address is not permitted.</p> <p>For more information about SSL certificates and JDBC, see the procedures at the following links:</p> <ul style="list-style-type: none"> <li><a href="https://www.ibm.com/support/pages/node/246077">QRadar: Configuring JDBC Over SSL with a Self-signed certificate</a> (<a href="https://www.ibm.com/support/pages/node/246077">https://www.ibm.com/support/pages/node/246077</a>)</li> <li><a href="https://www.ibm.com/support/pages/node/246079">Configuring JDBC Over SSL with an Externally-signed Certificate</a> (<a href="https://www.ibm.com/support/pages/node/246079">https://www.ibm.com/support/pages/node/246079</a>)</li> </ul>

Table 938. JDBC protocol parameters (continued)

Parameter	Description
<b>Use Oracle Encryption</b> (Oracle only)	<p><i>Oracle Encryption and Data Integrity settings</i> is also known as <i>Oracle Advanced Security</i>.</p> <p>If selected, Oracle JDBC connections require the server to support similar Oracle Data Encryption settings as the client.</p>
<b>Database Locale</b> (Informix only)	<p>For multilingual installations, specify the language to use for the installation process (or software?).</p> <p>After you choose a language, you can then choose the character set that is used in the installation in the <b>Code-Set</b> parameter.</p>
<b>Code-Set</b> (Informix only)	<p>The <b>Code-Set</b> parameter displays after you choose a language for multilingual installations.</p> <p>Use this field to specify the character set to use.</p>
<b>Enabled</b>	Select this checkbox to enable the log source. By default, the checkbox is selected.
<b>Credibility</b>	<p>From the list, select the <b>Credibility</b> of the log source. The range is 0 - 10.</p> <p>The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.</p>
<b>Target Event Collector</b>	Select the <b>Target Event Collector</b> to use as the target for the log source.
<b>Coalescing Events</b>	<p>Select the <b>Coalescing Events</b> checkbox to enable the log source to coalesce (bundle) events.</p> <p>By default, automatically discovered log sources inherit the value of the <b>Coalescing Events</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.</p>
<b>Store Event Payload</b>	<p>Select the <b>Store Event Payload</b> checkbox to enable the log source to store event payload information.</p> <p>By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.</p>
<b>Enable Advanced Options</b>	Select this checkbox to enable advanced options. When disabled, the default value is used.
<b>Use With (No Lock) in SQL statements</b>	Enable this option to append the tables in all SQL statements with "WITH (NOLOCK)".

# Chapter 139. SAP Enterprise Threat Detection

The IBM QRadar DSM for SAP Enterprise Threat Detection collects events from an SAP Enterprise Threat Detection server. SAP Enterprise Threat Detection enables real-time security intelligence to help protect against cybersecurity threats and help ensure data loss prevention.

To integrate SAP Enterprise Threat Detection with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Protocol-Common RPM
  - SAP ETD Alert API Protocol RPM
  - SAP Enterprise Threat Detection DSM RPM
2. Configure QRadar to receive events from SAP Enterprise Threat Detection. See “[SAP Enterprise Threat Detection Alert API log source parameters for SAP Enterprise Threat Detection](#)” on page 1452.
3. Configure SAP Enterprise Threat Detection to communicate with QRadar. See the [Enterprise ThreatMonitor Integration documentation](#). (<https://www.enterprise-threat-monitor.com/sap-qradar-enterprise-threat-detection-siem-integration/>)
4. If QRadar does not automatically detect the log source, add an SAP Enterprise Threat Detection log source on the QRadar Console.

The following table describes the specifications for the SAP Enterprise Threat Detection DSM.

## SAP Enterprise Threat Detection DSM specifications

The following table describes the specifications for the SAP Enterprise Threat Detection DSM.

Table 939. SAP Enterprise Threat Detection DSM specifications	
Specification	Value
Manufacturer	SAP
DSM name	SAP Enterprise Threat Detection
RPM file name	DSM-SAPEnterpriseThreatDetection-QRadar_version-build_number.noarch.rpm
Supported versions	SAP Enterprise Threat Detection V1.0 SP6 to V2.0 SP5
Protocol	SAP Enterprise Threat Detection Alert API
Event format	LEEF
Recorded event types	Alerts
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No

Table 939. SAP Enterprise Threat Detection DSM specifications (continued)

Specification	Value
More information	<a href="https://www.sap.com/products/enterprise-threat-detection.html#why-sap">SAP Help Portal (<a href="https://www.sap.com/products/enterprise-threat-detection.html#why-sap">https://www.sap.com/products/enterprise-threat-detection.html#why-sap</a>)</a>

## SAP Enterprise Threat Detection Alert API log source parameters for SAP Enterprise Threat Detection

If QRadar does not automatically detect the log source, add a SAP Enterprise Threat Detection log source on the QRadar Console by using the SAP Enterprise Threat Detection Alert API protocol.

When using the SAP Enterprise Threat Detection Alert API protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect SAP Enterprise Threat Detection Alert API events from SAP Enterprise Threat Detection:

Table 940. SAP Enterprise Threat Detection Alert API log source parameters for the SAP Enterprise Threat Detection DSM

Parameter	Value
<b>Log Source type</b>	SAP Enterprise Threat Detection
<b>Protocol Configuration</b>	SAP Enterprise Threat Detection Alert API
<b>Log Source Identifier</b>	A unique identifier for the log source.  The Log Source Identifier can be any valid value, including the same value as the Log Source Name, and doesn't need to reference a specific server. If you configured multiple SAP Enterprise Threat Detection Alert API log sources, you might want to identify the first log source as SAPETD-1, the second log source as SAPETD-2, and the third log source as SAPETD-3.
<b>Server URL</b>	Specify the URL used to access the SAP Enterprise Threat Detection Alert API, including the port. For example, “ <a href="http://192.0.2.1:8003">http://192.0.2.1:8003</a> ” or “ <a href="https://192.0.2.1:9443">https://192.0.2.1:9443</a> ”.s
<b>Username/Password</b>	Enter the user name and password that are required to access the SAP ETD server, and then confirm that you entered the password correctly. The confirmation password must be identical to the password you typed for the <i>password</i> parameter.  <b>Important:</b> SAP Enterprise Threat Detection has a login attempt limit of three attempts. If your account is locked because of multiple login attempts, you cannot connect QRadar to the SAP Enterprise Threat Detection Server until the account is unlocked. Contact SAP Support for assistance.

Table 940. SAP Enterprise Threat Detection Alert API log source parameters for the SAP Enterprise Threat Detection DSM (continued)

Parameter	Value
<b>Use Pattern Filter</b>	Select this option to limit the query to only a specific pattern filter. Leave the field cleared to query for all the events.
<b>Pattern Filter ID</b>	The pattern filter Id that is used to filter the query. The field accepts a UUID that is created when a pattern filter is made.  The <b>Filter ID</b> is the UUID mentioned in the protocol parameters table for parameter <b>Pattern Filter Id</b> .
<b>Use Proxy</b>	If QRadar accesses the SAP Enterprise Threat Detection Alert API by using a proxy, enable Use Proxy.  If the proxy requires authentication, configure the <b>Proxy Hostname or IP</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy</b> fields.  If the proxy does not require authentication, configure the <b>Proxy Hostname or IP</b> and <b>Proxy Port</b> .
<b>Automatically Acquire Server Certificates</b>	If you choose <b>Yes</b> from the list, QRadar automatically downloads the certificate and begins trusting the target server. If <b>No</b> is selected, QRadar does not attempt to retrieve any server certificates.  <b>Note:</b> If the SAP Enterprise Threat Detection Server is configured for HTTPS, a valid certificate is required. Either set this value to <b>Yes</b> or manually retrieve a certificate for the Log Source.
<b>Recurrence</b>	The time interval between log source queries to the SAP Enterprise Threat Detection Alert API for new events. The time interval can be in hours (H), minutes (M), or days (D). The default is 5 minutes (5M).
<b>Throttle</b>	The maximum number of events per second. The default is 5000.

#### Related tasks

[“Adding a log source” on page 5](#)

## Creating a pattern filter on the SAP server

A **Pattern Filter** is a user configured setting that can be used to limit queries to specific events. When a **Pattern Filter** is generated on the SAP server, a **Filter Id** is provided. The **Filter Id** can then be entered into the **Pattern Filter Id** field of the QRadar log source to filter the patterns that are retrieved.

#### Procedure

1. To create the **Pattern Filter** on the SAP Server, use the following steps:
  - a) Log in into the SAP server by using the administrator user name and password.

- b) Go to **Administration > Settings**.
- c) Select **Pattern Filter** and click **Add**.
- d) Enter a name for the **Pattern Filter**. This name is only used for identification purposes.

**Note:** The name appears in the **Name Column** with a corresponding **Filter Id** (UUID). Record the **Filter Id** for future reference.

- e) Click the pattern filter name to see a new table with **Namespace** as a column header.

- f) To add patterns to the **Pattern Filter**, click **Add**.

**Note:** A new window appears called **Pattern**.

- g) Select any **Pattern** you want to filter on and click **OK**.
- h) Refresh the page and ensure that the **Pattern** was added to the table with the **Namespace** header.

2. To use a **Pattern Filter** with QRadar, use the following steps:

- a) Either select or create an SAP ETD Alert API log source.
- b) Find the **Use Pattern Filter Id** check box and select it.
- c) Enter the **Filter Id** obtained in step 1d and enter it in the **Pattern Filter Id** field.
- d) Save the log source.

**Note:** If you receive a 500 Internal Server Error after you save the log source with the **Filter Id**, double check that there is at least one pattern that is being filtered for.

## Troubleshooting the SAP Enterprise Threat Detection Alert API

The SAP Enterprise Threat Detection DSM relies on the default pattern names of alerts to identify the events. Modifying the default patterns might result in events that appear as "Unknown".

### Procedure

1. Verify that the SAP Enterprise Threat Detection server login credentials are valid by following these steps:
  - a) In a Web browser, enter the IP address or domain name of your SAP Enterprise Threat Detection server. For example, `http://192.0.2.1:8003`.
  - b) Enter your user name and password.
2. Query the SAP Enterprise Threat Detection server to verify that QRadar can receive events. Use the following example as a starting point to create your query:

```
<Server_URL>/sap/secmon/services/Alerts.xsjs?$
query=AlertCreationTimestamp%20ge%20<Date>T15:00:00.00Z&$format=LEEF&$batchSize=10
```

In the example, replace the following parameters with your own values:

**<Server\_URL>**

The address of the SAP Enterprise Threat Detection server you are trying to access.

**<Date>**

The current day's date in the YYYY-MM-DD format. Choose a date where you know that events came in; for example, 2017-10-15.

The resulting query might look like this example:

```
http://192.0.2.1:8003/sap/secmon/services/Alerts.xsjs?query=AlertCreationTimestamp
%20ge%202017-10-15T15:00:00.00Z&$format=LEEF&$batchSize=10
```

If a problem exists with the query, it's unlikely that QRadar can successfully connect with SAP Enterprise Threat Detection.

3. Check that the server port is not blocked by a firewall.

**Note:** If the port is blocked, contact your security or network administrator to open the port.

### Related concepts

[“SAP Enterprise Threat Detection V1.0 SP6 sample event messages” on page 1455](#)

Use these sample event messages as a way of verifying a successful integration with QRadar. Replace the sample IP addresses, and so on with your own content.

### Related reference

[“SAP Enterprise Threat Detection DSM specifications” on page 1451](#)

The following table describes the specifications for the SAP Enterprise Threat Detection DSM.

## SAP Enterprise Threat Detection V1.0 SP6 sample event messages

Use these sample event messages as a way of verifying a successful integration with QRadar. Replace the sample IP addresses, and so on with your own content.

The following table provides sample event messages for the SAP Enterprise Threat Detection DSM.

# Chapter 140. Seculert

The IBM QRadar DSM for Seculert collects events from the Seculert cloud service.

The following table describes the specifications for the Seculert DSM:

Table 943. Seculert DSM specifications	
Specification	Value
Manufacturer	Seculert
DSM name	Seculert
RPM file name	DSM-SeculertSeculert-Qradar_version-build_number.noarch.rpm
Supported versions	v1
Protocol	Seculert Protection REST API Protocol
Recorded event types	All malware communication events
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://www.seculert.com">Seculert website</a> ( <a href="http://www.seculert.com">http://www.seculert.com</a> )

To integrate Seculert with QRadar, complete the following steps:

1. Download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Protocol-Common
  - DSM-DSMCommon
  - Seculert DSM RPM
  - SeculertProtectionRESTAPI PROTOCOL RPM
2. Add a Seculert log source on the QRadar Console. The following table describes the parameters that require specific values for Seculert event collection:

Table 944. Seculert log source parameters

Parameter	Value
Log Source type	Seculert
Protocol Configuration	Seculert Protection REST API
API Key	32 character UUID For more information about obtaining an API key, see <a href="#">“Seculert Protection REST API protocol configuration options” on page 211</a> .

For more information about this protocol, see [“Seculert Protection REST API protocol configuration options” on page 211](#).

# Chapter 141. Sentrigo Hedgehog

You can integrate a Sentrigo Hedgehog device with IBM QRadar.

## About this task

A Sentrigo Hedgehog device accepts LEEF events by using syslog. Before you configure QRadar to integrate with a Sentrigo Hedgehog device, take the following steps:

## Procedure

1. Log in to the Sentrigo Hedgehog command-line interface (CLI).
2. Open the following file for editing:

```
<Installation directory>/conf/sentrigo-custom.properties
```

Where *<Installation directory>* is the directory that contains your Sentrigo Hedgehog installation.

3. Add the following *log.format* entries to the custom properties file:

**Note:** Depending on your Sentrigo Hedgehog configuration or installation, you might need to replace or overwrite the existing *log.format* entry.

```
sentrigo.comm.ListenAddress=1996
log.format.body.custom=osUser:20$|duser=$execUser:20$|
severity=$severity$|identHostName=$sourceHost$|src=$sourceIP$|
dst=$agent.ip$|devTime=$logonTime$|
devTimeFormat=EEE MMM dd HH:mm:ss z yyyy|
cmdType=$cmdType$|externalId=$id$|
execTime=$executionTime.time$|
dstServiceName=$database.name:20$|
srcHost=$sourceHost:30$|execProgram=$execProgram:20$|
cmdType=$cmdType:15$|oper=$operation:225$|
accessedObj=$accessedObjects.name:200$
```

```
log.format.header.custom=LEEF:1.0|
Sentrigo|Hedgehog|$serverVersion$|$rules.name:150$|
log.format.header.escaping.custom=\\|
log.format.header.separator.custom=,
log.format.header.escape.char.custom=\=
log.format.body.escaping.custom=\=
log.format.body.escape.char.custom=\|
log.format.body.separator.custom=|
log.format.empty.value.custom=NULL
log.format.length.value.custom=10000
log.format.convert.newline.custom=true
```

4. Save the custom properties file.
5. Stop and restart your Sentrigo Hedgehog service to implement the *log.format* changes.

You can now configure the log source in QRadar.

6. To configure QRadar to receive events from a Sentrigo Hedgehog device: From the **Log Source Type** list, select the **Sentrigo Hedgehog** option.

For more information about Sentrigo Hedgehog see your vendor documentation.

# Chapter 142. Snowflake

The IBM QRadar DSM for Snowflake collects events from a Snowflake database.

To integrate Snowflake with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from [IBM support](#). Download and install the most recent version of the following RPM on your QRadar Console.
  - a. Snowflake DSM RPM
  - b. JDBC Protocol RPM
2. Configure your Snowflake device to send events to QRadar. For more information, see [JDBC protocol configuration options](#).

## Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Snowflake DSM specifications

The IBM QRadar DSM for Snowflake supports events (Login history, Query history, and Snowalerts) that are collected from the Snowflake database.

The following table lists the specifications for the Snowflake DSM.

Table 945. Snowflake DSM specifications	
Specification	Value
Manufacturer	Snowflake
DSM name	Snowflake
RPM file name	DSM-Snowflake-QRadar_version-Build_number.noarch.rpm
Supported protocols	JDBC Syslog
Event format	Name value pair (NVP)
Automatically discovered?	Yes
Includes identity?	Yes
Includes custom properties?	No
More information	<a href="#">Snowflake Database - Account Usage</a>

## Snowflake sample event message

The following sample events are from Snowflake database when you use the JDBC protocol.

### Login History View event

In the following sample event message, the event indicates the results of a query that returns the login attempt details of the Snowflake users.

```
EVENT_ID: "11111111111111xx" EVENT_TIMESTAMP: "2024-03-26 16:24:57.936"  
EVENT_TYPE: "LOGIN" USER_NAME: "TEST" CLIENT_IP: "10.0.x.x"
```

```

# Chapter 143. SolarWinds Orion

The IBM QRadar DSM for SolarWinds Orion collects events from a SolarWinds Orion appliance.

The following table describes the specifications for the SolarWinds Orion DSM:

Table 949. SolarWinds Orion DSM specifications	
Specification	Value
Manufacturer	SolarWinds
DSM name	SolarWinds Orion
RPM file name	DSM-SolarWindsOrion-QRadar_version-build_number.noarch.rpm
Supported versions	2013.2.0
Protocol	SNMPv2 SNMPv3
Event format	name-value pair (NVP)
Recorded event types	All events
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	For more information, see the SolarWinds Orion link to public site website ( <a href="https://www.solarwinds.com/orion">https://www.solarwinds.com/orion</a> ).

To integrate SolarWinds Orion with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the SolarWinds Orion DSM RPM on your QRadar Console:
2. Configure your SolarWinds Orion device to send events to QRadar.
3. Add a SolarWinds Orion log source on the QRadar Console.
4. Verify that QRadar is configured correctly.

The following table shows a normalized sample event message from SolarWinds Orion:

Table 950. SolarWinds Orion sample message

Event name	Low level category	Sample log message
Domain controller UnManaged	Warning	<pre> 1.3.6.1.2.1.1.3.0=0:00:00.00 1.3.6.1.6.3.1.1.4.1.0=1.3.6.1.4.1.1130 7.10 1.3.6.1.6.3.1.1.4.3.0=1.3.6.1.4.1.1130 7 1.3.6.1.4.1.11307.10.2=hostname 1.3.6.1.4.1.11307.10.3=127.0.0.1 1.3.6.1.4.1.11307.10.4=2466 1.3.6.1.4.1.11307.10.5=hostname 1.3.6.1.4.1.11307.10.6=Node 1.3.6.1.4.1.11307.10.7=2466 1.3.6.1.4.1.11307.10.1=InfoSec - EMAIL ONLY - Domain Controller UnManaged - hostname - Status = Unknown 1.3.6.1.4.1.11307.10.8=InfoSec -EMAIL ONLY - Domain Controller UnManaged hostname is Unknown. </pre>

## Configuring SolarWinds Orion to communicate with QRadar

To collect events in IBM QRadar from SolarWinds Orion, you must configure your SolarWinds Orion Alert Manager device to create SNMP traps.

### Procedure

1. Log in to your SolarWinds Orion Alert Manager device.
2. Select **Start > All Programs > SolarWinds Orion > Alerting, Reporting, and Mapping > Advanced Alert Manager**.
3. In the **Alert Manager Quick Start** window, click **Configure Alerts**.
4. In the **Manage Alerts** window, select an existing alert and then click **Edit**.
5. Click the **Triggered Actions** tab.
6. Click **Add New Action**.
7. In the **Select an Action** window, select **Send an SNMP Trap** and then click **OK**.
8. To configure **SNMP Trap Destinations**, type the IP address of the QRadar Console or QRadar Event Collector.
9. To configure the **Trap Template**, select **ForwardSyslog**.
10. To configure the **SNMP Version**, select the SNMP version that you want to use to forward the event:  
**SNMPv2c** - Type the **SNMP Community String** to use for SNMPv2c authentication. The default **SNMP Community String** value is public.

Figure 46. Edit SNMP Trap Action configuration for SNMPv2c

**Note:** To verify that your SNMP trap is configured properly, select an alert that you edited and click **Test**. This action triggers and forwards the events to QRadar.

**SNMPv3** - Type the **Username** and then select the **Authentication Method** to use for SNMPv3.

Figure 47. Edit SNMP Trap Action configuration for SNMPv3

**Note:** To verify that your SNMP trap is configured properly, select an alert that you edited and click **Test**. This action triggers and forwards the events to QRadar.

11. Click **OK**.

### What to do next

Repeat these steps to configure the SolarWinds Orion Alert Manager with all of the SNMP trap alerts that you want to monitor in QRadar.

## SNMP log source parameters for SolarWinds Orion

If QRadar does not automatically detect the log source, add a SolarWinds Orion log source on the QRadar Console by using the SNMP protocol.

When using the SNMP protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect SNMP events from SolarWinds Orion:

Table 951. SNMP log source parameters for the SolarWinds Orion DSM	
Parameter	Value
<b>Log Source type</b>	SolarWinds Orion
<b>Protocol Configuration</b>	SNMPv2 or SNMPv3

Table 951. SNMP log source parameters for the SolarWinds Orion DSM (continued)

Parameter	Value
<b>Log Source Identifier</b>	Type the IP address or the host name of your SolarWinds Orion appliance to use as the identifier.

For a complete list of SNMPv2 protocol parameters and their values, see [SNMPv2 protocol configuration options](#).

For a complete list of SNMPv3 protocol parameters and their values, see [SNMPv3 protocol configuration options](#).

## Installing the Java Cryptography Extension on QRadar

The Java Cryptography Extension (JCE) is a Java framework that is required for IBM QRadar to decrypt advanced cryptography algorithms for AES192 or AES256. The following information describes how to install Oracle JCE on your QRadar appliance.

### Procedure

1. Optional: If you are using QRadar 7.2x, 7.3.0, or 7.31, complete the following steps:

- Download the latest version of the Java Cryptography Extension from the [IBM website](https://www14.software.ibm.com/webapp/iwm/web/preLogin.do?source=jcesdk) (<https://www14.software.ibm.com/webapp/iwm/web/preLogin.do?source=jcesdk>).

The Java Cryptography Extension version must match the version of the Java that is installed on QRadar.

- Extract the JCE file.

The following Java archive (JAR) files are included in the JCE download:

- local\_policy.jar
- US\_export\_policy.jar

- Log in to your QRadar Console or QRadar Event Collector as a root user.

- Copy the JCE JAR files to the following directory on your QRadar Console or Event Collector:

/store/configservices/staging/globalconfig/java\_security

**Note:** The JCE JAR files are only copied to the system that receives the AES192 or AE256 encrypted files.

- Restart the QRadar services by typing one of the following commands:

- If you are using QRadar 7.2.x, type service ecs-ec restart.
- If you are using QRadar 7.3.0, type systemctl restart ecs-ec.service.
- If you are using QRadar 7.3.1, type systemctl restart ecs-ec-ingress.service.

2. Optional: If you are using QRadar 7.4.3 Fix Pack 4 or earlier, complete the [Installing unrestricted SDK JCE policy files procedure](https://www.ibm.com/docs/en/qsip/7.4?topic=authentication-installing-unrestricted-sdk-jce-policy-files) (<https://www.ibm.com/docs/en/qsip/7.4?topic=authentication-installing-unrestricted-sdk-jce-policy-files>).

**Important:** If you are using QRadar 7.4.3 Fix Pack 5 or later, do not install these files.

## Solar Winds Orion sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## Solar Winds Orion sample message when you use the Syslog protocol

The following sample event message shows that a network device is up.

```
1.3.6.1.2.1.1.3.0=0:00:00.00    1.3.6.1.6.3.1.1.4.1.0=1.3.6.1.4.1.11307.10

# Chapter 144. SonicWALL

The SonicWALL SonicOS DSM accepts events by using syslog.

IBM QRadar records all relevant syslog events that are forwarded from SonicWALL appliances by using SonicOS firmware. Before you can integrate with a SonicWALL SonicOS device, you must configure syslog forwarding on your SonicWALL SonicOS appliance.

## Configuring SonicWALL to forward syslog events

SonicWALL captures all SonicOS event activity. The events can be forwarded to IBM QRadar by using SonicWALL's default event format.

### Procedure

1. Log in to your SonicWALL web interface.
2. From the navigation menu, select **Log > Syslog**.
3. From the **Syslog Servers** pane, click **Add**.
4. In the **Name or IP Address** field, type the IP address of your QRadar Console or Event Collector.
5. In the **Port** field, type 514.  
SonicWALL syslog forwarders send events to QRadar by using UDP port 514.
6. Click **OK**.
7. From the **Syslog Format** list, select **Default**.
8. Click **Apply**.

Syslog events are forwarded to QRadar. SonicWALL events that are forwarded to QRadar are automatically discovered and log sources are created automatically. For more information on configuring your SonicWALL appliance or for information on specific events, see your vendor documentation.

## Syslog log source parameters for SonicWALL

If QRadar does not automatically detect the log source, add a SonicWALL log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from SonicWALL:

Table 953. Syslog log source parameters for the SonicWALL DSM	
Parameter	Value
<b>Log Source type</b>	SonicWALL SonicOS
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from SonicWALL appliances.  Each log source that you create for your SonicWALL SonicOS appliance ideally includes a unique identifier, such as an IP address or host name.

# Chapter 145. Sophos

IBM QRadar supports a number of Sophos DSMs.

## Sophos Astaro Security Gateway

---

The Sophos Astaro Security Gateway DSM for IBM QRadar accepts events by using syslog, enabling QRadar to record all relevant events.

### About this task

To configure syslog for Sophos Astaro Security Gateway:

### Procedure

1. Log in to the Sophos Astaro Security Gateway console.
2. From the navigation menu, select **Logging > Settings**.
3. Click the **Remote Syslog Server** tab.

The **Remote Syslog Status** window is displayed.

4. From **Syslog Servers** panel, click the + icon.

The **Add Syslog Server** window is displayed.

5. Configure the following parameters:

- a) **Name** - Type a name for the syslog server.
- b) **Server** - Click the folder icon to add a pre-defined host, or click + and type in new network definition
- c) **Port** - Click the folder icon to add a pre-defined port, or click + and type in a new service definition.  
By default, QRadar communicates by using the syslog protocol on UDP/TCP port 514.
- d) Click **Save**.
6. From the **Remote syslog log selection** field, you must select check boxes for the following logs:
  - a) **POP3 Proxy** - Select this check box.
  - b) **Packet Filter** - Select this check box.
  - c) **Packet Filter** - Select this check box.
  - d) **Intrusion Prevention System** - Select this check box
  - e) **Content Filter(HTTPS)** - Select this check box.
  - f) **High availability** - Select this check box
  - g) **FTP Proxy** - Select this check box.
  - h) **SSL VPN** - Select this check box.
  - i) **PPTP daemon** - Select this check box.
  - j) **IPSEC VPN** - Select this check box.
  - k) **HTTP daemon** - Select this check box
  - l) **User authentication daemon** - Select this check box.
  - m) **SMTP proxy** - Select this check box.
  - n) Click **Apply**.
  - o) From **Remote syslog status** section, click **Enable**

You can now configure the log source in QRadar.

- To configure QRadar to receive events from your Sophos Astaro Security Gateway device: From the **Log Source Type** list, select **Sophos Astaro Security Gateway**.

## Sophos Central

The IBM QRadar DSM for Sophos Central collects events from the Sophos Central database.

To integrate Sophos Central with QRadar, complete the following steps:

- If automatic updates are not enabled, RPMs are available for download from the [IBM support](#). Download and install the most recent version of the following RPMs on your QRadar Console.
  - Sophos Central DSM RPM
  - Sophos Central PROTOCOL RPM
- Configure your Sophos Central device to send events to QRadar. For more information, see [Sophos Central protocol configuration options](#).

## Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Sophos Central DSM specifications

The IBM QRadar DSM for Sophos Central supports events and alerts that are collected from Sophos Central database.

The following table lists the specifications for the Sophos Central DSM.

Table 958. Sophos Central DSM specifications	
Specification	Value
Manufacturer	Sophos
DSM name	Sophos Central
RPM file name	DSM-SophosCentral-QRadar_version-Build_number.noarch.rpm
Supported protocols	Sophos Central Syslog
Event format	JSON
QRadar recorded events	Event Alert
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="#">Sophos Central</a>

## Sophos Central log source parameters for the Sophos Central DSM

If QRadar does not automatically detect the log source, add a Sophos Central log source on the QRadar Console by using the Sophos Central protocol.

Configure specific parameters when you are using the Sophos Central protocol.

The following table describes the parameters that require specific values to collect the Sophos Central events from Sophos:

Table 959. Sophos Central log source parameters for the Sophos Central DSM	
Parameter	Value
<b>Log Source type</b>	Sophos Central
<b>Protocol Configuration</b>	Sophos Central
<b>Log Source Identifier</b>	Type a unique name for the log source. The Log Source Identifier can be any valid value and does not need to reference a specific server. The Log Source Identifier can have the same value as the Log Source Name. If you have more than one configured log source per DSM, ensure to give unique name to each log source.

For a complete list of Sophos Central protocol parameters and their values, see [Sophos Central protocol configuration options](#).

For more information about the protocol parameters and their values, see [Adding a log source](#).

## Sophos Central sample event message

The following sample events are from the Sophos Central when you use the Sophos Central protocol.

### Event - Endpoint

In the following sample event message, the event indicates the results of an action that returns the details of that Sophos Central generated event.

```
{"source": "n/a", "when": "2024-04-23T16:22:10.159Z", "severity": "low", "type": "Event::Endpoint::UpdateRebootRequired", "location": "AA1AAAA-1234AAA1", "id": "111111aa-1a0a-11aa-a111-1111a1a01a11", "group": "UPDATING", "endpoint_id": "111111aa-1a0a-11aa-a111-1111aaaaaa", "endpoint_type": "server", "customer_id": "111111aa-1a0a-11aa-a111-1111a1a01a11", "created_at": "2024-04-23T16:22:10.170Z", "source_info": {"ip": "10.0.0.1"}, "name": "Reboot to complete update; computer stays protected in the meantime"}
```

## Sophos Enterprise Console

---

The IBM QRadar DSM for Sophos Enterprise Console provides two options for gathering events by using Java database connectivity (JDBC).

QRadar records all relevant anti-virus events.

To use the Sophos Enterprise Console JDBC protocol, the Sophos Reporting Interface must be installed with your Sophos Enterprise Console. If you do not have the Sophos Reporting Interface installed, configure QRadar by using the JDBC protocol. For information about installing the Sophos Reporting Interface, go to the [Sophos Enterprise Console documentation](https://www.sophos.com/en-us/support/documentation/enterprise-console.aspx) (<https://www.sophos.com/en-us/support/documentation/enterprise-console.aspx>).

To integrate Sophos Enterprise Console with QRadar, complete the following steps:

1. [Configure the database view for Sophos Enterprise Console](#).
2. **Optional:** If the Sophos Reporting Interface is installed on your Sophos Enterprise console, use the Sophos Enterprise Console JDBC log source to collect events. For more information, see [“Sophos Enterprise Console JDBC log source parameters for Sophos Enterprise Console” on page 1491](#).
3. **Optional:** If the Sophos Reporting Interface is not installed on your Sophos Enterprise Console, use the standard JDBC protocol to collect events. For more information, see [“JDBC log source parameters for Sophos Enterprise Console” on page 1492](#).

## Sophos Enterprise Console DSM specifications

When you configure the Sophos Enterprise DSM, understanding the specifications for the DSM can help ensure a successful integration. For example, knowing what the supported version of Sophos Enterprise Console is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Sophos Enterprise Console DSM.

<i>Table 962. Sophos Enterprise Console DSM specifications</i>	
Specification	Value
Manufacturer	Sophos
DSM name	Sophos Enterprise Console
RPM file name	DSM-SophosEnterpriseConsole-QRadar_version-build_number.noarch.rpm
Supported version	4.5.1 and 5.1
Protocols	Sophos Enterprise Console JDBC JDBC
Event format	JDBC
Recorded event types	all relevant anti-virus events
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No
More information	<a href="#">Sophos Enterprise Console documentation</a> ( <a href="https://www.sophos.com/en-us/support/documentation/enterprise-console.aspx">https://www.sophos.com/en-us/support/documentation/enterprise-console.aspx</a> )

## Configuring the database view for Sophos Enterprise Console

To collect events in IBM QRadar, you need to configure a database view on your Sophos Enterprise Console device.

### Procedure

1. Log in to your Sophos Enterprise Console device command-line interface (CLI).
2. Type the following command to create a custom view in your Sophos database to support QRadar:

```
CREATE VIEW threats_view AS SELECT t.ThreatInstanceID, t.ThreatType, t.FirstDetectedAt, c.Name, c.LastLoggedOnUser, c.IPAddress, c.DomainName, c.OperatingSystem, c.ServicePack, t.ThreatSubType, t.Priority, t.ThreatLocalID, t.ThreatLocalIDSouce, t.ThreatName, t.FullFilePathCheckSum, t.FullFilePath, t.FileNameOffset, tFileVersion, t.CheckSum, t.ActionSubmittedAt, t.DealtWithAt, t.CleanUpable, t.IsFragment, t.IsRebootRequired, t.Outstanding, t.Status, InsertedAt FROM <Database Name>.dbo.ThreatInstancesAll t, <Database Name>.dbo.Computers c WHERE t.ComputerID = c.ID;
```

Where *<DatabaseName>* is the name of the Sophos database.

**Important:** The database name must not contain any spaces.

### What to do next

After you create your custom view, you must configure QRadar to receive event information that uses the JDBC protocol or the Sophos Enterprise Console JDBC protocol.

#### Related concepts

## Sophos Enterprise Console JDBC log source parameters for Sophos Enterprise Console

If QRadar does not automatically detect the log source, add a Sophos Enterprise Console log source on the QRadar Console by using the Sophos Enterprise Console JDBC protocol.

When using the Sophos Enterprise Console JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Sophos Enterprise Console JDBC events from Sophos:

Table 963. Sophos Enterprise Console JDBC log source parameters for the Sophos Enterprise Console DSM	
Parameter	Value
<b>Log Source type</b>	Sophos Enterprise Console
<b>Protocol Configuration</b>	Sophos Enterprise Console JDBC

*Table 963. Sophos Enterprise Console JDBC log source parameters for the Sophos Enterprise Console DSM (continued)*

Parameter	Value
<b>Log Source Identifier</b>	<p>Type the identifier for the log source. Type the log source identifier in the following format:</p> <p><code>&lt;Sophos Database&gt;@&lt;Sophos Database Server IP or Host Name&gt;</code></p> <p>Where:</p> <ul style="list-style-type: none"> <li>• <code>&lt;Sophos Database&gt;</code> is the database name, as entered in the <b>Database Name</b> parameter.</li> <li>• <code>&lt;Sophos Database Server IP or Host Name&gt;</code> is the host name or IP address for this log source, as entered in the <b>IP or Hostname</b> parameter.</li> </ul> <p>When you define a name for your log source identifier, you must use the values of the Sophos Database and Database Server IP address or host name from the Management Enterprise Console.</p>

For a complete list of Sophos Enterprise Console JDBC protocol parameters and their values, see “[Sophos Enterprise Console JDBC protocol configuration options](#)” on page 221.

## Sophos PureMessage

---

The Sophos PureMessage DSM for IBM QRadar accepts events by using Java Database Connectivity (JDBC).

QRadar records all relevant quarantined email events. This document provides information about configuring QRadar to access the Sophos PureMessage database by using the JDBC protocol.

QRadar supports the following Sophos PureMessage versions:

- Sophos PureMessage for Microsoft Exchange - Stores events in a Microsoft SQL Server database that is specified as `savexquar`.
- Sophos PureMessage for Linux - Stores events in a PostgreSQL database that is specified as `pmx_quarantine`.

Here's information on integrating QRadar with Sophos:

- [“Integrating QRadar with Sophos PureMessage for Microsoft Exchange” on page 1493](#)
- [“Integrating QRadar with Sophos PureMessage for Linux” on page 1494](#)

### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Integrating QRadar with Sophos PureMessage for Microsoft Exchange

You can integrate QRadar with Sophos PureMessage for Microsoft Exchange.

### Procedure

1. Log in to the Microsoft SQL Server command-line interface (CLI):

```
osql -E -S localhost\sophos
```

2. Type which database you want to integrate with QRadar:

```
use savexquar; go
```

3. Type the following command to create a SIEM view in your Sophos database to support QRadar:

```
create view siem_view as select  
'Windows PureMessage' as application, id, reason,  
timecreated, emailonly as sender, filesize, subject,  
messageid, filename from dbo.quaritems,  
dbo.quaraddresses where ItemID = ID and Field = 76;
```

### What to do next

After you create your SIEM view, you must configure QRadar to receive event information by using the JDBC protocol. To configure the Sophos PureMessage DSM with QRadar, see [“JDBC log source parameters for Sophos PureMessage” on page 1493](#).

## JDBC log source parameters for Sophos PureMessage

If QRadar does not automatically detect the log source, add a Sophos PureMessage log source on the QRadar Console by using the JDBC protocol.

When using the JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from Sophos:

Table 965. JDBC log source parameters for the Sophos PureMessage DSM

Parameter	Value
<b>Log Source type</b>	Sophos PureMessage
<b>Protocol Configuration</b>	JDBC
<b>Log Source Identifier</b>	Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.  If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2.
<b>Database Type</b>	MSDE
<b>Database Name</b>	Type savexquar.
<b>Table Name</b>	Type siem_view as the name of the table or view that includes the event records.
<b>Compare Field</b>	Type ID.

**Note:** You must refer to the database configuration settings on your Sophos PureMessage device to define the parameters that are required to configure the Sophos PureMessage DSM in QRadar.

For a complete list of JDBC protocol parameters and their values, see “[JDBC protocol configuration options](#)” on page 147.

#### Related tasks

[“Adding a log source” on page 5](#)

## Integrating QRadar with Sophos PureMessage for Linux

You can integrate IBM QRadar with Sophos PureMessage for Linux.

### Procedure

1. Navigate to your Sophos PureMessage PostgreSQL database directory:

```
cd /opt/pmx/postgres-8.3.3/bin
```

2. Access the pmx\_quarantine database SQL prompt:

```
./psql -d pmx_quarantine
```

3. Type the following command to create a SIEM view in your Sophos database to support QRadar:

```
create view siem_view as select 'Linux PureMessage' as application, id, b.name, m_date,
h_from_local, h_from_domain, m_global_id, m_message_size, outbound, h_to, c_subject_utf8
from message a, m_reason b where a.reason_id = b.reason_id;
```

## What to do next

After you create your database view, you must configure QRadar to receive event information by using the JDBC protocol.

## JDBC log source parameters for Sophos PureMessage for Microsoft Exchange

If QRadar does not automatically detect the log source, add a Sophos PureMessage log source on the QRadar Console by using the JDBC protocol.

When using the JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from Sophos:

Table 966. JDBC log source parameters for the Sophos PureMessage for Microsoft Exchange DSM	
Parameter	Value
<b>Log Source type</b>	Sophos PureMessage
<b>Protocol Configuration</b>	JDBC
<b>Log Source Identifier</b>	Type the identifier for the log source. Type the log source identifier in the following format:  <i>&lt;Sophos PureMessage Database&gt;@&lt;Sophos PureMessage Database Server IP or Host Name&gt;</i>  Where: <ul style="list-style-type: none"><li>• <i>&lt;Sophos PureMessage Database&gt;</i> is the database name, as entered in the Database Name parameter.</li><li>• <i>&lt;Sophos PureMessage Database Server IP or Host Name&gt;</i> is the hostname or IP address for this log source, as entered in the IP or Hostname parameter.</li></ul> When defining a name for your log source identifier, you must use the values of the Database and Database Server IP address or host name of the Sophos PureMessage device.
<b>Database Type</b>	Postgres
<b>Database Name</b>	Type pmx_quarantine.
<b>Table Name</b>	Type siem_view as the name of the table or view that includes the event records.
<b>Compare Field</b>	Type ID.

**Note:** You must refer to the **Configure Database Settings** on your Sophos PureMessage to define the parameters required to configure the Sophos PureMessage DSM in QRadar.

For a complete list of JDBC protocol parameters and their values, see “[JDBC protocol configuration options](#)” on page 147.

# Sophos Web Security Appliance

---

The Sophos Web Security Appliance (WSA) DSM for IBM QRadar accepts events using syslog.

## About this task

QRadar records all relevant events forwarded from the transaction log of the Sophos Web Security Appliance. Before configuring QRadar, you must configure your Sophos WSA appliance to forward syslog events.

To configure your Sophos Web Security Appliance to forward syslog events:

## Procedure

1. Log in to your Sophos Web Security Appliance.
2. From the menu, select **Configuration > System > Alerts & Monitoring**.
3. Select the **Syslog** tab.
4. Select the **Enable syslog transfer of web traffic** check box.
5. In the **Hostname/IP** text box, type the IP address or host name of QRadar.
6. In the **Port** text box, type 514.
7. From the **Protocol** list, select a protocol. The options are:
  - **TCP** - The TCP protocol is supported with QRadar on port 514.
  - **UDP** - The UDP protocol is supported with QRadar on port 514.
  - **TCP - Encrypted** - TCP Encrypted is an unsupported protocol for QRadar.
8. Click **Apply**.  
You can now configure the Sophos Web Security Appliance DSM in QRadar.
9. QRadar automatically detects syslog data from a Sophos Web Security Appliance. To manually configure QRadar to receive events from Sophos Web Security Appliance: From the **Log Source Type** list, select **Sophos Web Security Appliance**.

# Chapter 146. Sourcefire Intrusion Sensor

The Sourcefire Intrusion Sensor DSM for IBM QRadar accepts Snort based intrusion and prevention syslog events from Sourcefire devices.

## Configuring Sourcefire Intrusion Sensor

To configure your Sourcefire Intrusion Sensor, you must enable policy alerts and configure your appliance to forward the event to QRadar.

### Procedure

1. Log in to your Sourcefire user interface.
2. On the navigation menu, select **Intrusion Sensor > Detection Policy > Edit**.
3. Select an active policy and click **Edit**.
4. Click **Alerting**.
5. In the **State** field, select on to enable the syslog alert for your policy.
6. From the Facility list, select **Alert**.
7. From the Priority list, select **Alert**.
8. In the **Logging Host** field, type the IP address of the QRadar Console or Event Collector.
9. Click **Save**.
10. On the navigation menu, select **Intrusion Sensor > Detection Policy > Apply**.
11. Click **Apply**.

### What to do next

You are now ready to configure the log source in QRadar.

## Syslog log source parameters for Sourcefire Intrusion Sensor

If QRadar does not automatically detect the log source, add a Sourcefire Intrusion Sensor log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Sourcefire Intrusion Sensor:

Table 967. Syslog log source parameters for the Sourcefire Intrusion Sensor DSM	
Parameter	Value
<b>Log Source type</b>	Snort Open Source IDS
<b>Protocol Configuration</b>	Syslog

### Related tasks

[“Adding a log source” on page 5](#)

# Chapter 147. Splunk

IBM QRadar accepts and parses multiple event types that are forwarded from Splunk appliances.

For Check Point events that are forwarded from Splunk, see [Chapter 38, “Check Point,” on page 603](#).

## Collecting Windows events that are forwarded from Splunk

To collect events, you can configure your Windows end points to forward events to your QRadar Console and your Splunk indexer.

Forwarding Windows events from aggregation nodes in your Splunk deployment is not recommended. Use Splunk forwarder to send Windows event data to IBM QRadar. Splunk indexers that forward events from multiple Windows end points to QRadar can obscure the true source of the events with the IP address of the Splunk indexer. To prevent a situation where an incorrect IP address association might occur in the log source, you can update your Windows end-point systems to forward to both the indexer and your QRadar Console.

Splunk events are parsed by using the Microsoft Windows Security Event Log DSM with the TCP multiline syslog protocol. The regular expression that is configured in the protocol defines where a Splunk event starts or ends in the event payload. The event pattern allows QRadar to assemble the raw Windows event payload as a single-line event that is readable by QRadar. The regular expression that is required to collect Windows events is outlined in the log source configuration.

To configure event collection for Splunk syslog events, you must complete the following tasks:

1. On your QRadar appliance, configure a log source to use the Microsoft Windows Security Event Log DSM.

**Note:** You must configure 1 log source for Splunk events. QRadar can use the first log source to autodiscover more Windows end points.

2. On your Splunk appliance, configure each Splunk Forwarder on the Windows instance to send Windows event data to your QRadar Console or Event Collector.

To configure a Splunk Forwarder, you must edit the `props.conf`, `transforms.conf`, and `output.conf` configuration files. For more information on event forwarding, see your Splunk documentation.

3. Ensure that no firewall rules block communication between your Splunk appliance and the QRadar Console or managed host that is responsible for retrieving events.
4. On your QRadar appliance, verify the **Log Activity** tab to ensure that the Splunk events are forwarded to QRadar.

## TCP Multiline Syslog log source parameters for Splunk

If QRadar does not automatically detect the log source, add a Splunk log source on the QRadar Console by using the TCP Multiline Syslog protocol.

When using the TCP Multiline Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect TCP Multiline Syslog events from Splunk:

Table 968. TCP Multiline Syslog log source parameters for the Splunk DSM	
Parameter	Value
<b>Log Source type</b>	Microsoft Windows Security Event Log
<b>Protocol Configuration</b>	TCP Multiline Syslog

*Table 968. TCP Multiline Syslog log source parameters for the Splunk DSM (continued)*

Parameter	Value
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Splunk appliance. The log source identifier must be unique value.

For a complete list of TCP Multiline Syslog protocol parameters and their values, see [“TCP Multiline Syslog protocol configuration options” on page 226](#).

**Related tasks**

[“Adding a log source” on page 5](#)

# Chapter 148. Squid Web Proxy

The IBM QRadar DSM for Squid Web Proxy records all cache and access log events by using syslog.

To integrate QRadar with Squid Web Proxy, you must configure your Squid Web Proxy to forward your cache and access logs by using syslog.

## Configuring syslog forwarding

You can configure Squid to use syslog to forward your access and cache events.

### Procedure

1. Use SSH to log in to the Squid device command line interface.

2. Open the following file:

```
/etc/rc3.d/S99local
```

**Note:** If /etc/rc3.d/S99local does not exist, use /etc/rc.d/rc.local.

3. Add the following line:

```
tail -f /var/log/squid/access.log | logger -p <facility>. <priority> &
• <facility> is any valid syslog facility, which is written in lowercase such as authpriv, daemon, local0 to local7, or user.
• <priority> is any valid priority that is written in lowercase such as err, warning, notice, info, debug.
```

4. Save and close the file.

Logging begins the next time that the system is restarted.

5. To begin logging immediately, type the following command:

```
nohup sh -c "tail -f /var/log/squid/access.log | logger -p
<facility>. <priority>" &
```

The <facility> and <priority> options are the same values that you entered.

6. Open the following file:

```
/etc/syslog.conf
```

**Note:** When using rsyslog, open /etc/rsyslog.conf instead of /etc/syslog.conf.

7. Add the following line to send the logs to QRadar:

```
<facility>. <priority> @<QRadar_IP_address>
```

The following example shows a priority and facility for Squid messages and a QRadar IP address:

```
local4.info @<IP_address>
```

8. Confirm that access\_log format ends in common.

#### Example:

```
access_log /path/to/access.log common
```

If the access\_log format end value is squid, change squid to common, as displayed in the example.

If the access\_log format does not have an ending value, add the following line to the Squid conf file to turn on httpd log file emulation:

```
emulate_httpd_log on
```

9. Choose one of the following options:

- To restart the Squid service, type the following command:

```
service squid restart
```

- To reload the configuration without restarting the service, type the following command:

```
/usr/sbin/squid -k reconfigure
```

**10. Save and close the file.**

11. Type the following command to restart the syslog daemon:

```
/etc/init.d/syslog restart
```

For more information about configuring Squid, see your vendor documentation.

## Results

After you configure syslog forwarding for your cache and access logs, the configuration is complete. QRadar can automatically discover syslog events that are forwarded from Squid.

## Syslog log source parameters for Squid Web Proxy

If QRadar does not automatically detect the log source, add a Squid Web Proxy log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Squid Web Proxy:

Table 969. Syslog log source parameters for the Squid Web Proxy DSM

Parameter	Value
<b>Log Source type</b>	Squid Web Proxy
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from the Squid Web Proxy.

# Chapter 149. SSH CryptoAuditor

The IBM QRadar DSM for SSH CryptoAuditor collects logs from an SSH CryptoAuditor.

The following table identifies the specifications for the SSH CryptoAuditor DSM.

Table 972. SSH CryptoAuditor DSM specifications	
Specification	Value
Manufacturer	SSH Communications Security
Product	CryptoAuditor
DSM Name	SSH CryptoAuditor
RPM filename	DSM-SSHCryptoAuditor-QRadar_release-Build_number.noarch.rpm
Supported versions	1.4.0 or later
Event format	Syslog
QRadar recorded event types	Audit, Forensics
Log source type in QRadar UI	SSH CryptoAuditor
Auto discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://www.ssh.com/">SSH Communications Security website (http://www.ssh.com/)</a>

To send events from SSH CryptoAuditor to QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM
  - SSH CryptoAuditor RPM
2. For each instance of SSH CryptoAuditor, configure your SSH CryptoAuditor system to communicate with QRadar.
3. If QRadar does not automatically discover SSH CryptoAuditor, create a log source on the QRadar Console for each instance of SSH CryptoAuditor. Use the following SSH CryptoAuditor specific parameters:

Parameter	Value
<b>Log Source Type</b>	SSH CryptoAuditor
<b>Protocol Configuration</b>	Syslog

To collect SSH CryptoAuditor events, you must configure your third-party appliance to send events to IBM QRadar.

[Adding a DSM](#)

# Configuring an SSH CryptoAuditor appliance to communicate with QRadar

---

To collect SSH CryptoAuditor events, you must configure your third-party appliance to send events to IBM QRadar.

## Procedure

1. Log in to SSH CryptoAuditor.
2. Go to the syslog settings in **Settings > External Services > External Syslog Servers**.
3. To create server settings for QRadar, click **Add Syslog Server**.
4. Type the QRadar server settings: address (IP address or FQDN) and port in which QRadar collects log messages.
5. To set the syslog format to Universal LEEF, select the **Leef format** check box.
6. To save the configuration, click **Save**.
7. Configure SSH CryptoAuditor alerts in **Settings > Alerts**. The SSH CryptoAuditor alert configuration defines which events are sent to external systems (email or SIEM/syslog).
  - a) Select an existing alert group, or create new alert group by clicking **Add alert group**.
  - b) Select the QRadar server that you defined earlier in the **External Syslog Server** drop box.
  - c) If you created a new alert group, click **Save**. Save the group before binding alerts to the group.
  - d) Define which alerts are sent to QRadar by binding alerts to the alert group. Click **[+]** next to the alert that you want to collect in QRadar, and select the alert group that has QRadar as external syslog server. Repeat this step for each alert that you want to collect in QRadar.
  - e) Click **Save**.
8. Apply the pending configuration changes. The saved configuration changes do not take effect until you apply them from pending state.

# Chapter 150. Configuring Starent Networks device to forward syslog events to QRadar

The Starent Networks DSM for IBM QRadar accepts Event, Trace, Active, and Monitor events.

## About this task

Before you configure a Starent Networks device in QRadar, you must configure your Starent Networks device to forward syslog events to QRadar.

## Procedure

1. Log in to your Starent Networks device.
2. Configure the syslog server:

```
logging syslog <IP address> [facility <facilities>] [<rate value>] [pdu-verbosity <pdu_level>] [pdu-data <format>] [event-verbosity <event_level>]
```

The following table provides the necessary parameters:

Table 973. Syslog server parameters

Parameter	Description
syslog <IP address>	Type the IP address of your QRadar
facility <facilities>	Type the local facility for which the logging options are applied. The options are as follows: <ul style="list-style-type: none"><li>• local0</li><li>• local1</li><li>• local2</li><li>• local3</li><li>• local4</li><li>• local5</li><li>• local6</li><li>• local7</li></ul> The default is local7.
rate value	Type the rate that you want log entries to be sent to the system log server. This value must be an integer 0 - 100000. The default is 1000 events per second.
pdu-verbosity <pdu-level>	Type the level of verboseness you want to use in logging the Protocol Data Units (PDUs). The range is 1 - 5 where 5 is the most detailed. This parameter affects only protocol logs.

Table 973. Syslog server parameters (continued)

Parameter	Description
pdu-data <format>	Type the output format for the PDU when logged as one of following formats: <ul style="list-style-type: none"> <li>• none - Displays results in raw or unformatted text.</li> <li>• hex - Displays results in hexadecimal format.</li> <li>• hex-ascii - Displays results in hexadecimal and ASCII format similar to a main frame dump.</li> </ul>
event-verbosity <event_level>	Type the level of detail you want to use in logging of events, that includes: <ul style="list-style-type: none"> <li>• min - Provides minimal information about the event, such as, event name, facility, event ID, severity level, data, and time.</li> <li>• concise - Provides detailed information about the event, but does not provide the event source.</li> <li>• full - Provides detailed information about the event and includes the source information that identifies the task or subsystem that generated the event.</li> </ul>

3. From the root prompt for the Exec mode, identify the session for which the trace log is to be generated:

```
logging trace {callid <call_id> | ipaddr <IP address> | msid <ms_id> | name <username>}
```

The following table provides the necessary parameters:

Table 974. Trace log parameters

Parameter	Description
callid <call_id>	Indicates a trace log is generated for a session that is identified by the call identification number. This value is a 4-byte hexadecimal number.
ipaddr <IP address>	Indicates a trace log is generated for a session that is identified by the specified IP address.
msid <ms_id>	Indicates a trace log is generated for a session that is identified by the mobile station identification (MSID) number. This value must be 7 - 16 digits, which are specified as an IMSI, MIN, or RMI.
name <username>	Indicates a trace log is generated for a session that is identified by the username. This value is the name of the subscriber that was previously configured.

4. To write active logs to the active memory buffer, in the config mode:

```
logging runtime buffer store all-events
```

5. Configure a filter for the active logs:

```
logging filter active facility <facility> level <report_level> [critical-info | no-critical-info]
```

The following table provides the necessary parameters:

Table 975. Active log parameters

Parameter	Description
facility <facility>	<p>Type the facility message level. A facility is a protocol or task that is in use by the system. The local facility defines which logging options are applied for processes that run locally. The options are as follows:</p> <ul style="list-style-type: none"> <li>• local0</li> <li>• local1</li> <li>• local2</li> <li>• local3</li> <li>• local4</li> <li>• local5</li> <li>• local6</li> <li>• local7</li> </ul> <p>The default is local7.</p>
level <report_level>	<p>Type the log severity level, including:</p> <ul style="list-style-type: none"> <li>• critical - Logs only those events that indicate a serious error is occurring and that is causing the system or a system component to cease functioning. Critical is the highest level severity.</li> <li>• error - Logs events that indicate an error is occurring that is causing the system or a system component to operate in a degraded state. This level also logs events with a higher severity level.</li> <li>• warning - Logs events that can indicate a potential problem. This level also logs events with a higher severity level.</li> <li>• unusual - Logs events that are unusual and might need to be investigated. This level also logs events with a higher severity level.</li> <li>• info - Logs informational events and events with a higher severity level.</li> <li>• debug - Logs all events regardless of the severity.</li> </ul> <p>It is suggested that a level of error or critical can be configured to maximize the value of the logged information and lower the quantity of logs that are generated.</p>
critical-info	The critical-info parameter identifies and displays events with a category attribute of critical information. Examples of these types of events can be seen at bootup when system processes or tasks are being initiated.
no-critical-info	The no-critical-info parameter specifies that events with a category attribute of critical information are not displayed.

6. Configure the monitor log targets:

```
logging monitor {msid <ms_id>|username <username>}
```

The following table provides the necessary parameters:

*Table 976. Monitor log parameters*

Parameter	Description
msid <md_id>	Type an msid to define that a monitor log is generated for a session that is identified by using the Mobile Station Identification (MDID) number. This value must be 7 - 16 digits that are specified as a IMSI, MIN, or RMI.
username <username>	Type user name to identify a monitor log generated for a session by the user name. The user name is the name of the subscriber that was previously configured.

7. You are now ready to configure the log source in QRadar.

To configure QRadar to receive events from a Starent device:

- From the **Log Source Type** list, select the **Starent Networks Home Agent (HA)** option.

For more information about the device, see your vendor documentation.

# Chapter 151. STEALTHbits

IBM QRadar supports a range of STEALTHbits DSMs.

## STEALTHbits StealthINTERCEPT

The IBM QRadar DSM for STEALTHbits StealthINTERCEPT can collect event logs from your STEALTHbits StealthINTERCEPT and File Activity Monitor services.

The following table identifies the specifications for the STEALTHbits StealthINTERCEPT DSM.

Table 977. STEALTHbits StealthINTERCEPT DSM specifications	
Specification	Value
Manufacturer	STEALTHbits Technologies
DSM	STEALTHbits StealthINTERCEPT
RPM file name	DSM-STEALTHbitsStealthINTERCEPT-QRadar_Version-build_number.noarch.rpm
Supported versions	3.3
Protocol	Syslog
Event format	LEEF
QRadar recorded events	Active Directory Audit Events, File Activity Monitor Events
Automatically discovered	Yes
Includes identity	No
More information	<a href="http://www.stealthbits.com/resources">http://www.stealthbits.com/resources</a>

## Syslog log source parameters for STEALTHbits StealthINTERCEPT

If QRadar does not automatically detect the log source, add a STEALTHbits StealthINTERCEPT log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from STEALTHbits StealthINTERCEPT:

Table 978. Syslog log source parameters for the STEALTHbits StealthINTERCEPT DSM	
Parameter	Value
<b>Log Source type</b>	STEALTHbits StealthINTERCEPT
<b>Protocol Configuration</b>	Syslog

## Configuring your STEALTHbits StealthINTERCEPT to communicate with QRadar

To collect all audit logs and system events from STEALTHbits StealthINTERCEPT, you must specify IBM QRadar as the syslog server and configure the message format.

### Procedure

1. Log in to your STEALTHbits StealthINTERCEPT server.
2. Start the Administration Console.
3. Click **Configuration > Syslog Server**.
4. Configure the following parameters:

Table 979. Syslog parameters

Parameter	Description
<b>Host Address</b>	The IP address of the QRadar Console
<b>Port</b>	514

5. Click **Import mapping file**.
6. Select the `SyslogLeefTemplate.txt` file and press Enter.
7. Click **Save**.
8. On the **Administration Console**, click **Actions**.
9. Select the mapping file that you imported, and then select the **Send to Syslog** check box.  
Leave the **Send to Events DB** check box selected. StealthINTERCEPT uses the events database to generate reports.
10. Click **Add**.

## Configuring your STEALTHbits File Activity Monitor to communicate with QRadar

To collect events from STEALTHbits File Activity Monitor, you must specify IBM QRadar as the Syslog server and configure the message format.

### Procedure

1. Log in to the server that runs STEALTHbits File Activity Monitor.
2. Select the **Monitored Hosts** tab.
3. Select a monitored host and click **Edit** to open the host's properties window.
4. Select the **Syslog** tab and configure the following parameters:

Parameter	Description
<b>Bulk Syslog server in SERVER[:PORT] format</b>	<QRadar event collector IP address>:514 Example: 192.0.2.1:514 <qradarhostname>:514
<b>Syslog message template file path</b>	<code>SyslogLeefTemplate.txt</code> The template is stored in the STEALTHbits File Activity Monitor Install Directory

5. Click **OK**.

## Syslog log source parameters for STEALTHbits File Activity Monitor

If QRadar does not automatically detect the log source, add a STEALTHbits StealthINTERCEPT log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from STEALTHbits File Activity Monitor:

*Table 980. Syslog log source parameters for the STEALTHbits File Activity Monitor DSM*

Parameter	Value
<b>Log Source type</b>	STEALTHbits StealthINTERCEPT
<b>Protocol Configuration</b>	Syslog

### Related tasks

## STEALTHbits StealthINTERCEPT Alerts

IBM QRadar collects alerts logs from a STEALTHbits StealthINTERCEPT server by using STEALTHbits StealthINTERCEPT Alerts DSM

The following table identifies the specifications for the STEALTHbits StealthINTERCEPT Alerts DSM:

*Table 981. STEALTHbits StealthINTERCEPT Alerts DSM specifications*

Specification	Value
Manufacturer	STEALTHbits Technologies
DSM name	STEALTHbits StealthINTERCEPT Alerts
RPM file name	DSM-STEALTHbitsStealthINTERCEPTAlerts-Qradar_version-build_number.noarch.rpm
Supported versions	3.3
Protocol	Syslog LEEF
Recorded event types	Active Directory Alerts Events
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://www.stealthbits.com/products/stealthintercept">StealthINTERCEPT</a> ( <a href="http://www.stealthbits.com/products/stealthintercept">http://www.stealthbits.com/products/stealthintercept</a> )

To integrate STEALTHbits StealthINTERCEPT with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM
  - STEALTHbitsStealthINTERCEPT RPM
  - STEALTHbitsStealthINTERCEPTAlerts RPM
2. Configure your STEALTHbits StealthINTERCEPT device to send syslog events to QRadar.

3. If QRadar does not automatically detect the log source, add a STEALTHbits StealthINTERCEPT Alerts log source on the QRadar Console. The following table describes the parameters that require specific values for STEALTHbits StealthINTERCEPT Alerts event collection:

*Table 982. STEALTHbits StealthINTERCEPT Alerts log source parameters*

Parameter	Value
Log Source type	STEALTHbits StealthINTERCEPT Alerts
Protocol Configuration	Syslog

---

# Chapter 152. Sun

IBM QRadar supports a range of Sun DSMs.

## Sun ONE LDAP

The Sun ONE LDAP DSM for QRadar accepts multiline UDP access and LDAP events from Sun ONE Directory Servers.

Sun ONE LDLAP is known as Oracle Directory Server.

QRadar retrieves access and LDAP events from Sun ONE Directory Servers by connecting to each server to download the event log. The event file must be written to a location accessible by the log file protocol of QRadar with FTP, SFTP, or SCP. The event log is written in a multiline event format, which requires a special event generator in the log file protocol to properly parse the event. The ID-Linked Multiline event generator is capable of using regex to assemble multiline events for QRadar when each line of a multiline event shares a common starting value.

The Sun ONE LDAP DSM also can accept events streamed using the UDP Multiline Syslog protocol. However, in most situations your system requires a 3rd party syslog forwarder to forward the event log to QRadar. This can require you to redirect traffic on your QRadar Console to use the port defined by the UDP Multiline protocol.

### Related concepts

[“UDP multiline syslog protocol configuration options” on page 237](#)

To create a single-line syslog event from a multiline event, configure a log source to use the UDP multiline protocol. The UDP multiline syslog protocol uses a regular expression to identify and reassemble the multiline syslog messages into single event payload.

### Related tasks

## Enabling the event log for Sun ONE Directory Server

To collect events from your Sun ONE Directory Server, you must enable the event log to write events to a file.

### Procedure

1. Log in to your Sun ONE Directory Server console.
2. Click the **Configuration** tab.
3. From the navigation menu, select **Logs**.
4. Click the **Access Log** tab.
5. Select the **Enable Logging** check box.
6. Type or click **Browse** to identify the directory path for your Sun ONE Directory Server access logs.
7. Click **Save**.

### What to do next

You are now ready to configure a log source in QRadar.

## Log File log source parameters for Sun ONE LDAP

If QRadar does not automatically detect the log source, add a Sun ONE LDAP log source on the QRadar Console by using the Log File protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from Sun ONE LDAP:

Table 985. Log File log source parameters for the Sun ONE LDAP DSM	
Parameter	Value
<b>Log Source name</b>	Type a name for your log source.
<b>Log Source description</b>	Type a description for the log source.
<b>Log Source type</b>	<b>Sun ONE LDAP</b>
<b>Protocol Configuration</b>	<b>Log File</b>
<b>Log Source Identifier</b>	Type an IP address, host name, or name to identify the event source. IP addresses or host names enable QRadar to identify a log file to a unique event source.  For example, if your network contains multiple devices, such as a management console or a file repository, specify the IP address or host name of the device that created the event. This enables events to be identified at the device level in your network, instead of identifying the event for the management console or file repository.
<b>Service Type</b>	Type the TCP port on the remote host that is running the selected Service Type. The valid range is 1 - 65535. The options include:  <b>FTP</b> TCP Port 21.  <b>SFTP</b> TCP Port 22.  <b>SCP</b> TCP Port 22.  <b>Important:</b> If the host for your event files is using a non-standard port number for FTP, SFTP, or SCP, you must adjust the port value.
<b>Remote User</b>	Type the user name necessary to log in to the host that contains your event files.  The user name can be up to 255 characters in length.
<b>Confirm Password</b>	Confirm the password necessary to log in to the host.
<b>SSH Key File</b>	If you select SCP or SFTP as the <b>Service Type</b> , this parameter enables you to define an SSH private key file. When you provide an SSH Key File, the <b>Remote Password</b> field is ignored.

Table 985. Log File log source parameters for the Sun ONE LDAP DSM (continued)

Parameter	Value
<b>Remote Directory</b>	Type the directory location on the remote host from which the files are retrieved, relative to the user account you are using to log in.  <b>Important:</b> For FTP only. If your log files are in the remote user's home directory, you can leave the remote directory blank. This is to support operating systems where a change in the working directory (CWD) command is restricted.
<b>Recursive</b>	Enable this check box to allow FTP or SFTP connections to recursively search sub folders of the remote directory for event data. Data that is collected from sub folders depends on matches to the regular expression in the FTP File Pattern. The <b>Recursive</b> option is not available for SCP connections.
<b>FTP File Pattern</b>	For example, if you want to list all files that start with the word log, followed by one or more digits and ending with tar.gz, use the following entry: log[0-9]+\.tar\.gz. Use of this parameter requires knowledge of regular expressions (regex). For more information about regular expressions, see the Oracle website ( <a href="http://docs.oracle.com/javase/tutorial/essential/regex/">http://docs.oracle.com/javase/tutorial/essential/regex/</a> )  If you select SFTP or FTP as the Service Type, this option enables you to configure the regular expression (regex) that is required to filter the list of files that are specified in the Remote Directory. All matching files are included in the processing.
<b>FTP Transfer Mode</b>	From the list box, select the transfer mode that you want to apply to this log source:  <b>Binary</b> Select <b>Binary</b> for log sources that require binary data files or compressed zip, gzip, tar, or tar+gzip archive files.  <b>ASCII</b> Select <b>ASCII</b> for log sources that require an ASCII FTP file transfer.  <b>Important:</b> You must select <b>NONE</b> for the <b>Processor</b> parameter and <b>LINEBYLINE</b> the <b>Event Generator</b> parameter when you use ASCII as the FTP Transfer Mode.  This option only appears if you select FTP as the Service Type. The FTP Transfer Mode parameter enables you to define the file transfer mode when you retrieve log files over FTP.
<b>SCP Remote File</b>	If you select SCP as the <b>Service Type</b> you must type the file name of the remote file.

Table 985. Log File log source parameters for the Sun ONE LDAP DSM (continued)

Parameter	Value
<b>Start Time</b>	Type the time of day you want the processing to begin. This parameter functions with the Recurrence value to establish when and how often the Remote Directory is scanned for files. Type the start time, based on a 24-hour clock, in the following format: HH: MM.
<b>Recurrence</b>	Type the frequency, beginning at the Start Time, that you want the remote directory to be scanned. Type this value in hours (H), minutes (M), or days (D). For example, 2H if you want the directory to be scanned every 2 hours. The default is 1H.
<b>Run On Save</b>	Select this check box if you want the log file protocol to run immediately after you click <b>Save</b> . After the <b>Run On Save</b> completes, the log file protocol follows your configured start time and recurrence schedule.  Selecting <b>Run On Save</b> clears the list of previously processed files for the <b>Ignore Previously Processed File</b> parameter.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The valid range is 100 to 5000.
<b>Processor</b>	If the files on the remote host are stored in a zip, gzip, tar, or tar+gzip archive format, select the processor that allows the archives to be expanded and contents to be processed.
<b>Ignore Previously Processed File(s)</b>	This only applies to FTP and SFTP Service Types.  Select this check box to track files that were processed and you do not want the files to be processed a second time.
<b>Change Local Directory?</b>	Select this check box to define the local directory on your QRadar that you want to use for storing downloaded files during processing.  Most configurations can leave this check box clear. When you select the check box, the <b>Local Directory</b> field is displayed, which enables you to configure a local directory to use for temporarily storing files.

Table 985. Log File log source parameters for the Sun ONE LDAP DSM (continued)

Parameter	Value
<b>Event Generator</b>	The ID-Linked Multiline format processes multiline event logs that contain a common value at the start of each line in a multiline event message. This option displays the <b>Message ID Pattern</b> field that uses regex to identify and reassemble the multiline event into single event payload. Select <b>ID-Linked Multiline</b> to process the retrieved event log as multiline events.
<b>Folder Separator</b>	Most configurations can use the default value in the <b>Folder Separator</b> field. This field is only used by operating systems that use an alternate character to define separate folders. For example, periods that separate folders on mainframe systems. Type the character that is used to separate folders for your operating system. The default value is /.

## UDP Multiline Syslog log source parameters for Sun ONE LDAP

If QRadar does not automatically detect the log source, add a Sun ONE LDAP log source on the QRadar Console by using the UDP Multiline Syslog protocol.

When using the UDP Multiline Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect UDP Multiline Syslog events from Sun ONE LDAP:

Table 986. UDP Multiline Syslog log source parameters for the Sun ONE LDAP DSM

Parameter	Value
<b>Log Source type</b>	<b>Sun ONE LDAP</b>
<b>Protocol Configuration</b>	<b>UDP Multiline Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Sun ONE LDAP devices.

For a complete list of UDP Multiline Syslog protocol parameters and their values, see [UDP multiline syslog protocol configuration options](#).

#### Related tasks

[Adding a log source](#)

## Configuring IPTables for UDP Multiline Syslog events

You might be unable to send events directly to the standard UDP Multiline port 517 or any unused available ports when you collect UDP Multiline Syslog events in IBM QRadar. If this error occurs, then you must redirect events from port 514 to the default port 517 or your chosen alternative port by using IPTables. You must configure IPTables on your QRadar Console or for each QRadar Event Collector

that receives UDP Multiline Syslog events from an SunOne LDAP server. Then, you must complete the configuration for each SunOne LDAP server IP address that you want to receive logs from.

## Before you begin

**Important:** Complete this configuration method when you can't send UDP Multiline Syslog events directly to the chosen UDP Multiline port on QRadar from your SunOne LDAP server. Also, you must complete this configuration when you are restricted to send only to the standard syslog port 514.

## Procedure

1. Using SSH, log in to QRadar as the root user.

Login: *root*

Password: *password*

2. Type the following command to edit the IPtables file:

```
vi /opt/qradar/conf/iptables-nat.post
```

The IPtables NAT configuration file is displayed.

3. Type the following command to instruct QRadar to redirect syslog events from UDP port 514 to UDP port 517:

```
-A PREROUTING -p udp --dport 514 -j REDIRECT --to-port <new-port> -s <IP address>
```

Where:

*IP address* is the IP address of your SunOne LDAP server.

*New port* is the port number that is configured in the UDP Multiline protocol for SunOne LDAP.

You must include a redirect for each SunOne LDAP IP address that sends events to your QRadar Console or Event Collector. Example:

```
-A PREROUTING -p udp --dport 514 -j REDIRECT --to-port 517 -s <IP_address>
```

4. Save your IPtables NAT configuration.

You are now ready to configure IPtables on your QRadar Console or Event Collector to accept events from your SunOne LDAP servers.

5. Type the following command to edit the IPtables file:

```
vi /opt/qradar/conf/iptables.post
```

The IPtables configuration file is displayed.

6. Type the following command to instruct QRadar to allow communication from your SunOne LDAP servers:

```
-I QChain 1 -m udp -p udp --src <IP_address> --dport <New port> -j ACCEPT
```

Where:

*IP address* is the IP address of your SunOne LDAP server.

*New port* is the port number that is configured in the UDP Multiline protocol for SunOne LDAP.

You must include a redirect for each SunOne LDAP IP address that sends events to your QRadar Console or Event Collector. Example:

```
-I QChain 1 -m udp -p udp --src <IP_address> --dport 517 -j ACCEPT
```

7. Type the following command to update IPtables in QRadar:

```
./opt/qradar/bin/iptables_update.pl
```

## **Example**

If you need to configure another QRadar Console or Event Collector that receives syslog events from an SunOne LDAP server, repeat these steps.

## **What to do next**

Configure your SunOne LDAP server to forward events to QRadar.

# **Sun Solaris Basic Security Mode (BSM)**

---

Sun Solaris Basic Security Mode (BSM) is an audit tracking tool for the system administrator to retrieve detailed auditing events from Sun Solaris systems.

IBM QRadar retrieves Sun Solaris BSM events by using the log file Protocol. For you to configure QRadar to integrate with Solaris Basic Security Mode, take the following steps:

1. Enable Solaris Basic Security Mode.
2. Convert audit logs from binary to a human-readable format.
3. Schedule a cron job to run the conversion script on a schedule.
4. Collect Sun Solaris events in QRadar by using the log file protocol.

## **Enabling Basic Security Mode in Solaris 10**

To configure Sun Solaris BSM in Solaris 10, you must enable Solaris Basic Security Mode and configure the classes of events the system logs to an audit log file.

### **About this task**

Configure Basic Security Mode and enable auditing in Sun Solaris 10.

### **Procedure**

1. Log in to your Solaris console as a superuser or root user.
2. Enable single-user mode on your Solaris console.
3. Type the following command to run the bsmconv script and enable auditing:

```
/etc/security/bsmconv
```

The bsmconv script enables Solaris Basic Security Mode and starts the auditing service audited.

4. Type the following command to open the audit control log for editing:

```
vi /etc/security/audit_control
```

5. Edit the audit control file to contain the following information:

```
dir:/var/audit flags:lo,ad,ex,-fw,-fc,-fd,-fr naflags:lo,ad
```

6. Save the changes to the audit\_control file, and then reboot the Solaris console to start audited.

7. Type the following command to verify that audited starts :

```
/usr/sbin/auditconfig -getcond
```

If the audited process is started, the following string is returned:

```
audit condition = auditing
```

## **What to do next**

You can now convert the binary Solaris Basic Security Mode logs to a human-readable log format.

## Enabling Basic Security Mode in Solaris 11

To configure Sun Solaris BSM in Solaris 11, you must enable Solaris Basic Security Mode and configure the classes of events the system logs to an audit log file.

### Procedure

1. Log in to Solaris 11 console as a superuser or root.
2. Start the audit service by typing the following command:

```
audit -s
```

3. Set up the attributable classes by typing the following command:

```
auditconfig -setflags lo,ps,fw
```

4. Set up the non-attributable classes by typing the following command:

```
auditconfig -setnaflags lo,na
```

5. To verify that audit service starts, type the following command:

```
/usr/sbin/auditconfig -getcond
```

If the auditd process is started, the following string is returned:

```
audit condition = auditing
```

## Converting Sun Solaris BSM audit logs

IBM QRadar doesn't process binary files directly from Sun Solaris BSM. You must convert the audit log from the existing binary format to a human-readable log format by using praudit before the audit log data can be retrieved by QRadar.

### Procedure

1. Type the following command to create a new script on your Sun Solaris console:

```
vi /etc/security/newauditlog.sh
```

2. Add the following information to the newauditlog.sh script:

```
#!/bin/bash
#
# newauditlog.sh - Start a new audit file and expire the old logs
#
AUDIT_EXPIRE=30
AUDIT_DIR="/var/audit"
LOG_DIR="/var/log/"
/usr/sbin/audit -n
cd $AUDIT_DIR
# Get a listing of the files based on creation date that are not current in use
FILES=$(ls -lrt | tr -s " " | cut -d" " -f9 | grep -v "not_terminated")
# We created a new audit log so that the last file in the list is the latest archived binary log file.
lastFile=""
for file in $FILES; do
    lastFile=$file
done
# Extract a human-readable file from the binary log file
echo "Beginning praudit of $lastFile"
praudit -l $lastFile > "$LOG_DIR$lastFile.log"
echo "Done praudit, creating log file at: $LOG_DIR$lastFile.log"
/usr/bin/find . $AUDIT_DIR -type f -mtime +$AUDIT_EXPIRE \ -exec rm {} > /dev/null 2>&1 \
# End script
```

The script outputs log files in the <starttime>.<endtime>.<hostname>.log format.

For example, the log directory in /var/log contains a file with the following name:

20111026030000.20111027030000.qasparc10.log

3. Optional: Edit the script to change the default directory for the log files.

- a) AUDIT\_DIR="/var/audit" - The Audit directory must match the location that is specified by the audit control file you configured in ["Enabling Basic Security Mode in Solaris 10" on page 1523](#).

4. `LOG_DIR="/var/log/"` - The log directory is the location of the human-readable log files of your Sun Solaris system that are ready to be retrieved by QRadar.
5. Save your changes to the `newauditlog.sh` script.
6. Optional: If you want to make the script executable, type the following command:  
`chmod +x /etc/security/newauditlog.sh`

## What to do next

If this script is executable, you can automate it by using CRON to convert the Sun Solaris Basic Security Mode log to human-readable format.

## Creating a cron job

Cron is a Solaris daemon utility that automates scripts and commands to run system-wide on a scheduled basis.

### About this task

The following steps provide an example for automating `newauditlog.sh` to run daily at midnight. If you need to retrieve log files multiple times a day from your Solaris system, you must alter your cron schedule.

### Procedure

1. Type the following command to create a copy of your cron file:

```
crontab -l > cronfile
```

2. Type the following command to edit the `cronfile`:

```
vi cronfile
```

3. Add the following information to your `cronfile`:

```
0 0 * * * /etc/security/newauditlog.sh
```

4. Save the change to the `cronfile`.

5. Type the following command to add the `cronfile` to `crontab`:

```
crontab cronfile
```

6. You can now configure the log source in IBM QRadar to retrieve the Sun Solaris BSM audit log files.

## What to do next

You are now ready to configure a log source in QRadar.

## Log File log source parameters for Sun Solaris BSM

If QRadar does not automatically detect the log source, add a Sun Solaris BSM log source on the QRadar Console by using the Log File protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from Sun Solaris BSM:

Table 987. Log File log source parameters for the Sun Solaris BSM DSM	
Parameter	Value
<b>Log Source type</b>	<b>Solaris BSM</b>
<b>Protocol Configuration</b>	<b>Log File</b>

Table 987. Log File log source parameters for the Sun Solaris BSM DSM (continued)

Parameter	Value
<b>Log Source Identifier</b>	Type the IP address or host name for the log source. The log source identifier must be unique for the log source type.
<b>Service Type</b>	<p>From the list, select the protocol that you want to use when retrieving log files from a remove server. The default is SFTP.</p> <ul style="list-style-type: none"> <li>• <b>SFTP</b> - SSH File Transfer Protocol</li> <li>• <b>FTP</b> - File Transfer Protocol</li> <li>• <b>SCP</b> - Secure Copy</li> </ul> <p>The underlying protocol that is used to retrieve log files for the SCP and SFTP service types requires that the server specified in the <b>Remote IP or Hostname</b> field has the SFTP subsystem enabled.</p>
<b>Remote IP or Hostname</b>	Type the IP address or host name of the Sun Solaris BSM system.
<b>Remote Port</b>	<p>Type the TCP port on the remote host that is running the selected Service Type. If you configure the Service Type as FTP, the default is 21. If you configure the Service Type as SFTP or SCP, the default is 22.</p> <p>The valid range is 1 - 65535.</p>
<b>Remote User</b>	<p>Type the user name necessary to log in to your Sun Solaris system.</p> <p>The user name can be up to 255 characters in length.</p>
<b>Remote Password</b>	Type the password necessary to log in to your Sun Solaris system.
<b>Confirm Password</b>	Confirm the <b>Remote Password</b> to log in to your Sun Solaris system.
<b>SSH Key File</b>	If you select <b>SCP</b> or <b>SFTP</b> from the <b>Service Type</b> field you can define a directory path to an SSH private key file. The SSH Private Key File gives the option to ignore the <b>Remote Password</b> field.
<b>Remote Directory</b>	Type the directory location on the remote host from which the files are retrieved. By default, the newauditlog.sh script writes the human-readable logs files to the /var/log/ directory.
<b>Recursive</b>	Select this check box if you want the file pattern to also search sub folders. The Recursive parameter is not used if you configure SCP as the Service Type. By default, the check box is clear.

Table 987. Log File log source parameters for the Sun Solaris BSM DSM (continued)

Parameter	Value
<b>FTP File Pattern</b>	If you select <b>SFTP</b> or <b>FTP</b> as the <b>Service Type</b> , this gives the option to configure the regular expression (regex) that is needed to filter the list of files that are specified in the <b>Remote Directory</b> . All matching files are included in the processing.  For example, if you want to retrieve all files in the <starttime>.<endtime>.<hostname>.log format, use the following entry: \d+\.\d+\.\w+\.\log.  Use of this parameter requires knowledge of regular expressions (regex). For more information, see the following website: <a href="http://download.oracle.com/javase/tutorial/essential/regex/">http://download.oracle.com/javase/tutorial/essential/regex/</a>
<b>FTP Transfer Mode</b>	This option appears only if you select FTP as the Service Type. The <b>FTP Transfer Mode</b> parameter gives the option to define the file transfer mode when you retrieve log files over FTP.  From the list, select the transfer mode that you want to apply to this log source: <ul style="list-style-type: none"> <li>• <b>Binary</b> - Select Binary for log sources that require binary data files or compressed .zip, .gzip, .tar, or .tar+gzip archive files.</li> <li>• <b>ASCII</b> - Select ASCII for log sources that require an ASCII FTP file transfer. You must select <b>NONE</b> for the <b>Processor</b> field and <b>LINEBYLINE</b> the <b>Event Generator</b> field when you use the ASCII as the transfer mode.</li> </ul>
<b>SCP Remote File</b>	If you select <b>SCP</b> as the Service Type, you must type the file name of the remote file.
<b>Start Time</b>	Type the time of day you want the processing to begin. This parameter functions with the Recurrence value to establish when and how often the Remote Directory is scanned for files. Type the start time, based on a 24-hour clock, in the following format: HH: MM.
<b>Recurrence</b>	Type the frequency, beginning at the Start Time, that you want the remote directory to be scanned. Type this value in hours (H), minutes (M), or days (D).  For example, type 2H if you want the directory to be scanned every 2 hours. The default is 1H.

Table 987. Log File log source parameters for the Sun Solaris BSM DSM (continued)

Parameter	Value
<b>Run On Save</b>	Select this check box if you want the log file protocol to run immediately after you click Save. After the Run On Save completes, the log file protocol follows your configured start time and recurrence schedule.  Selecting <b>Run On Save</b> clears the list of previously processed files for the <b>Ignore Previously Processed File(s)</b> parameter.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The valid range is 100 to 5000.
<b>Processor</b>	If the files on the remote host are stored in a .zip, .gzip, .tar, or tar+gzip archive format, select the processor that allows the archives to be expanded and contents processed.
<b>Ignore Previously Processed File(s)</b>	Select this check box to track files that are processed already, and you do not want the files to be processed a second time. This applies only to FTP and SFTP Service Types.
<b>Change Local Directory?</b>	Select this check box to define the local directory on your QRadar system that you want to use for storing downloaded files during processing. It is suggested that you leave the check box clear. When the check box is selected, the <b>Local Directory</b> field is displayed, which gives you the option to configure the local directory to use for storing files.
<b>Event Generator</b>	From the <b>Event Generator</b> list, select <b>LINEBYLINE</b> .

## Sun Solaris DHCP

The IBM QRadar DSM for Sun Solaris DHCP collects Syslog events from a Sun Solaris DHCP system.

To integrate Sun Solaris DHCP with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - DSM Common Rational Portfolio Manager

- Sun Solaris DHCP DSM RPM
- Configure your Sun Solaris DHCP system to send events to QRadar. For more information about configuring Sun Solaris DHCP to communicate with QRadar, see [Configuring Sun Solaris DHCP](#).
  - If QRadar does not automatically detect the log source, add a Sun Solaris DHCP log source on the QRadar Console. For more information about configuring Syslog log source parameters, see [Syslog log source parameters for Sun Solaris DHCP](#).

## **Configuring Sun Solaris DHCP to communicate with QRadar**

The Sun Solaris DHCP DSM for IBM QRadar records all relevant DHCP events by using syslog.

#### **About this task**

To collect events from Sun Solaris DHCP, you must configure syslog to forward events to QRadar.

#### **Procedure**

- Log in to the Sun Solaris command-line interface.
- Edit the /etc/default/dhcp file.
- Enable logging of DHCP transactions to syslog by adding the following line:

```
LOGGING_FACILITY=X
```

Where X is the number corresponding to a local syslog facility, for example, a number 0 - 7.

4. Save and exit the file.
5. Edit the `/etc/syslog.conf` file.
6. To forward system authentication logs to QRadar, add the following line to the file:

```
localX.notice @<IP address>
```

Where:

X is the logging facility number that you specified in [“Configuring Sun Solaris DHCP to communicate with QRadar” on page 1529](#).

`<IP address>` is the IP address of your QRadar. Use tabs instead of spaces to format the line.

7. Save and exit the file.
8. Type the following command:

```
kill -HUP `cat /etc/syslog.pid`
```

## What to do next

You are now ready to configure the log source in QRadar.

## Sun Solaris OS

---

The IBM QRadar DSM for Sun Solaris OS collects Syslog events from a Sun Solaris OS system.

To integrate Sun Solaris OS with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](#) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - DSM Common RPM
  - Sun Solaris OS DSM RPM
2. Configure your Sun Solaris OS system to send events to QRadar. For more information, see [Configuring Sun Solaris OS to communicate with QRadar](#).
3. If QRadar does not automatically detect the log source, add a Sun Solaris OS log source on the QRadar Console. For more information, see [Syslog log source parameters for Sun Solaris OS](#).

## Sun Solaris OS DSM specifications

When you configure the Sun Solaris OS, understanding the specifications for the Sun Solaris OS DSM can help ensure a successful integration. For example, knowing what the supported version of Sun Solaris OS is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Sun Solaris OS DSM.

<i>Table 989. Sun Solaris OS DSM specifications</i>	
Specification	Value
Manufacturer	Sun
DSM name	Sun Solaris OS
RPM file name	<code>DSM-SunSolarisOS-QRadar_version-build_number.noarch.rpm</code>
Supported version	Sun OS 5.8, 5.9

Table 989. Sun Solaris OS DSM specifications (continued)

Specification	Value
Protocol	Syslog
Event format	All events
Automatically discovered?	Yes
Includes identity?	Yes
Includes custom properties?	No

## Configuring Sun Solaris OS to communicate with QRadar

The Sun Solaris OS DSM for IBM QRadar records all relevant Solaris Operating System Authentication Messages events by using the Syslog protocol.

### About this task

To collect events from Sun Solaris OS, you must configure syslog to forward events to QRadar.

### Procedure

1. Log in to the Sun Solaris command-line interface (CLI).
2. Open the /etc/syslog.conf file.
3. To forward system authentication logs to QRadar, add the following line to the file:

```
*.err;auth.notice;auth.info@<IP_address>
```

Where <IP\_address> is the IP address of your QRadar Console or Event Collector. Use tabs instead of spaces to format the line.

**Tip:** Depending on your version of Sun Solaris, you might need to add more log types to the file. Contact your system administrator for more information.

4. Save and exit the file.
5. Type the following command:

```
kill -HUP `cat /etc/syslog.pid`
```

### What to do next

Configure a log source in QRadar. For more information, see [Syslog log source parameters for Sun Solaris OS](#).

**Important:** If a Linux log source is created for the Solaris System that is sending events, disable the Linux log source, and then adjust the parsing order. Ensure that the Sun Solaris OS DSM is listed first.

## Syslog log source parameters for Sun Solaris OS

If QRadar does not automatically detect the log source, add a Sun Solaris OS log source on the QRadar Console by using the Syslog protocol.

When you use the Syslog protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect Syslog events from Sun Solaris OS:

Table 990. Syslog log source parameters for the Sun Solaris OS DSM

Parameter	Value
<b>Log Source type</b>	<b>Sun Solaris Operating System Authentication Messages</b>
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	A unique name for the log source. The Log Source Identifier can be any valid value and does not need to reference a specific server. <b>The Log Source Identifier</b> can be the same value as the log source <b>Name</b> . If you have more than one Sun Solaris OS log source that is configured, you might want to identify the first log source as solarisos1, the second log source as solarisos2, and the third log source as solarisos3.

## Sun Solaris OS sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Sun Solaris OS sample messages when you use the Syslog protocol

Sample 1: The following sample event message shows that a session to the authentication server was opened in Sun Solaris OS.

```
<38>Oct 6 10:35:59 sshd[16942]: [ID 800047 auth.info] Accepted keyboard-interactive for testuser from 2001:DB8:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF port 51730 ssh2
```

```
<38>Oct 6 10:35:59 sshd[16942]: [ID 800047 auth.info] Accepted keyboard-interactive for testuser from 2001:DB8:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF port 51730 ssh2
```

Table 991. Highlighted values in the Sun Solaris OS sample event message

QRadar field name	Highlighted values in the event payload
<b>Event ID</b>	login (inferred from the event content)
<b>Source IPv6</b>	<b>2001:DB8:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF</b>
<b>Source Port</b>	<b>51730</b>
<b>Username</b>	<b>testuser</b>
<b>Identity Username</b>	<b>testuser</b>
<b>Device Time</b>	<b>Oct 6 10:35:59</b> (extracted from date and time fields)

Sample 2: The following sample event message shows mail information events in Sun Solaris OS.

```
<38>Mar 1 17:32:05 10.10.25.2 <22>Mar 1 17:32:00 sendmail[14359]: [ID 801593 mail.info] a1AA111: to=envmgr, ctladdr=envmgr (11011/111100), delay=00:00:00, xdelay=00:00:00, mailer=abcde, pri=11111, relay=[127.0.0.1] [127.0.0.1], dsn=2.0.0, stat=Sent (a1AA111 Message accepted for delivery)
```

```
<38>Mar 1 17:32:05 10.10.25.2 <22>Mar 1 17:32:00 sendmail[14359]: [ID 801593
mail.info] a1AA111: to=envmgr, ctldaddr=envmgr (11011/111100), delay=00:00:00, xdelay=00:00:00,
mailer=abcde, pri=11111, relay=[127.0.0.1] [127.0.0.1], dsn=2.0.0, stat=Sent (a1AA111 Message
accepted for delivery)
```

*Table 992. Highlighted values in the Sun Solaris OS sample event message*

QRadar field name	Highlighted values in the event payload
Event ID	<b>mail.info</b>
Source IP	<b>10.10.25.2</b>
Destination IP	<b>10.10.25.2</b>
Device Time	<b>Mar 1 17:32:05</b> (extracted from date and time fields)

## Sun Solaris Sendmail

The Sun Solaris Sendmail DSM for IBM QRadar accepts Solaris authentication events by using syslog and records all relevant sendmail events.

### About this task

To collect events from Sun Solaris Sendmail, you must configure syslog to forward events to QRadar.

### Procedure

1. Log in to the Sun Solaris command-line interface.
2. Open the /etc/syslog.conf file.
3. To forward system authentication logs to QRadar, add the following line to the file:

```
mail.*; @<IP address>
```

Where <IP address> is the IP address of your QRadar. Use tabs instead of spaces to format the line.

**Note:** Depending on the version of Solaris, you are running, you might need to add more log types to the file. Contact your system administrator for more information.

4. Save and exit the file.
5. Type the following command:

```
kill -HUP 'cat /etc/syslog.pid'
```

You are now ready to configure the log source QRadar.

## Syslog log source parameters for Sun Solaris Sendmail

If QRadar does not automatically detect the log source, add a Sun Solaris Sendmail log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Sun Solaris Sendmail.

*Table 993. Syslog log source parameters for the Sun Solaris Sendmail DSM*

Parameter	Value
<b>Log Source name</b>	Type a name for your log source.
<b>Log Source description</b>	Type a description for the log source.
<b>Log Source type</b>	<b>Solaris Operating System Sendmail Logs</b>

*Table 993. Syslog log source parameters for the Sun Solaris Sendmail DSM (continued)*

Parameter	Value
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from Sun Solaris Sendmail installations  Each additional log source that you create when you have multiple installations ideally includes a unique identifier, such as an IP address or host name.

## Suricata DSM specifications

When you configure the Suricata device, understanding the specifications for the Suricata DSM can help ensure a successful integration. For example, knowing what the supported version of Suricata is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Suricata DSM.

<i>Table 994. Suricata DSM specifications</i>	
<b>Specification</b>	<b>Value</b>
Manufacturer	Open Information Security Foundation
DSM name	Suricata
RPM file name	DSM-Suricata-QRadar_version-build_number.noarch.rpm
Supported version	6.0.3 and earlier
Protocol	Syslog TLS Syslog
Event format	JSON
Recorded event types	Alerts
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://suricata.io/">https://suricata.io/</a>

# Configuring Suricata to communicate with QRadar

To send events to IBM QRadar, you must configure a Syslog integration.

## Before you begin

You must have access to the Suricata device and have the permissions to write to configuration files and to restart services. You need a username and password, such as Windows or Linux login information, for the system where you installed Suricata.

Ensure that rsyslog is installed on the system where you installed Suricata. For more information, see the [rsyslog website](https://www.rsyslog.com) (<https://www.rsyslog.com>).

## Procedure

1. Log in to the Suricata device.
2. Open the Suricata configuration file called `suricata.yaml`, located in the Suricata installation directory. Update the `eve-log` entry under the `outputs` header.  
Use the following example as a guide:

```
outputs:  
  - eve-log:  
    enabled: yes  
    filetype: syslog  
    identity: "suricata"  
    facility: <facility>  
    types:  
      - alert:
```

The `<facility>` variable is a Syslog facility name between `local0` and `local7`, such as `local5`.

3. Open the rsyslog configuration file called `/etc/rsyslog.conf` and add a forwarding rule to send the alerts to QRadar.  
Use the following example as a guide:

```
<facility>.* @@<QRadar IP/hostname>:514
```

The `<facility>` variable is the same Syslog facility that you configured in the previous step. The `<QRadar IP/hostname>` is the IP or hostname of the QRadar Console or managed host that you want to forward Suricata alerts to.

4. Restart the Suricata and rsyslog services.

## What to do next

[“Syslog log source parameters for Suricata” on page 1536](#)

## Syslog log source parameters for Suricata

If IBM QRadar does not automatically detect the log source, add a Suricata log source on the QRadar Console by using the Syslog protocol.

The following table describes the parameters that require specific values to collect Syslog events from Suricata:

Table 995. Syslog log source parameters for the Suricata DSM	
Parameter	Value
Log Source type	Suricata
Protocol Configuration	Syslog
Log Source Identifier	A unique identifier for the log source.

## Related tasks

“Adding a log source” on page 5

## TLS Syslog log source parameters for Suricata

If IBM QRadar does not automatically detect the log source, add a Suricata log source on the QRadar Console by using the TLS Syslog protocol.

The following table describes the parameters that require specific values to collect Syslog events from Suricata:

*Table 996. TLS Syslog log source parameters for the Suricata DSM*

Parameter	Value
Log Source type	Suricata
Protocol Configuration	TLS Syslog
Log Source Identifier	A unique identifier for the log source.
TLS Protocols	Select the version of TLS that is installed on the client.

For a complete list of TLS Syslog protocol parameters and their values, see [“TLS Syslog protocol configuration options”](#) on page 231.

# Suricata sample event message

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## **Suricata sample message when you use the Syslog protocol**

The following sample event message shows that Suricata detected that malware was being downloaded by an HTTP request.

*Table 997. Highlighted fields in the Suricata event*

<b>QRadar field name</b>	<b>Highlighted payload field name</b>
<b>Event ID</b>	<code>gid + ":" + signature_id</code>
<b>Source IP</b>	<code>src_ip</code>
<b>Source Port</b>	<code>src_port</code>
<b>Destination IP</b>	<code>dest_ip</code>
<b>Destination Port</b>	<code>dest_port</code>
<b>Protocol</b>	<code>proto</code>
<b>Device Time</b>	<code>timestamp</code>

---

# Chapter 154. Sybase ASE

You can integrate a Sybase Adaptive Server Enterprise (ASE) device with IBM QRadar SIEM to record all relevant events by using JDBC.

## About this task

To configure a Sybase ASE device:

## Procedure

1. Configure Sybase auditing.

For information about configuring Sybase auditing, see your *Sybase documentation*.

2. Log in to the Sybase database as a sa user:

```
isql -Usa -P<password>
```

Where <password> is the password necessary to access the database.

3. Switch to the security database:

- use sybsecurity
- go

4. Create a view for IBM QRadar SIEM.

- create view audit\_view
- as
- select audit\_event\_name(event) as event\_name, \* from <audit\_table\_1>
- union
- select audit\_event\_name(event) as event\_name, \* from <audit\_table\_2>
- go

5. For each additional audit table in the audit configuration, make sure that the **union select** parameter is repeated for each additional audit table.

For example, if you want to configure auditing with four audit tables (sysaudits\_01, sysaudits\_02, sysaudits\_03, sysaudits\_04), type the following commands:

- create view audit\_view as select audit\_event\_name(event) as event\_name, \* from sysaudits\_01
- union select audit\_event\_name(event) as event\_name, \* from sysaudits\_02,
- union select audit\_event\_name(event) as event\_name, \* from sysaudits\_03,
- union select audit\_event\_name(event) as event\_name, \* from sysaudits\_04

## What to do next

You can now configure the log source IBM QRadar SIEM.

## JDBC log source parameters for Sybase ASE

---

If QRadar does not automatically detect the log source, add a Sybase ASE log source on the QRadar Console by using the JDBC protocol.

When using the JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from Sybase ASE:

Table 998. JDBC log source parameters for the Sybase ASE DSM	
Parameter	Value
<b>Log Source Name</b>	Type a unique name for the log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	<b>Sybase ASE</b>
<b>Protocol Configuration</b>	<b>JDBC</b>
<b>Log Source Identifier</b>	<p>Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.</p> <p>If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2.</p>
<b>Database Type</b>	Sybase
<b>Database Name</b>	The name of the database to which you want to connect.
<b>IP or Hostname</b>	The IP address or host name of the database server.
<b>Port</b>	<p>Enter the JDBC port. The JDBC port must match the listener port that is configured on the remote database. The database must permit incoming TCP connections. The valid range is 1 - 65535.</p> <p>The defaults are:</p> <ul style="list-style-type: none"> <li>• MSDE - 1433</li> <li>• Postgres - 5432</li> <li>• MySQL - 3306</li> <li>• Sybase - 1521</li> <li>• Oracle - 1521</li> <li>• Informix - 9088</li> <li>• DB2 - 50000</li> </ul> <p>If a database instance is used with the MSDE database type, you must leave the <b>Port</b> field blank.</p>
<b>Username</b>	A user account for QRadar in the database.
<b>Password</b>	The password that is required to connect to the database.

Table 998. JDBC log source parameters for the Sybase ASE DSM (continued)

Parameter	Value
<b>Confirm Password</b>	The password that is required to connect to the database.
<b>Predefined Query</b>	Select a predefined database query for the log source. If a predefined query is not available for the log source type, administrators can select the <b>none</b> option.
<b>Table Name</b>	The name of the table or view that includes the event records. The table name can include the following special characters: dollar sign (\$), number sign (#), underscore (_), en dash (-), and period (.).
<b>Select List</b>	The list of fields to include when the table is polled for events. You can use a comma-separated list or type an asterisk (*) to select all fields from the table or view. If a comma-separated list is defined, the list must contain the field that is defined in the <b>Compare Field</b> .
<b>Compare Field</b>	A numeric value or time stamp field from the table or view that identifies new events that are added to the table between queries. Enables the protocol to identify events that were previously polled by the protocol to ensure that duplicate events are not created.
<b>Use Prepared Statements</b>	Prepared statements enable the JDBC protocol source to set up the SQL statement, and then run the SQL statement numerous times with different parameters. For security and performance reasons, most JDBC protocol configurations can use prepared statements.
<b>Start Date and Time</b>	Type the start date and time for database polling in the following format: yyyy-MM-dd HH:mm with HH specified by using a 24-hour clock. If the start date or time is clear, polling begins immediately and repeats at the specified polling interval.
<b>Polling Interval</b>	Enter the amount of time between queries to the event table. To define a longer polling interval, append H for hours or M for minutes to the numeric value  The maximum polling interval is one week.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The valid range is 100 to 20,000.

Table 998. JDBC log source parameters for the Sybase ASE DSM (continued)

Parameter	Value
<b>Enabled</b>	Select this check box to enable the log source. By default, the check box is selected.
<b>Credibility</b>	<p>From the list, select the <b>Credibility</b> of the log source. The range is 0 - 10.</p> <p>The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.</p>
<b>Target Event Collector</b>	Select the <b>Target Event Collector</b> to use as the target for the log source.
<b>Coalescing Events</b>	<p>Select the <b>Coalescing Events</b> check box to enable the log source to coalesce (bundle) events.</p> <p>By default, automatically discovered log sources inherit the value of the <b>Coalescing Events</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.</p>
<b>Store Event Payload</b>	<p>Select the <b>Store Event Payload</b> check box to enable the log source to store event payload information.</p> <p>By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.</p>

#### Related tasks

[“Adding a log source” on page 5](#)

# Chapter 155. Symantec

IBM QRadar supports a number of Symantec DSMs.

## Symantec Critical System Protection

The IBM QRadar DSM for Symantec Critical System Protection can collect event logs from Symantec Critical System Protection systems.

The following table identifies the specifications for the Symantec Critical System Protection DSM.

Table 999. Symantec Critical System Protection DSM specifications	
Specification	Value
Manufacturer	Symantec
DSM Name	Critical System Protection
RPM file name	DSM-SymantecCriticalSystemProtection-QRadar_version_build_number.noarch.rpm
Supported versions	5.1.1
Event format	DB Entries
QRadar recorded event types	All events from the 'CSPEVENT_VW' view
Log source type in QRadar UI	Symantec Critical System Protection
Auto discovered?	No
Includes identity?	No
Includes custom properties	No
For more information	<a href="http://www.symantec.com/">Symantec Web Page</a> ( <a href="http://www.symantec.com/">http://www.symantec.com/</a> )

To integrate Symantec Critical System Protection with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most current version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Protocol-JDBC RPM
  - Symantec Critical System Protection RPM
2. For each Symantec Critical System Protection instance, configure Symantec Critical System Protection to enable communication with QRadar.  
Ensure that QRadar can poll the database for events by using TCP port 1433 or the port that is configured for your log source. Protocol connections are often disabled on databases and extra configuration steps are required in certain situations to allow connections for event polling. Configure firewalls that are located between Symantec Critical System Protection and QRadar to allow traffic for event polling.
3. If QRadar does not automatically discover Symantec Critical System Protection, create a log source for each Symantec Critical System Protection instance on the QRadar Console. The following table describes the parameters that require specific values to collect events from Symantec Critical System Protection:

Parameter	Description
Log Source Type	Symantec Critical System Protection

Parameter	Description
<b>Protocol Configuration</b>	JDBC
<b>Log Source Identifier</b>	<p>Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.</p> <p>If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2.</p>
<b>Database Type</b>	MSDE
<b>Database Name</b>	SCSPDB
<b>IP or Hostname</b>	The IP address or host name of the database server.
<b>Port</b>	<p>Enter the JDBC port. The JDBC port must match the listener port that is configured on the remote database. The database must permit incoming TCP connections. The valid range is 1 - 65535.</p> <p>The defaults are:</p> <ul style="list-style-type: none"> <li>• MSDE - 1433</li> <li>• Postgres - 5432</li> <li>• MySQL - 3306</li> <li>• Sybase - 1521</li> <li>• Oracle - 1521</li> <li>• Informix - 9088</li> <li>• DB2 - 50000</li> </ul> <p>If a database instance is used with the MSDE database type, you must leave the <b>Port</b> field blank.</p>
<b>Username</b>	A user account for QRadar in the database.
<b>Password</b>	The password that is required to connect to the database.
<b>Authentication Domain</b>	<p>If you did not select <b>Use Microsoft JDBC</b>, <b>Authentication Domain</b> is displayed.</p> <p>The domain for MSDE that is a Windows domain. If your network does not use a domain, leave this field blank.</p>
<b>Database Instance</b>	SCSP

Parameter	Description
<b>Predefined Query</b> (Optional)	Select a predefined database query for the log source. If a predefined query is not available for the log source type, administrators can select the <b>none</b> option.
<b>Table Name</b>	CSPEVENT_VW
<b>Select List</b>	The list of fields to include when the table is polled for events. You can use a comma-separated list or type an asterisk (*) to select all fields from the table or view. If a comma-separated list is defined, the list must contain the field that is defined in the <b>Compare Field</b> .
<b>Compare Field</b>	EVENT_ID
<b>Use Prepared Statements</b>	Prepared statements enable the JDBC protocol source to set up the SQL statement, and then run the SQL statement numerous times with different parameters. For security and performance reasons, most JDBC protocol configurations can use prepared statements.
<b>Start Date and Time</b> (Optional)	Type the start date and time for database polling in the following format: yyyy-MM-dd HH:mm with HH specified by using a 24-hour clock. If the start date or time is clear, polling begins immediately and repeats at the specified polling interval.
<b>Polling Interval</b>	Enter the amount of time between queries to the event table. To define a longer polling interval, append H for hours or M for minutes to the numeric value  The maximum polling interval is one week.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The valid range is 100 to 20,000.
<b>Use Named Pipe Communication</b>	If you did not select <b>Use Microsoft JDBC</b> , <b>Use Named Pipe Communication</b> is displayed.  MSDE databases require the user name and password field to use a Windows authentication user name and password and not the database user name and password. The log source configuration must use the default that is named pipe on the MSDE database.

Parameter	Description
<b>Database Cluster Name</b>	<p>If you selected <b>Use Named Pipe Communication</b>, the <b>Database Cluster Name</b> parameter is displayed.</p> <p>If you are running your SQL server in a cluster environment, define the cluster name to ensure named pipe communication functions properly.</p>
<b>Use NTLMv2</b>	<p>If you did not select <b>Use Microsoft JDBC</b>, <b>Use NTLMv2</b> is displayed.</p> <p>Select this option if you want MSDE connections to use the NTLMv2 protocol when they are communicating with SQL servers that require NTLMv2 authentication. This option does not interrupt communications for MSDE connections that do not require NTLMv2 authentication.</p> <p>Does not interrupt communications for MSDE connections that do not require NTLMv2 authentication.</p>
<b>Use Microsoft JDBC</b>	<p>If you want to use the Microsoft JDBC driver, you must enable <b>Use Microsoft JDBC</b>.</p>
<b>Use SSL</b>	<p>Select this option if your connection supports SSL. This option appears only for MSDE.</p>
<b>Microsoft SQL Server Hostname</b>	<p>If you selected <b>Use Microsoft JDBC</b> and <b>Use SSL</b>, the <b>Microsoft SQL Server Hostname</b> parameter is displayed.</p> <p>You must type the host name for the Microsoft SQL server.</p>

For more information about configuring the JDBC protocol parameters, see [c\\_logsource\\_JDBCprotocol.dita](#)

[“Adding a log source” on page 5](#)

## Symantec Data Loss Prevention (DLP)

The Symantec Data Loss Protection (DLP) DSM for IBM QRadar accepts events from a Symantec DLP appliance by using syslog.

Before you configure QRadar, you must configure response rules on your Symantec DLP. The response rule allows the Symantec DLP appliance to forward syslog events to QRadar when a data loss policy violation occurs. Integrating Symantec DLP requires you to create two protocol response rules (SMTP and None of SMTP) for QRadar. These protocol response rules create an action to forward the event information, using syslog, when an incident is triggered.

To configure Symantec DLP with QRadar, take the following steps:

1. Create an SMTP response rule.
2. Create a None of SMTP response rule.
3. Configure a log source in QRadar.
4. Map Symantec DLP events in QRadar.

## Creating an SMTP response rule

You can configure an SMTP response rule in Symantec DLP.

### Procedure

1. Log in to Symantec DLP user interface.
2. From the menu, select the **Manage > Policies > Response Rules**.
3. Click **Add Response Rule**.
4. Select one of the following response rule types:
  - **Automated Response** - Automated response rules are triggered automatically as incidents occur. It is the default value.
  - **Smart Response** - Smart response rules are added to the Incident Command screen and handled by an authorized Symantec DLP user.
5. Click **Next**.  
Configure the following values:
  6. **Rule Name** - Type a name for the rule that you are creating. This name is descriptive enough for policy authors to identify the rule.  
For example, QRadar Syslog SMTP.
  7. **Description** - Optional. Type a description for the rule that you are creating.
  8. Click **Add Condition**.
  9. On the **Conditions** panel, select the following conditions:
    - From the first list, select **Protocol or Endpoint Monitoring**.
    - From the second list, select **Is Any Of**.
    - From the third list, select **SMTP**.
  10. On the **Actions** pane, click **Add Action**.
  11. From the **Actions** list, select **All: Log to a Syslog Server**.
  12. Configure the following options:
    - a) **Host** - Type the IP address of your IBM QRadar.
    13. **Port** - Type 514 as the syslog port.
    14. **Message** - Type the following string to add a message for SMTP events.

```
LEEF:2.0|Symantec|DLP|2:medium|$POLICY$|||usrName=$SENDER$|duser=$RECIPIENTS$|rules=$RULESS$|matchCount=$MATCH_COUNT$|blocked=$BLOCKED$|incidentID=$INCIDENT_ID$|incidentSnapshot=$INCIDENT_SNAPSHOT$|subject=$SUBJECT$|fileName=$FILE_NAME$|parentPath=$PARENT_PATH$|path=$PATH$|quarantineParentPath=$QUARANTINE_PARENT_PATH$|scan=$SCAN$|target=$TARGET${color}
```
  15. **Level** - From this list, select **6 - Informational**.
  16. Click **Save**.

### What to do next

You can now configure your None Of SMTP response rule.

## Creating a None Of SMTP response rule

You can configure a None Of SMTP response rule in Symantec DLP:

### Procedure

1. From the menu, select the **Manage > Policies > Response Rules**.
2. Click **Add Response Rule**.

3. Select one of the following response rule types:
  - **Automated Response** - Automated response rules are triggered automatically as incidents occur. This is the default value.
  - **Smart Response** - Smart response rules are added to the Incident Command screen and handled by an authorized Symantec DLP user.
4. Click **Next**.
 

Configure the following values:
5. **Rule Name** - Type a name for the rule you are creating. This name ideally is descriptive enough for policy authors to identify the rule. For example, QRadar Syslog None Of SMTP
6. **Description** - Optional. Type a description for the rule you are creating.
7. Click **Add Condition**.
8. On the **Conditions** pane, select the following conditions:
  - From the first list, select **Protocol or Endpoint Monitoring**.
  - From the second list, select **Is Any Of**.
  - From the third list, select **None Of SMTP**.
9. On the **Actions** pane, click **Add Action**.
10. From the **Actions** list, select **All: Log to a Syslog Server**.
11. Configure the following options:
  - a) **Host** - Type the IP address of your QRadar.
12. Port - Type 514 as the syslog port.
13. **Message** - Type the following string to add a message for *None Of SMTP* events.

```
LEEF:1.0|Symantec|DLP|2:medium|$POLICY$|src=$SENDER$|dst=$RECIPIENTS$|
rules=$RULES$|matchCount=$MATCH_COUNT$|blocked=$BLOCKED$|incidentID=$INCIDENT_ID$|
incidentSnapshot=$INCIDENT_SNAPSHOT$|subject=$SUBJECT$|fileName=$FILE_NAME$|
parentPath=$PARENT_PATH$|path=$PATH$|quarantineParentPath=$QUARANTINE_PARENT_PATH$|
scan=$SCAN$|target=$TARGET$
```

14. **Level** - From this list, select **6 - Informational**.

15. Click **Save**.

## What to do next

You are now ready to configure IBM QRadar.

## Configuring a log source

You can configure the log source in IBM QRadar to receive events from a Symantec DLP appliance.

### About this task

QRadar automatically detects syslog events for the SMTP and None of SMTP response rules that you create. However, if you want to manually configure QRadar to receive events from a Symantec DLP appliance:

### Procedure

From the **Log Source Type** list, select the **Symantec DLP** option.

For more information about Symantec DLP, see your vendor documentation.

### Related tasks

["Adding a log source" on page 5](#)

## Event map creation for Symantec DLP events

Event mapping is required for a number of Symantec DLP events. Due to the customizable nature of policy rules, most events, except the default policy events do not contain a predefined QRadar Identifier (QID) map to categorize security events.

You can individually map each event for your device to an event category in QRadar. Mapping events allows QRadar to identify, coalesce, and track reoccurring events from your network devices. Until you map an event, all events that are displayed in the **Log Activity** tab for Symantec DLP are categorized as unknown. *Unknown* events are easily identified as the **Event Name** column and **Low Level Category** columns display *Unknown*.

## Discovering unknown events

As your device forwards events to IBM QRadar, it can take time to categorize all of the events for a device, as some events might not be generated immediately by the event source appliance or software.

### About this task

It is helpful to know how to quickly search for *unknown* events. When you know how to search for *unknown* events, it is suggested you repeat this search until you are comfortable that you can identify most of your events.

### Procedure

1. Log in to QRadar.
2. Click the **Log Activity** tab.
3. Click **Add Filter**.
4. From the first list, select **Log Source**.
5. From the **Log Source Group** list, select the log source group or **Other**.

Log sources that are not assigned to a group are categorized as *Other*.

6. From the **Log Source** list, select your Symantec DLP log source.
7. Click **Add Filter**.

The **Log Activity** tab is displayed with a filter for your log source.

8. From the **View** list, select **Last Hour**.

Any events that are generated by the Symantec DLP DSM in the last hour are displayed. Events that are displayed as *unknown* in the **Event Name** column or **Low Level Category** column require event mapping in QRadar.

**Note:** You can save your existing search filter by clicking **Save Criteria**.

### What to do next

You can now modify the event map.

## Modifying the event map

Modifying an event map gives you the option to manually categorize events to a QRadar Identifier (QID) map.

### About this task

Any event that is categorized to a log source can be remapped to a new QRadar Identifier (QID).

**Note:** Events that do not have a defined log source cannot be mapped to an event. Events without a log source display SIM Generic Log in the **Log Source** column.

## Procedure

1. On the **Event Name** column, double-click an *unknown* event for Symantec DLP.

The detailed event information is displayed.
2. Click **Map Event**.
3. From the **Browse for QID** pane, select any of the following search options to narrow the event categories for a IBM QRadar Identifier (QID):
  - a) From the **High-Level Category** list, select a high-level event categorization.

For a full list of high-level and low-level event categories or category definitions, see the Event Categories section of the *IBM QRadar Administration Guide*.
4. From the **Low-Level Category** list, select a low-level event categorization.
5. From the **Log Source Type** list, select a log source type.

The **Log Source Type** list gives you the option to search for QIDs from other log sources. Searching for QIDs by log source is useful when events are similar to another existing network device. For example, Symantec provides policy and data loss prevention events, you might select another product that likely captures similar events.
6. To search for a QID by name, type a name in the **QID/Name** field.

The **QID/Name** field gives you the option to filter the full list of QIDs for a specific word, for example, policy.
7. Click **Search**.

A list of QIDs are displayed.
8. Select the QID you want to associate to your unknown event.
9. Click **OK**.

Maps any additional events that are forwarded from your device with the same QID that matches the event payload. The event count increases each time that the event is identified by QRadar.

If you update an event with a new QRadar Identifier (QID) map, past events that are stored in QRadar are not updated. Only new events are categorized with the new QID.

## Symantec Endpoint Protection

The IBM QRadar DSM for Symantec Endpoint Protection collects events from a Symantec Endpoint Protection system.

**The IBM® QRadar® DSM for Symantec Endpoint Protection parses events from Symantec Endpoint Protection System in the following languages: English, French, German, Italian, Japanese, Russian, and Polish.**

The following table describes the specifications for the Symantec Endpoint Protection DSM:

Table 1000. Symantec Endpoint Protection DSM specifications	
Specification	Value
Manufacturer	Symantec
DSM name	Symantec Endpoint Protection
RPM file name	DSM-SymantecEndpointProtection-QRadar_version-build_number.noarch.rpm
Supported versions	Endpoint Protection V11, V12, and V14
Protocol	Syslog
Event format	Syslog

*Table 1000. Symantec Endpoint Protection DSM specifications (continued)*

Specification	Value
Recorded event types	All Audit and Security Logs
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.symantec.com">Symantec website</a> ( <a href="https://www.symantec.com">https://www.symantec.com</a> )

To integrate Symantec Endpoint Protection with QRadar , complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM
  - Symantec Endpoint Protection DSM RPM
2. Configure your Symantec Endpoint Protection device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a Symantec Endpoint Protection log source on the QRadar Console.
4. Verify that QRadar is configured correctly.

The following table shows a sample normalized event message from Symantec Endpoint Protection:

*Table 1001. Symantec Endpoint Protection sample message*

Event name	Low level category	Sample log message
Blocked	Access Denied	<51>Mar 3 13:52:13 <Server> SymantecServer: USER,<IP_address>, Blocked,[AC13-1.5] Block from loading other DLLs - Caller MD5=xxxxxxxxxxxxxxxxxxxxxx,Load Dl1,Begin: 2017-03-03 13:48:18,End: 2017-03-03 13:48:18,Rule: Corp Endpoint - Browser Restrictions   [AC13-1.5] Block from loading other DLLs, 6804,C:/Program Files (x86)/Microsoft Office/Office14/WINPROJ.EXE,0,N0 Module Name,C:/Users/USER/AppData/Local/assembly/dl3/DMD7K4QX.8GW/WQ9LV1W4.8HL/e705c114/006fef9d_f364d101/ProjectPublisher2010.DLL,User: USER,Domain: LAB,Action Type: ,File size (bytes): 4216832,Device ID: SCSI\Disk&Ven_AT&Prod_SAMSUNG_SSD_PM83\4&27c82505&0&000000

## Configuring Symantec Endpoint Protection to Communicate with QRadar

Before you can add the Symantec Endpoint Protection log source in QRadar, you need to configure your Symantec Endpoint Protection device to forward syslog events.

#### Procedure

1. Log in to your Symantec Endpoint Protection Manager system.

2. In the left pane, click the **Admin** icon.
3. In the bottom of the **View Servers** pane, click **Servers**.
4. In the **View Servers** pane, click **Local Site**.
5. In the **Tasks** pane, click **Configure External Logging**.
6. From the **Generals** tab, select the **Enable Transmission of Logs to a Syslog Server** check box.
7. In the **Syslog Server** field, type the IP address of your QRadar that you want to parse the logs.
8. In the **UDP Destination Port** field, type 514.
9. In the **Log Facility** field, type 6.
10. In the **Log Filter** tab, under **Management Server Logs**, select the **Audit Logs** check box.
11. In the **Client Log** pane, select the **Security Logs** check box.
12. In the **Client Log** pane, select the **Risks** check box.
13. Click **OK**.

## Symantec Encryption Management Server

---

The Symantec Encryption Management Server DSM for IBM QRadar collects syslog events from Symantec Encryption Management Servers.

Symantec Encryption Management Server is formerly known as Symantec PGP Universal Server.

QRadar collects all relevant events from the following categories:

- Administration
- Software updates
- Clustering
- Backups
- Web Messenger
- Verified Directory
- Postfix
- Client logs
- Mail
- Whole Disk Encryption logs

Before you can integrate Symantec Encryption Management Server events with QRadar, you must configure Symantec Encryption Management Server to communicate with QRadar.

### Related concepts

[“Syslog log source parameters for Symantec Encryption Management Servers” on page 1554](#)

### Related tasks

[“Configuring Symantec Encryption Management Server to communicate with QRadar” on page 1553](#)

Enable external logging to forward syslog events to IBM QRadar.

[“Adding a DSM” on page 4](#)

## Configuring Symantec Encryption Management Server to communicate with QRadar

Enable external logging to forward syslog events to IBM QRadar.

### Procedure

1. In a web browser, log in to your Encryption Management server's administrative interface.

`https://<Encryption Management Server IP address>:9000`

2. Click **Settings**.

3. Select the **Enable External Syslog** check box.

4. From the **Protocol** list, select either **UDP** or **TCP**.

By default, QRadar uses port 514 to receive UDP syslog or TCP syslog event messages.

5. In the **Hostname** field, type the IP address of your QRadar Console or Event Collector.

6. In the **Port** field, type 514.

7. Click **Save**.

The configuration is complete. The log source is added to QRadar as Symantec Encryption Management Server events are automatically discovered. Events that are forwarded to QRadar by the Symantec Encryption Management Servers are displayed on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Symantec Encryption Management Servers

If QRadar does not automatically detect the log source, add a Symantec Encryption Management Servers log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Symantec Encryption Management Servers:

Table 1003. Syslog log source parameters for the Symantec Encryption Management Servers DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	<b>Symantec Encryption Management Server</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Symantec Encryption Management Server.

### Related tasks

[“Adding a log source” on page 5](#)

## Symantec SGS

The IBM QRadar DSM for Symantec Gateway Security (SGS) Appliance collects events from a Symantec Gateway Security (SGS) device|appliance|service.

QRadar records all relevant events from SGS. Before you configure QRadar to integrate with an SGS, you must configure syslog within your SGS appliance. For more information on Symantec SGS, see your vendor documentation.

After you configure syslog to forward events to QRadar, the configuration is complete. Events forward from Symantec SGS to QRadar using syslog are automatically discovered.

[“Syslog log source parameters for Symantec SGS” on page 1554](#)

### Related tasks

[“Adding a DSM” on page 4](#)

## Syslog log source parameters for Symantec SGS

If QRadar does not automatically detect the log source, add a Symantec SGS log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Symantec SGS:

Table 1004. Syslog log source parameters for the Symantec SGS DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	<b>Symantec Gateway Security (SGS) Appliance</b>

Table 1004. Syslog log source parameters for the Symantec SGS DSM (continued)

Parameter	Value
Protocol Configuration	Syslog
Log Source Identifier	Type the IP address or host name for the log source.

#### Related tasks

[“Adding a log source” on page 5](#)

## Symantec System Center

The Symantec System Center (SSC) DSM for IBM QRadar retrieves events from an SSC database by using a custom view that is created for QRadar.

QRadar records all SSC events. You must configure the SSC database with a user that has read and write privileges for the custom QRadar view to be able to poll the view for information. Symantec System Center (SSC) supports only the JDBC protocol.

## Configuring a database view for Symantec System Center

A database view is required by the JDBC protocol to poll for SSC events.

### Procedure

In the Microsoft SQL Server database that is used by the SSC device, configure a custom default view to support IBM QRadar:

**Note:** The database name must not contain any spaces.

- CREATE VIEW dbo.vw\_qradar AS SELECT
- dbo.alerts.Idx AS idx,
- dbo.inventory.IP\_Address AS ip,
- dbo.inventory.Computer AS computer\_name,
- dbo.virus.Virusname AS virus\_name,
- dbo.alerts.Filepath AS filepath,
- dbo.alerts.NoOfViruses AS no\_of\_virus,
- dbo.actualaction.Actualaction AS [action],
- dbo.alerts.Alertdatetime AS [date],
- dbo.clientuser.Clientuser AS user\_name FROM
- dbo.alerts INNER JOIN
- dbo.virus ON dbo.alerts.Virusname\_Idx = dbo.virus.Virusname\_Idx INNER JOIN
- dbo.inventory ON dbo.alerts.Computer\_Idx = dbo.inventory.Computer\_Idx INNER JOIN
- dbo.actualaction ON dbo.alerts.Actualaction\_Idx =
- dbo.actualaction.Actualaction\_Idx INNER JOIN
- dbo.clientuser ON dbo.alerts.Clientuser\_Idx = dbo.clientuser.Clientuser\_Idx

### What to do next

After you create your custom view, you must configure QRadar to receive event information by using the JDBC protocol.

## JDBC log source parameters for Symantec System Center

If QRadar does not automatically detect the log source, add a Symantec System Center log source on the QRadar Console by using the JDBC protocol.

When using the JDBC protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect JDBC events from Symantec System Center:

Table 1005. JDBC log source parameters for the Symantec System Center DSM	
Parameter	Value
<b>Log Source Name</b>	Type a unique name for the log source.
<b>Log Source Description (Optional)</b>	Type a description for the log source.
<b>Log Source Type</b>	<b>Symantec System Center</b>
<b>Protocol Configuration</b>	<b>JDBC</b>
<b>Log Source Identifier</b>	Type a name for the log source. The name can't contain spaces and must be unique among all log sources of the log source type that is configured to use the JDBC protocol.  If the log source collects events from a single appliance that has a static IP address or host name, use the IP address or host name of the appliance as all or part of the <b>Log Source Identifier</b> value; for example, 192.168.1.1 or JDBC192.168.1.1. If the log source doesn't collect events from a single appliance that has a static IP address or host name, you can use any unique name for the <b>Log Source Identifier</b> value; for example, JDBC1, JDBC2.
<b>Database Type</b>	<b>MSDE.</b>
<b>Database Name</b>	Type Reporting as the name of the Symantec System Center database.
<b>IP or Hostname</b>	Type the IP address or host name of the Symantec System Center SQL Server.
<b>Port</b>	Type the port number that is used by the database server. The default port for MSDE is 1433.  The JDBC configuration port must match the listener port of the Symantec System Center database. The Symantec System Center database must have incoming TCP connections that are enabled to communicate with QRadar.  If you define a <b>Database Instance</b> when you use MSDE as the database type, you must leave the <b>Port</b> field blank in your configuration.
<b>Username</b>	Type the user name that is required to access the database.
<b>Password</b>	Type the password that is required to access the database. The password can be up to 255 characters in length.
<b>Confirm Password</b>	Confirm the password that is required to access the database. The confirmation password must be identical to the password entered in the <b>Password</b> field.

Table 1005. JDBC log source parameters for the Symantec System Center DSM (continued)

Parameter	Value
<b>Authentication Domain</b>	If you did not select <b>Use Microsoft JDBC</b> , <b>Authentication Domain</b> is displayed.  The domain for MSDE that is a Windows domain. If your network does not use a domain, leave this field blank.
<b>Database Instance</b>	The database instance, if required. MSDE databases can include multiple SQL server instances on one server.  When a non-standard port is used for the database or access is blocked to port 1434 for SQL database resolution, the <b>Database Instance</b> parameter must be blank in the log source configuration.
<b>Table Name</b>	Type vw_qradar as the name of the table or view that includes the event records.
<b>Select List</b>	Type * for all fields from the table or view.  You can use a comma-separated list to define specific tables or views, if you need it for your configuration. The comma-separated list can be up to 255 alphanumeric characters in length. The list can include the following special characters: dollar sign (\$), number sign (#), underscore (_), en dash (-), and period(.)
<b>Compare Field</b>	Type idx as the compare field. The compare field is used to identify new events that are added between queries to the table.
<b>Use Prepared Statements</b>	Prepared statements enable the JDBC protocol source to set up the SQL statement, and then run the SQL statement numerous times with different parameters. For security and performance reasons, most JDBC protocol configurations can use prepared statements.
<b>Start Date and Time</b> (Optional)	Type the start date and time for database polling in the following format: yyyy-MM-dd HH:mm with HH specified by using a 24-hour clock. If the start date or time is clear, polling begins immediately and repeats at the specified polling interval.
<b>Polling Interval</b>	Type the polling interval, which is the amount of time between queries to the event table. The default polling interval is 10 seconds.  You can define a longer polling interval by appending H for hours or M for minutes to the numeric value. The maximum polling interval is 1 week in any time format. Numeric values that are entered without an H or M poll in seconds.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The default is 20,000 EPS.

Table 1005. JDBC log source parameters for the Symantec System Center DSM (continued)

Parameter	Value
<b>Use Named Pipe Communication</b>	If you did not select <b>Use Microsoft JDBC, Use Named Pipe Communication</b> is displayed.  Clear the <b>Use Named Pipe Communication</b> check box.  MSDE databases require the user name and password field to use a Windows authentication user name and password and not the database user name and password. The log source configuration must use the default that is named pipe on the MSDE database
<b>Database Cluster Name</b>	If you selected the <b>Use Named Pipe Communication</b> check box, the <b>Database Cluster Name</b> parameter is displayed. If you are running your SQL server in a cluster environment, define the cluster name to ensure Named Pipe communication functions properly.
<b>Use NTLMv2</b>	If you did not select <b>Use Microsoft JDBC, Use NTLMv2</b> is displayed.  Select this option if you want MSDE connections to use the NTLMv2 protocol when they are communicating with SQL servers that require NTLMv2 authentication. This option does not interrupt communications for MSDE connections that do not require NTLMv2 authentication.  Does not interrupt communications for MSDE connections that do not require NTLMv2 authentication.
<b>Use Microsoft JDBC</b>	If you want to use the Microsoft JDBC driver, you must enable <b>Use Microsoft JDBC</b> .
<b>Use SSL</b>	Select this option if your connection supports SSL.
<b>Microsoft SQL Server Hostname</b>	If you selected <b>Use Microsoft JDBC</b> and <b>Use SSL</b> , the <b>Microsoft SQL Server Hostname</b> parameter is displayed.  You must type the host name for the Microsoft SQL server.

For a complete list of JDBC protocol parameters and their values, see [c\\_logsource\\_JDBCprotocol.dita](#).

**Note:** Selecting a value greater than 5 for the **Credibility** parameter weights your Symantec System Center log source with a higher importance compared to other log sources in QRadar.

# Chapter 156. SysFlow

The IBM QRadar DSM for SysFlow collects syslog events from a SysFlow agent.

To integrate SysFlow with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - DSM Common RPM
  - SysFlow DSM RPM
2. Configure your SysFlow agent to send events to QRadar. For more information, see [Configuring SysFlow agent to communicate with QRadar](#).
3. If QRadar does not automatically detect the log source, add a SysFlow log source on the QRadar Console. For more information, see [Syslog log source parameters for SysFlow](#).

## SysFlow DSM specifications

When you configure SysFlow, understanding the specifications for the SysFlow DSM can help ensure a successful integration. For example, knowing what the supported version of SysFlow is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the SysFlow DSM.

<i>Table 1006. SysFlow DSM specifications</i>	
Specification	Value
Manufacturer	SysFlow is an open source project initiated by IBM.
DSM name	SysFlow
RPM file name	DSM-SysFlow-QRadar_version-build_number.noarch.rpm
Supported version	1.0
Protocol	Syslog
Event format	JSON
Recorded event types	SysFlow
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://sysflow.readthedocs.io/en/latest/">SysFlow Telemetry Pipeline Documentation</a> ( <a href="https://sysflow.readthedocs.io/en/latest/">https://sysflow.readthedocs.io/en/latest/</a> )

# Configuring SysFlow agent to communicate with QRadar

---

To forward events to IBM QRadar, you must install a SysFlow collector by using OpenShift or Kubernetes cluster.

## About this task

The SysFlow installation uses the OpenShift or Kubernetes operator. The operator uses custom resources to manage the SysFlow agent and its associated components. This installation deploys the operator pod and then applies custom resources. When the custom resources are created, the operator deploys SysFlow agent pods to all worker nodes in the cluster. During the installation process, OpenShift or Kubernetes cluster downloads container images from the internet.

## Procedure

1. Use SSH to log in as administrator to the master node of your OpenShift or Kubernetes cluster.
2. Download the SysFlow installation package and then extract the files.
3. Go to the root folder `sf-operator` of the extracted installation package, and then go to the `/scripts/run` directory.
4. To run the script, type the following command:  
`cd scripts/run/`
5. To deploy the operator, type the following command:  
`./deployOperator.sh`
6. To deploy the SysFlow agent, type the following command:  
`./applyCR.sh <QRadar_Console_IP_address> 514 tcp`

## What to do next

If QRadar does not automatically detect the log source, [add a SysFlow log source](#) on the QRadar Console.

## Syslog log source parameters for SysFlow

---

If IBM QRadar does not automatically detect the log source, add a SysFlow log source on the QRadar Console by using the Syslog protocol.

When you use the Syslog protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect Syslog events from SysFlow:

Table 1007. Syslog log source parameters for the SysFlow DSM	
Parameter	Value
<b>Log Source type</b>	SysFlow
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	SysFlow

For a complete list of common protocol parameters and their values, see [Adding a log source](#).

# Chapter 157. ThreatGRID Malware Threat Intelligence Platform

The ThreatGRID Malware Threat Intelligence Platform DSM for IBM QRadar collects malware events by using the log file protocol or syslog.

QRadar supports ThreatGRID Malware Threat Intelligence Platform appliances with v2.0 software that use the QRadar Log Event Extended Format (LEEF) Creation script.

## Supported event collection protocols for ThreatGRID Malware Threat Intelligence

ThreatGRID Malware Threat Intelligence Platform writes malware events that are readable by IBM QRadar.

The LEEF creation script is configured on the ThreatGRID appliance and queries the ThreatGRID API to write LEEF events that are readable by QRadar. The event collection protocol your log source uses to collect malware events is based on the script you install on your ThreatGRID appliance.

Two script options are available for collecting LEEF formatted events:

- **Syslog** - The syslog version of the LEEF creation script allows your ThreatGRID appliance to forward events directly to QRadar. Events that are forwarded by the syslog script are automatically discovered by QRadar.
- **Log file** - The log file protocol version of the LEEF creation script allows the ThreatGRID appliance to write malware events to a file. QRadar uses the log file protocol to communicate with the event log host to retrieve and parse malware events.

The LEEF creation script is available from ThreatGRID customer support. For more information, see the ThreatGRID website <http://www.threatgrid.com> or email ThreatGRID support at [support@threatgrid.com](mailto:support@threatgrid.com).

## ThreatGRID Malware Threat Intelligence configuration overview

You can integrate ThreatGRID Malware Threat Intelligence events with IBM QRadar.

You must complete the following tasks:

1. Download the QRadar Log Enhanced Event Format Creation script for your collection type from the ThreatGRID support website to your appliance.
2. On your ThreatGRID appliance, install and configure the script to poll the ThreatGRID API for events.
3. On your QRadar appliance, configure a log source to collect events based on the script you installed on your ThreatGRID appliance.
4. Ensure that no firewall rules block communication between your ThreatGRID installation and the QRadar Console or managed host that is responsible for retrieving events.

## Syslog log source parameters for ThreatGRID Malware Threat Intelligence Platform

If QRadar does not automatically detect the log source, add a ThreatGRID Malware Threat Intelligence Platform log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from ThreatGRID Malware Threat Intelligence Platform:

Table 1009. Syslog log source parameters for the ThreatGRID Malware Threat Intelligence Platform DSM

Parameter	Value
<b>Log Source Name</b>	Type a name for your log source
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	<b>ThreatGRID Malware Intelligence Platform</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	<p>Type the IP address or host name for the log source as an identifier for events from your ThreatGRID Malware Intelligence Platform.</p> <p>The log source identifier must be unique for the log source type.</p>
<b>Enabled</b>	Select this check box to enable the log source. By default, the check box is selected.
<b>Credibility</b>	<p>From the list, select the credibility of the log source. The range is 0 - 10.</p> <p>The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.</p>
<b>Target Event Collector</b>	From the list, select the <b>Target Event Collector</b> to use as the target for the log source.
<b>Coalescing Events</b>	<p>Select this check box to enable the log source to coalesce (bundle) events.</p> <p>By default, automatically discovered log sources inherit the value of the <b>Coalescing Events</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.</p>
<b>Incoming Event Payload</b>	From the list, select the incoming payload encoder for parsing and storing the logs.
<b>Store Event Payload</b>	<p>Select this check box to enable the log source to store event payload information.</p> <p>By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the System Settings in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.</p>

#### Related tasks

## Log File log source parameters for ThreatGRID Malware Threat Intelligence Platform

If QRadar does not automatically detect the log source, add a ThreatGRID Malware Threat Intelligence Platform log source on the QRadar Console by using the Log File protocol.

When using the Log File protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Log File events from ThreatGRID Malware Threat Intelligence Platform:

Table 1010. Log File log source parameters for the ThreatGRID Malware Threat Intelligence Platform DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	<b>ThreatGRID Malware Intelligence Platform</b>
<b>Protocol Configuration</b>	<b>Log File</b>
<b>Log Source Identifier</b>	Type an IP address, host name, or name to identify the event source.  The log source identifier must be unique for the log source type.
<b>Service Type</b>	From the list, select the protocol that you want to use to retrieve log files from a remote server. The default is SFTP. <ul style="list-style-type: none"><li>• <b>SFTP</b> - SSH File Transfer Protocol</li><li>• <b>FTP</b> - File Transfer Protocol</li><li>• <b>SCP</b> - Secure Copy Protocol</li></ul> The SCP and SFTP service type requires that the host server in the <b>Remote IP or Hostname</b> field has the SFTP subsystem enabled.
<b>Remote IP or Hostname</b>	Type the IP address or host name of the ThreatGRID server that contains your event log files.
<b>Remote Port</b>	Type the port number for the protocol that is selected to retrieve the event logs from your ThreatGRID server. The valid range is 1 - 65535.  The list of default service type port numbers: <ul style="list-style-type: none"><li>• <b>FTP</b> - TCP Port 21</li><li>• <b>SFTP</b> - TCP Port 22</li><li>• <b>SCP</b> - TCP Port 22</li></ul>
<b>Remote User</b>	Type the user name that is required to log in to the ThreatGRID web server that contains your audit event logs.  The user name can be up to 255 characters in length.

Table 1010. Log File log source parameters for the ThreatGRID Malware Threat Intelligence Platform DSM (continued)

Parameter	Value
<b>Remote Password</b>	Type the password to log in to your ThreatGRID server.
<b>Confirm Password</b>	Confirm the password to log in to your ThreatGRID server
<b>SSH Key File</b>	If you select <b>SCP</b> or <b>SFTP</b> as the <b>Service Type</b> , use this parameter to define an SSH private key file. When you provide an <b>SSH Key File</b> , the <b>Remote Password</b> field is ignored.
<b>Remote Directory</b>	Type the directory location on the remote host from which the files are retrieved, relative to the user account you are using to log in.  For FTP only. If your log files are in the remote user's home directory, you can leave the remote directory blank. Blank values in the <b>Remote Directory</b> field support systems that have operating systems where a change in the working directory (CWD) command is restricted.
<b>Recursive</b>	Select this check box if you want the file pattern to search sub folders in the remote directory. By default, the check box is clear.  The <b>Recursive</b> parameter is ignored if you configure SCP as the <b>Service Type</b> .
<b>FTP File Pattern</b>	Type the regular expression (regex) required to filter the list of files that are specified in the Remote Directory. All files that match the regular expression are retrieved and processed.  The FTP file pattern must match the name that you assigned to your ThreatGRID event log. For example, to collect files that start with leef or LEEF and ends with a text file extension, type the following value:  (leef LEEF)+.*\.\txt  Use of this parameter requires knowledge of regular expressions (regex). This parameter applies to log sources that are configured to use FTP or SFTP.
<b>FTP Transfer Mode</b>	If you select <b>FTP</b> as the <b>Service Type</b> , from the list, select ASCII.  ASCII is required for text-based event logs.
<b>SCP Remote File</b>	If you select <b>SCP</b> as the <b>Service Type</b> , type the file name of the remote file.

*Table 1010. Log File log source parameters for the ThreatGRID Malware Threat Intelligence Platform DSM (continued)*

Parameter	Value
<b>Start Time</b>	Type a time value to represent the time of day you want the log file protocol to start. The start time is based on a 24 hour clock and uses the following format: HH:MM.  For example, type 00 : 00 to schedule the Log File protocol to collect event files at midnight.  This parameter functions with the <b>Recurrence</b> field value to establish when your ThreatGRID server is polled for new event log files.
<b>Recurrence</b>	Type the frequency that you want to scan the remote directory on your ThreatGRID server for new event log files. Type this value in hours (H), minutes (M), or days (D).  For example, type 2H to scan the remote directory every 2 hours from the start time. The default recurrence value is 1H. The minimum time interval is 15M.
<b>Run On Save</b>	Select this check box if you want the log file protocol to run immediately after you click <b>Save</b> .  After the save action completes, the log file protocol follows your configured start time and recurrence schedule.  Selecting <b>Run On Save</b> clears the list of previously processed files for the <b>Ignore Previously Processed File</b> parameter.
<b>EPS Throttle</b>	The maximum number of events per second that QRadar ingests.  If your data source exceeds the EPS throttle, data collection is delayed. Data is still collected and then it is ingested when the data source stops exceeding the EPS throttle.  The valid range is 100 to 5000.
<b>Processor</b>	From the list, select <b>NONE</b> .  Processors allow event file archives to be expanded and processed for their events. Files are processed after they are downloaded. QRadar can process files in zip, gzip, tar, or tar+gzip archive format.

Table 1010. Log File log source parameters for the ThreatGRID Malware Threat Intelligence Platform DSM (continued)

Parameter	Value
<b>Ignore Previously Processed File(s)</b>	Select this check box to track and ignore files that are already processed.  QRadar examines the log files in the remote directory to determine whether the event log was processed by the log source. If a previously processed file is detected, the log source does not download the file. Only new or unprocessed event log files are downloaded by QRadar.  This option applies to <b>FTP</b> and <b>SFTP</b> service types.
<b>Change Local Directory?</b>	Select this check box to define a local directory on your QRadar appliance to store event log files during processing.  In most scenarios, you can leave this check box not selected. When this check box is selected, the <b>Local Directory</b> field is displayed. You can configure a local directory to temporarily store event log files. After the event log is processed, the events added to QRadar and event logs in the local directory are deleted.
<b>Event Generator</b>	From the <b>Event Generator</b> list, select <b>LineByLine</b> .  The <b>Event Generator</b> applies extra processing to the retrieved event files. Each line of the file is a single event. For example, if a file has 10 lines of text, 10 separate events are created.

# Chapter 158. TippingPoint

IBM QRadar supports a number of TippingPoint DSMs.

## TippingPoint Intrusion Prevention System

The TippingPoint Intrusion Prevention System (IPS) DSM for IBM QRadar collects TippingPoint events by using the Syslog protocol.

QRadar records all relevant events from either a Local Security Management (LMS) device or multiple devices with a Security Management System (SMS).

Before you configure QRadar to integrate with TippingPoint, you must configure your device based on type:

- If you are using SMS, see [“Configuring remote syslog for SMS” on page 1569](#).
- If you are using LSM, see [“Configuring notification contacts for LSM” on page 1570](#).

### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Configuring remote syslog for SMS

To configure SMS you must enable and configure your TippingPoint device to send events to a remote host by using syslog.

### Before you begin

TippingPoint SMS V5.2.0 is supported in IBM QRadar.

### Procedure

1. Log in to the TippingPoint system.
2. On the **Admin** Navigation menu, select **Server Properties**.
3. Select the **Management** tab.
4. Click **Add**.  
The **Edit Syslog Notification** window is displayed.
5. Select the **Enable** check box.
6. Configure the following values:
  - a) **Syslog Server** - Type the IP address of the QRadar to receive syslog event messages.
  - b) **Port** - Type 514 as the port address.
  - c) **Log Type** - Select **SMS 2.0 / 2.1 Syslog format** from the list.
  - d) **Facility** - Select **Log Audit** from the list.
  - e) **Severity** - Select **Severity in Event** from the list.
  - f) **Delimiter** - Select **TAB** as the delimiter for the generated logs.
  - g) **Include Timestamp in Header** - Select **Use original event timestamp**.
  - h) Select the **Include SMS Hostname in Header** check box.
  - i) Click **OK**.
  - j) You are now ready to configure the log source in QRadar.
7. To configure QRadar to receive events from a TippingPoint device: From the **Log Source Type** list, select the **TippingPoint Intrusion Prevention System (IPS)** option.

For more information about your TippingPoint device, see your vendor documentation.

#### Related tasks

["Adding a log source" on page 5](#)

## Configuring notification contacts for LSM

If you are using an LSM device, you need to configure LSM notification contacts.

#### Procedure

1. Log in to the TippingPoint system.
2. From the **LSM** menu, select **IPS > Action Sets**.  
The **IPS Profile - Action Sets** window is displayed.
3. Click the **Notification Contacts** tab.
4. In the **Contacts List**, click **Remote System Log**.  
The **Edit Notification Contact** page is displayed.
5. Configure the following values:
  - a) **Syslog Server** - Type the IP address of the QRadar to receive syslog event messages.
  - b) **Port** - Type 514 as the port address.
  - c) **Alert Facility** - Select none or a numeric value 0-31 from the list. Syslog uses these numbers to identify the message source.
  - d) **Block Facility** - Select none or a numeric value 0-31 from the list. Syslog uses these numbers to identify the message source.
  - e) **Delimiter** - Select **TAB** from the list.
  - f) Click **Add to table below**.
  - g) Configure a Remote system log aggregation period in minutes.
6. Click **Save**.

**Note:** If your QRadar is in a different subnet than your TippingPoint device, you might have to add static routes. For more information, see your vendor documentation.

#### What to do next

You are now ready to configure the action set for LSM, see ["Configuring an Action Set for LSM" on page 1570](#).

## Configuring an Action Set for LSM

If you are using LSM, you need to configure an action set for your LSM.

#### Procedure

1. Log in to the TippingPoint system.
2. From the **LSM** menu, select **IPS Action Sets**.  
The **IPS Profile - Action Sets** window is displayed.
3. Click **Create Action Set**.  
The **Create/Edit Action Set** window is displayed.
4. Type the Action Set Name.
5. For Actions, select a flow control action setting:
  - **Permit** - Allows traffic.
  - **Rate Limit** - Limits the speed of traffic. If you select Rate Limit, you must also select the desired rate.

- **Block** - Does not permit traffic.
- **TCP Reset** - When this is used with the *Block action*, it resets the source, destination, or both IP addresses of an attack. This option resets blocked TCP flows.
- **Quarantine** - When this is used with the *Block action*, it blocks an IP address (source or destination) that triggers the filter.

6. Select the **Remote System Log** check box for each action you that you select.

7. Click **Create**.

You are now ready to configure the log source in QRadar.

8. To configure QRadar to receive events from a TippingPoint device: From the **Log Source Type** list, select the **TippingPoint Intrusion Prevention System (IPS)** option.

For more information about your TippingPoint device, see your vendor documentation.

#### Related tasks

[“Adding a log source” on page 5](#)

## TippingPoint X505/X506 Device

---

The TippingPoint X505/X506 DSM for IBM QRadar collects events by using syslog.

QRadar records all relevant system, audit, VPN, and firewall session events.

## Configuring your TippingPoint X506/X506 device to communicate with QRadar

To retrieve events in IBM QRadar, you must configure your TippingPoint X505/X506 device to send events to QRadar.

### Procedure

1. Log in to your TippingPoint X505/X506 device.
2. From the **LSM** menu, select **System > Configuration > Syslog Servers**.

The **Syslog Servers** window is displayed.

3. For each log type you want to forward, select a check box and type the IP address of your QRadar.

**Note:** If your QRadar is in a different subnet than your TippingPoint device, you might have to add static routes. For more information, see your vendor documentation.

You are now ready to configure the log source in QRadar.

4. To configure QRadar to receive events from a TippingPoint X505/X506 device: From the **Log Source Type** list, select the **TippingPoint X Series Appliances** option.

**Note:** If you have a previously configured TippingPoint X505/X506 DSM installed and configured on your QRadar, the TippingPoint X Series Appliances option is still displayed in the **Log Source Type** list. However, for any new TippingPoint X505/X506 DSM that you configure, you must select the **TippingPoint Intrusion Prevention System (IPS)** option.

## TippingPoint Intrusion Prevention System sample event message

Use this sample event message to verify a successful integration with QRadar.

### TippingPoint Intrusion Prevention System (IPS) sample message when you use the Syslog protocol

**Important:** Due to formatting issues, paste the message formats into a text editor and then remove any carriage return or line feed characters.

The following sample detects an attempt to use a memory corruption vulnerability in vulnerable installations of Microsoft Excel. The specific flaw exists in the way that Microsoft Excel parses certain Binary Interchange File Format (BIFF) structures. An attacker might use the vulnerability to gain remote code execution in the privilege context of the current user. User interaction is required in that a user must download a malicious file. For more information, see the [Microsoft Security Bulletin](https://docs.microsoft.com/en-us/security-updates/securitybulletins/2012/ms12-030) (<https://docs.microsoft.com/en-us/security-updates/securitybulletins/2012/ms12-030>).

# Chapter 159. Top Layer IPS

The Top Layer IPS DSM for IBM QRadar accepts Top Layer IPS events by using syslog.

QRadar records and processes Top Layer events. Before you configure QRadar to integrate with a Top Layer device, you must configure syslog within your Top Layer IPS device. For more information on configuring Top Layer, see your Top Layer documentation.

The configuration is complete. The log source is added to QRadar as Top Layer IPS events are automatically discovered. Events that are forwarded to QRadar by Top Layer IPS are displayed on the **Log Activity** tab of QRadar.

To configure QRadar to receive events from a Top Layer IPS device:

From the **Log Source Type** list, select the **Top Layer Intrusion Prevention System (IPS)** option.

For more information about your Top Layer device, see your vendor documentation.

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

# Chapter 160. Townsend Security LogAgent

IBM QRadar can collect CEF format events from Townsend Security LogAgent installations on IBM i infrastructure.

QRadar supports CEF events from Townsend Security software that is installed on IBM i V5.1 and above.

## Supported event types

Townsend Security LogAgent installations on IBM i can write to forward syslog events for security, compliance, and auditing to QRadar.

All syslog events that are forwarded by Raz-Lee iSecurity automatically discover and the events are parsed and categorized with the IBM i DSM.

## Configuring Raz-Lee iSecurity

To collect security and audit events, you must configure your Raz-Lee iSecurity installation to forward syslog events to IBM QRadar.

### Procedure

1. Log in to the IBM i command-line interface.
2. Type the following command to access the audit menu options:

STRAUD

3. From the **Audit** menu, select **81. System Configuration**.
4. From the **iSecurity/Base System Configuration** menu, select **31. SYSLOG Definitions**.
5. Configure the following parameters:
  - a) **Send SYSLOG message** - Select **Yes**.
  - b) **Destination address** - Type the IP address of QRadar.
  - c) **"Facility" to use** - Type a facility level.
  - d) **"Severity" range to auto send** - Type a severity level.
  - e) **Message structure** - Type any additional message structure parameters that are needed for your syslog messages.

### What to do next

Syslog events that are forwarded by Raz-Lee iSecurity are automatically discovered by QRadar by the IBM i DSM. In most cases, the log source is automatically created in QRadar after a few events are detected. If the event rate is low, then you might be required to manually create a log source for Raz-Lee iSecurity in QRadar.

Until the log source is automatically discovered and identified, the event type displays as *Unknown* on the **Log Activity** tab of QRadar.

## Syslog log source parameters for Raz-Lee i Security

If QRadar does not automatically detect the log source, add a Raz\_Lee i Security log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Raz-Lee i Security:

*Table 1011. Syslog log source parameters for the Raz-Lee i Security: DSM*

<b>Parameter</b>	<b>Value</b>
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	<b>IBM i</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your IBM i system with Raz-Lee iSecurity.

# Chapter 161. Trend Micro

IBM QRadar supports several Trend Micro DSMs.

## Trend Micro Apex Central

The IBM QRadar DSM for Trend Micro Apex Central collects Syslog or TLS syslog events from a Trend Micro Apex Central device.

To integrate Trend Micro Apex Central with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - DSM Common RPM
  - Trend Micro Apex Central DSM RPM
2. Configure your Trend Micro Apex Central device to send events to QRadar. For more information, see [Configuring Trend Micro Apex Central to communicate with QRadar](#).
3. If QRadar does not automatically detect the log source, add a Trend Micro Apex Central log source on the QRadar Console.

## Trend Micro Apex Central DSM specifications

When you configure the Trend Micro Apex Central, understanding the specifications for the Trend Micro Apex Central DSM can help ensure a successful integration. For example, knowing what the supported version of Trend Micro Apex Central is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Trend Micro Apex Central DSM.

Table 1012. Trend Micro Apex Central DSM specifications	
Specification	Value
Manufacturer	Trend Micro
DSM name	Trend Micro Apex Central
RPM file name	DSM-TrendMicroApexCentral-QRadar_version-build_number.noarch.rpm
Supported version	1
Protocol	Syslog, TLS syslog
Event format	CEF

Table 1012. Trend Micro Apex Central DSM specifications (continued)

Specification	Value
Recorded event types	Attack discovery detection logs Behavior monitoring logs C&C callback logs Content security logs Data loss prevention logs Device access control logs Endpoint application control logs Engine update status log Intrusion prevention logs Network content inspection logs Pattern Update Status Logs Predictive machine learning logs Sandbox detection logs Spyware/Grayware logs Suspicious file logs Virus/Malware logs Web security logs
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	Trend Micro Apex Central website ( <a href="https://www.trendmicro.com/en_ca/business/technologies/control-manager.html">https://www.trendmicro.com/en_ca/business/technologies/control-manager.html</a> )

## Configuring Trend Micro Apex Central to communicate with QRadar

Configure your Trend Micro Apex Central device to forward Common Event Format (CEF) events to IBM QRadar.

### Procedure

1. Log in to your Apex Central console as Administrator.
2. Configure the syslog settings.
  - a) Click **Detections > Notifications > Notifications Method Settings**.
  - b) In the **Syslog Settings** section, configure the following parameters:

Table 1013. Syslog Settings parameters

Parameter	Value
<b>Server IP address</b>	The IPv4 or IPv6 address of your syslog server.
<b>Port</b>	The port number of your syslog server.

*Table 1013. Syslog Settings parameters (continued)*

Parameter	Value
<b>Facility</b>	Select the facility code.

- c) Click **Save**.
3. Enable syslog forwarding.
  - a) Click **Administration > Settings > Syslog Settings**.
  - b) Select the **Enable syslog forwarding** checkbox.
  - c) To send events to QRadar, configure the following syslog forwarding parameters:

*Table 1014. Syslog forwarding parameters*

Parameter	Value
<b>Server address</b>	The IP address of your QRadar Console or Event Collector.
<b>Port</b>	<ul style="list-style-type: none"><li>• SSL/TLS - 6514 (default port)</li><li>• TCP - 514</li><li>• UDP - 514</li></ul>
<b>Protocol</b>	<ul style="list-style-type: none"><li>• SSL/TLS</li><li>• TCP</li><li>• UDP</li></ul>
<b>Format</b>	CEF
<b>Log type</b>	Select <b>Security logs</b> from the list, and then select the types of events that you want to forward to QRadar.

- d) To test the connection, click **Test Connection**.

- e) Click **Save**.

For more information about configuring Trend Micro Apex Central, see the [Trend Micro Technical Support documentation](https://success.trendmicro.com/solution/000152501-SIEM-solutions-integration-with-Apex-Central#collapseTwo) (<https://success.trendmicro.com/solution/000152501-SIEM-solutions-integration-with-Apex-Central#collapseTwo>).

## Syslog log source parameters for Trend Micro Apex Central

If IBM QRadar does not automatically detect the log source, add a Trend Micro Apex Central log source on the QRadar Console by using the Syslog protocol.

When you use the Syslog protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect Syslog events from Trend Micro Apex Central:

*Table 1015. Syslog log source parameters for the Trend Micro Apex Central DSM*

Parameter	Value
<b>Log Source type</b>	Trend Micro Apex Central
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	The IP address or host name for the log source.

For more information about common protocols and their values, see [Adding a log source](#).

## Related tasks

[Adding a log source](#)

## TLS Syslog log source parameters for Trend Micro Apex Central

If IBM QRadar does not automatically detect the log source, add a Trend Micro Apex Central log source on the QRadar Console by using the TLS syslog protocol.

When you use the TLS syslog protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect TLS syslog events from Trend Micro Apex Central:

Table 1016. TLS syslog log source parameters for the Trend Micro Apex Central DSM	
Parameter	Value
<b>Log Source type</b>	Trend Micro Apex Central
<b>Protocol Configuration</b>	<b>TLS Syslog</b>
<b>Log Source Identifier</b>	A unique name to identify the log source.
<b>TLS Protocols</b>	Select the version of TLS that is installed on the client.

For a complete list of TLS syslog protocol parameters and their values, see [TLS syslog protocol configuration options](#).

## Trend Micro Apex One

A Trend Micro Apex One DSM for IBM QRadar accepts events by using SNMPv2.

Trend Micro Apex One is formerly known as Trend Micro OfficeScan. The name remains the same in QRadar.

QRadar records events relevant to virus and spyware events. Before you configure a Trend Micro device in QRadar, you must configure your device to forward SNMPv2 events.

QRadar has several options for integrating with a Trend Micro device. The integration option that you choose depends on your device version:

- [“Integrating with Trend Micro Apex One 8.x” on page 1581](#)
- [“Integrating with Trend Micro Apex One 10.x” on page 1582](#)
- [“Integrating with Trend Micro Apex One XG” on page 1584](#)

### Related concepts

## Integrating with Trend Micro Apex One 8.x

You can integrate a Trend Micro Apex One 8.x device with IBM QRadar.

### Procedure

1. Log in to the Apex One Administration interface.

2. Select **Notifications**.
3. Configure the General Settings for SNMP Traps: In the **Server IP Address** field, type the IP address of the QRadar.

**Note:** Do not change the community trap information.
4. Click **Save**.
5. Configure the Standard Alert Notification: Select **Standard Notifications**.
6. Click the **SNMP Trap** tab.
7. Select the **Enable notification via SNMP Trap for Virus/Malware Detections** check box.
8. Type the following message in the field (this should be the default):

Virus/Malware: %v Computer: %s Domain: %m File: %p Date/Time: %y Result: %a
9. Select the **Enable notification via SNMP Trap for Spyware/Grayware Detections** check box.
10. Type the following message in the field (this should be the default):

Spyware/Grayware: %v Computer: %s Domain: %m Date/Time: %y Result: %a
11. Click **Save**.
12. Configure Outbreak Alert Notifications: Select **Out Notifications**.
13. Click the **SNMP Trap** tab.
14. Select the **Enable notification via SNMP Trap for Virus/Malware Outbreaks** check box.
15. Type the following message in the field (this should be the default):

Number of viruses/malware: %CV Number of computers: %CC Log Type Exceeded: %A Number of firewall violation logs: %C Number of shared folder sessions: %S Time Period: %T
16. Select the **Enable notification via SNMP Trap for Spyware/Grayware Outbreaks** check box.
17. Type the following message in the field (this should be the default):

Number of spyware/grayware: %CV Number of computers: %CC Log Type Exceeded: %A Number of firewall violation logs: %C Number of shared folder sessions: %S Time Period: %T
18. Click **Save**.

### What to do next

Configure a log source in QRadar by using the SNMPv2 protocol. For more information, see “[SNMPv2 log source parameters for Trend Micro Apex One](#)” on page 1586.

## Integrating with Trend Micro Apex One 10.x

Several preparatory steps are necessary before you configure IBM QRadar to integrate with a Trend Micro Apex One 10.x device.

### About this task

You must:

1. Configure the SNMP settings for Trend Micro Apex One 10.x.
2. Configure standard notifications.
3. Configure outbreak criteria and alert notifications.

## Configuring General Settings in Trend Micro Apex One

You can integrate a Trend Micro Apex One 10.x device with IBM QRadar.

### Procedure

1. Log in to the Apex One Administration interface.
2. Select **Notifications > Administrator Notifications > General Settings**.
3. Configure the General Settings for SNMP Traps: In the **Server IP Address** field, type the IP address of your QRadar.
4. Type a community name for your Trend Micro Apex One device.
5. Click **Save**.

### What to do next

You must now configure the Standard Notifications for Apex One.

## Configure Standard Notifications in Trend Micro Apex One

You can configure standard notifications.

### Procedure

1. Select **Notifications > Administrator Notifications > Standard Notifications**.
2. Define the Criteria settings. Click the **Criteria** tab.
3. Select the option to alert administrators on the detection of virus/malware and spyware/grayware, or when the action on these security risks is unsuccessful.
4. To enable notifications: Configure the **SNMP Trap** tab.
5. Select the **Enable notification via SNMP Trap** check box.
6. Type the following message in the field:  
`Virus/Malware: %v Spyware/Grayware: %T Computer: %s IP address: %i Domain: %m File: %p Date/Time: %y Result: %a User name: %n`
7. Click **Save**.

### What to do next

You must now configure Outbreak Notifications.

## Configuring Outbreak Criteria and Alert Notifications in Trend Micro Apex One

You can configure outbreak criteria and alert notifications for your Trend Micro Apex One device.

### Procedure

1. Select **Notifications > Administrator Notifications > Outbreak Notifications**.
2. Click the **Criteria** tab.
3. Type the number of detections and detection period for each security risk.

Notification messages are sent to an administrator when the criteria exceeds the specified detection limit.

**Note:** Trend Micro suggests that you use the default values for the detection number and detection period.

4. Select **Shared Folder Session Link** and enable Apex One to monitor for firewall violations and shared folder sessions.

**Note:** To view computers on the network with shared folders or computers currently browsing shared folders, you can select the number link in the interface.

5. Click the **SNMP Trap** tab.
  - a) Select the **Enable notification via SNMP Trap** check box.
6. Type the following message in the field:

Number of virus/malware: %CV Number of computers: %CC Log Type Exceeded: %A  
Number of firewall violation logs: %C Number of shared folder sessions: %S  
Time Period: %T
7. Click **Save**.

### What to do next

Configure a log source in QRadar by using the SNMPv2 protocol. For more information, see “[SNMPv2 log source parameters for Trend Micro Apex One](#)” on page 1586.

## Integrating with Trend Micro Apex One XG

You can integrate a Trend Micro Apex One XG device with the QRadar system.

### About this task

Before you can integrate a Trend Micro Apex One XG device with the QRadar system you must configure the following items:

- SNMP settings for Trend Micro Apex One XG
- Administrator notifications
- Outbreak notifications

## Configuring General Settings in Trend Micro Apex One XG

You can integrate a Trend Micro Apex One XG device with IBM QRadar.

### Procedure

1. Log in to the Apex One Administration interface.
2. Click **Administration > Notifications > General Settings**.
3. Configure the General Notification Settings for SNMP Traps.
4. In the **Server IP Address** field, type the IP address of the QRadar Console.
5. Type a community name for your Trend Micro Apex One device.
6. Click **Save**.

### What to do next

You must now configure the Administrator Notifications for Apex One.

## Configuring Administrator Notifications in Trend Micro Apex One XG

Administrators can be notified when certain security risks are detected by Trend Micro Apex One XG. Configure the device to send notifications through SNMP Trap.

### Procedure

1. Click **Administration > Notifications > Administrator**.
2. Click the **Criteria** tab.
3. Select the following options for notification:
  - Virus/Malware Detection

- Spyware/Grayware Detection
  - C&C Callbacks
4. Optional: To enable notifications, configure the **SNMP Trap** tab.
  5. Select the **Enable notification via SNMP Trap** check box.
  6. Type the following message in the field:  
 Virus/Malware: %v Spyware/Grayware: %T Computer: %s IP address: %i Domain: %m File: %p Date/Time: %y Result: %a User name: %n  
 Spyware/Grayware: %v Endpoint: %s Domain: %m Date/Time: %y Result: %a  
 Compromised Host: %CLIENTCOMPUTER% IP Address: %IP% Domain: %DOMAIN% Date/Time: %DATETIME% Callback address: %CALLBACKADDRESS% C&C risk level: %CNCRISKLEVEL% C&C list source: %CNCLISTSOURCE% Action: %ACTION%
  7. Click **Save**.

## What to do next

You must now configure Outbreak Notifications.

## Configuring Outbreak Notifications in Trend Micro Apex One XG

You can configure your Trend Micro Apex One XG device to notify you of security risk outbreaks. Define an outbreak by the number of detections and the detection period.

### Procedure

1. Click **Administration > Notifications > Outbreak**.
2. Click the **Criteria** tab.
3. Type the number of detections and detection period for each security risk.  
**Note:** Notification messages are sent to an administrator when the criteria exceeds the specified detection limit.  
**Tip:** Trend Micro suggests that you use the default values for the detection number and detection period.
4. To enable notifications, click the **SNMP Trap** tab, and select the **Enable notification via SNMP Trap** check box.
5. Type the following message in the field:  
 Number of virus/malware: %CV Number of computers: %CC  
 Number of spyware/grayware: %CV Number of endpoints: %CC  
 C&C callback detected: Accumulated log count: %C in the last %T hour(s)
6. Click **Save**.

## What to do next

Configure a log source in QRadar by using the SNMPv2 protocol. For more information, see [“SNMPv2 log source parameters for Trend Micro Apex One” on page 1586](#).

## Changing the date format in QRadar to match the date format for your Trend Micro Apex One device

If your Trend Micro Apex One device uses the dd/MM/yyyy date format, you can enable this date format in IBM QRadar by using the DSM Editor.

By default, the Trend Micro Apex One DSM uses the dd/MM/yyyy date format.

## Procedure

1. On the **Admin** tab, in the **Data Sources** section, click **DSM Editor**.
2. From the **Select Log Source Type** window, select **Trend Micro Office Scan** from the log source type list.
3. Click the **Configuration** tab, and then set **Display DSM Parameters Configuration** to on.
4. From the **Event Collector** list, select the event collector for the log source.
5. Set Use dd/MM/yyyy date format to on.
6. Click **Save**.

## What to do next

Configure a log source in QRadar by using the SNMPv2 protocol. For more information, see [SNMPv2 logsource parameters for Trend Micro Apex One](#).

## SNMPv2 log source parameters for Trend Micro Apex One

If QRadar does not automatically detect the log source, add a Trend Micro Apex One log source on the QRadar Console by using the SNMPv2 protocol.

When using the SNMPv2 protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect SNMPv2 events from Trend Micro Apex One:

Table 1018. SNMPv2 log source parameters for the Trend Micro Apex One DSM	
Parameter	Value
<b>Log Source type</b>	<b>Trend Micro Office Scan</b>
<b>Log Source Description</b>	A description for the log source.
<b>Protocol Configuration</b>	SNMPv2
<b>Log Source Identifier</b>	The IP address or host name for the log source can be used as an identifier for events from your Trend Micro Apex One appliance.
<b>Community</b>	The SNMP community name that is required to access the system that contains SNMP events. The default is Public.
<b>Include OIDs in Event Payload</b>	If selected, clear the <b>Include OIDs in Event Payload</b> check box.  This option allows the SNMP event payload to be constructed by using name-value pairs instead of the standard event payload format. Including OIDs in the event payload is required for processing SNMPv2 or SNMPv3 events from certain DSMs.

For a complete list of SNMPv2 protocol parameters and their values, see [SNMPv2 protocol configuration options](#).

## Related tasks

[Adding a log source](#)

## Trend Micro Control Manager

---

You can integrate a Trend Micro Control Manager device with IBM QRadar.

Trend Micro Control Manager accepts events using SNMPv1, SNMPv2 and SNMPv3. Before you configure QRadar to integrate with a Trend Micro Control Manager device, you must configure a log source, then configure SNMP trap settings for your Trend Micro Control Manager.

### SNMPv1 log source parameters for Trend Micro Control Manager

If QRadar does not automatically detect the log source, add a log source on the QRadar Console by using the SNMPv1 protocol.

When you use the SNMPv1 protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect SNMPv1 events from Trend Micro Control Manager:

Table 1019. SNMPv1 log source parameters for the Trend Micro Control Manager DSM	
Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	<b>Trend Micro Control Manager</b>
<b>Protocol Configuration</b>	<b>SNMPv1</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Trend Micro Control Manager appliance.
<b>Community</b>	Type the SNMP community name required to access the system containing SNMP events. The default is Public.
<b>Include OIDs in Event Payload</b>	Clear the <b>Include OIDs in Event Payload</b> check box, if selected.  This option allows the SNMP event payload to be constructed using name-value pairs instead of the standard event payload format. Including OIDs in the event payload is required for processing SNMPv2 or SNMPv3 events from certain DSMs.

### SNMPv2 log source parameters for Trend Micro Control Manager

If QRadar does not automatically detect the log source, add a Trend Micro Control Manager log source on the QRadar Console by using the SNMPv2 protocol.

When you use the SNMPv2 protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect SNMPv2 events from Trend Micro Control Manager:

*Table 1020. SNMPv2 log source parameters for the Trend Micro Control Manager DSM*

Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	<b>Trend Micro Control Manager</b>
<b>Protocol Configuration</b>	<b>SNMPv2</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Trend Micro Control Manager appliance.
<b>Community</b>	Type the SNMP community name required to access the system containing SNMP events. The default is Public.
<b>Include OIDs in Event Payload</b>	<p>Clear the <b>Include OIDs in Event Payload</b> check box, if selected.</p> <p>This option allows the SNMP event payload to be constructed using name-value pairs instead of the standard event payload format. Including OIDs in the event payload is required for processing SNMPv2 or SNMPv3 events from certain DSMs.</p>

[“Adding a log source” on page 5](#)

## SNMPv3 log source parameters for Trend Micro Control Manager

If QRadar does not automatically detect the log source, add a Trend Micro Control Manager log source on the QRadar Console by using the SNMPv3 protocol.

When you use the SNMPv3 protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect SNMPv3 events from Trend Micro Control Manager:

*Table 1021. SNMPv3 log source parameters for the Trend Micro Control Manager DSM*

Parameter	Value
<b>Log Source Name</b>	Type a name for your log source.
<b>Log Source Description</b>	Type a description for the log source.
<b>Log Source Type</b>	<b>Trend Micro Control Manager</b>
<b>Protocol Configuration</b>	<b>SNMPv3</b>
<b>Log Source Identifier</b>	Type a unique name for the log source.

For more information about SNMPv3 log source parameters, see [SNMPv3 protocol configuration options](#).

**Related tasks**

[“Adding a log source” on page 5](#)

## Configuring SNMP traps

You can configure SNMP traps for Trend Micro Control Manager. Versions v5.5 and v6.0 are supported.

### Procedure

1. Log in to the Trend Micro Control Manager device.
2. Choose one of the following options based on the Trend Micro Control Manager version you're using:
  - a) For v5.5, select **Administration > Settings > Event Center Settings**.

**Note:** Trend Micro Control Manager v5.5 requires hotfix 1697 or hotfix 1713 after Service Pack 1 Patch 1 to provide correctly formatted SNMPv2c events. For more information, see your vendor documentation.

  - b) For v6.0 and v7.0, select **Administration > Event Center > General Event Settings**.
3. Set the SNMP trap notifications: In the **SNMP Trap Settings** field, type the Community Name.
4. Type the IBM QRadar server IP address.
5. Click **Save**.

You are now ready to configure events in the Event Center.

6. Choose one of the following options based on the Trend Micro Control Manager version you're using:
  - a) For v5.5, select **Administration > Event Center**.
  - b) For v6.0, select **Administration > Event Center > Event Notifications**.
7. From the **Event Category** list, expand **Alert**.
8. Click **Recipients** for an alert.
9. In **Notification methods**, select the **SNMP Trap Notification** check box.
10. Click **Save**.

The **Edit Recipients Result** window is displayed.

11. Click **OK**.
12. Repeat “[Configuring SNMP traps](#)” on page 1589 for every alert that requires an SNMP Trap Notification.

The configuration is complete. Events from Trend Micro Control Manager are displayed on the **Log Activity** tab of QRadar. For more information about Trend Micro Control Manager, see your vendor documentation.

## Trend Micro Deep Discovery Analyzer

The IBM QRadar DSM for Trend Micro Deep Discovery Analyzer collects event logs from your Trend Micro Deep Discovery Analyzer console.

The following table identifies the specifications for the Trend Micro Deep Discovery Analyzer DSM:

Table 1022. Trend Micro Deep Discovery Analyzer DSM specifications	
Specification	Value
Manufacturer	Trend Micro
DSM name	Trend Micro Deep Discovery Analyzer
RPM file name	DSM-TrendMicroDeepDiscoveryAnalyzer-QRadar_version-build_number.noarch.rpm
Supported versions	5.0, 5.5, 5.8 and 6.0
Event format	LEEF
QRadar recorded event types	All events

*Table 1022. Trend Micro Deep Discovery Analyzer DSM specifications (continued)*

Specification	Value
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	Trend Micro website ( <a href="http://www.trendmicro.com/en_us/business/products/network/advanced-threat-protection/analyzer.html">http://www.trendmicro.com/en_us/business/products/network/advanced-threat-protection/analyzer.html</a> )

To send Trend Micro Deep Discovery Analyzer events to QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent versions of the following RPMs from the [IBM Support Website](#).
  - DSMCommon RPM
  - Trend Micro Deep Discovery Analyzer DSM
2. Configure your Trend Micro Deep Discovery Analyzer device to communicate with QRadar.
3. If QRadar does not automatically detect Trend Micro Deep Discovery Analyzer as a log source, create a Trend Micro Deep Discovery Analyzer log source on the QRadar Console. Configure all required parameters and use the following table to determine specific values that are required for Trend Micro Deep Discovery Analyzer event collection:

*Table 1023. Trend Micro Deep Discovery Analyzer log source parameters*

Parameter	Value
Log Source type	Trend Micro Deep Discovery Analyzer
Protocol Configuration	Syslog

#### Related tasks

## Configuring your Trend Micro Deep Discovery Analyzer instance for communication with QRadar

To collect Trend Micro Deep Discovery Analyzer events, configure your third-party instance to enable logging.

### Procedure

1. Log in to the Deep Discovery Analyzer web console.
2. To configure Deep Discovery Analyzer V5.0, follow these steps:
  - a) Click **Administration > Log Settings**.
  - b) Select **Forward logs to a syslog server**.
  - c) Select **LIEEEF** as the log format.
  - d) Select the protocol that you want to use to forward the events.

- e) In the **Syslog server** field, type the host name or IP address of your QRadar Console or Event Collector.
  - f) In the **Port** field, type 514.
3. To configure Deep Discovery Analyzer V5.5, follow these steps:
- a) Click **Administration > Log Settings**.
  - b) Select **Send logs to a syslog server**.
  - c) In the **Server** field, type the host name or IP address of your QRadar Console or Event Collector.
  - d) In the **Port** field, type 514.
  - e) Select the protocol that you want to use to forward the events.
  - f) Select **LEEF** as the log format.
4. To configure Deep Discovery Analyzer V5.8 or V6.0, follow these steps:
- a) Click **Administration > Integrated Products/Services > Log Settings**.
  - b) Select **Send logs to a syslog server**.
  - c) In the **Server address** field, type the host name or IP address of your QRadar console or Event Collector.
  - d) In the **Port** field, type the port number.
- Note:** Trend Micro suggests that you use the following default syslog ports: UDP: 514; TCP: 601; and SSL: 443.
- e) Select the protocol that you want to use to forward the events; UDP/TCP/SSL.
  - f) Select **LEEF** as the log format.
  - g) Select the **Scope** of logs to send to the syslog server.
  - h) Optional: Select the **Extensions** check box if you want to exclude any logs from sending data to the syslog server.
5. Click **Save**.

## Trend Micro Deep Discovery Director

---

The IBM QRadar DSM for Trend Micro Deep Discovery Director collects LEEF formatted events from a Trend Micro Deep Discovery Director device.

To integrate Trend Micro Deep Discovery Director with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - Trend Micro Deep Discovery Inspector DSM RPM
  - Trend Micro Deep Discovery Director DSM RPM
2. Configure your Trend Micro Deep Discovery Director device to send events to QRadar.
3. If QRadar does not automatically detect the log source, add a Trend Micro Deep Discovery Director log source on the QRadar Console. The following table describes the parameters that require specific values to collect Syslog events from Trend Micro Deep Discovery Director:

*Table 1024. Trend Micro Deep Discovery Director Syslog log source parameters*

Parameter	Value
<b>Log Source type</b>	Trend Micro Deep Discovery Director
<b>Protocol Configuration</b>	Syslog

Table 1024. Trend Micro Deep Discovery Director Syslog log source parameters (continued)

Parameter	Value
<b>Log Source Identifier</b>	The IPv4 address or host name that identifies the log source. If your network contains multiple devices that are attached to a single management console, specify the IP address of the individual device that created the event. A unique identifier, such as an IP address, prevents event searches from identifying the management console as the source for all of the events.

## Trend Micro Deep Discovery Director DSM specifications

The following table describes the specifications for the Trend Micro Deep Discovery Director DSM.

Table 1025. Trend Micro Deep Discovery Director DSM specifications

Specification	Value
Manufacturer	Trend Micro
DSM name	Trend Micro Deep Discovery Director
RPM file name	DSM-TrendMicroDeepDiscoveryDirector-QRadar_version-build_number.noarch.rpm
Supported versions	3.0
Protocol	Syslog
Event format	LEEF
Recorded event types	Trend Micro Deep Discovery Inspector Events
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="#">Trend Micro Deep Discovery Director product information (http://docs.trendmicro.com/en-us/enterprise/deep-discovery-director.aspx)</a>

## Configuring Trend Micro Deep Discovery Director to communicate with QRadar

To collect events from Trend Micro Deep Discovery Director, configure your Trend Micro Deep Discovery Director device to forward syslog events to QRadar.

### Procedure

1. Log in to your Trend Micro Deep Discovery Director device.
2. Click **Administration > Integrated Products/Services > Syslog**.
3. Click **Add**, and then select **Enabled**.
4. Configure the parameters in the following table.

Parameter	Description
Profile name	The name for the Deep Discovery Director syslog server.
Server address	The IP address of your QRadar Console or Event Collector.
Port	<ul style="list-style-type: none"> <li>SSL/TLS - 6514 (default port)</li> <li>TCP - 601</li> <li>UDP - 514</li> </ul>
Protocol	<ul style="list-style-type: none"> <li>SSL/TLS</li> <li>TCP</li> <li>UDP</li> </ul>
Log format	LEEF
Scope	The events that you want to forward to QRadar.

5. Click **Save**.

## Trend Micro Deep Discovery Director sample event messages

Use these sample event messages as a way of verifying a successful integration with QRadar.

The following table provides sample event messages when you use the Syslog protocol for the Trend Micro Deep Discovery Director DSM:

Table 1026. Trend Micro Deep Discovery Director sample message supported by Trend Micro Deep Discovery Director.

## Trend Micro Deep Discovery Email Inspector

The IBM QRadar DSM for Trend Micro Deep Discovery Email Inspector collects events from a Trend Micro Deep Discovery Email Inspector device.

The following table describes the specifications for the Trend Micro Deep Discovery Email Inspector DSM:

*Table 1027. Trend Micro Deep Discovery Email Inspector DSM specifications*

<b>Specification</b>	<b>Value</b>
Manufacturer	Trend Micro

*Table 1027. Trend Micro Deep Discovery Email Inspector DSM specifications (continued)*

Specification	Value
DSM name	Trend Micro Deep Discovery Email Inspector
RPM file name	DSM-TrendMicroDeepDiscoveryEmailInspector-Qradar_version-build_number.noarch.rpm
Supported versions	V3.0
Event format	Log Event Extended Format (LEEF)
Recorded event types	Detections Virtual analyzer analysis logs System events Alert events
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://www.trendmicro.ca">Trend Micro website</a> ( <a href="http://www.trendmicro.ca">http://www.trendmicro.ca</a> )

To integrate Trend Micro Deep Discovery Email Inspector with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Trend Micro Deep Discovery Email Inspector DSM RPM
  - DSM Common RPM
2. Configure your Trend Micro Deep Discovery Email Inspector device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a Trend Micro Deep Discovery Email Inspector log source on the QRadar Console. The following table describes the parameters that require specific values for Trend Micro Deep Discovery Email Inspector event collection:

*Table 1028. Trend Micro Deep Discovery Email Inspector log source parameters*

Parameter	Description
Log Source type	Trend Micro Deep Discovery Email Inspector
Protocol Configuration	Syslog

#### Related tasks

## Configuring Trend Micro Deep Discovery Email Inspector to communicate with QRadar

To collect events from Trend Micro Deep Discovery Email Inspector, configure a syslog server profile for the IBM QRadar host.

#### Procedure

1. Log in to the Trend Micro Deep Discovery Email Inspector user interface.

2. Click **Administration > Log Settings**.
3. Click **Add**.
4. Verify that **Enabled** is selected for **Status**. The default is **Enabled**.
5. Configure the following parameters:

Parameter	Description
<b>Profile name</b>	Specify a name for the profile.
<b>Syslog server</b>	The host name or IP of the QRadar server.
<b>Port</b>	514
<b>Log format</b>	LEEF

6. Select **Detections**, **Virtual Analyzer Analysis logs**, and **System events** for the types of events to send to QRadar.

## Trend Micro Deep Discovery Inspector

The IBM QRadar DSM for Trend Micro Deep Discovery Inspector can receive event logs from your Trend Micro Deep Discovery Inspector console.

The following table identifies the specifications for the Trend Micro Deep Discovery Inspector DSM:

<i>Table 1029. Trend Micro Deep Discovery Inspector DSM specifications</i>	
<b>Specification</b>	<b>Value</b>
Manufacturer	Trend Micro
DSM name	Trend Micro Deep Discovery Inspector
RPM file name	DSM-TrendMicroDeepDiscovery-QRadar_version-build_number.noarch.rpm
Supported versions	V3.0 to V3.8, V5.0 and V5.1
Event format	LEEF
QRadar recorded event types	Malicious content Malicious behavior Suspicious behavior Exploit Grayware Web reputation Disruptive application Sandbox Correlation System Update
Automatically discovered?	Yes
Included identity?	No
Includes custom properties?	No

*Table 1029. Trend Micro Deep Discovery Inspector DSM specifications (continued)*

Specification	Value
More information	Trend Micro website ( <a href="https://www.trendmicro.com/en_us/business/products/network/advanced-threat-protection/inspector.html">https://www.trendmicro.com/en_us/business/products/network/advanced-threat-protection/inspector.html</a> )

To send Trend Micro Deep Discovery Inspector events to QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent versions of the following RPMs from the [IBM Support Website](#):
  - DSMCommon RPM
  - Trend Micro Deep Discovery Inspector DSM
2. Configure your Trend Micro Deep Discovery Inspector device to send events to QRadar.
3. If QRadar does not automatically detect Trend Micro Deep Discovery Inspector as a log source, create a Trend Micro Deep Discovery Inspector log source on the QRadar Console. The following table shows the protocol-specific values for Trend Micro Deep Discovery Inspector event collection:

*Table 1030. Trend Micro Deep Discovery Inspector log source parameters*

Parameter	Value
Log Source type	Trend Micro Deep Discovery Inspector
Protocol Configuration	Syslog

#### Related tasks

## Configuring Trend Micro Deep Discovery Inspector V3.0 to send events to QRadar

To collect Trend Micro Deep Discovery Inspector events, configure the device to send events to IBM QRadar.

#### Procedure

1. Log in to Trend Micro Deep Discovery Inspector.
2. From the navigation menu, select **Logs > Syslog Server Settings**.
3. Select **Enable Syslog Server**.
4. Configure the following parameters:

Parameter	Description
<b>IP address</b>	The IP address of your QRadar Console or Event Collector.
<b>Port</b>	514
<b>Syslog facility</b>	The local facility, for example, <b>local 3</b> .
<b>Syslog severity</b>	The minimum severity level that you want to include.
<b>Syslog format</b>	LEEF

5. In the **Detections** pane, select the check boxes for the events that you want to forward to QRadar.

6. Click **Save**.

## Configuring Trend Micro Deep Discovery Inspector V3.8, V5.0 and V5.1 to send events to QRadar

To collect Trend Micro Deep Discovery Inspector events, configure the device to send events to IBM QRadar.

### Procedure

1. Log in to Trend Micro Deep Discovery Inspector.
2. Click **Administration > Integrated Products/Services > Syslog**.
3. Click **Add**, and then select **Enable Syslog Server**.
4. Configure the following parameters:

Parameter	Description
<b>Server Name or IP address</b>	The IP address of your QRadar Console or Event Collector.
<b>Port</b>	514
<b>Protocol</b>	TCP
<b>Facility level</b>	Select a facility level that specifies the source of a message.
<b>Severity level</b>	Select a severity level of the type of messages to be sent to the syslog server.
<b>Log format</b>	LEEF

5. In the **Detections** pane, select the check boxes for the events that you want to forward to QRadar.
6. If you need proxy servers for your connections, select **Connect through a proxy server**. The device uses the settings that are configured in the **Administrator > System Settings > Proxy** screen.

**Note:** If you require the use of proxy servers for intranet connections, select this option.

7. Click **Save**.

## Trend Micro Deep Security

The IBM QRadar DSM for Trend Micro Deep Security can collect logs from your Trend Micro Deep Security server.

The following table identifies the specifications for the Trend Micro Deep Security DSM:

Table 1031. Trend Micro Deep Security DSM specifications	
Specification	Value
Manufacturer	Trend Micro
DSM name	Trend Micro Deep Security
RPM file name	DSM-TrendMicroDeepSecurity-Qradar_version-build_number.noarch.rpm
Supported versions	V9.6.1532 to V12.0
Event format	Log Event Extended Format

*Table 1031. Trend Micro Deep Security DSM specifications (continued)*

Specification	Value
Recorded event types	Anti-Malware Deep Security Firewall Integrity Monitor Intrusion Prevention Log Inspection System Web Reputation
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.trendmicro.com/us/">Trend Micro website (https://www.trendmicro.com/us/)</a>

To integrate Trend Micro Deep Security with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Trend Micro Deep Security DSM RPM
  - DSMCommon RPM
2. Configure your Trend Micro Deep Security device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a Trend Micro Deep Security DSM log source on the QRadar Console. The following table describes the parameters that require specific values for Trend Micro Deep Security DSM event collection:

*Table 1032. Trend Micro Deep Security DSM log source parameters*

Parameter	Value
Log Source type	Trend Micro Deep Security
Protocol Configuration	Syslog

#### Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

## Configuring Trend Micro Deep Security to communicate with QRadar

To collect all events from Trend Micro Deep Security, you must specify IBM QRadar as the Syslog server and configure the Syslog format on your Trend Micro Deep Security device.

### Before you begin

Ensure that Deep Security Manager is installed and configured on your Trend Micro Deep Security Device.

## Procedure

1. Click **Administration > System Settings > SIEM**.
2. From the **System Event Notification** pane in the Manager section, enable the **Forward System Events to remote computer (via Syslog)** option.
3. Type the host name or the IP address of the QRadar system.
4. Type **514** for the UDP port.
5. Select the **Syslog Facility** that you want to use.
6. Select **LEEF** for the **Syslog Format**.

**Note:** Trend Micro Deep Security sends events only in LEEF format from the Deep Security Manager. If you select the **Direct forward** option on the **SIEM** tab, you can't select **Log Event Extended Format 2.0** for the **Syslog Format**.

## Trend Micro Deep Security sample event message

Use this sample event message to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage returns or line feed characters.

## Trend Micro Deep Security sample message when you use the Syslog protocol

The following sample event message shows an attempt to scan a computer, or that a network was detected.

```
<182>Jul 14 01:32:31 trendmicro.deepsecurity.test LEEF:2.0|Trend Micro|Deep Security Manager|11.0.221|851|cat=System name=Reconnaissance Detected: Network or Port Scan desc=The Agent/Appliance detected an attempt to scan a computer or a network. Check the Agent/Appliance Events to see the details of the scan. sev=6 src=192.168.187.196 usrName=qradar target=testTarget6 msg=The Agent/Appliance detected an attempt to scan a computer or a network. Check the Agent/Appliance Events to see the details of the scan. TrendMicroDsTenant=Primary TrendMicroDsTenantId=0
```

```
<182>Jul 14 01:32:31 trendmicro.deepsecurity.test LEEF:2.0|Trend Micro|Deep Security Manager|11.0.221|851|cat=System name=Reconnaissance Detected: Network or Port Scan desc=The Agent/Appliance detected an attempt to scan a computer or a network. ```

---

# Chapter 162. Tripwire

The Tripwire DSM accepts resource additions, removal, and modification events by using syslog.

## Procedure

1. Log in to the Tripwire interface.
2. On the left navigation, click **Actions**.
3. Click **New Action**.
4. Configure the new action.
5. Select **Rules** and click the rule that you want to monitor.
6. Select the **Actions** tab.
7. Make sure that the new action is selected.
8. Click **OK**.
9. Repeat Chapter 162, “Tripwire,” on page 1601 to Chapter 162, “Tripwire,” on page 1601 for each rule you want to monitor.

You are now ready to configure the log source in QRadar.

10. To configure QRadar to receive events from a Tripwire device: From the **Log Source Type** list, select the **Tripwire Enterprise** option.

For more information about your Tripwire device, see your vendor documentation.

## Related tasks

- “Adding a DSM” on page 4
- “Adding a log source” on page 5

---

# Chapter 163. Tropos Control

The Tropos Control DSM for IBM QRadar accepts events by using syslog.

## About this task

QRadar can record all fault management, login and logout events, provisioning events, and device image upload events. Before you configure QRadar, you must configure your Tropos Control to forward syslog events.

You can configure Tropos Control to forward logs by using syslog to QRadar.

## Procedure

1. Use an SSH to log in to your Tropos Control device as a root user.
2. Open the following file for editing:

```
/opt/ControlServer/ems/conf/logging.properties
```

3. To enable syslog, remove the comment marker (#) from the following line:

```
#log4j.category.syslog = INFO, syslog
```

4. To configure the IP address for the syslog destination, edit the following line:

```
log4j.appenders.syslog.SyslogHost = <IP address>
```

Where *<IP address>* is the IP address or host name of QRadar.

By default, Tropos Control uses a facility of **USER** and a default log level of **INFO**. These default settings are correct for syslog event collection from a Tropos Control device.

5. Save and exit the file.
6. You are now ready to configure the Tropos Control DSM in QRadar.

To configure QRadar to receive events from Tropos Control:

- a) From the **Log Source Type** list, select **Tropos Control**.

## Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

# Chapter 164. Universal CEF

The IBM QRadar DSM for Universal CEF accepts events from any device that produces events in the Common Event Format (CEF).

The following table identifies the specifications for the Universal CEF DSM:

Table 1033. Universal CEF DSM specifications	
Specification	Value
DSM name	Universal CEF
RPM file name	DSM-UniversalCEF-Qradar_version-build_number.noarch.rpm
Protocol	Syslog Log File
Event Format	Common Event Format (CEF). CEF:0 is supported.
Recorded event types	CEF-formatted events
Automatically discovered?	No
Includes identity?	No
Includes custom properties?	No

To send events from a device that generates CEF-formatted events to QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - DSMCommon RPM
  - Universal CEF RPM
2. Add a Universal CEF log source on the QRadar Console. Use the following values that are specific to Universal CEF:

Parameter	Description
Log Source Type	Universal CEF
Protocol Configuration	Syslog or Log File

3. Configure your third-party device to send events to QRadar. For more information about how to configure your third-party device, see your vendor documentation.
4. Configure event mapping for Universal CEF events.

## Configuring event mapping for Universal CEF events

Universal CEF events do not contain a predefined QRadar Identifier (QID) map to categorize security events. You must search for unknown events from the Universal CEF log source and map them to high and low-level categories.

### Before you begin

Ensure that you installed the Universal CEF DSM and added log source for it in QRadar.

## About this task

By default, the Universal CEF DSM categorizes all events as unknown. All Universal CEF events display a value of **unknown** in the **Event Name** and **Low Level Category** columns on the **Log Activity** tab. You must modify the QID map to individually map each event for your device to an event category in QRadar. Mapping events allows QRadar to identify, coalesce, and track events from your network devices.

For more information about event mapping, see the *IBM QRadar User Guide*.

## Procedure

1. Log in to QRadar.
2. Click the **Log Activity** tab.
3. Click **Add Filter**.
4. From the first list, select **Log Source**.
5. From the **Log Source Group** list, select **Other**.
6. From the **Log Source** list, select your Universal CEF log source.
7. Click **Add Filter**.
8. From the **View** list, select **Last Hour**.
9. Optional: Click **Save Criteria** to save your existing search filter.
10. On the **Event Name** column, double-click an unknown event for your Universal CEF DSM.
11. Click **Map Event**.
12. From the Browse for QID pane, select any of the following search options to narrow the event categories for a QRadar Identifier (QID):
  - From the **High-Level Category** list, select a high-level event category. For a full list of high-level and low-level event categories or category definitions, see the Event Categories section of the *IBM QRadar Administration Guide*.
  - From the **Low-Level Category** list, select a low-level event category.
  - From the **Log Source Type** list, select a log source type.
- Tip: Searching for QIDs by log source is useful when the events from your Universal CEF DSM are similar to another existing network device. For example, if your Universal CEF provides firewall events, you might select Cisco ASA, as another firewall product that likely captures similar events.
13. Click **Search**.
14. Select the QID that you want to associate to your unknown Universal CEF DSM event and click **OK**.

# Chapter 165. Universal LEEF

The Universal LEEF DSM for IBM QRadar collects events from devices that produce events that use the Log Event Extended Format (LEEF).

The LEEF event format is a proprietary event format, which allows hardware manufacturers and software product manufacturers to read and map device events specifically designed for QRadar integration.

LEEF formatted events sent to QRadar outside of the partnership program require you to have installed the Universal LEEF DSM and manually identify each event forwarded to QRadar by mapping unknown events. The Universal LEEF DSM can parse events forwarded from syslog or files containing events in the LEEF format polled from a device or directory using the Log File protocol.

To configure events in QRadar using Universal LEEF, you must:

1. Configure a Universal LEEF log source in QRadar.
2. Send LEEF formatted events from your device to QRadar. For more information on forwarding events, see your vendor documentation.
3. Map unknown events to QRadar Identifiers (QIDs).

## Syslog protocol log source parameters for Universal LEEF

Add a Universal LEEF log source on the QRadar Console by using the Syslog protocol.

QRadar receives events from a real-time source by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Universal LEEF:

Table 1034. Syslog log source parameters for the Universal LEEF DSM	
Parameter	Value
<b>Log Source type</b>	Universal LEEF
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or hostname for the log source as an identifier for Universal LEEF events.

### Related tasks

[Adding a log source](#)

## Forwarding events to IBM QRadar

After you create your log source, you can forward or retrieve events for QRadar. Forwarding events by using syslog might require more configuration of your network device.

As events are discovered by QRadar, either using syslog or polling for log files, events are displayed in the **Log Activity** tab. Events from the devices that forward LEEF events are identified by the name that you type in the **Log Source Name** field. The events for your log source are not categorized by default in QRadar and they require categorization. For more information on categorizing your Universal LEEF events, see “[Universal LEEF event map creation](#)” on page 1608.

## Universal LEEF event map creation

---

Event mapping is required for the Universal LEEF DSM, because Universal LEEF events do not contain a predefined QRadar Identifier (QID) map to categorize security events.

Members of the SIPP Partner Program have QID maps designed for their network devices, whereby the configuration is documented, and the QID maps are tested by IBM Corp.

The Universal LEEF DSM requires that you individually map each event for your device to an event category in IBM QRadar. Mapping events allows QRadar to identify, coalesce, and track events that recur from your network devices. Until you map an event, all events that are displayed in the **Log Activity** tab for the Universal LEEF DSM are categorized as unknown. Unknown events are easily identified as the **Event Name** column and **Low-Level Category** columns display *Unknown*.

## Discovering unknown events

As your device forwards events to IBM QRadar, it can take time to categorize all of the events from a device, because some events might not be generated immediately by the event source appliance or software.

### About this task

It is helpful to know how to quickly search for unknown events. When you know how to search for unknown events, you can repeat this search until you are happy that most of your Universal LEEF events are identified.

### Procedure

1. Log in to QRadar.
2. Click the **Log Activity** tab.
3. Click **Add Filter**.
4. From the first list, select **Log Source**.
5. From the **Log Source Group** list, select the log source group or **Other**.

Log sources that are not assigned to a group are categorized as Other.

6. From the **Log Source** list, select your Universal LEEF log source.
7. Click **Add Filter**.

The **Log Activity** tab is displayed with a filter for your Universal LEEF DSM.

8. From the **View** list, select **Last Hour**.

Any events that are generated by your Universal LEEF DSM in the last hour are displayed. Events that are displayed as *unknown* in the **Event Name** column or **Low Level Category** column require event mapping in QRadar.

**Note:** You can save your existing search filter by clicking **Save Criteria**.

You are now ready to modify the event map for your Universal LEEF DSM.

## Modifying an event map

Modifying an event map allows you to manually categorize events to a IBM QRadar Identifier (QID) map.

### About this task

Any event categorized to a log source can be remapped to a new QRadar Identifier (QID). By default, the Universal LEEF DSM categorizes all events as unknown.

**Note:** Events that do not have a defined log source cannot be mapped to an event. Events without a log source display SIM Generic Log in the Log Source column.

## Procedure

1. On the Event Name column, double-click an unknown event for your Universal LEEF DSM.

The detailed event information is displayed.
  2. Click **Map Event**.
  3. From the Browse for QID pane, select any of the following search options to narrow the event categories for a QRadar Identifier (QID):
    - a) From the **High-Level Category** list, select a high-level event categorization.

For a full list of high-level and low-level event categories or category definitions, see the Event Categories section of the *IBM QRadar Administration Guide*.
  4. From the **Low-Level Category** list, select a low-level event categorization.
  5. From the **Log Source Type** list, select a log source type.

The **Log Source Type** list allows you to search for QIDs from other individual log sources. Searching for QIDs by log source is useful when the events from your Universal LEEF DSM are similar to another existing network device. For example, if your Universal LEEF DSM provides firewall events, you might select Cisco ASA, as another firewall product that likely captures similar events.
  6. To search for a QID by name, type a name in the **QID/Name** field.

The QID/Name field allows you to filter the full list of QIDs for a specific word, for example, MySQL.
  7. Click **Search**.

A list of QIDs is displayed.
  8. Select the QID you want to associate to your unknown Universal LEEF DSM event.
  9. Click **OK**.
- QRadar maps any additional events forwarded from your device with the same QID that matches the event payload. The event count increases each time the event is identified by QRadar.
- Note:** If you update an event with a new QRadar Identifier (QID) map, past events stored in QRadar are not updated. Only new events are categorized with the new QID.

# Chapter 166. Vectra Networks Vectra

The IBM QRadar DSM for Vectra Networks Vectra collects events from the Vectra Networks Vectra X-Series platform.

**Important:** The IBM QRadar DSM for Vectra Networks Vectra is deprecated.

To continue taking advantage of this integration, please download the Vectra Networks Vectra DSM from the [IBM Security App Exchange](https://exchange.xforce.ibmcloud.com/hub/extension/47f3e9aff5e0281d6684bb633d769f2) website (<https://exchange.xforce.ibmcloud.com/hub/extension/47f3e9aff5e0281d6684bb633d769f2>).

The following table describes the specifications for the Vectra Networks Vectra DSM:

<i>Table 1035. Vectra Networks Vectra DSM specifications</i>	
<b>Specification</b>	<b>Value</b>
Manufacturer	Vectra Networks
DSM name	Vectra Networks Vectra
RPM file name	DSM-VectraNetworksVectra-QRadar_version-build_number.noarch.rpm
Supported versions	2.2
Protocol	Syslog
Event Format	Common Event Format (CEF). CEF:0 is supported.
Recorded event types	Host scoring, command and control, botnet activity, reconnaissance, lateral movement, exfiltration
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="http://www.vectranetworks.com">Vectra Networks Website</a> ( <a href="http://www.vectranetworks.com">http://www.vectranetworks.com</a> )

To integrate Vectra Networks Vectra with QRadar, complete the following steps:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) (onto your QRadar Console in the order that they are listed):
  - DSMCommon RPM
  - Vectra Networks Vectra DSM RPM
2. Configure your Vectra Networks Vectra device to send syslog events to QRadar.
3. If QRadar does not automatically detect the log source, add a Vectra Networks Vectra log source on the QRadar Console. The following table describes the parameters that require specific values for Vectra Networks Vectra event collection:

*Table 1036. Vectra Networks Vectra log source parameters*

<b>Parameter</b>	<b>Value</b>
Log Source type	Vectra Networks Vectra
Protocol Configuration	Syslog
Log Source Identifier	A unique identifier for the log source.

## Related tasks

[“Adding a DSM” on page 4](#)

[“Adding a log source” on page 5](#)

# Configuring Vectra Networks Vectra to communicate with QRadar

To collect Vectra Networks Vectra events, configure the QRadar syslog daemon listener.

## Before you begin

**Important:** The IBM QRadar DSM for Vectra Networks Vectra is deprecated.

To continue taking advantage of this integration, please download the Vectra Networks Vectra DSM from the [IBM Security App Exchange website](#) (<https://exchange.xforce.ibmcloud.com/hub/extension/47f3e9aff5e0281d6684bb633d769f2>).

## Procedure

1. Log in to the Vectra web console.
2. Click **settings > Notifications**.
3. In the **Syslog** section, click **Edit**.
4. Configure the following QRadar syslog daemon listener parameters:

Option	Description
<b>Destination</b>	The QRadar Event Collector IP address.
<b>Port</b>	514
<b>Protocol</b>	UDP
<b>Format</b>	CEF

## Vectra Networks Vectra sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** The IBM QRadar DSM for Vectra Networks Vectra is deprecated.

To continue taking advantage of this integration, please download the Vectra Networks Vectra DSM from the [IBM Security App Exchange website](#) (<https://exchange.xforce.ibmcloud.com/hub/extension/47f3e9aff5e0281d6684bb633d769f2>).

**Tip:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

## Vectra Networks Vectra sample messages when you use the Syslog protocol

**Sample 1:** The following sample event message shows when samba is exploited.

```

# Chapter 167. Venustech Venusense

The Venustech Venusense DSM for IBM QRadar can collect events from Venusense appliances by using syslog.

QRadar records all relevant unified threat, firewall, or network intrusion prevention events that are forwarded by using syslog on port 514.

The following Venustech appliances are supported by QRadar:

- Venustech Venusense Security Platform
- Venusense Unified Threat Management (UTM)
- Venusense Firewall
- Venusense Network Intrusion Prevention System (NIPS)

## Venusense configuration overview

IBM QRadar can collect events from Venustech appliances that are configured to forward filtered event logs in syslog format to QRadar.

The following process outlines the steps that are required to collect events from a Venusense Venustech appliance:

1. Configure the syslog server on your Venusense appliance.
2. Configure a log filter on your Venusense appliance to forward specific event logs.
3. Configure a log source in QRadar to correspond to the filtered log events.

## Configuring a Venusense syslog server

To forward events to IBM QRadar, you must configure and enable a syslog server on your Venusense appliance with the IP address of your QRadar Console or Event Collector.

### Procedure

1. Log in to the configuration interface for your Venusense appliance.
2. From the navigation menu, select **Logs > Log Configuration > Log Servers**.
3. In the **IP Address** field, type the IP address of your QRadar Console or Event Collector.
4. In the **Port** field, type 514.
5. Select the **Enable** check box.
6. Click **OK**.

### What to do next

You are ready to configure your Venusense appliance to filter which events are forwarded to QRadar.

## Configuring Venusense event filtering

Event filtering determines which events your Venusense appliance forwards to IBM QRadar.

### Procedure

1. From the navigation menu, select **Logs > Log Configuration > Log Filtering**.
2. In the **Syslog Log** column, select a check box for each event log you want to forward to QRadar.
3. From the list, select a syslog facility for the event log you enabled.

4. Repeat “Configuring Venusense event filtering” on page 1615 and “Configuring Venusense event filtering” on page 1615 to configure any additional syslog event filters.
5. Click **OK**.

## What to do next

You can now configure a log source for your Venusense appliance in QRadar. QRadar does not automatically discover or create log sources for syslog events from Venusense appliances.

## Syslog log source parameters for Venustech Venusense

If QRadar does not automatically detect the log source, add a Venustech Venusense log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Venustech Venusense:

Table 1039. Syslog log source parameters for the Venustech Venusense DSM	
Parameter	Value
<b>Log Source type</b>	Select your Venustech Venusense appliance from the list.  The type of log source that you select is determined by the event filter that is configured on your Venusense appliance. The options include the following types: <ul style="list-style-type: none"> <li>• <b>Venustech Venusense Security Platform</b> - Select this option if you enabled all event filter options.</li> <li>• <b>Venustech Venusense UTM</b> - Select this option if you enabled unified filtering events.</li> <li>• <b>Venustech Venusense Firewall</b> - Select this option if you enabled filtering for firewall events.</li> <li>• <b>Venustech Venusense NIPS</b> - Select this option if you enabled filtering for firewall events.</li> </ul>
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	The IP address or hostname for your Venusense appliance. The log source identifier must be a unique value.

# Chapter 168. Verdasys Digital Guardian

The Verdasys Digital Guardian DSM for IBM QRadar accepts and categorizes all alert events from Verdasys Digital Guardian appliances.

Verdasys Digital Guardian is a comprehensive Enterprise Information Protection (EIP) *platform*. Digital Guardian serves as a cornerstone of policy driven, data-centric security by enabling organizations to solve the information risk challenges that exist in today's highly collaborative and mobile business environment. Digital Guardian's endpoint agent architecture makes it possible to implement a data-centric security framework.

Verdasys Digital Guardian allows business and IT managers to:

- Discover and classify sensitive data by context and content.
- Monitor data access and usage by user or process.
- Implement policy driven information protection automatically.
- Alert, block, and record high risk behavior to prevent costly and damaging data loss incidents.

Digital Guardian's integration with QRadar provides context from the endpoint and enables a new level of detection and mitigation for Insider Threat and Cyber Threat (Advanced Persistent Threat).

Digital Guardian provides QRadar with a rich data stream from the end-point that includes: visibility of every data access by users or processes that include the file name, file classification, application that is used to access the data and other contextual variables.

The following table describes the specifications for the Verdasys Digital Guardian DSM:

Specification	Value
Manufacturer	Verdasys Digital Guardian
DSM name	<b>Verdasys Digital Guardian</b>
RPM file name	DSM-VerdasysDigitalGuardian-QRadar_version-Build_number.noarch.rpm
Supported versions	V6.1.x and V7.2.1.0248 with the QRadar LEEF format V6.0x with the Syslog event format
Protocol	Syslog, LEEF
Event format	Syslog
Recorded event types	All events
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://digitalguardian.com">Digital Guardian website</a> ( <a href="https://digitalguardian.com">https://digitalguardian.com</a> )

# Configuring IPTables

Before you configure your Verdasys Digital Guardian to forward events, you must configure IPTables in IBM QRadar to allow ICMP requests from Verdasys Digital Guardian.

## Procedure

1. Use an SSH to log in to QRadar as the root user.

Login: root

Password: <password>

2. Type the following command to edit the IPTables file:

```
vi /opt/qradar/conf/iptables.post
```

The IPTables configuration file is displayed.

3. Type the following commands to allow QRadar to accept ICMP requests from Verdasys Digital Guardian:

```
-I QChain 1 -m icmp -p icmp --icmp-type 8 --src <IP address> -j ACCEPT  
-I QChain 1 -m icmp -p icmp --icmp-type 0 --src <IP address> -j ACCEPT
```

Where <IP address> is the IP address of your Verdasys Digital Guardian appliance. For example,

```
-I QChain 1 -m icmp -p icmp --icmp-type 8 --src <Source_IP_address> -j ACCEPT  
-I QChain 1 -m icmp -p icmp --icmp-type 0 --src <Source_IP_address> -j ACCEPT
```

**Note:** Make sure that you specify "--icmp-type" in the commands to avoid failures when you're upgrading the IPTables.

4. Save your IPTables configuration.

5. Type the following command to update IPTables in QRadar:

```
/opt/qradar/bin/iptables_update.pl
```

6. To verify that QRadar accepts ICMP traffic from your Verdasys Digital Guardian, type the following command:

```
iptables --list --line-numbers
```

The following output is displayed:

Chain QChain (1 references)						
num	target	prot	opt	source	destination	
1	ACCEPT	icmp	--	<IP address>	anywhere	icmp echo-reply
2	ACCEPT	icmp	--	<IP address>	anywhere	icmp echo-request
3	ACCEPT	tcp	--	anywhere	anywhere	state NEW tcp dpt:https
4	ACCEPT	tcp	--	anywhere	anywhere	state NEW tcp dpt:http

The IPTables configuration for QRadar is complete.

# Configuring a data export

---

Data exports give you the option to configure the events Verdasys Digital Guardian forwards to IBM QRadar.

## Procedure

1. Log in to the Digital Guardian Management Console.
2. Select **Workspace > Data Export > Create Export**.
3. From the **Data Sources** list, select **Alerts** or **Events** as the data source.
4. From the **Export type** list, select QRadar **LEEF**.

If your Verdasys Digital Guardian is v6.0.x, you can select **Syslog** as the **Export Type**. QRadar LEEF is the preferred export type format for all Verdasys Digital Guardian appliances with v6.1.1 and later.

5. From the **Type** list, select **UDP** or **TCP** as the transport protocol.

QRadar can accept syslog events from either transport protocol. If the length of your alert events typically exceeds 1024 bytes, then you can select **TCP** to prevent the events from being truncated.

6. In the **Server** field, type the IP address of your QRadar Console or Event Collector.

7. In the **Port** field, type 514.

8. From the **Severity Level** list, select a severity level.

9. Select the **Is Active** check box.

10. Click **Next**.

11. From the list of available fields, add the following Alert or Event fields for your data export:

- **Agent Local Time**
- **Application**
- **Computer Name**
- **Detail File Size**
- **IP Address**
- **Local Port**
- **Operation** (required)
- **Policy**
- **Remote Port**
- **Rule**
- **Severity**
- **Source IP Address**
- **User Name**
- **Was Blocked**
- **Was Classified**

12. Select a Criteria for the fields in your data export and click **Next**.

By default, the Criterion is blank.

13. Select a group for the criteria and click **Next**.

By default, the Group is blank.

14. Click **Test Query**.

A Test Query ensures that the database runs properly.

15. Click **Next**.

16. Save the data export.

The configuration is complete.

## What to do next

The data export from Verdasys Digital Guardian occurs on a 5-minute interval. You can adjust this timing with the job scheduler in Verdasys Digital Guardian, if required. Events that are exported to QRadar by Verdasys Digital Guardian are displayed on the **Log Activity** tab.

## Syslog log source parameters for Verdasys Digital Guardian

---

If QRadar does not automatically detect the log source, add a Verdasys Digital Guardian log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Verdasys Digital Guardian:

Table 1040. Syslog log source parameters for the Verdasys Digital Guardian DSM	
Parameter	Value
<b>Log Source Name</b> (Optional)	Type a name for your log source.
<b>Log Source Description</b> (Optional)	Type a description for the log source.
<b>Log Source type</b>	<b>Verdasys Digital Guardian</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your Verdasys Digital Guardian appliance.

# Chapter 169. Vericept Content 360 DSM

The Vericept Content 360 DSM for IBM QRadar accepts Vericept events by using syslog.

## About this task

QRadar records all relevant and available information from the event. Before you configure a Vericept device in QRadar, you must configure your device to forward syslog. For more information about configuring your Vericept device, consult your vendor documentation.

After you configure syslog to forward events to QRadar, the configuration is complete. The log source is added to QRadar as Vericept Content 360 events are automatically discovered. Events that are forwarded to QRadar by your Vericept Content 360 appliance are displayed on the **Log Activity** tab.

To manually configure a log source for QRadar to receive events from a Vericept device:

## Procedure

From the **Log Source Type** list, select the **Vericept Content 360** option.

# Chapter 170. VMware

IBM QRadar supports a range of VMware products.

## VMware AppDefense

The IBM QRadar DSM for VMware AppDefense collects events from a VMware AppDefense system.

To integrate VMware AppDefense with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the [IBM support website](http://www.ibm.com/support) (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - Protocol-Common RPM
  - VMWare AppDefense API Protocol RPM
  - DSMCommon RPM
  - VMware AppDefense DSM RPM
2. Configure your VMware AppDefense device to send events to QRadar.
3. Add a VMware AppDefense log source that uses the VMWare AppDefense API protocol on the QRadar Console.

#### Related concepts

[VMware AppDefense](#)

The IBM QRadar DSM for VMware AppDefense collects events from a VMware AppDefense system.

## Configuring VMware AppDefense to communicate with QRadar

To send events to QRadar from your VMware AppDefense system, you must create a new API key on your VMware AppDefense system.

#### Before you begin

Ensure that you have access to the Integrations settings in the VMware AppDefense user interface so that you can generate the Endpoint URL and API Key that are required to configure a log source in QRadar. You must have the correct user permissions for the VMware AppDefense user interface to complete the following procedure:

#### Procedure

1. Log in to your VMware AppDefense user interface.
2. From the navigation menu, click the icon to the right of your user name, and then select **Integrations**.
3. Click **PROVISION NEW API KEY**.
4. In the **Integration Name** field, type a name for your integration.
5. Select an integration from the **Integration Type** list.
6. Click **PROVISION**, and then record and save the following information from the message in the window that opens. You need this information when you configure a log source in QRadar:
  - **EndPoint URL**
  - **API Key** - This is the **Authentication Token** parameter value when you configure a log source in QRadar.

**Note:** If you click **OK** or close the window, the information in the message can't be recovered.

[VMware AppDefense](#)

The IBM QRadar DSM for VMware AppDefense collects events from a VMware AppDefense system.

## VMWare AppDefense API log source parameters for VMware AppDefense

If QRadar does not automatically detect the log source, add a VMware AppDefense log source on the QRadar Console by using the VMWare AppDefense API protocol.

When using the VMWare AppDefense API protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect VMWare AppDefense API events from VMware AppDefense:

Table 1042. VMWare AppDefense API log source parameters for the VMware AppDefense DSM

Parameter	Value
<b>Log Source type</b>	<b>VMware AppDefense</b>
<b>Protocol Configuration</b>	<b>VMWare AppDefense API</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for events from your VMware AppDefense devices.
<b>Endpoint URL</b>	The endpoint URL for accessing VMware AppDefense. Example revision: <code>https://server_name.vmwaredrx.com/partnerapi/v1/orgs/&lt;organization ID&gt;</code>
<b>Authentication Token</b>	A single authentication token that is generated by the AppDefense console and must be used for all API transactions.
<b>Use Proxy</b>	If QRadar accesses the VMWare AppDefense API by using a proxy, enable <b>Use Proxy</b> . If the proxy requires authentication, configure the <b>Hostname</b> , <b>Proxy Port</b> , <b>Proxy Username</b> , and <b>Proxy</b> fields. If the proxy does not require authentication, configure the <b>Hostname</b> and <b>Proxy Port</b> fields.
<b>Automatically Acquire Server Certificates</b>	If you choose <b>Yes</b> from the drop down list, QRadar automatically downloads the certificate and begins trusting the target server. If <b>No</b> is selected QRadar does not attempt to retrieve any server certificates.
<b>Recurrence</b>	Beginning at the Start Time, type the frequency for how often you want the remote directory to be scanned. Type this value in hours(H), minutes(M), or days(D). For example, 2H if you want the directory to be scanned every 2 hours. The default is 5M.
<b>Throttle</b>	The maximum number of events per second. The default is 5000.

## VMware Carbon Black App Control (formerly known as Carbon Black Protection)

The IBM QRadar DSM for VMware Carbon Black App Control collects Syslog events from a Carbon Black App Control device.

To integrate Carbon Black App Control with QRadar, complete the following steps:

- If automatic updates are not enabled, download the most recent version of the following RPMs from the IBM support website (<http://www.ibm.com/support>).
  - DSM Common RPM
  - Carbon Black App Control DSM RPM
- Configure your Carbon Black App Control device to send events to QRadar. For more information, see [Configuring VMware Carbon Black App Control to communicate with QRadar](#).
- If QRadar does not automatically detect the log source, add a Carbon Black App Control log source on the QRadar Console. For more information, see [Syslog log source parameters for VMware Carbon Black App Control](#).

### Related tasks

## VMware Carbon Black App Control DSM specifications

When you configure the Carbon Black App Control DSM, understanding the specifications for the Carbon Black App Control DSM can help ensure a successful integration. For example, knowing what the

supported version of Carbon Black App Control is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Carbon Black App Control DSM.

Table 1047. Carbon Black App Control DSM specifications	
Specification	Value
Manufacturer	VMware
DSM name	Carbon Black App Control
RPM file name	DSM-CarbonBlackProtection-QRadar_version-build_number.noarch.rpm
Supported version	8.0.x to 8.5.x
Protocol	Syslog
Event format	LEEF
Recorded event types	computer management, server management, session management, policy management, policy enforcement, internal events, general management, discovery
Automatically discovered?	Yes
Includes identity?	Yes
Includes custom properties?	No
More information	<a href="https://www.carbonblack.com/products/app-control/">VMware Carbon Black App Control (https://www.carbonblack.com/products/app-control/)</a>

## Configuring VMware Carbon Black App Control to communicate with QRadar

Configure your Carbon Black App Control console to forward events to IBM QRadar in LEEF format.

### Procedure

1. Access the Carbon Black App Control console by entering the Carbon Black App Control server URL in your browser.
2. Log in to the Carbon Black App Control console. You must have Administrator or Power® User privileges.
3. From the navigation menu, select **Administration > System Configuration**.
4. On the **System Configuration** page, click the **Events** tab.
5. In the **External Events Logging** section, click **Edit** and then configure the following parameters.
  - a) Type the IP address of the QRadar Event Collector in the **Syslog address** field.
  - b) Type 514 in the **Syslog port** field.
6. From the **Syslog format** list, select **LEEF (Q1Labs)**.
7. Select the **Syslog Enabled** checkbox and then click **Update**.

## Syslog log source parameters for VMware Carbon Black App Control

If QRadar does not automatically detect the log source, add a Carbon Black App Control log source on the QRadar Console by using the Syslog protocol.

When you use the Syslog protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect Syslog events from Carbon Black App Control:

*Table 1048. Syslog log source parameters for the Carbon Black App Control DSM*

Parameter	Value
<b>Log Source type</b>	Carbon Black App Control
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for metric events from your Carbon Black App Control appliances.

## VMware Carbon Black App Control (formerly known as Carbon Black Protection)

The IBM QRadar DSM for VMware Carbon Black App Control collects Syslog events from a Carbon Black App Control device.

To integrate Carbon Black App Control with QRadar, complete the following steps:

- If automatic updates are not enabled, download the most recent version of the following RPMs from the IBM support website (<http://www.ibm.com/support>).
  - DSM Common RPM
  - Carbon Black App Control DSM RPM
- Configure your Carbon Black App Control device to send events to QRadar. For more information, see [Configuring VMware Carbon Black App Control to communicate with QRadar](#).
- If QRadar does not automatically detect the log source, add a Carbon Black App Control log source on the QRadar Console. For more information, see [Syslog log source parameters for VMware Carbon Black App Control](#).

### Related tasks

[“Adding a log source” on page 5](#)

## VMware Carbon Black App Control DSM specifications

When you configure the Carbon Black App Control DSM, understanding the specifications for the Carbon Black App Control DSM can help ensure a successful integration. For example, knowing what the supported version of Carbon Black App Control is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Carbon Black App Control DSM.

Table 1051. Carbon Black App Control DSM specifications	
Specification	Value
Manufacturer	VMware
DSM name	Carbon Black App Control
RPM file name	DSM-CarbonBlackProtection-QRadar_version-build_number.noarch.rpm

*Table 1051. Carbon Black App Control DSM specifications (continued)*

Specification	Value
Supported version	8.0.x to 8.5.x
Protocol	Syslog
Event format	LEEF
Recorded event types	computer management, server management, session management, policy management, policy enforcement, internal events, general management, discovery
Automatically discovered?	Yes
Includes identity?	Yes
Includes custom properties?	No
More information	<a href="https://www.carbonblack.com/products/app-control/">VMware Carbon Black App Control</a> ( <a href="https://www.carbonblack.com/products/app-control/">https://www.carbonblack.com/products/app-control/</a> )

## Configuring VMware Carbon Black App Control to communicate with QRadar

Configure your Carbon Black App Control console to forward events to IBM QRadar in LEEF format.

### Procedure

1. Access the Carbon Black App Control console by entering the Carbon Black App Control server URL in your browser.
2. Log in to the Carbon Black App Control console. You must have Administrator or Power User privileges.
3. From the navigation menu, select **Administration > System Configuration**.
4. On the **System Configuration** page, click the **Events** tab.
5. In the **External Events Logging** section, click **Edit** and then configure the following parameters.
  - a) Type the IP address of the QRadar Event Collector in the **Syslog address** field.
  - b) Type 514 in the **Syslog port** field.
6. From the **Syslog format** list, select **LEEF (Q1Labs)**.
7. Select the **Syslog Enabled** checkbox and then click **Update**.

## Syslog log source parameters for VMware Carbon Black App Control

If QRadar does not automatically detect the log source, add a Carbon Black App Control log source on the QRadar Console by using the Syslog protocol.

When you use the Syslog protocol, there are specific parameters that you must configure.

The following table describes the parameters that require specific values to collect Syslog events from Carbon Black App Control:

*Table 1052. Syslog log source parameters for the Carbon Black App Control DSM*

Parameter	Value
<b>Log Source type</b>	Carbon Black App Control
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source as an identifier for metric events from your Carbon Black App Control appliances.

## Related tasks

## VMware ESX and ESXi

The EMC VMware DSM for IBM QRadar collects ESX and ESXi server events by using the VMware protocol or the syslog protocol.

When you use the VMware protocol, the EMC VMware DSM supports events from VMware ESX or ESXi 3.x, 4.x, 5.x and 6.x servers.

When you use the syslog protocol, the EMC VMware DSM supports events from VMware ESX or ESXi 3.x, 4.x, 5.x and 6.x and 7.x servers.

To collect VMware ESX or ESXi events, you can select one of the following event collection methods:

- [“Configuring syslog on VMware ESX and ESXi servers” on page 1636](#)
- [“Configuring the EMC VMWare protocol for ESX or ESXi servers” on page 1638](#)

## Configuring syslog on VMware ESX and ESXi servers

To collect syslog events for VMware, you must configure the server to forward events by using syslogd from your ESXi server to IBM QRadar.

### Procedure

1. Log in to your VMware vSphere Client.
2. Select the host that manages your VMware inventory.
3. Click the **Configuration** tab.
4. From the **Software** pane, click **Advanced Settings**.
5. In the navigation menu, click **Syslog**.
6. Configure values for the following parameters:

*Table 1055. VMware syslog protocol parameters*

Parameter	ESX version	Description
Syslog.Local.DatastorePath	ESX or ESXi 3.5.x or 4.x	Type the directory path for the local syslog messages on your ESXi server. The default directory path is [] / scratch/log/messages.
Syslog.Remote.Hostname	ESX or ESXi 3.5.x or 4.x	Type the IP address or host name of QRadar.
Syslog.Remote.Port	ESX or ESXi 3.5.x or 4.x	Type the port number the ESXi server uses to forward syslog data. The default is port 514.

Table 1055. VMware syslog protocol parameters (continued)

Parameter	ESX version	Description
Syslog.global.logHost	ESXi v5.x, ESXi v6.x or ESXi v7.x	Type the URL and port number that the ESXi server uses to forward syslog data.  Examples: udp://<QRadar IP address>:514 tcp://<QRadar IP address>:514

7. Click **OK** to save the configuration.

The default firewall configuration on VMware ESXi v5.x, VMware ESXi v6.x and VMware ESXi v7.x servers, disable outgoing connections by default. Outgoing syslog connections that are disabled restrict the internal syslog forwarder from sending security and access events to QRadar.

## Enabling syslog firewall settings on vSphere Clients

To forward syslog events from ESXi v5.x or ESXi v6.x servers, you must edit your security policy to enable outgoing syslog connections for events.

### Procedure

1. Log in to your ESXi v5.x or ESXi v6.x server from a vSphere client.
2. From the **Inventory** list, select your ESXi Server.
3. Click the **Manage** tab and select **Security Profile**.
4. In the **Firewall** section, click **Properties**.
5. In the **Firewall Properties** window, select the **syslog** check box.
6. Click **OK**.

## Enabling syslog firewall settings on vSphere Clients by using the esxcli command

To forward syslog events from ESXi v5.x or ESXi v6.x servers, as an alternative, you can configure ESXi Firewall Exception by using the esxcli command.

**Note:** To forward syslog logs, you might need to manually open the Firewall rule set. This firewall rule does not effect ESXi 5.0 build 456551. The UDP port 514 traffic flows.

To open outbound traffic through the ESXi Firewall on UDP port 514 and on TCP ports 514 and 1514, run the following commands:

```
esxcli network firewall ruleset set --ruleset-id=syslog --enabled=true
```

```
esxcli network firewall refresh
```

## Syslog log source parameters for VMware ESX or ESXi

If QRadar does not automatically detect the log source, add an EMC VMWare log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from VMware ESX or ESXi:

Table 1056. Syslog log source parameters for the EMC VMWare DSM

Parameter	Description
<b>Log Source Name</b> (Optional)	Type a name for your log source.
<b>Log Source Type</b>	<b>EMC VMWare</b>
<b>Protocol Configuration</b>	<b>Syslog</b>
<b>Log Source Identifier</b>	Type the IP address or hostname for the log source as an identifier for events from your EMC VMWare server.
<b>Enabled</b>	Select to enable the log source. By default, the check box is selected.
<b>Credibility</b>	From the list, select the credibility of the log source. The range is 0 - 10. The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.
<b>Target Event Collector</b>	From the list, select the <b>Target Event Collector</b> to use as the target for the log source.
<b>Coalescing Events</b>	Select to enable the log source to coalesce (bundle) events. By default, automatically discovered log sources inherit the value of the <b>Coalescing Events</b> list from the <b>System Settings</b> in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.
<b>Incoming Event Payload</b>	From the list, select the incoming payload encoder for parsing and storing the logs.
<b>Store Event Payload</b>	Select to enable the log source to store event payload information. By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the <b>System Settings</b> in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.

#### Related information

[“Adding a log source” on page 5](#)

## Configuring the EMC VMWare protocol for ESX or ESXi servers

You can configure the EMC VMWare protocol to read events from your VMware ESXi server. The EMC VMWare protocol uses HTTPS to poll for ESX and ESXi servers for events.

#### About this task

Before you configure your log source to use the EMC VMWare protocol, it is suggested that you create a unique user to poll for events. This user can be created as a member of the root or administrative group, but you must provide the user with an assigned role of read-only permission. This ensures that IBM QRadar can collect the maximum number of events and retain a level of security for your virtual servers. For more information about user roles, see your VMware documentation.

To integrate EMC VMWare with QRadar, you must complete the following tasks:

1. Create an ESX account for QRadar.
2. Configure account permissions for the QRadar user.
3. Configure the EMC VMWare protocol in QRadar.

Creating a user who is not part of the root or an administrative group might lead to some events not being collected by QRadar. It is suggested that you create your QRadar user to include administrative privileges, but assign this custom user a read-only role.

## Creating an account for QRadar in ESX

You can create a IBM QRadar user account for EMC VMWare to allow the protocol to properly poll for events.

### Procedure

1. Log in to your ESX host by using the vSphere Client.
2. Click the **Local Users & Groups** tab.
3. Click **Users**.
4. Right-click and select **Add**.
5. Configure the following parameters:
  - a) **Login** - Type a login name for the new user.
  - b) **UID** - Optional. Type a user ID.
  - c) **User Name** - Type a user name for the account.
  - d) **Password** - Type a password for the account.
  - e) **Confirm Password** - Type the password again as confirmation.
  - f) **Group** - From the **Group** list, select **root**
6. Click **Add**.
7. Click **OK**.

## Configuring read-only account permissions

For security reasons, configure your IBM QRadar user account as a member of your root or admin group, but select an assigned role of read-only permissions.

### About this task

Read-only permission allows the QRadar user account to view and collect events by using the EMC VMWare protocol.

### Procedure

1. Click the **Permissions** tab.
2. Right-click and select **Add Permissions**.
3. On the **Users and Groups** window, click **Add**.
4. Select your QRadar user and click **Add**.
5. Click **OK**.
6. From the **Assigned Role** list, select **Read-only**.
7. Click **OK**.

## EMC VMWare log source parameters for VMware ESX or ESXi

If QRadar does not automatically detect the log source, add an EMC VMWare log source on the QRadar Console by using the EMC VMWare protocol.

When using the EMC VMWare protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect EMC VMWare events from VMware ESX or ESXi:

Table 1057. EMC VMWare protocol log source parameters for the EMC VMWare DSM	
Parameter	Description
<b>Log Source Name</b> (Optional)	Type a name for your log source.
<b>Log Source Type</b>	<b>EMC VMWare</b>
<b>Protocol Configuration</b>	<b>EMC VMWare</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source. This value must match the value that is configured in the <b>ESX IP</b> field.
<b>VMware IP</b>	Type the IP address of the VMware ESX or ESXi server. The VMware protocol prepends the IP address of your VMware ESX or ESXi server with HTTPS before the protocol requests event data.
<b>User Name</b>	Type the user name that is required to access the VMware server.
<b>Password</b>	Type the password that is required to access the VMware server.

For more information about the EMC VMWare protocol, see [EMC VMWare protocol configuration options](#).

## VMware vCenter

The VMware vCenter DSM for IBM QRadar collects vCenter server events by using the EMC VMWare protocol.

The EMC VMWare protocol uses HTTPS to poll for vCenter appliances for events. You must configure a log source in QRadar to collect VMware vCenter events. For more information about configuring EMC VMWare log source parameters, see “[EMC VMWare log source parameters for VMware vCenter](#)” on page 1641.

Before you configure your log source to use the EMC VMWare protocol, it is suggested that you create a unique user to poll for events. This user can be created as a member of the Linux root or Windows administrative group, but you must [provide the user with an assigned role of read-only permission in vSphere](#). This ensures that QRadar can collect the maximum number of events and retain a level of security for your virtual servers. For more information about user roles, see your VMware documentation.

## EMC VMWare log source parameters for VMware vCenter

Add a VMware vCenter log source on the QRadar Console by using the EMC VMWare protocol.

When using the EMC VMWare protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect EMC VMWare events from VMware vCenter:

Table 1061. EMC VMWare log source parameters for the VMware vCenter DSM	
Parameter	Description
<b>Log Source type</b>	<b>VMware vCenter</b>
<b>Protocol Configuration</b>	<b>EMC VMWare</b>
<b>Log Source Identifier</b>	Type the IP address or host name for the log source. This value must match the value that is configured in the <b>ESX IP</b> field.
<b>VMware IP</b>	Type the IP address of the VMware vCenter server. The EMC VMWare protocol appends the IP address of your VMware vCenter server with HTTPS before the protocol requests event data.
<b>User Name</b>	Type the user name that is required to access the VMware vCenter server.
<b>Password</b>	Type the password that is required to access the VMware vCenter server.

For more information about EMC VMWare protocol parameters, see [“EMC VMware protocol configuration options” on page 117](#).

## VMware vCloud Director

You can use the VMware vCloud Director DSM and the VMware vCloud Director protocol for IBM QRadar to poll the vCloud REST API for events.

QRadar supports polling for VMware vCloud Director events from vCloud Directory 5.1 appliances. Events that are collected by using the vCloud REST API are assembled as Log Event Extended Format (LEEF) events.

To integrate vCloud events with QRadar, you must complete the following tasks:

1. On your vCloud appliance, configure a public address for the vCloud REST API.
2. On your QRadar appliance, configure a log source to poll for vCloud events. For information about VMware vCloud Director log source protocol parameters, see [“VMware vCloud Director log source parameters for VMware vCloud Director” on page 1644](#).
3. Ensure that no firewall rules block communication between your vCloud appliance and the QRadar Console or the managed host that is responsible for polling the vCloud REST API.

### Configuring the vCloud REST API public address

IBM QRadar collects security data from the vCloud API by polling the REST API of the vCloud appliance for events. Before QRadar can collect any data, you must configure the public REST API base URL.

#### Procedure

1. Log in to your vCloud appliance as an administrator.
2. Click the **Administration** tab.
3. From the **Administration** menu, select **System Settings > Public Addresses**.
4. In the **VCD public REST API base URL** field, type an IP address or host name.

The address that you specify becomes a publicly available address outside of the firewall or NAT on your vCloud appliance.

5. Click **Apply**.

The public API URL is created on the vCloud appliance.

#### What to do next

You can now configure a log source in QRadar.

### Supported VMware vCloud Director event types logged by IBM QRadar

The VMware vCloud Director DSM for QRadar can collect events from several categories.

Each event category contains low-level events that describe the action that is taken within the event category. For example, user events can have *user created* or *user deleted* as a low-level event.

The following list is the default event categories that are collected by QRadar from vCloud Director:

- User events
- Group events
- User role events

- Session events
- Organization events
- Network events
- Catalog events
- Virtual data center (VDC) events
- Virtual application (vApp) events
- Virtual machine (VM) events
- Media events
- Task operation events

## VMware vCloud Director log source parameters for VMware vCloud Director

If QRadar does not automatically detect the log source, add a VMware vCloud Director log source on the QRadar Console by using the VMware vCloud Director protocol.

When using the VMware vCloud Director protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect VMware vCloud Director events from VMware vCloud Director:

Table 1064. VVMware vCloud Director log source parameters for the VMware vCloud Director DSM	
Parameter	Description
<b>Log Source Name</b> (Optional)	A unique name for your log source.
<b>Log Source Description</b> (Optional)	A description for your log source.
<b>Log Source Type</b>	<b>VMware vCloud Director</b>
<b>Protocol Configuration</b>	<b>VMware vCloud Director</b>
<b>Enabled</b>	Select this checkbox to enable the log source. By default, the checkbox is selected.
<b>Credibility</b>	From the list, select the credibility of the log source. The range is 0 - 10. The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.
<b>Target Event Collector</b>	From the list, select the <b>Target Event Collector</b> to use as the target for the log source.
<b>Coalescing Events</b>	Select this checkbox to enable the log source to coalesce (bundle) events. By default, automatically discovered log sources inherit the value of the <b>Coalescing Events</b> list from the <b>System Settings</b> in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.
<b>Incoming Event Payload</b>	From the list, select the incoming payload encoder for parsing and storing the logs.

*Table 1064. VMware vCloud Director log source parameters for the VMware vCloud Director DSM (continued)*

Parameter	Description
<b>Store Event Payload</b>	Select this checkbox to enable the log source to store event payload information. By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the <b>System Settings</b> in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.

For a complete list of VMware vCloud Director protocol parameters and their values, see [VMware vCloud Director protocol configuration options](#).

## VMware vShield

The IBM QRadar DSM for VMware vShield collects event logs from VMware vShield servers.

The following table identifies the specifications for the VMware vShield Server DSM:

<i>Table 1065. VMware vShield DSM specifications</i>	
Specification	Value
Manufacturer	VMware
DSM	VMware vShield
RPM file name	DSM-VMwarevShield-QRadar_version-build_number.noarch.rpm
Protocol	Syslog
QRadar recorded events	All events
Automatically discovered	Yes
Includes identity	No
More information	<a href="http://www.vmware.com/">http://www.vmware.com/</a>

## VMware vShield DSM integration process

You can integrate VMware vShield DSM with IBM QRadar.

Use the following procedures:

1. If automatic updates are not enabled, download and install the most recent version of the VMware vShield RPM from the [IBM Support Website](#) onto your QRadar Console.
2. For each instance of VMware vShield, configure your VMware vShield system to enable communication with QRadar. This procedure must be completed for each instance of VMware vShield.
3. If QRadar does not automatically discover the log source, for each VMware vShield server that you want to integrate, create a log source on the QRadar Console. For more information about configuring

VMware vShield log source parameters, see “[Syslog log source parameters for VMware vShield](#)” on page 1646.

## Related tasks

- “[Configuring your VMware vShield system for communication with IBM QRadar](#)” on page 1646
- “[Adding a log source](#)” on page 5

## Configuring your VMware vShield system for communication with IBM QRadar

To collect all audit logs and system events from VMware vShield, you must configure the vShield Manager. When you configure VMware vShield, you must specify IBM QRadar as the syslog server.

### Procedure

1. Access your **vShield Manager inventory** pane.
2. Click **Settings & Reports**.
3. Click **Configuration > General**.
4. Click **Edit** next to the **Syslog Server** option.
5. Type the IP address of your QRadar Console.
6. Optional: Type the port for your QRadar Console. If you do not specify a port, the default UDP port for the IP address/host name of your QRadar Console is used.
7. Click **OK**.

## Syslog log source parameters for VMware vShield

If QRadar does not automatically detect the log source, add a VMware vShield log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from VMware vShield:

Table 1066. Syslog log source parameters for the VMware vShield DSM	
Parameter	Value
<b>Log Source type</b>	VMware vShield
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or hostname of the VMware device. The log source identifier must be unique value.

# Chapter 171. Vormetric Data Security

The Vormetric Data Security DSM for IBM QRadar can collect event logs from your Vormetric Data Security servers.

The following table identifies the specifications for the Vormetric Data Security DSM:

Vormetric Data Security DSM specifications	
Specification	Value
Manufacturer	Vormetric, Inc.
DSM	Vormetric Data Security
RPM file name	DSM-VormetricDataSecurity-7.1-804377.noarch.rpm DSM-VormetricDataSecurity-7.2-804381.noarch.rpm
Supported versions	Vormetric Data Security Manager v5.1.3 and later Vormetric Data Firewall FS Agent v5.2 and later
Protocol	Syslog (LEEF)
QRadar recorded events	Audit, Alarm, Warn, Learn Mode, System
Auto discovered	Yes
Includes identity	No
More information	<a href="http://www.vormetric.com">Vormetric website</a> ( <a href="http://www.vormetric.com">http://www.vormetric.com</a> )

## Vormetric Data Security DSM integration process

You can integrate Vormetric Data Security DSM with IBM QRadar.

Use the following procedures:

1. If automatic updates are not enabled, download and install the most recent version of the following RPMs from the [IBM Support Website](#) onto your QRadar Console:
  - Syslog protocol RPM
  - DSMCommon RPM

The minimum version of the DSMCommon RPM that you can use is the DSM-DSMCommon-7.1-530016.noarch.rpm or DSM-DSMCommon-7.2-572972.noarch.rpm

- Vormetric Data Security RPM

3. For each instance of Vormetric Data Security, configure your Vormetric Data Security system to enable communication with QRadar.
4. If QRadar does not automatically discover the DSM, for each Vormetric Data Security server you want to integrate, create a log source on the QRadar Console.

### Related tasks

[“Configuring your Vormetric Data Security systems for communication with IBM QRadar” on page 1648](#)

# Configuring your Vormetric Data Security systems for communication with IBM QRadar

---

To collect all audit logs and system events from Vormetric Data Security, you must configure your Vormetric Data Security Manager to enable communication with QRadar.

## About this task

Your Vormetric Data Security Manager user account must have System Administrator permissions.

## Procedure

1. Log in to your Vormetric Data Security Manager as an administrator that is assigned System Administrator permissions.
2. On the navigation menu, click **Log > Syslog**.
3. Click **Add**.
4. In the **Server Name** field, type the IP address or host name of your QRadar system.
5. From the **Transport Protocol** list, select **TCP** or a value that matches the log source protocol configuration on your QRadar system.
6. In the **Port Number** field, type 514 or a value that matches the log source protocol configuration on your QRadar system.
7. From the **Message Format** list, select **LEEF**.
8. Click **OK**.
9. On the Syslog Server summary screen, verify the details that you have entered for your QRadar system. If the **Logging to SysLog** value is **OFF**, complete the following steps. On the navigation menu, click **System > General Preferences**
10. Click the **System** tab.
11. In the **Syslog Settings** pane, select the **Syslog Enabled** check box.

## What to do next

[“Configuring Vormetric Data Firewall FS Agents to bypass Vormetric Data Security Manager” on page 1648](#)

# Configuring Vormetric Data Firewall FS Agents to bypass Vormetric Data Security Manager

---

When the Vormetric Data Security Manager is enabled to communicate with IBM QRadar, all events from the Vormetric Data Firewall FS Agents are also forwarded to the QRadar system through the Vormetric Data Security Manager.

## About this task

To bypass the Vormetric Data Security Manager, you can configure Vormetric Data Firewall FS Agents to send LEEF events directly to the QRadar system.

Your Vormetric Data Security Manager user account must have System Administrator permissions.

## Procedure

1. Log in to your Vormetric Data Security Manager.
2. On the navigation menu, click **System > Log Preferences**.
3. Click the **FS Agent Log** tab.
4. In the **Policy Evaluation** row, configure the following parameters:

- a) Select the **Log to Syslog/Event Log** check box.
5. Clear the **Upload to Server** check box.
6. From the **Level** list, select **INFO**.

This set up enables a full audit trail from the policy evaluation module to be sent directly to a syslog server, and not to the Security Manager. Leaving both destinations enabled might result in duplication of events to the QRadar system.

7. Under the Syslog Settings section, configure the following parameters. In the **Server** field, use the following syntax to type the IP address or host name and port number of your QRadar system.

*qradar\_IP address\_or\_host:port*

8. From the **Protocol** list, select **TCP** or a value that matches the log source configuration on your QRadar system.
9. From the **Message Format** list, select **LEEF**.

### What to do next

This configuration is applied to all hosts or host groups later added to the Vormetric Data Security Manager. For each existing host or host group, select the required host or host group from the **Hosts** list and repeat the procedure.

## Syslog log source parameters for Vormetric Data Security

---

If QRadar does not automatically detect the log source, add a Vormetric Data Security log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Vormetric Data Security:

<i>Table 1067. Syslog log source parameters for the Vormetric Data Security DSM</i>	
Parameter	Value
<b>Log Source type</b>	Vormetric Data Security
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or hostname of the Vormetric Data Security device.  The log source identifier must be unique value.

# Chapter 172. WatchGuard Fireware OS

The IBM QRadar DSM for WatchGuard Fireware OS can collect event logs from your WatchGuard Fireware OS.

The following table identifies the specifications for the WatchGuard Fireware OS DSM:

Table 1068. WatchGuard Fireware DSM specifications	
Specification	Value
Manufacturer	WatchGuard
DSM name	WatchGuard Fireware OS
RPM file name	DSM-WatchGuardFirewareOS-QRadar-version-Build_number.noarch.rpm
Supported versions	Fireware XTM OS v11.9 and later
Event format	syslog
QRadar recorded event types	All events
Automatically discovered?	Yes
Includes identity?	No
More information	<a href="http://www.watchguard.com/">WatchGuard Website (http://www.watchguard.com/)</a>

To integrate the WatchGuard Fireware OS with QRadar, use the following steps:

1. If automatic updates are not enabled, download and install the most recent versions of the following RPMs from the [IBM Support Website](#) onto your QRadar Console.
  - DSMCommon RPM
  - WatchGuard Fireware OS RPM
2. For each instance of WatchGuard Fireware OS, configure your WatchGuard Fireware OS appliance to enable communication with QRadar. You can use one of the following procedures:
  - “[Configuring your WatchGuard Fireware OS appliance in Policy Manager for communication with QRadar](#)” on page 1652
  - “[Configuring your WatchGuard Fireware OS appliance in Fireware XTM for communication with QRadar](#)” on page 1652
3. If QRadar does not automatically discover the WatchGuard Fireware OS log source, create a log source for each instance of WatchGuard Fireware OS on your network. For more information about configuring the log source, see “[Syslog log source parameters for WatchGuard Fireware OS](#)” on page 1653.

# Configuring your WatchGuard Fireware OS appliance in Policy Manager for communication with QRadar

---

To collect WatchGuard Fireware OS events, you can use the Policy Manager to configure your third-party appliance to send events to QRadar.

## Before you begin

You must have Device Administrator access credentials.

## Procedure

1. Open the WatchGuard System Manager.
2. Connect to your Firebox or XTM device.
3. Start the Policy Manager for your device.
4. To open the **Logging Setup** window, select **Setup > Logging**.
5. Select the **Send log messages to this syslog server** check box.
6. In the **IP address** text box, type the IP address for your QRadar Console or Event Collector.
7. In the **Port** text box, type 514.
8. From the **Log Format** list, select IBM LEEF.
9. Optional: Specify the details to include in the log messages.
  - a) Click **Configure**.
  - b) To include the serial number of the XTM device in the log message details, select the **The serial number of the device** check box.
  - c) To include the syslog header in the log message details, select the **The syslog header** check box.
  - d) For each type of log message, select one of the following syslog facilities:
    - For high-priority syslog messages, such as alarms, select **Local0**.
    - To assign priorities to other types of log messages, select an option from **Local1** through **Local7**. Lower numbers have greater priority.
    - To not send details for a log message type, select **NONE**.
  - e) Click **OK**.
10. Click **OK**.
11. Save the configuration file to your device.

# Configuring your WatchGuard Fireware OS appliance in Fireware XTM for communication with QRadar

---

To collect WatchGuard Fireware OS events, you can use the Fireware XTM web user interface to configure your third-party appliance to send events to QRadar.

## Before you begin

You must have Device Administrator access credentials.

## Procedure

1. Log in to the Fireware XTM web user interface for your Fireware or XTM device.
2. Select **System > Logging**.
3. In the Syslog Server pane, select the **Send log messages to the syslog server at this IP address** check box.

4. In the **IP Address** text box, type the IP address for the QRadar Console or Event Collector.
5. In the **Port** text box, type 514.
6. From the **Log Format** list, select IBM **LIEEEF**.
7. Optional: Specify the details to include in the log messages.
  - a) To include the serial number of the XTM device in the log message details, select the **The serial number of the device** check box.
  - b) To include the syslog header in the log message details, select the **The syslog header** check box.
  - c) For each type of log message, select one of the following syslog facilities:
    - For high-priority syslog messages, such as alarms, select **Local0**.
    - To assign priorities to other types of log messages, select an option from **Local1** through **Local7**. Lower numbers have greater priority.
    - To not send details for a log message type, select **NONE**.
8. Click **Save**.

## Syslog log source parameters for WatchGuard Fireware OS

---

If QRadar does not automatically detect the log source, add a WatchGuard Fireware OS log source on the QRadar Console by using the Syslog protocol.

When using the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from WatchGuard Fireware OS:

<i>Table 1069. Syslog log source parameters for the WatchGuard Fireware OS DSM</i>	
<b>Parameter</b>	<b>Value</b>
<b>Log Source type</b>	WatchGuard Fireware OS
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or hostname of the WatchGuard Fireware OS device. The log source identifier must be unique value.

## Chapter 173. Websense

Websense is now known as Forcepoint.

### Related concepts

[Forcepoint](#)

IBM QRadar supports a range of Forcepoint DSMs.

# Chapter 174. Zscaler Nanolog Streaming Service

The IBM QRadar DSM for Zscaler Nanolog Streaming Service (Zscaler NSS) collects Syslog events from either Web logs or Firewall logs.

To integrate Zscaler Streaming Service with QRadar, complete the following steps:

1. If automatic updates are not enabled, RPMs are available for download from the IBM support website (<http://www.ibm.com/support>). Download and install the most recent version of the following RPMs on your QRadar Console:
  - DSM Common RPM
  - Zscaler NSS DSM RPM
2. Configure your Zscaler NSS device to send events to QRadar. For more information about configuring Zscaler NSS, see the [Zscaler and IBM QRadar Deployment Guide](https://help.zscaler.com/zia/zscaler-ibm-qradar-deployment-guide) (<https://help.zscaler.com/zia/zscaler-ibm-qradar-deployment-guide>).

**Important:** When you configure your Zscaler NSS device, QRadar supports the following feeds:

- Firewall logs. For more information about Firewall logs, see [Adding NSS Feeds for Firewall logs](https://help.zscaler.com/zia/adding-nss-feeds-firewall-logs) (<https://help.zscaler.com/zia/adding-nss-feeds-firewall-logs>).
- Web logs. For more information about Web logs, see [Adding NSS Feeds for Web Logs](https://help.zscaler.com/zia/adding-nss-feeds-web-logs) (<https://help.zscaler.com/zia/adding-nss-feeds-web-logs>).

Use the following LEEF output feed format for Web logs when you configure a Syslog feed in Zscaler NSS:

```
%s{mon} %02d{dd} %02d{hh}:%02d{mm}:%02d{ss} zscaler-nss:  
LEEF:1.0|Zscaler|NSS|4.1|%s{reason}|cat=%s{action}\tdevTime=%s{mon} %02d{dd}  
%d{yy} %02d{hh}:%02d{mm}:%02d{ss} %s{tz}\tdevTimeFormat=MMM  
yyyy HH:mm:ss z\tsrc=%s{cip}\tdst=%s{sip}\tsrcPostNAT=%s{cintip}\trealm=%s{location}  
\tusrName=%s{login}\tsrcBytes=%d{reqsize}\tdstBytes=%d{respsize}\trole=%s{dept}  
\tpolicy=%s{reason}\trecordid=%d{recordid}\tbwthrottle=%s{bwthrottle}\tuseragent=%s{ua}  
\treferer=%s{referrer}\thostname=%s{ehost}\tappproto=%s{proto}\turlcategory=%s{urlcat}  
\turlsupercategory=%s{urlsupercat}\turlclass=%s{urlclass}\tappclass=%s{appclass}  
\tappname=%s{appname}\tmalwaretype=%s{malwarecat}\tmalwareclass=%s{malwareclass}  
\tthreatname=%s{threatname}\triskscore=%d{riskscore}\tdlpdict=%s{dlpdict}  
\tdlpeng=%s{dlpeng}\tficlass=%s{fileclass}\tfiltype=%s{filetype}\treqmethod=%s{reqmethod}  
\trespcode=%s{respcode}\tbamd5=%s{bamd5}\turl=%s{url}
```

Use the following LEEF output feed format for Firewall logs when you configure a Syslog feed in Zscaler NSS:

```
%s{mon} %02d{dd} %02d{hh}:%02d{mm}:%02d{ss}  
zscaler-nss: LEEF:1.0|Zscaler|NSS-FW|6.0|%s{action}|usrName=%s{login}\trole=%s{dept}  
\trealm=%s{location}\tsrc=%s{cip}\tdst=%s{cdip}\tsrcPort=%d{csport}\tdstPort=%d{cdport}  
\tdstPreNATPort=%d{cdport}\tsrcPreNATPort=%d{csport}\tdstPostNATPort=%d{sdport}  
\tsrcPostNATPort=%d{ssport}\tsrcPreNAT=%s{cip}\tdstPreNAT=%s{cdip}\tsrcPostNAT=%s{ssip}  
\tdstPostNAT=%s{sdip}\ttsip=%s{tsip}\ttsport=%d{tsport}\tttype=%s{tttype}\tcat=nss-  
fw\tdnat=%s{dnat}\tstateful=%s{stateful}\taggregate=%s{aggregate}\tnwsvc=%s{nwsvc}  
\tnwapp=%s{nwapp}\tproto=%s{ipproto}\tipcat=%s{ipcat}\tdestcountry=%s{destcountry}  
\tavgduration=%ld{avgduration}\trulelabel=%s{rulelabel}\tdstBytes=%ld{inbytes}  
\tsrcBytes=%ld{outbytes}\tduration=%d{duration}\tdurationms=%d{durationms}  
\tnumsessions=%d{numsessions}\n
```

3. If QRadar does not automatically detect the log source, add a Zscaler NSS log source on the QRadar Console. For more information about adding a Syslog log source, see [Syslog log source parameters for Zscaler NSS](#).
4. Optional: Configure your Zscaler NSS device to send HTTP receiver events to QRadar.

**Important:** You need a certificate that is issued by a certificate authority (CA). It can't be a self-signed certificate because it must be validated by a CA. For more information about certificates and configuring the log source parameters for HTTP receiver, see [HTTP Receiver protocol configuration options](#).

## Related concepts

## Zscaler NSS DSM specifications

When you configure Zscaler NSS, understanding the specifications for the Zscaler NSS DSM can help ensure a successful integration. For example, knowing what the supported version of Zscaler NSS is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Zscaler NSS DSM.

Table 1070. Zscaler NSS DSM specifications	
Specification	Value
Manufacturer	Zscaler
DSM name	Zscaler NSS
RPM file name	DSM-ZscalerNSS-QRadar_version-build_number.noarch.rpm
Supported version	6.0
Protocol	Syslog HTTP receiver
Event format	LEEF
Recorded event types	Weblog events, Firewall events (including DNS)
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="#">About Nanolog Streaming Service (NSS) (<a href="https://help.zscaler.com/zia/about-nanolog-streaming-service">https://help.zscaler.com/zia/about-nanolog-streaming-service</a>)</a>

## Syslog log source parameters for Zscaler NSS

If IBM QRadar does not automatically detect the log source, add a Zscaler NSS log source on the QRadar Console by using the Syslog protocol.

When you use the Syslog protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect Syslog events from Zscaler NSS:

Table 1071. Syslog log source parameters for the Zscaler NSS DSM

Parameter	Description
<b>Log Source type</b>	Zscaler NSS
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address as an identifier for events from your Zscaler NSS installation. The log source identifier must be a unique value.
<b>Enabled</b>	By default, the check box is selected.
<b>Credibility</b>	Select the credibility of the log source. The range is 0 - 10. The credibility indicates the integrity of an event or offense as determined by the credibility rating from the source devices. Credibility increases if multiple sources report the same event. The default is 5.
<b>Target Event Collector</b>	Select the <b>Target Event Collector</b> to use as the target for the log source.
<b>Coalescing Events</b>	Select this option for the log source to coalesce (bundle) events. By default, automatically discovered log sources inherit the value of the <b>Coalescing Events</b> list from the <b>System Settings</b> in QRadar. When you create a log source or edit an existing log source configuration, you can override the default value by configuring this option for each log source.
<b>Incoming Event Payload</b>	Select the <b>Incoming Payload Encoder</b> option for parsing and storing the logs from the list.
<b>Store Event Payload</b>	Select this option to enable the log source to store event payload information. By default, automatically discovered log sources inherit the value of the <b>Store Event Payload</b> list from the <b>System Settings</b> in QRadar. When you create a log source or edit an existing configuration, you can override the default value by configuring this option for each log source.
<b>Log Source Language</b>	Select the language of the events that are generated by Zscaler NSS.

#### Related information

[“Adding a log source” on page 5](#)

## HTTP Receiver log source parameters for Zscaler NSS

If IBM QRadar does not automatically detect the log source, add a Zscaler NSS log source on the QRadar Console by using the HTTP Receiver protocol.

When you use the HTTP Receiver protocol, there are specific parameters that you must use.

The following table describes the parameters that require specific values to collect HTTP Receiver events from Zscaler NSS:

*Table 1072. HTTP Receiver log source parameters for the Zscaler NSS DSM*

Parameter	Description
<b>Log Source type</b>	Zscaler NSS
<b>Protocol Configuration</b>	HTTP Receiver
<b>Log Source Identifier</b>	Type the IP address as an identifier for events from your Zscaler NSS installation. The log source identifier must be a unique value.

**Important:** When you use the HTTP protocol, you must use a certificate that is issued by a certificate authority (CA). It can't be a self-signed certificate because it must be validated by a CA. For more information about certificates and configuring the log source parameters for HTTP receiver, see [HTTP Receiver protocol configuration options](#).

# Chapter 175. Zscaler Private Access

The IBM QRadar DSM for Zscaler Private Access (ZPA) collects syslog events from a Zscaler Private Access service.

To integrate Zscaler Private Access with QRadar, complete the following steps:

1. If automatic updates are not enabled, download the most recent versions of the RPMs from the [IBM support website](https://www.ibm.com/support) (<https://www.ibm.com/support>).
  - DSM Common RPM
  - ZscalerPrivateAccess DSM RPM
2. Configure your Zscaler Private Access service to send events to QRadar. For more information, see [Configuring Zscaler Private Access to send events to QRadar](#).
3. If QRadar does not automatically detect the log source, add a Zscaler Private Access log source on the QRadar Console.

## Zscaler Private Access DSM specifications

When you configure the Zscaler Private Access DSM, understanding the specifications for the DSM can help ensure a successful integration. For example, knowing what the supported protocol is before you begin can help reduce frustration during the configuration process.

The following table describes the specifications for the Zscaler Private Access DSM.

Table 1075. Zscaler Private Access DSM specifications	
Specification	Value
Manufacturer	Zscaler
DSM name	Zscaler Private Access
RPM file name	DSM-ZscalerPrivateAccess-QRadar_version-build_number.noarch.rpm
Protocol	Syslog
Event format	LEEF
Recorded event types	User Status App Connector Status Audit User Activity
Automatically discovered?	Yes
Includes identity?	No
Includes custom properties?	No
More information	<a href="https://www.zscaler.com/products/zscaler-private-access">ZScaler Private Access</a> ( <a href="https://www.zscaler.com/products/zscaler-private-access">https://www.zscaler.com/products/zscaler-private-access</a> ) <a href="https://help.zscaler.com/zpa">Zscaler ZPA help</a> ( <a href="https://help.zscaler.com/zpa">https://help.zscaler.com/zpa</a> )

# Configuring Zscaler Private Access to send events to QRadar

To send events to IBM QRadar, you must redirect the log stream for Zscaler Private Access. IBM supports user status, app connector status, and audit log types for Zscaler Private Access devices.

For more information about redirecting the log stream, see your Zscaler documentation about the [Log Streaming Service](#) (<https://help.zscaler.com/zpa/about-log-streaming-service>).

## Procedure

1. To use the **User Status** log type, see your Zscaler documentation [About User Status Log Fields](#) (<https://help.zscaler.com/zpa/about-user-status-log-fields>).

When you configure a Syslog format, use the following LEEF output log format for User Status logs:

```
<166>%s{LogTimestamp:time} zpa-lss LEEF:1.0|Zscaler|ZPA|4.1|%s{SessionStatus}|cat=ZPA User Status\tCustomer=%s{Customer}\tusrName=%s{Username}\tSessionID=%s{SessionID}\tSessionStatus=%s{SessionStatus}\tVersion=%s{Version}\tZEN=%s{ZEN}\tCertificateCN=%s{CertificateCN}\tsrcPreNAT=%s{PrivateIP}\tsrc=%s{PublicIP}\tLatitude=%f{Latitude}\tLongitude=%f{Longitude}\tCountryCode=%s{CountryCode}\tTimestampAuthentication:iso8601=%s{TimestampAuthentication:iso8601}\tTimestampUnAuthentication:iso8601=%s{TimestampUnAuthentication:iso8601}\tdstBytes=%d{TotalBytesRx}\tsrcBytes=%d{TotalBytesTx}\tIdp=%s{Idp}\tidentHostName=%s{Hostname}\tPlatform=%s{Platform}\tClientType=%s{ClientType}\tTrustedNetworks=%s{TrustedNetworks}\tSAMLAtributes=%s{SAMLAttributes}\tPosturesHit=%s{PosturesHit}\tPosturesMiss=%s{PosturesMiss}\tZENLatitude=%f{ZENLatitude}\tZENLongitude=%f{ZENLongitude}\tZENCountryCode=%s{ZENCountryCode}\n
```

2. To use the **App Connector Status** log type, see your Zscaler documentation [About App Connector Status Log Fields](#) (<https://help.zscaler.com/zpa/about-connector-status-log-fields>).

When you configure a Syslog format, use the following LEEF output log format for App Connector Status logs:

```
<166>%s{LogTimestamp:time} zpa-lss LEEF:1.0|Zscaler|ZPA|4.1|%s{SessionStatus}|cat=Connector Status\tCustomer=%s{Customer}\tSessionID=%s{SessionID}\tSessionType=%s{SessionType}\tVersion=%s{Version}\tPlatform=%s{Platform}\tZEN=%s{ZEN}\tConnector=%s{Connector}\tConnectorGroup=%s{ConnectorGroup}\tsrcPreNAT=%s{PrivateIP}\tsrc=%s{PublicIP}\tLatitude=%f{Latitude}\tLongitude=%f{Longitude}\tCountryCode=%s{CountryCode}\tTimestampAuthentication:iso8601=%s{TimestampAuthentication:iso8601}\tTimestampUnAuthentication:iso8601=%s{TimestampUnAuthentication:iso8601}\tCPUUtilization=%d{CPUUtilization}\tMemUtilization=%d{MemUtilization}\tServiceCount=%d{ServiceCount}\tInterfaceDefRoute=%s{InterfaceDefRoute}\tDefRouteGW=%s{DefRouteGW}\tPrimaryDNSResolver=%s{PrimaryDNSResolver}\tHostUpTime=%s{HostUpTime}\tConnectorUpTime=%s{ConnectorUpTime}\tNumOfInterfaces=%d{NumOfInterfaces}\tBytesRxInterface=%d{BytesRxInterface}\tPacketsRxInterface=%d{PacketsRxInterface}\tErrorsRxInterface=%d{ErrorsRxInterface}\tDiscardsRxInterface=%d{DiscardsRxInterface}\tBytesTxInterface=%d{BytesTxInterface}\tPacketsTxInterface=%d{PacketsTxInterface}\tErrorsTxInterface=%d{ErrorsTxInterface}\tDiscardsTxInterface=%d{DiscardsTxInterface}\tTotalBytesRx=%d{TotalBytesRx}\tTotalBytesTx=%d{TotalBytesTx}\n
```

3. To use the **Audit** log type, see your Zscaler documentation [About Audit Log Fields](#) (<https://help.zscaler.com/zpa/about-audit-log-fields>).

When you configure a Syslog format, use the following LEEF output log format for Audit logs:

```
<166>%s{modifiedTime:iso8601} zpa-lss LEEF:1.0|Zscaler|ZPA|4.1|%s{auditOperationType}|cat=ZPA_Audit_Log\tcreationTime=%s{creationTime:iso8601}\trequestId=%s{requestId}\tsessionId=%s{sessionId}\tauditOldValue=%s{auditOldValue}\tauditNewValue=%s{auditNewValue}\tauditOperationType=%s{auditOperationType}\tobjectType=%s{objectType}\tobjectName=%s{objectName}\tobjectId=%d{objectId}\taccountName=%d{customerId}\tusrName=%s{modifiedByUser}\n
```

4. To use the **User Activity** log type, see your Zscaler documentation about [User Activity Log Fields](#) (<https://help.zscaler.com/zpa/about-user-activity-log-fields>).

When you configure a Syslog format, use the following LEEF output log format for User Activity logs:

```
<166>%s{LogTimestamp:time} zpa-lss LEEF:1.0|Zscaler|ZPA|4.1|%s{ConnectionStatus}\%s{InternalReason}|cat=ZPA User Activity\tCustomer=%s{Customer}\tSessionID=%s{SessionID}\tConnectionID=%s{ConnectionID}\tInternalReason=%s{InternalReason}\tConnectionStatus=%s{ConnectionStatus}\tproto=%d{IPProtocol}
```

```

\tDoubleEncryption=%d{DoubleEncryption}\tusrName=%s{Username}\tdstPort=%d{ServicePort}
\tsrc=%s{ClientPublicIP}\tsrcPreNAT=%s{ClientPrivateIP}\tClientLatitude=%f{ClientLatitude}
\tClientLongitude=%f{ClientLongitude}\tClientCountryCode=%s{ClientCountryCode}
\tClientZEN=%s{ClientZEN}\tpolicy=%s{Policy}\tConnector=%s{Connector}
\tConnectorZEN=%s{ConnectorZEN}\tConnectorIP=%s{ConnectorIP}\tConnectorPort=%d{ConnectorPort}
\tApplicationName=%s{Host}\tApplicationSegment=%s{Application}\tAppGroup=%s{AppGroup}
\tServer=%s{Server}\tdst=%s{ServerIP}\tServerPort=%d{ServerPort}
\tPolicyProcessingTime=%d{PolicyProcessingTime}\tServerSetupTime=%d{ServerSetupTime}
\tTimestampConnectionStart:iso8601=%s{TimestampConnectionStart:iso8601}\tTimestampConnectionEnd:iso8601=%s{TimestampConnectionEnd:iso8601}\tTimestampCATx:iso8601=%s{TimestampCATx:iso8601}
\tTimestampCARx:iso8601=%s{TimestampCARx:iso8601}\tTimestampAppLearnStart:iso8601=%s{TimestampAppLearnStart:iso8601}\tTimestampZENFirstRxClient:iso8601=%s{TimestampZENFirstRxClient:iso8601}\tTimestampZENFirstTxClient:iso8601=%s{TimestampZENFirstTxClient:iso8601}\tTimestampZENLastTxClient:iso8601=%s{TimestampZENLastTxClient:iso8601}\tTimestampZENLastRxClient:iso8601=%s{TimestampZENLastRxClient:iso8601}\tTimestampZENSetupComplete:iso8601=%s{TimestampZENSetupComplete:iso8601}\tTimestampZENFirstRxConnector:iso8601=%s{TimestampZENFirstRxConnector:iso8601}\tTimestampZENFirstTxConnector:iso8601=%s{TimestampZENFirstTxConnector:iso8601}\tTimestampZENLastRxConnector:iso8601=%s{TimestampZENLastRxConnector:iso8601}\tTimestampZENLastTxConnector:iso8601=%s{TimestampZENLastTxConnector:iso8601}\tZENTotalBytesRxClient=%d{ZENBytesRxClient}
\tZENTotalBytesTxClient=%d{ZENTotalBytesTxClient}\tZENBytesTxClient=%d{ZENBytesTxClient}

\tZENTotalBytesTxConnector=%d{ZENTotalBytesTxConnector}
\tZENBytesTxConnector=%d{ZENBytesTxConnector}\tIdp=%s{Idp}\n

```

## What to do next

[Syslog log source parameters for Zscaler Private Access](#)

## Syslog log source parameters for Zscaler Private Access

If QRadar does not automatically detect the log source, add a Zscaler Private Access log source on the QRadar Console by using the Syslog protocol.

The following table describes the parameters that require specific values to collect Syslog events from Zscaler Private Access:

Table 1076. Syslog log source parameters for the Zscaler Private Access DSM	
Parameter	Value
<b>Log Source type</b>	Zscaler Private Access
<b>Protocol Configuration</b>	Syslog
<b>Log Source Identifier</b>	Type the IP address or host name for the log source. The log source identifier must be unique for the log source type.

### Related tasks

[“Adding a log source” on page 5](#)

## Zscaler Private Access sample event messages

Use these sample event messages to verify a successful integration with IBM QRadar.

**Important:** Due to formatting issues, paste the message format into a text editor and then remove any carriage return or line feed characters.

### Zscaler Private Access sample message when you use the Syslog protocol

**Sample 1:** The following sample event message shows that a user is successfully authenticated in Zscaler Private Access (ZPA).

# Chapter 176. QRadar supported DSMs

IBM QRadar can collect events from your security products by using a plug-in file that is called a Device Support Module (DSM).

**Note:** Download the QRadar DSM Configuration Guide in [PDF format](#).

QRadar can receive logs from systems and devices by using the Syslog protocol, which is a standard protocol. Supported DSMs can use other protocols, as mentioned in the Supported DSM table. You can try to configure third-party applications to send logs to QRadar through the Syslog protocol. For more information, see [“Adding a log source” on page 5](#).

If you want to send logs by using a supported DSM that is not supported by the auto discovery feature in QRadar, you need to manually add a log source. For more information about adding a log source in QRadar, see [“Adding a log source” on page 5](#).

**Important:** When you upgrade your IBM QRadar system, custom DSMs are not removed during the upgrade.

## What do you do if the product version or device you have is not listed in the DSM Configuration Guide?

Sometimes a version of a vendor product or a device is not listed as supported. If the product or device is not listed, follow these guidelines:

### Version not listed

If the DSM for your product is officially supported by QRadar, but your product version is not listed in the *IBM QRadar DSM Configuration Guide*, you have the following options:

- Try the DSM to see whether it works. The product versions that are listed in the guide are tested by IBM, but newer untested versions can also work.
- If you tried the DSM and it didn’t work, open a support ticket for a review of the log source to troubleshoot and rule out any potential issues.

**Tip:** In most cases, no changes are necessary, or perhaps a minor update to the IBM QRadar Identifier (QID) Map might be all that is required. Software updates by vendors might on rare occasions add or change event formats that break the DSM, requiring an RFE for the development of a new integration. This is the only scenario where an RFE is required.

### Device not listed

When a device is not officially supported, you have the following options:

- Open a request for enhancement (RFE) to have your device become officially supported.
  - Go to the QRadar [SIEM RFE page](#) (<https://ibm.biz/BdRPx5>).
  - Log in to the support portal page.
  - Click the **Submit** tab and type the necessary information.

**Tip:** If you have event logs from a device, attach the event information and include the product version of the device that generated the event log.

- Write a log source extension to parse events for your device. For more information, see [Chapter 4, “Log source extensions,” on page 19](#) and the [DSM Editor](#).
- You can use content extensions for sending events to QRadar that are provided by some third-party vendors. They can be found on the [IBM Security App Exchange](#) (<https://exchange.xforce.ibmcloud.com/hub/>). These third-party DSM integrations are supported by the vendor, not by IBM. For a list of available third-party DSMs, see [Chapter 177, “DSMs supported by third-party vendors,” on page 1687](#).

The following table lists supported DSMs for third-party and IBM QRadar solutions.

**Tip:** To view all seven columns in the table, you might need to scroll to the right.

Table 1079. QRadar Supported DSMs						
Manufacturer	Device name and version	Protocol	Recorded events and formats	Auto discovered?	Includes identity?	Includes custom properties?
3Com	8800 Series Switch V3.01.30	Syslog	Status and network condition events	Yes	No	No
AhnLab	AhnLab Policy Center	AhnLabPolicyCenterJdbc	Spyware detection Virus detection Audit	No	Yes	No
Akamai	Akamai KONA	HTTP Receiver Akamai Kona REST API	Event format: JSON Recorded event types: All security events	No	No	No

Ping Identity	PingFederate	Syslog	Event format: CEF	Yes	No	No

Table 1079. QRadar Supported DSMs (continued)

Manufacturer	Device name and version	Protocol	Recorded events and formats	Auto discovered?	Includes identity?	Includes custom properties?
Pirean	Access: One 2.2 with DB2 9.7	JDBC	Access management and authentication events	No	No	No
PostFix	Mail Transfer Agent 2.6.6 and later	UDP Multiline Protocol or Syslog	Mail events	No	No	No
ProFTPD	ProFTPD 1.2.x, 1.3.x	Syslog	All events	Yes	Yes	No
Proofpoint	Proofpoint Enterprise Protection and Enterprise Privacy versions 7.0.2, 7.1, 7.2, 7.5, 8.0	Syslog Log File	Event types: System Email security threat classification Email audit and encryption	No	No	No
Pulse Secure	Pulse Secure Infranet Controller 2.1, v3.1 and 4.0	Syslog	All events	No	Yes	Yes
Pulse Secure	Pulse Secure Pulse Connect Secure 8.2R5	Syslog TLS Syslog	Event types: Admin Authentication System Network Error	Yes	Yes	Yes
Radware	AppWall 6.5.2 and 8.2	Syslog	Event types: Administration Audit Learning Security System	Yes	No	No
Radware	DefensePro 4.23, 5.01, 6.x and 7.x	Syslog	All events (Event mapping is required when Event IDs are 300,000 or more.)  <b>Tip:</b> If you have custom events that display as unknown in QRadar, see the IBM Support article about QRadar: <a href="https://www.ibm.com/support/pages/node/6960301">Custom events for Radware DefensePro display "parsed, but not mapped"</a> ( <a href="https://www.ibm.com/support/pages/node/6960301">https://www.ibm.com/support/pages/node/6960301</a> ).	Yes	No	No
Raz-Lee iSecurity	IBM i Firewall 15.7 and Audit 11.7	Syslog	Security, compliance, firewall, and audit events	Yes	Yes	No
Redback Networks	ASE 6.1.5	Syslog	All events	Yes	No	No
Red Hat	Red Hat Advanced Cluster Security for Kubernetes	HTTP Receiver	JSON Recorded event types: audit and alert events	Yes	No	No
Resolution1	Resolution1 CyberSecurity Formerly known as AccessData InSight Resolution1 CyberSecurity.	Log file	Volatile Data, Memory Analysis Data, Memory Acquisition Data, Collection Data, Software Inventory, Process Dump Data, Threat Scan Data, Agent Remediation Data	No	No	No
Riverbed	SteelCentral NetProfiler	JDBC	Alert events	No	No	No
Riverbed	SteelCentral NetProfiler Audit	Log file protocol	Audit events	No	Yes	No
RSA	Authentication Manager 6.x, 7.x, and 8.x	v6.x and v7.x use Syslog or Log File Protocol v8.x uses Syslog only	All events	No	No	No
SafeNet	DataSecure 6.3.0 and later	Syslog	All events	Yes	No	No
Salesforce	Salesforce Security Auditing	Log File	Setup Audit Records	No	No	No
Salesforce	Salesforce Security	Salesforce REST API Protocol	Login History Account History Case History Entitlement History Service Contract History Contract Line Item History Contract History Contact History Lead History Opportunity History Solution History Salesforce Security Auditing audit trail	No	Yes	No
Samhain Labs	HIDS 2.4	Syslog JDBC	All events	Yes	No	No
SAP	SAP Enterprise Threat Detection V1.0 SP6 to V2.0 SP5	SAP Enterprise Threat Detection Alert API	LEEF	No	No	No

Table 1079. QRadar Supported DSMs (continued)

Manufacturer	Device name and version	Protocol	Recorded events and formats	Auto discovered?	Includes identity?	Includes custom properties?
Seculert	Seculert v1	Seculert Protection REST API Protocol	All malware communication events	No	No	No
Seculert	Seculert	Seculert protection REST API Protocol	All malware communication events	No	No	No
SentriGo	Hedgehog 2.5.3	Syslog	All events	Yes	No	No
Snowflake	Snowflake	JDBC	Event format: Name value pair (NVP)	Yes	Yes	No
Skyhigh Networks (now known as McAfee)	Skyhigh Networks Cloud Security Platform 2.4 and 3.3 (now known as McAfee MVISION Cloud 2.4 and 3.3)					
SolarWinds	SolarWinds Orion 2011.2	Syslog	All events	No	No	No
SonicWALL	UTM/Firewall/VPN Appliance 3.x and later	Syslog	All events	Yes	No	No
Sophos	Sophos Astaro Security Gateway 17.x	Syslog	All events	Yes	No	No
Sophos	Sophos Central	Sophos Central	Event format: JSON	Yes	No	No
Sophos	Sophos Enterprise Console 4.5.1 and 5.1	Sophos Enterprise Console protocol JDBC protocol	All relevant anti-virus events	No	No	No
Sophos	Sophos PureMessage 3.1.0.0 for Microsoft Exchange 5.6.0 for Linux	JDBC	Quarantined email events	No	No	No
Sophos	Sophos Web Security Appliance 3.x	Syslog	Transaction log events	Yes	No	No
Sourcefire	Sourcefire Intrusion Sensor IS 500, 2.x, 3.x, 4.x	Syslog	All events	Yes	No	No
Sourcefire	Sourcefire Defense Center (Now known as Cisco FireSIGHT Management Center)					
Splunk	Microsoft Windows Security Event Log	Windows-based event provided by Splunk Forwarders	All events	No	Yes	No
Squid	Squid Web Proxy 2.5 and later	Syslog	All cache and access log events	Yes	No	No
Startent Networks	Startent Networks	Syslog	All events	Yes	No	No
STEALTHbits Technologies	STEALTHbits File Activity Monitor	Syslog LEEF	File Activity Monitor Events			
STEALTHbits Technologies	StealthINTERCEPT	Syslog LEEF	Active Directory Audit Events	Yes	No	No
STEALTHbits Technologies	STEALTHbits StealthINTERCEPT Alerts	Syslog LEEF	Active Directory Alerts Events	Yes	No	No
STEALTHbits Technologies	STEALTHbits StealthINTERCEPT Analytics	Syslog LEEF	Active Directory Analytics Events	Yes	No	No
Sun	Sun Solaris DHCP 2.8	Syslog	All events	Yes	Yes	No
Sun	Sun Solaris OS 5.8, 5.9	Syslog	All events	Yes	Yes	No
Sun	Sun Solaris Sendmail 2.x	Syslog Log File Protocol Proofpoint 7.5 and 8.0 Sendmail log	All events	Yes	No	No
Sun	Sun Solaris Basic Security Mode (BSM) 5.10 and 5.11	Log File Protocol	All events	No	Yes	No
Sun	Sun ONE LDAP v11.1 (Known as Oracle Directory Server)	Log File Protocol UDP Multiline Syslog	All relevant access and LDAP events	No	No	No
Sybase	Sybase ASE 15.0 and later	JDBC	All events	No	No	No
Symantec	Symantec Endpoint Protection 11, 12, and 14	Syslog	All Audit and Security Logs	Yes	No	Yes
Symantec	Symantec SGS Appliance 3.x and later	Syslog	All events	Yes	No	Yes
Symantec	Symantec SSC 10.1	JDBC	All events	Yes	No	No
Symantec	Symantec Data Loss Prevention (DLP) 8.x	Syslog	All events	No	No	No
Symantec	Symantec Encryption Management Server 3.0x formerly known as PGP Universal Server	Syslog	All events	Yes	No	No
Symark	Symark PowerBroker 4.0	Syslog	All events	Yes	No	No
SysFlow is an open source project initiated by IBM.	SysFlow 1.0	Syslog	Event format: JSON Recorded event types: SysFlow	Yes	No	No
ThreatGRID	Malware Threat Intelligence Platform 2.0	Log file protocol Syslog	Malware events	No	No	No
TippingPoint	Intrusion Prevention System (IPS) 1.4.2 to 3.2.x TippingPoint SMS 5.2.0	Syslog	All events	No	No	No
TippingPoint	X505/X506 2.5 and later	Syslog	All events	Yes	Yes	No

Table 1079. QRadar Supported DSMs (continued)

Manufacturer	Device name and version	Protocol	Recorded events and formats	Auto discovered?	Includes identity?	Includes custom properties?
Top Layer	IPS 5500 4.1 and later	Syslog	All events	Yes	No	No
Trend Micro	Trend Micro Apex Central (version 1)	Syslog, TLS syslog	Event format: CEF Event types: Attack discovery detection logs Behavior monitoring logs C&C callback logs Content security logs Data loss prevention logs Device access control logs Endpoint application control logs Engine update status logs Intrusion prevention logs Network content inspection logs Pattern Update Status Logs Predictive machine learning logs Sandbox detection logs Spyware/Grayware logs Suspicious file logs Virus/Malware logs Web security logs	Yes	No	No
Trend Micro	Trend Micro Apex One 8.x and 10.x  Formerly known as Trend Micro Office Scan. The name remains the same in QRadar.	SNMPv2	All events	No	No	No
Trend Micro	Trend Micro Control Manager 5.0 or 5.5 with hotfix 1697 or hotfix 1713 after SP1 Patch 1; 6.0 and 7.0.	SNMPv1 SNMPv2 SNMPv3	All events	Yes	No	No
Trend Micro	Trend Micro Deep Discovery Analyzer 5.0, 5.5, 5.8 and 6.0	Syslog	Event format: LEEF Events: All events	Yes	No	No
Trend Micro	Trend Micro Deep Discovery Director 3.0	Syslog	Event format: LEEF Events: Trend Micro Deep Discovery Inspector events	Yes	No	No
Trend Micro	Trend Micro Deep Discovery Email Inspector 3.0	Syslog	Event format: LEEF Events: Detections, Virtual Analyzer Analysis logs, System events, Alert events	Yes	No	No
Trend Micro	Trend Micro Deep Discovery Inspector 3.0 to V3.8, 5.0 and 5.1	Syslog	Event format: LEEF Events: Malicious content Malicious behavior Suspicious behavior Exploit Grayware Web reputation Disruptive application Sandbox Correlation System Update	Yes	No	No
Trend Micro	Trend Micro Deep Security 9.6.1532 to 12.0	Syslog	Event format: LEEF Events: Anti-Malware Deep Security Firewall Integrity Monitor Intrusion Prevention Log Inspection System Web Reputation	Yes	No	No
Tripwire	Tripwire Enterprise Manager 5.2 and later	Syslog	Event format: CEF (CEF:0 is supported) Event types: Resource additions, removal, and modification events	Yes	No	No
Tropos Networks	Tropos Control 7.7	Syslog	Fault management, login/logout, provision, and device image upload events	No	No	No
Trusteer	Apex Local Event Aggregator 1304.x and later	Syslog	Malware, exploit, and data exfiltration detection events	Yes	No	No

Table 1079. QRadar Supported DSMs (continued)

Manufacturer	Device name and version	Protocol	Recorded events and formats	Auto discovered?	Includes identity?	Includes custom properties?
Vectra Networks	Vectra Networks Vectra v2.2 <b>Important:</b> The IBM QRadar DSM for Vectra Networks Vectra is deprecated. To continue taking advantage of this integration, please download the Vectra Networks Vectra DSM from the <a href="https://exchange.xforce.ibmcloud.com/hub/extension/47f3e9afff5e0281d6684bb633d769f2">IBM Security App Exchange</a> website ( <a href="https://exchange.xforce.ibmcloud.com/hub/extension/47f3e9afff5e0281d6684bb633d769f2">https://exchange.xforce.ibmcloud.com/hub/extension/47f3e9afff5e0281d6684bb633d769f2</a> ).	Syslog	Host scoring, command and control, botnet activity, reconnaissance, lateral movement, exfiltration Event format: CEF (CEF:0 is supported)	Yes	No	No
Verdasys	Digital Guardian 6.0.x (Syslog only) Digital Guardian 6.1.1 and 7.2 (LEEF only)	Syslog	Event format: LEEF Events: All events	Yes	No	No
Vericept	Content 360 up to 8.0	Syslog	All events	Yes	No	No
VMware	VMware AppDefense 1.0	JSON VMWare AppDefense API protocol	All events	No	No	No
VMware	VMware AVIWF and Load Balancer	Syslog	Client Logs	Yes	No	No
VMware	Carbon Black App Control 8.0.x to 8.5.x (Formerly known as Carbon Black Protection)	Syslog	Event format: LEEF Event types: computer management, server management, session management, policy management, policy enforcement, internal events, general management, discovery	Yes	Yes	No
VMware	VMware ESX or ESXi 3.x, 4.x, 5.x and 6.x	Syslog EMC VMware protocol	Account Information Notice Warning Error System Informational System Configuration System Error User Login Misc Suspicious Event Access Denied License Expired Information Authentication Session Tracking	Yes if syslog	No	No
VMware	VMware vCenter v5.x and v6.x	EMC VMware protocol	Account Information Notice Warning Error System Informational System Configuration System Error User Login Misc Suspicious Event Access Denied License Expired Information Authentication Session Tracking	No	No	No
VMware	VMware vCloud Director 5.1 - 10.0	VMware vCloud Director protocol	All events	No	Yes	No
VMware	VMware vShield	Syslog	All events	Yes	No	No
Vormetric, Inc.	Vormetric Data Security	Syslog (LEEF)	Audit Alarm Warn Learn Mode System	Yes	No	No
Watchguard	WatchGuard Fireware OS	Syslog	All events	Yes	No	No
Websense (now known as Forcepoint)						
Zscaler	Zscaler Nanolog Streaming Service (Zscaler NSS) 6.0	Syslog HTTP receiver <b>Important:</b> When you use the HTTP receiver protocol with Zscaler NSS, you need a certificate that is issued by a certificate authority (CA). It can't be a self-signed certificate because it must be validated by a CA. For more information about certificates and configuring the log source parameters for HTTP receiver, see <a href="#">HTTP Receiver protocol configuration options</a> .	Event format: LEEF Event types: Web log events, Firewall events (including DNS)	Yes	No	No

*Table 1079. QRadar Supported DSMs (continued)*

Manufacturer	Device name and version	Protocol	Recorded events and formats	Auto discovered?	Includes identity?	Includes custom properties?
Zscaler	Zscaler Private Access	Syslog	Event format: LEEF Event types: User Status, App Connector Status, Audit, User Activity	Yes	No	No

# Chapter 177. DSMs supported by third-party vendors

Some content extensions on the IBM Security App Exchange are provided by third-party vendors and contain custom DSMs. These third-party DSM integrations are supported by the vendor, not by IBM.

The following table shows the third-party DSMs that are on the IBM Security App Exchange.

**Important:** New third-party DSMs are continually added to the IBM Security App Exchange, so the data in this table might be incomplete. If you don't see the vendor you're looking for in this table, go to [IBM Security App Exchange](https://exchange.xforce.ibmcloud.com/hub/) (<https://exchange.xforce.ibmcloud.com/hub/>), and search for the vendor. If you see a warning banner about QRadar CentOS 6 apps, do not install it.

Table 1080. Third-party DSMs that are available on the IBM Security App Exchange	
DSM integration	IBM Security App Exchange link

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

IBM Director of Licensing  
IBM Corporation  
North Castle Drive, MD-NC119  
Armonk, NY 10504-1785  
US

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

The performance data and client examples cited are presented for illustrative purposes only. Actual performance results may vary depending on specific configurations and operating conditions..

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

Statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

All IBM prices shown are IBM's suggested retail prices, are current and are subject to change without notice. Dealer prices may vary.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to actual people or business enterprises is entirely coincidental.

## Trademarks

---

IBM, the IBM logo, and ibm.com® are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the Web at "Copyright and trademark information" at [www.ibm.com/legal/copytrade.shtml](http://www.ibm.com/legal/copytrade.shtml).

Linux is a registered trademark of Linus Torvalds in the United States, other countries, or both.

UNIX is a registered trademark of The Open Group in the United States and other countries.

Java and all Java-based trademarks and logos are trademarks or registered trademarks of Oracle and/or its affiliates.

Microsoft, Windows, Windows NT, and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.

VMware, the VMware logo, VMware Cloud Foundation, VMware Cloud Foundation Service, VMware vCenter Server, and VMware vSphere are registered trademarks or trademarks of VMware, Inc. or its subsidiaries in the United States and/or other jurisdictions.

## Terms and conditions for product documentation

---

Permissions for the use of these publications are granted subject to the following terms and conditions.

### Applicability

These terms and conditions are in addition to any terms of use for the IBM website.

## **Personal use**

You may reproduce these publications for your personal, noncommercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative work of these publications, or any portion thereof, without the express consent of IBM.

## **Commercial use**

You may reproduce, distribute and display these publications solely within your enterprise provided that all proprietary notices are preserved. You may not make derivative works of these publications, or reproduce, distribute or display these publications or any portion thereof outside your enterprise, without the express consent of IBM.

## **Rights**

Except as expressly granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the publications is detrimental to its interest or, as determined by IBM, the above instructions are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

IBM MAKES NO GUARANTEE ABOUT THE CONTENT OF THESE PUBLICATIONS. THE PUBLICATIONS ARE PROVIDED "AS-IS" AND WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO IMPLIED WARRANTIES OF MERCHANTABILITY, NON-INFRINGEMENT, AND FITNESS FOR A PARTICULAR PURPOSE.

## **IBM Online Privacy Statement**

---

IBM Software products, including software as a service solutions, ("Software Offerings") may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth below.

Depending upon the configurations deployed, this Software Offering may use session cookies that collect each user's session id for purposes of session management and authentication. These cookies can be disabled, but disabling them will also eliminate the functionality they enable.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, see IBM's Privacy Policy at <http://www.ibm.com/privacy> and IBM's Online Privacy Statement at <http://www.ibm.com/privacy/details/> the section entitled "Cookies, Web Beacons and Other Technologies".

## **General Data Protection Regulation**

---

Clients are responsible for ensuring their own compliance with various laws and regulations, including the European Union General Data Protection Regulation. Clients are solely responsible for obtaining advice of competent legal counsel as to the identification and interpretation of any relevant laws and regulations that may affect the clients' business and any actions the clients may need to take to comply with such laws and regulations. The products, services, and other capabilities described herein are not suitable for all client situations and may have restricted availability. IBM does not provide legal, accounting or auditing

advice or represent or warrant that its services or products will ensure that clients are in compliance with any law or regulation.

## Privacy policy considerations

---

IBM Software products, including software as a service solutions, (“Software Offerings”) may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering’s use of cookies is set forth below.

Depending upon the configurations deployed, this Software Offering may use session cookies that collect each user’s session id for purposes of session management and authentication. These cookies can be disabled, but disabling them will also eliminate the functionality they enable.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, See IBM’s Privacy Policy at <http://www.ibm.com/privacy> and IBM’s Online Privacy Statement at <http://www.ibm.com/privacy/details> the section entitled “Cookies, Web Beacons and Other Technologies” and the “IBM Software Products and Software-as-a-Service Privacy Statement” at <http://www.ibm.com/software/info/product-privacy>.

# Glossary

---

This glossary provides terms and definitions for the IBM QRadar SIEM software and products.

The following cross-references are used in this glossary:

- *See* refers you from a nonpreferred term to the preferred term or from an abbreviation to the spelled-out form.
- *See also* refers you to a related or contrasting term.

For other terms and definitions, see the [IBM Terminology website](#) (opens in new window).

## A

---

### **accumulator**

A register in which one operand of an operation can be stored and subsequently replaced by the result of that operation.

### **active system**

In a high-availability (HA) cluster, the system that has all of its services running.

### **Address Resolution Protocol (ARP)**

A protocol that dynamically maps an IP address to a network adapter address in a local area network.

### **administrative share**

A network resource that is hidden from users without administrative privileges. Administrative shares provide administrators with access to all resources on a network system.

### **anomaly**

A deviation from the expected behavior of the network.

### **application signature**

A unique set of characteristics that are derived by the examination of packet payload and then used to identify a specific application.

### **ARP**

See [Address Resolution Protocol](#).

### **ARP Redirect**

An ARP method for notifying the host if a problem exists on a network.

### **ASN**

See [autonomous system number](#).

### **asset**

A manageable object that is either deployed or intended to be deployed in an operational environment.

### **autonomous system number (ASN)**

In TCP/IP, a number that is assigned to an autonomous system by the same central authority that assigns IP addresses. The autonomous system number makes it possible for automated routing algorithms to distinguish autonomous systems.

## B

---

### **behavior**

The observable effects of an operation or event, including its results.

### **bonded interface**

See [link aggregation](#).

### **burst**

A sudden sharp increase in the rate of incoming events or flows such that the licensed flow or event rate limit is exceeded.

## C

---

**CIDR**

See [Classless Inter-Domain Routing](#).

**Classless Inter-Domain Routing (CIDR)**

A method for adding class C Internet Protocol (IP) addresses. The addresses are given to Internet Service Providers (ISPs) for use by their customers. CIDR addresses reduce the size of routing tables and make more IP addresses available within organizations.

**client**

A software program or computer that requests services from a server.

**cluster virtual IP address**

An IP address that is shared between the primary or secondary host and the HA cluster.

**coalescing interval**

The interval at which events are bundled. Event bundling occurs in 10 second intervals and begins with the first event that does not match any currently coalescing events. Within the coalescing interval, the first three matching events are bundled and sent to the event processor.

**Common Vulnerability Scoring System (CVSS)**

A scoring system by which the severity of a vulnerability is measured.

**console**

A display station from which an operator can control and observe the system operation.

**content capture**

A process that captures a configurable amount of payload and then stores the data in a flow log.

**credential**

A set of information that grants a user or process certain access rights.

**credibility**

A numeric rating between 0-10 that is used to determine the integrity of an event or an offense. Credibility increases as multiple sources report the same event or offense.

**CVSS**

See [Common Vulnerability Scoring System](#).

## D

---

**database leaf object**

A terminal object or node in a database hierarchy.

**datapoint**

A calculated value of a metric at a point in time.

**Device Support Module (DSM)**

A configuration file that parses received events from multiple log sources and converts them to a standard taxonomy format that can be displayed as output.

**DHCP**

See [Dynamic Host Configuration Protocol](#).

**DNS**

See [Domain Name System](#).

**Domain Name System (DNS)**

The distributed database system that maps domain names to IP addresses.

**DSM**

See [Device Support Module](#).

**duplicate flow**

Multiple instances of the same data transmission received from different flow sources.

## **Dynamic Host Configuration Protocol (DHCP)**

A communications protocol that is used to centrally manage configuration information. For example, DHCP automatically assigns IP addresses to computers in a network.

## **E**

---

### **encryption**

In computer security, the process of transforming data into an unintelligible form in such a way that the original data either cannot be obtained or can be obtained only by using a decryption process.

### **endpoint**

The address of an API or service in an environment. An API exposes an endpoint and at the same time invokes the endpoints of other services.

### **external scanning appliance**

A machine that is connected to the network to gather vulnerability information about assets in the network.

## **F**

---

### **false positive**

An event or flow that the user can decide should not create an offense, or an offense that the user decides is not a security incident.

### **flow**

A single transmission of data passing over a link during a conversation.

### **flow log**

A collection of flow records.

### **flow sources**

The origin from which flow is captured. A flow source is classified as internal when flow comes from hardware installed on a managed host or it is classified as external when the flow is sent to a flow collector.

### **forwarding destination**

One or more vendor systems that receive raw and normalized data from log sources and flow sources.

### **FQDN**

See [fully qualified domain name](#).

### **FQNN**

See [fully qualified network name](#).

### **fully qualified domain name (FQDN)**

In Internet communications, the name of a host system that includes all of the subnames of the domain name. An example of a fully qualified domain name is rchland.vnet.ibm.com.

### **fully qualified network name (FQNN)**

In a network hierarchy, the name of an object that includes all of the departments. An example of a fully qualified network name is CompanyA.Department.Marketing.

## **G**

---

### **gateway**

A device or program used to connect networks or systems with different network architectures.

## **H**

---

### **HA**

See [high availability](#).

### **HA cluster**

A high-availability configuration consisting of a primary server and one secondary server.

**Hash-Based Message Authentication Code (HMAC)**

A cryptographic code that uses a cryptic hash function and a secret key.

**high availability (HA)**

Pertaining to a clustered system that is reconfigured when node or daemon failures occur so that workloads can be redistributed to the remaining nodes in the cluster.

**HMAC**

See [Hash-Based Message Authentication Code](#).

**host context**

A service that monitors components to ensure that each component is operating as expected.

**I****ICMP**

See [Internet Control Message Protocol](#).

**identity**

A collection of attributes from a data source that represent a person, organization, place, or item.

**IDS**

See [intrusion detection system](#).

**Internet Control Message Protocol (ICMP)**

An Internet protocol that is used by a gateway to communicate with a source host, for example, to report an error in a datagram.

**Internet Protocol (IP)**

A protocol that routes data through a network or interconnected networks. This protocol acts as an intermediary between the higher protocol layers and the physical network. See also [Transmission Control Protocol](#).

**Internet service provider (ISP)**

An organization that provides access to the Internet.

**intrusion detection system (IDS)**

Software that detects attempts or successful attacks on monitored resources that are part of a network or host system.

**intrusion prevention system (IPS)**

A system that attempts to deny potentially malicious activity. The denial mechanisms could involve filtering, tracking, or setting rate limits.

**IP**

See [Internet Protocol](#).

**IP multicast**

Transmission of an Internet Protocol (IP) datagram to a set of systems that form a single multicast group.

**IPS**

See [intrusion prevention system](#).

**ISP**

See [Internet service provider](#).

**K****key file**

In computer security, a file that contains public keys, private keys, trusted roots, and certificates.

**L****L2L**

See [Local To Local](#).

## L2R

See [Local To Remote](#).

## LAN

See [local area network](#).

## LDAP

See [Lightweight Directory Access Protocol](#).

## leaf

In a tree, an entry or node that has no children.

## Lightweight Directory Access Protocol (LDAP)

An open protocol that uses TCP/IP to provide access to directories that support an X.500 model and that does not incur the resource requirements of the more complex X.500 Directory Access Protocol (DAP). For example, LDAP can be used to locate people, organizations, and other resources in an Internet or intranet directory.

## link aggregation

The grouping of physical network interface cards, such as cables or ports, into a single logical network interface. Link aggregation is used to increase bandwidth and network availability.

## live scan

A vulnerability scan that generates report data from the scan results based on the session name.

## local area network (LAN)

A network that connects several devices in a limited area (such as a single building or campus) and that can be connected to a larger network.

## Local To Local (L2L)

Pertaining to the internal traffic from one local network to another local network.

## Local To Remote (L2R)

Pertaining to the internal traffic from one local network to another remote network.

## log source

Either the security equipment or the network equipment from which an event log originates.

## log source extension

An XML file that includes all of the regular expression patterns required to identify and categorize events from the event payload.

## M

---

### Magistrate

An internal component that analyzes network traffic and security events against defined custom rules.

### magnitude

A measure of the relative importance of a particular offense. Magnitude is a weighted value calculated from relevance, severity, and credibility.

## N

---

### NAT

See [network address translation](#).

### NetFlow

A Cisco network protocol that monitors network traffic flow data. NetFlow data includes the client and server information, which ports are used, and the number of bytes and packets that flow through the switches and routers connected to a network. The data is sent to NetFlow collectors where data analysis takes place.

### network address translation (NAT)

In a firewall, the conversion of secure Internet Protocol (IP) addresses to external registered addresses. This enables communications with external networks but masks the IP addresses that are used inside the firewall.

## **network hierarchy**

A type of container that is a hierarchical collection of network objects.

## **network layer**

In OSI architecture, the layer that provides services to establish a path between open systems with a predictable quality of service.

## **network object**

A component of a network hierarchy.

# **O**

---

## **offense**

A message sent or an event generated in response to a monitored condition. For example, an offense will provide information on whether a policy has been breached or the network is under attack.

## **offsite source**

A device that is away from the primary site that forwards normalized data to an event collector.

## **offsite target**

A device that is away from the primary site that receives event or data flow from an event collector.

## **Open Source Vulnerability Database (OSVDB)**

Created by the network security community for the network security community, an open source database that provides technical information on network security vulnerabilities.

## **open systems interconnection (OSI)**

The interconnection of open systems in accordance with standards of the International Organization for Standardization (ISO) for the exchange of information.

## **OSI**

See [open systems interconnection](#).

## **OSVDB**

See [Open Source Vulnerability Database](#).

# **P**

---

## **parsing order**

A log source definition in which the user can define the order of importance for log sources that share a common IP address or host name.

## **payload data**

Application data contained in an IP flow, excluding header and administrative information.

## **primary HA host**

The main computer that is connected to the HA cluster.

## **protocol**

A set of rules controlling the communication and transfer of data between two or more devices or systems in a communication network.

# **Q**

---

## **QID Map**

A taxonomy that identifies each unique event and maps the events to low-level and high-level categories to determine how an event should be correlated and organized.

# **R**

---

## **R2L**

See [Remote To Local](#).

## **R2R**

See [Remote To Remote](#).

**recon**

See [reconnaissance](#).

**reconnaissance (recon)**

A method by which information pertaining to the identity of network resources is gathered. Network scanning and other techniques are used to compile a list of network resource events which are then assigned a severity level.

**reference map**

A data record of direct mapping of a key to a value, for example, a user name to a global ID.

**reference map of maps**

A data record of two keys mapped to many values. For example, the mapping of the total bytes of an application to a source IP.

**reference map of sets**

A data record of a key mapped to many values. For example, the mapping of a list of privileged users to a host.

**reference set**

A list of single elements that are derived from events or flows on a network. For example, a list of IP addresses or a list of user names.

**reference table**

A table where the data record maps keys that have an assigned type to other keys, which are then mapped to a single value.

**refresh timer**

An internal device that is triggered manually or automatically at timed intervals that updates the current network activity data.

**relevance**

A measure of relative impact of an event, category, or offense on the network.

**Remote To Local (R2L)**

The external traffic from a remote network to a local network.

**Remote To Remote (R2R)**

The external traffic from a remote network to another remote network.

**report**

In query management, the formatted data that results from running a query and applying a form to it.

**report interval**

A configurable time interval at the end of which the event processor must send all captured event and flow data to the console.

**routing rule**

A condition that when its criteria are satisfied by event data, a collection of conditions and consequent routing are performed.

**rule**

A set of conditional statements that enable computer systems to identify relationships and run automated responses accordingly.

## S

---

**scanner**

An automated security program that searches for software vulnerabilities within web applications.

**secondary HA host**

The standby computer that is connected to the HA cluster. The secondary HA host assumes responsibility of the primary HA host if the primary HA host fails.

**severity**

A measure of the relative threat that a source poses on a destination.

## **Simple Network Management Protocol (SNMP)**

A set of protocols for monitoring systems and devices in complex networks. Information about managed devices is defined and stored in a Management Information Base (MIB).

### **SNMP**

See [Simple Network Management Protocol](#).

### **SOAP**

A lightweight, XML-based protocol for exchanging information in a decentralized, distributed environment. SOAP can be used to query and return information and invoke services across the Internet.

### **standby system**

A system that automatically becomes active when the active system fails. If disk replication is enabled, replicates data from the active system.

### **subnet**

See [subnetwork](#).

### **subnet mask**

For internet subnetworking, a 32-bit mask used to identify the subnetwork address bits in the host portion of an IP address.

### **subnetwork (subnet)**

A network that is divided into smaller independent subgroups, which still are interconnected.

### **sub-search**

A function that allows a search query to be performed within a set of completed search results.

### **superflow**

A single flow that is comprised of multiple flows with similar properties in order to increase processing capacity by reducing storage constraints.

### **system view**

A visual representation of both primary and managed hosts that compose a system.

## **T**

### **TCP**

See [Transmission Control Protocol](#).

### **Transmission Control Protocol (TCP)**

A communication protocol used in the Internet and in any network that follows the Internet Engineering Task Force (IETF) standards for internetwork protocol. TCP provides a reliable host-to-host protocol in packet-switched communication networks and in interconnected systems of such networks. See also [Internet Protocol](#).

### **truststore file**

A key database file that contains the public keys for a trusted entity.

## **V**

### **violation**

An act that bypasses or contravenes corporate policy.

### **vulnerability**

A security exposure in an operating system, system software, or application software component.

## **W**

### **whois server**

A server that is used to retrieve information about a registered Internet resources, such as domain names and IP address allocations.

**IBM.**<sup>®</sup>
