Precede and follow character literals with a double quotation mark, followed by a single quotation mark, followed by another double quotation mark ("'").

For example, Specify the string the string 100 as "'"100"'".

Enclosing the string in apostrophes is not adequate, because REXX removes the apostrophes when it assigns a literal to a variable. For example, suppose that you want to pass the value in a host variable called stringvar to Db2. The value that you want to pass is the string '100'. First, you assign the string to the host variable by issuing the following REXX command:

```
stringvar = '100'
```

After the command executes, stringvar contains the characters 100 (without the apostrophes). Db2 REXX Language Support then passes the numeric value 100 to Db2, which is not what you intended.

However, suppose that you write the following command:

```
stringvar = "'"100"'"
```

In this case, REXX assigns the string '100' to stringvar, including the single quotation marks. Db2 REXX Language Support then passes the string '100' to Db2, which is the result that you want.

Passing the data type of an input data type to Db2 for REXX programs

In certain situations, you should tell Db2 the data type to use for input data in a REXX program. For example, if you are assigning or comparing input data to columns of type SMALLINT, CHAR, or GRAPHIC, you should tell Db2 to use those data types.

About this task

Db2 does not assign data types of SMALLINT, CHAR, or GRAPHIC to input data. If you assign or compare this data to columns of type SMALLINT, CHAR, or GRAPHIC, Db2 must do more work than if the data types of the input data and columns match.

Procedure

Use an SQLDA.

Examples

Example: Specifying CHAR as an input data type

Suppose that you want to tell Db2 that the data with which you update the MIDINIT column of the EMP table is of type CHAR, rather than VARCHAR. You need to set up an SQLDA that contains a description of a CHAR column, and then prepare and execute the UPDATE statement using that SQLDA, as shown in the following example.

```
INSQLDA.SQLD = 1
                                  /* SQLDA contains one variable
                                  /* Type of the variable is CHAR, */
/* and the value can be null */
INSOLDA.1.SOLTYPE = 453
INSQLDA.1.SQLLEN = 1
                                  /* Length of the variable is 1
                                                                      */
INSQLDA.1.SQLDATA = 'H'
                                  /* Value in variable is H
INSQLDA.1.SQLIND = 0
                                  /* Input variable is not null
SOLSTMT="UPDATE EMP" ,
   SET MIDINIT = ?"
  "WHERE EMPNO = '000200'"
"EXECSQL PREPARE S100 FROM :SQLSTMT"
"EXECSOL EXECUTE S100 USING DESCRIPTOR :INSOLDA"
```

Example: specifying the input data type as DECIMAL with precision and scale

Suppose that you want to tell Db2 that the data is of type DECIMAL with precision and nonzero scale. You need to set up an SQLDA that contains a description of a DECIMAL column, as shown in the following example.

SQL descriptor area (SQLDA) (Db2 SQL) The REXX SQLDA (Db2 SQL)

Setting the isolation level of SQL statements in a REXX program

Isolation levels specify the locking behavior for SQL statements. You can set the isolation level for SQL statements in your REXX program to repeatable read (RR), read stability (RS), cursor stability (CS), or uncommitted read (UR).

Procedure

Execute the SET CURRENT PACKAGESET statement to select one of the following Db2 REXX Language Support packages with the isolation level that you need.

T	LO DEVVI	. C		!I I I
IANIE I IX II	b2 REXX Language	, Siinnart nackage	s ana associatea	ISOIATION IPVPIS
rable TTO. D	DE NENN EURSUUSU	, oupport package.	o aria associatea	isolation tovets

Package name ^a	Isolation level
DSNREXRR	Repeatable read (RR)
DSNREXRS	Read stability (RS)
DSNREXCS	Cursor stability (CS)
DSNREXUR	Uncommitted read (UR)

Note:

a. These packages enable your program to access Db2 and are bound when you install Db2 REXX Language Support.

For example, to change the isolation level to cursor stability, execute the following SQL statement:

```
"EXECSQL SET CURRENT PACKAGESET='DSNREXCS'"
```

Retrieving data from Db2 tables in REXX programs

All output data in REXX programs is string data. Although, you can determine the data type that the data represents from its format and from the data type of the column from which the data was retrieved.

About this task

The following table gives the format for each type of output data.

Table 119. SQL output dat	Table 119. SQL output data types and REXX data formats	
SQL data type	REXX output data format	
SMALLINT INTEGER BIGINT	A string of numerics that does not contain leading zeroes, a decimal point, or an exponent identifier. If the string represents a negative number, it begins with a minus (-) sign. The numeric value is between -9223372036854775808 and 9223372036854775807, inclusive.	
DECIMAL(p,s)	A string of numerics with one of the following formats:	
	 Contains a decimal point but not an exponent identifier. The string is padded with zeroes to match the scale of the corresponding table column. If the value represents a negative number, it begins with a minus (-) sign. 	
	 Does not contain a decimal point or an exponent identifier. The numeric value is less than -9223372036854775808 or greater than 9223372036854775807. If the value is negative, it begins with a minus (-) sign. 	
FLOAT(n) REAL DOUBLE	A string that represents a number in scientific notation. The string consists of a numeric, a decimal point, a series of numerics, and an exponent identifier. The exponent identifier is an E followed by a minus (-) sign and a series of numerics if the number is between -1 and 1. Otherwise, the exponent identifier is an E followed by a series of numerics. If the string represents a negative number, it begins with a minus (-) sign.	
DECFLOAT	REXX emulates the DECFLOAT data type with DOUBLE, so support for DECFLOAT is limited to the REXX support for DOUBLE. The following special values are not supported:	
	• INFINITY	
	• SNAN	
	• NAN	
CHAR(n) VARCHAR(n) CLOB(n) BLOB(n)	A character string or LOB value of length <i>n</i> bytes. The string is not enclosed in single or double quotation marks.	
GRAPHIC(n) VARGRAPHIC(n) DBCLOB(n)	A string of length 2*n bytes. Each pair of bytes represents a double-byte character. This string does not contain a leading G, is not enclosed in quotation marks, and does not contain shift-out or shift-in characters.	

Because you cannot use the SELECT INTO statement in a REXX procedure, to retrieve data from a Db2 table you must prepare a SELECT statement, open a cursor for the prepared statement, and then fetch

rows into host variables or an SQLDA using the cursor. The following example demonstrates how you can retrieve data from a Db2 table using an SQLDA:

```
SQLSTMT=
'SELECT EMPNO, FIRSTNME, MIDINIT, LASTNAME,',
' WORKDEPT, PHONENO, HIREDATE, JOB,',
' EDLEVEL, SEX, BIRTHDATE, SALARY,',
   BONUS, COMM'
   FROM EMP
EXECSOL DECLARE C1 CURSOR FOR S1
EXECSOL PREPARE S1 INTO :OUTSOLDA FROM :SOLSTMT
EXECSQL OPEN C1
Do Until(SQLCODE ¬= 0)
  EXECSQL FETCH C1 USING DESCRIPTOR :OUTSQLDA
  If SQLCODE = 0 Then Do
     Line =
     Do I = 1 To OUTSQLDA.SQLD
       Line = Line OUTSQLDA.I.SQLDATA
    Say Line
   End
End
```

Cursors and statement names in REXX

In REXX applications that contain SQL statements, you must use a predefined set of names for cursors or prepared statements.

The following names are valid for cursors and prepared statements in REXX applications:

c1 to c100

Cursor names for DECLARE CURSOR, OPEN, CLOSE, and FETCH statements. By default, c1 to c100 are defined with the WITH RETURN clause, and c51 to c100 are defined with the WITH HOLD clause. You can use the ATTRIBUTES clause of the PREPARE statement to override these attributes or add additional attributes. For example, you might want to add attributes to make your cursor scrollable.

c101 to c200

Cursor names for ALLOCATE, DESCRIBE, FETCH, and CLOSE statements that are used to retrieve result sets in a program that calls a stored procedure.

s1 to s100

Prepared statement names for DECLARE STATEMENT, PREPARE, DESCRIBE, and EXECUTE statements.

Use only the predefined names for cursors and statements. When you associate a cursor name with a statement name in a DECLARE CURSOR statement, the cursor name and the statement must have the same number. For example, if you declare cursor c1, you need to declare it for statement s1:

```
EXECSQL 'DECLARE C1 CURSOR FOR S1'
```

Do not use any of the predefined names as host variables names.

Handling SQL error codes in REXX applications

REXX applications can request more information about SQL error codes by using the DSNTIAR subroutine or issuing a GET DIAGNOSTICS statement.

Procedure

Db2 does not support the SQL WHENEVER statement in a REXX program. To handle SQL errors and warnings, use the following methods:

- To test for SQL errors or warnings, test the SQLCODE or SQLSTATE value and the SQLWARN. values after each EXECSQL call. This method does not detect errors in the REXX interface to Db2.
- To test for SQL errors or warnings or errors or warnings from the REXX interface to Db2, test the REXX RC variable after each EXECSQL call.

The following table lists the values of the RC variable.

Table 120. REXX return codes after SQL statements	
Return code	Meaning
0	No SQL warning or error occurred.
+1	An SQL warning occurred.
-1	An SQL error occurred.
-3	The first token after ADDRESS DSNREXX is in error. For a description of the tokens allowed, see "Accessing the Db2 REXX language support application programming interfaces" on page 750.

You can also use the REXX SIGNAL ON ERROR and SIGNAL ON FAILURE keyword instructions to detect negative values of the RC variable and transfer control to an error routine.

GET DIAGNOSTICS statement (Db2 SQL)

Chapter 5. Calling a stored procedure from your application

To run a stored procedure, you can either call it from a client program or invoke it from the Db2 command line processor.

Before you begin

Before you call a stored procedure, ensure that you have all of the following authorizations that are required to run the stored procedure:

- Authorization to execute the stored procedure that is referenced in the CALL statement.
 - The authorizations that you need depend on whether the form of the CALL statement is CALL *procedure-name* or CALL :host-variable.
- Authorization to execute any triggers or user-defined functions that the stored procedure invokes.
- Authorization to execute the stored procedure package and any packages under the stored procedure package.

For example, if the stored procedure invokes any user-defined functions, you need authorization to execute the packages for those user-defined functions.

About this task

An application program that calls a stored procedure can perform one or more of the following actions:

- Call more than one stored procedure.
- Call a single stored procedure more than once at the same or at different levels of nesting. However, do not assume that the variables for the stored procedures persist between calls.

If a stored procedure runs as a main program, before each call, Language Environment reinitializes the storage that is used by the stored procedure. Program variables for the stored procedure do not persist between calls.

If a stored procedure runs as a subprogram, Language Environment does not initialize the storage between calls. Program variables for the stored procedure can persist between calls. However, you should not assume that your program variables are available from one stored procedure call to another call for the following reasons:

- Stored procedures from other users can run in an instance of Language Environment between two
 executions of your stored procedure.
- Consecutive executions of a stored procedure might run in different stored procedure address spaces.
- The z/OS operator might refresh Language Environment between two executions of your stored procedure.
- Call a local or remote stored procedure.

If both the client and server application environments support two-phase commit, the coordinator controls updates between the application, the server, and the stored procedures. If either side does not support two-phase commit, updates fail.

- Mix CALL statements with other SQL statements.
- Use any of the Db2 attachment facilities.

Db2 runs stored procedures under the Db2 thread of the calling application, which means that the stored procedures are part of the caller's unit of work.

JDBC and ODBC applications: These instructions do not apply to JDBC and ODBC applications. Instead, see the following information for how to call stored procedures from those applications:

- For ODBC applications, see <u>Stored procedure calls in a Db2 ODBC application (Db2 Programming for ODBC)</u>.
- For JDBC applications, see <u>Calling stored procedures in JDBC applications</u> (Db2 Application Programming for Java)

Procedure

To call a stored procedure from your application:

- 1. Assign values to the IN and INOUT parameters.
- 2. Optional: To improve application performance, initialize the length of LOB output parameters to zero.
- 3. If the stored procedure exists at a remote location, perform the following actions:
 - a) Assign values to the OUT parameters.

When you call a stored procedure at a remote location, the local Db2 server cannot determine whether the parameters are input (IN) or output (OUT or INOUT) parameters. Therefore, you must initialize the values of all output parameters before you call a stored procedure at a remote location.

b) Optional: Issue an explicit CONNECT statement to connect to the remote server.

If you do not issue this statement explicitly, you can implicitly connect to the server by using a three-part name to identify the stored procedure in the next step.

The advantage of issuing an explicit CONNECT statement is that your CALL statement, which is described in the next step, is portable to other operating systems. The advantage of implicitly connecting is that you do not need to issue this extra CONNECT statement.

Requirement: When deciding whether to implicitly or explicitly connect to the remote server, consider the requirement for programs that execute the ASSOCIATE LOCATORS or DESCRIBE PROCEDURE statements. You must use the same form of the procedure name on the CALL statement and on the ASSOCIATE LOCATORS or DESCRIBE PROCEDURE statement.

4. Invoke the stored procedure with the SQL CALL statement. Make sure that you pass parameter data types that are compatible.

If the stored procedure exists on a remote server and you did not issue an explicit CONNECT statement, specify a three-part name to identify the stored procedure, and implicitly connect to the server where the stored procedure is located.

For native SQL procedures, the active version of the stored procedure is invoked by default. Optionally, you can specify a version of the stored procedure other than the active version.

To allow null values for parameters, use indicator variables.

- 5. Optional: Retrieve the status of the procedure.
- 6. Process any output, including the OUT and INOUT parameters.
- 7. If the stored procedure returns multiple result sets, retrieve those result sets.

Recommendation: Close the result sets after you retrieve them, and issue frequent commits to prevent Db2 storage shortages and EDM POOL FULL conditions.

- 8. For PL/I applications, also perform the following actions:
 - a) Include the run time option NOEXECOPS in your source code.
 - b) Specify the compile-time option SYSTEM(MVS).

These additional steps ensure that the linkage conventions work correctly on z/OS.

9. For C applications, include the following line in your source code:

#pragma runopts(PLIST(OS))

This code ensures that the linkage conventions work correctly on z/OS.

This option is not applicable to other operating systems. If you plan to use a C stored procedure on other platforms besides z/OS, use one of the forms of conditional compilation, as shown in the following example, to include this option only when you compile on z/OS.

Form 1

```
#ifdef MVS
#pragma runopts(PLIST(OS))
#endif
```

Form 2

```
#ifndef WKSTN
#pragma runopts(PLIST(OS))
#endif
```

10. Prepare the application as you would any other application by precompiling, compiling, and linkediting the application and binding the DBRM.

If the application calls a remote stored procedure, perform the following additional steps when you bind the DBRM:

- Bind the DBRM into a package at the local Db2 server. Use the bind option DBPROTOCOL(DRDA).
 If the stored procedure name cannot be resolved until run time, also specify the bind option
 VALIDATE(RUN). The stored procedure name might not be resolved at run time if you use a variable for the stored procedure name or if the stored procedure exists on a remote server.
- Bind the DBRM into a package at the remote Db2 server. If your client program accesses multiple servers, bind the program at each server.
- Bind all packages into a plan at the local Db2 server. Use the bind option DBPROTOCOL(DRDA).
- 11. Ensure that stored procedure completed successfully.

If a stored procedure abnormally terminates, Db2 performs the following actions:

- The calling program receives an SQL error as notification that the stored procedure failed.
- Db2 places the calling program's unit of work in a must-rollback state.
- Db2 stops the stored procedure, and subsequent calls fail, in either of the following conditions:
 - The number of abnormal terminations equals the STOP AFTER *n* FAILURES value for the stored procedure.
 - The number of abnormal terminations equals the default MAX ABEND COUNT value for the subsystem.
- The stored procedure does not handle the abend condition, and Db2 refreshes the environment for Language Environment to recover the storage that the application uses. In most cases, the environment does not need to restart.
- A data set is allocated in the DD statement CEEDUMP in the JCL procedure that starts the stored procedures address space. In this case, Language Environment writes a small diagnostic dump to this data set. Use the information in the dump to debug the stored procedure.
- In a data sharing environment, the stored procedure is placed in STOPABN status only on the member where the abends occurred. A calling program can invoke the stored procedure from other members of the data sharing group. The status on all other members is STARTED.

Examples

Example 1: Simple CALL statement

The following example shows a simple CALL statement that you might use to invoke stored procedure A:

```
EXEC SQL CALL A (:EMP, :PRJ, :ACT, :EMT, :EMS, :EME, :TYPE, :CODE);
```

In this example, :EMP, :PRJ, :ACT, :EMT, :EMS, :EME, :TYPE, and :CODE are host variables that you have declared earlier in your application program.

Example 2: Using a host structure for multiple parameter values

Instead of passing each parameter separately, as shown in the example of a simple CALL statement, you can pass them together as a host structure. For example, assume that you defined the following host structure in your application:

```
struct {
  char EMP[7];
  char PRJ[7];
  short ACT;
  short EMT;
  char EMS[11];
  char EME[11];
} empstruc;
```

You can then issue the following CALL statement to invoke stored procedure A:

```
EXEC SQL CALL A (:empstruc, :TYPE, :CODE);
```

Example 3: Calling a remote stored procedure

• The following example shows how to explicitly connect to LOCA and then issue a CALL statement:

```
EXEC SQL CONNECT TO LOCA;
EXEC SQL CALL SCHEMAA.A (:EMP, :PRJ, :ACT, :EMT, :EMS, :EME,
:TYPE, :CODE);
```

• The following example shows how to implicitly connect to LOCA by specifying the three-part name for stored procedure A in the CALL statement:

Example 4: Passing parameters that can have null values

The preceding examples assume that none of the input parameters can have null values. The following example shows how to allow for null values for the parameters by passing indicator variables in the parameter list:

```
EXEC SQL CALL A (:EMP :IEMP, :PRJ :IPRJ, :ACT :IACT, :EMT :IEMT, :EMS :IEMS, :EME :IEME, :TYPE :ITYPE, :CODE :ICODE);
```

In this example, :IEMP, :IPRJ, :IACT, :IEMT, :IEMS, :IEME, :ITYPE, and :ICODE are indicator variables for the parameters.

Example 5: Passing string constants and null values

The following example CALL statement passes integer and character string constants, a null value, and several host variables:

```
EXEC SQL CALL A ('000130', 'IF1000', 90, 1.0, NULL, '2009-10-01', :TYPE, :CODE);
```

Example 6: of using a host variable for the stored procedure name

The following example CALL statement uses a host variable for the name of the stored procedure:

```
EXEC SQL CALL :procnm (:EMP, :PRJ, :ACT, :EMT, :EMS, :EME, :TYPE, :CODE);
```

Assume that the stored procedure name is A. The host variable *procnm* is a character variable of length 255 or less that contains the value 'A'. Use this technique if you do not know in advance the name of the stored procedure, but you do know the parameter list convention.

Example 7: Using an SQLDA to pass parameters in a single structure

The following example CALL statement shows how to pass parameters in a single structure, the SQLDA, rather than as separate host variables:

EXEC SQL CALL A USING DESCRIPTOR :sqlda;

sqlda is the name of an SQLDA.

One advantage of using an SQLDA is that you can change the encoding scheme of the stored procedure parameter values. For example, if the subsystem on which the stored procedure runs has an EBCDIC encoding scheme, and you want to retrieve data in ASCII CCSID 437, you can specify the CCSIDs for the output parameters in the SQLVAR fields of the SQLDA.

This technique for overriding the CCSIDs of parameters is the same as the technique for overriding the CCSIDs of variables. This technique involves including dynamic SQL for varying-list SELECT statements in your program. When you use this technique, the defined encoding scheme of the parameter must be different from the encoding scheme that you specify in the SQLDA. Otherwise, no conversion occurs.

The defined encoding scheme for the parameter is the encoding scheme that you specify in the CREATE PROCEDURE statement. If you do not specify an encoding scheme in this statement, the defined encoding scheme for the parameter is the default encoding scheme for the subsystem.

Example 8: Reusable CALL statement

Because the following example CALL statement uses a host variable name for the stored procedure and an SQLDA for the parameter list, it can be reused to call different stored procedures with different parameter lists:

EXEC SQL CALL :procnm USING DESCRIPTOR :sqlda;

Your client program must assign a stored procedure name to the host variable *procnm* and load the SQLDA with the parameter information before issuing the SQL CALL statement.

Related concepts

Stored procedure parameters

You can pass information between a stored procedure and the calling application program by using parameters. Applications pass the required parameters in the SQL CALL statement. Optionally, the application can also include an indicator variable with each parameter to allow for null values or to pass large output parameter values.

Related tasks

Including dynamic SQL for varying-list SELECT statements in your program

A varying-list SELECT statement returns rows that contain an unknown number of values of unknown type. When you use this type of statement, you do not know in advance exactly what kinds of host variables you need to declare for storing the results.

Preparing an application to run on Db2 for z/OS

To prepare and run applications that contain embedded static SQL statements or dynamic SQL statements, you must process, compile, link-edit, and bind the SQL statements.

Managing authorization for stored procedures (Managing Security)

Temporarily overriding the active version of a native SQL procedure

If you want a particular call to a native SQL procedure to use a version other than the active version, you can temporarily override the active version. Such an override might be helpful when you are testing a new version of a native SQL procedure.

Statements (Db2 SQL)

Procedures that are supplied with Db2 (Db2 SQL)

Passing large output parameters to stored procedures by using indicator variables

If any output parameters occupy a large amount of storage, passing the entire storage area to a stored procedure can degrade performance.

About this task

In the calling program, you can specify indicator variables for large output parameters to pass only a 2-byte area to the stored procedure, but receive the entire output data area from the stored procedure. When Db2 processes the CALL statement, it inspects the parameters before moving any data. If an output parameter has a NULL indicator, Db2 determines that it does not need to copy the associated data area to the Db2 address space, which avoids the need for acquisition of extra buffers or cross-memory moves.

You can use the following procedure regardless of whether the linkage convention for the stored procedure is GENERAL, GENERAL WITH NULLS, or SQL.

Procedure

To pass large output parameters to stored procedures by using indicator variables:

- Declare an indicator variable for every large output parameter in the stored procedure.
 If you are using the GENERAL WITH NULLS or SQL linkage convention, you must declare indicator variables for all of your parameters. In this case, you do not need to declare another indicator variable.
- 2. Assign a negative value to each indicator variable that is associated with a large output variable.
- 3. Include the indicator variables in the CALL statement.

Example

For example, suppose that a stored procedure that is defined with the GENERAL linkage convention takes one integer input parameter and one character output parameter of length 6000. You do not want to pass the 6000 byte storage area to the stored procedure. The following example PL/I program passes only 2 bytes to the stored procedure for the output variable and receives all 6000 bytes from the stored procedure:

Related reference

Linkage conventions for external stored procedures

The linkage convention for a stored procedure can be either GENERAL, GENERAL WITH NULLS, or SQL. These linkage conventions apply to only external stored procedures.

Data types for calling stored procedures

The data types that are available for calling applications are the same as the data types that are used when retrieving or updating stored procedures.

The format of the parameters that you pass in the CALL statement in an application must be compatible with the data types of the parameters in the CREATE PROCEDURE statement.

For languages other than REXX

For all data types except LOBs, ROWIDs, locators, and VARCHARs (for C language), see the tables listed in the following table for the host data types that are compatible with the data types in the stored procedure definition.

Table 121. Listing of tables of compatible data types	
Language	Compatible data types table
Assembler	"Equivalent SQL and assembler data types" on page 566
С	"Equivalent SQL and C data types" on page 614
COBOL	"Equivalent SQL and COBOL data types" on page 681
PL/I	"Equivalent SQL and PL/I data types" on page 724

Calling a stored procedure from a REXX procedure

The format of the parameters that you pass in the CALL statement in a REXX procedure must be compatible with the data types of the parameters in the CREATE PROCEDURE statement.

The following table lists each SQL data type that you can specify for the parameters in the CREATE PROCEDURE statement and the corresponding format for a REXX parameter that represents that data type.

SQL data type	REXX format
SMALLINT INTEGER BIGINT	A string of numerics that does not contain a decimal point or exponent identifier. The first character can be a plus or minus sign. This format also applies to indicator variables that are passed as parameters.
DECIMAL(p,s) NUMERIC(p,s)	A string of numerics that has a decimal point but no exponent identifier. The first character can be a plus or minus sign.
REAL FLOAT(n) DOUBLE DECFLOAT	A string that represents a number in scientific notation. The string consists of a series of numerics followed by an exponent identifier (an E or e followed by an optional plus or minus sign and a series of numerics).
CHARACTER(n) VARCHAR(n) VARCHAR(n) FOR BIT DATA	A string of length <i>n</i> , enclosed in single quotation marks.
GRAPHIC(n) VARGRAPHIC(n)	The character G followed by a string enclosed in single quotation marks. The string within the quotation marks begins with a shift-out character (X'0E') and ends with a shift-in character (X'0F'). Between the shift-out character and shift-in character are <i>n</i> double-byte characters.
BINARY	Recommendation: Pass BINARY and VARBINARY values by using the SQLDA.
VARBINARY	If you specify an SQLDA when you call the stored procedure, set the SQLTYPE in the SQLDA. SQLDATA is a string of characters.
	If you use host variables, the REXX format of BINARY and VARBINARY data is BX followed by a string that is enclosed in a single quotation mark.

Table 122. Parameter formats for a CALL statement in a REXX procedure (continued) SQL data type **REXX** format A string of length 10, enclosed in single quotation marks. The format of the DATE string depends on the value of field DATE FORMAT that you specify when you A string of length 8, enclosed in single quotation marks. The format of the TIME string depends on the value of field TIME FORMAT that you specify when you install Db2. A string of length 19 to 32, enclosed in single quotation marks. The string has **TIMESTAMP** the format yyyy-mm-dd-hh.mm.ss or yyyy-mm-dd-hh.mm.ss.nnnnnnnnnn, where the number of fractional second digits can range 0–12. A string of length 148 to 161, enclosed in single quotation marks. The string TIMESTAMP WITH TIME has the format yyyymm- dd-hh.mm.ss.nnnnnnnnnnntth:tm or yyyymm- dd-ZONE hh.mm.ss.nnnnnnnnnn ±th:tm, where the number of fractional second digits

The following figure demonstrates how a REXX procedure calls the stored procedure in <u>"REXX stored procedures"</u> on page 286. The REXX procedure performs the following actions:

- Connects to the Db2 subsystem that was specified by the REXX procedure invoker.
- Calls the stored procedure to execute a Db2 command that was specified by the REXX procedure invoker.
- Retrieves rows from a result set that contains the command output messages.

can range 0–12 No equivalent.

REXX stored procedures

A REXX stored procedure is similar to any other REXX procedure and follows the same rules as stored procedures in other languages. A REXX stored procedure receives input parameters, executes REXX commands, optionally executes SQL statements, and returns at most one output parameter. However, a few differences exist.

Preparing a client program that calls a remote stored procedure

If you call a remote stored procedure from an embedded SQL application, you need to do a few extra steps when you prepare the client program. You do not need to do any extra steps when you prepare the stored procedure.

Before you begin

For an ODBC or CLI application, ensure that the Db2 packages and plan that are associated with the ODBC driver are bound to Db2. These packages and plan must be bound before you can run your application.

Procedure

To prepare a client program that calls a remote stored procedure:

- 1. Precompile, compile, and link-edit the client program on the local Db2 subsystem.
- 2. Bind the resulting DBRM into a package at the local Db2 subsystem by using the BIND PACKAGE command with the option DBPROTOCOL(DRDA).
- 3. Bind the same DBRM, the one for the client program, into a package at the remote location by using the BIND PACKAGE command and specifying a location name. If your client program needs to access multiple servers, bind the program at each server.
 - For example, suppose that you want a client program to call a stored procedure at location LOCA. You precompile the program to produce DBRM A. Then you can use the following command to bind DBRM A into package collection COLLA at location LOCA:

```
BIND PACKAGE (LOCA.COLLA) MEMBER(A)
```

- 4. Bind all packages into a plan on the local Db2 subsystem. Specify the bind option DBPROTOCOL(DRDA).
- 5. Bind any stored procedures that run under Db2 ODBC on a remote Db2 database server as a package at the remote site.

Those procedures do not need to be bound into the Db2 ODBC plan.

How Db2 determines which stored procedure to run

A procedure is uniquely identified by its name and its qualifying schema name. You can tell Db2 exactly which stored procedure to run by qualifying it with its schema name when you call it. Otherwise, Db2 determines which stored procedure to run.

However, if you do not qualify the stored procedure name, Db2 uses the following method to determine which stored procedure to run:

1. Db2 searches the list of schema names from the PATH bind option or the CURRENT PATH special register from left to right until it finds a schema name for which a stored procedure definition exists with the name in the CALL statement.

Db2 uses schema names from the PATH bind option for CALL statements of the following form:

```
CALL procedure-name
```

Db2 uses schema names from the CURRENT PATH special register for CALL statements of the following form:

CALL host-variable

- 2. When Db2 finds a stored procedure definition, Db2 executes that stored procedure if the following conditions are true:
 - The caller is authorized to execute the stored procedure.
 - The stored procedure has the same number of parameters as in the CALL statement.

If both conditions are not true, Db2 continues to go through the list of schemas until it finds a stored procedure that meets both conditions or reaches the end of the list.

3. If Db2 cannot find a suitable stored procedure, it returns an SQL error code for the CALL statement.

Calling different versions of a stored procedure from a single application

You can call different versions of a stored procedure from the same application program, even though those versions all have the same load module name.

Procedure

To call different versions of a stored procedure from a single application:

- 1. When you define each version of the stored procedure, use the same stored procedure name but different schema names, different COLLID values, and different WLM environments.
- 2. In the program that invokes the stored procedure, specify the unqualified stored procedure name in the CALL statement.
- 3. Use the SQL path to indicate which version of the stored procedure that the client program should call. You can choose the SQL path in several ways:
 - If the client program is not an ODBC or JDBC application, use one of the following methods:
 - Use the CALL procedure-name form of the CALL statement. When you bind plans or packages for the program that calls the stored procedure, bind one plan or package for each version of the stored procedure that you want to call. In the PATH bind option for each plan or package, specify the schema name of the stored procedure that you want to call.
 - Use the CALL host-variable form of the CALL statement. In the client program, use the SET PATH statement to specify the schema name of the stored procedure that you want to call.
 - If the client program is an ODBC or JDBC application, choose one of the following methods:
 - Use the SET PATH statement to specify the schema name of the stored procedure that you want to call.

- When you bind the stored procedure packages, specify a different collection for each stored procedure package. Use the COLLID value that you specified when defining the stored procedure to Db2.
- 4. When you run the client program, specify the plan or package with the PATH value that matches the schema name of the stored procedure that you want to call.

Results

For example, suppose that you want to write one program, PROGY, that calls one of two versions of a stored procedure named PROCX. The load module for both stored procedures is named SUMMOD. Each version of SUMMOD is in a different load library. The stored procedures run in different WLM environments, and the startup JCL for each WLM environment includes a STEPLIB concatenation that specifies the correct load library for the stored procedure module.

First, define the two stored procedures in different schemas and different WLM environments:

```
CREATE PROCEDURE TEST.PROCX(IN V1 INTEGER, OUT V2 CHAR(9))
LANGUAGE C
EXTERNAL NAME SUMMOD
WLM ENVIRONMENT TESTENV;

CREATE PROCEDURE PROD.PROCX(IN V1 INTEGER, OUT V2 CHAR(9))
LANGUAGE C
EXTERNAL NAME SUMMOD
WLM ENVIRONMENT PRODENV;
```

When you write CALL statements for PROCX in program PROGY, use the unqualified form of the stored procedure name:

```
CALL PROCX(V1,V2);
```

Bind two plans for PROGY. In one BIND statement, specify PATH(TEST). In the other BIND statement, specify PATH(PROD).

To call TEST.PROCX, execute PROGY with the plan that you bound with PATH(TEST). To call PROD.PROCX, execute PROGY with the plan that you bound with PATH(PROD).

Invoking multiple instances of a stored procedure

Your application program can issue multiple CALL statements to the same local or remote stored procedure. Assume that your stored procedure returns result sets and the calling application leaves those result sets open before the next call to that same stored procedure. In that case, each CALL statement invokes a unique instance of the stored procedure.

About this task

When you invoke multiple instances of a stored procedure, each instance runs serially within the same Db2 thread and opens its own result sets. These multiple calls invoke multiple instances of any packages that are invoked while running the stored procedure. These instances are invoked at either the same or different level of nesting under one Db2 connection or thread.

For local stored procedures that issue remote SQL, instances of the applications are created at the remote server site. These instances are created regardless of whether result sets exist or are left open between calls.

If you call too many instances of a stored procedure or if you open too many cursors, Db2 storage shortages and EDM POOL FULL conditions might occur. If the stored procedure issues remote SQL statements to another Db2 server, these conditions can occur at both the Db2 client and at the Db2 server.

Procedure

To invoke multiple instances of a stored procedure:

1. To optimize storage usage and prevent storage shortages, ensure that you specify appropriate values for the following two subsystem parameters:

MAX ST PROC

Controls the maximum number of stored procedure instances that you can call within the same thread.

MAX_NUM_CUR

Controls the maximum number of cursors that can be opened by the same thread.

When either of the values from these subsystem parameters is exceeded while an application is running, the CALL statement or the OPEN statement receives SQLCODE -904.

- 2. In your application, issue CALL statements to the stored procedure.
- 3. In the calling application for the stored procedure, close the result sets and issue frequent commits. Even read-only applications should perform these actions.

Applications that fail to close result sets or issue an adequate number of commits might terminate abnormally with Db2 storage shortage and EDM POOL FULL conditions.

Designating the active version of a native SQL procedure

When a native SQL procedure is called, Db2 uses the version that is designated as the active version.

About this task

When you create a native SQL procedure, that first version is by default the active version. If you create additional versions of a stored procedure, you can designate another version to be the active version.

Exception: If an existing active version is still being used by a process, the new active version is not used until the next call to that procedure.

Procedure

To designate the active version of a native SQL procedure, issue an ALTER PROCEDURE statement with the following items:

- The name of the native SQL procedure for which you want to change the active version.
- The ACTIVATE VERSION clause with the name of the version that you want to be active.

When the ALTER statement is committed, the new version of the procedure becomes the active version and is used by the next call for that procedure.

Example

The following ALTER PROCEDURE statement makes version V2 of the UPDATE_BALANCE procedure the active version.

ALTER PROCEDURE UPDATE_BALANCE ACTIVATE VERSION V2;

Temporarily overriding the active version of a native SQL procedure

If you want a particular call to a native SQL procedure to use a version other than the active version, you can temporarily override the active version. Such an override might be helpful when you are testing a new version of a native SQL procedure.

About this task

Recommendation: If you want all calls to a native SQL procedure to use a particular version, do not temporarily override the active version in every call. Instead, make that version the active version. Otherwise, performance might be slower.

Procedure

To temporarily override the active version of a native SQL procedure, specify the following statements in your program:

- 1. The SET CURRENT ROUTINE VERSION statement with the name of the version of the procedure that you want to use. If the specified version does not exist, the active version is used.
- 2. The CALL statement with the name of the procedure.

Example

The following CALL statement invokes version V1 of the UPDATE_BALANCE procedure, regardless of what the current active version of that procedure is.

```
SET CURRENT ROUTINE VERSION = V1;
SET procname = 'UPDATE_BALANCE';
CALL :procname USING DESCRIPTOR :x;
```

Specifying the number of stored procedures that can run concurrently

Multiple stored procedures can run concurrently, each under its own z/OS task control block (TCB). The z/OS Workload Manager (WLM) manages how many concurrent stored procedures can run in an address space. The number of concurrent stored procedures in an address space cannot exceed the value of the NUMTCB field that was specified on the DSNTIPX installation panel, during Db2 installation.

Procedure

You can override that value in the following ways:

- Edit the JCL procedures that start stored procedures address spaces, and modify the value of the NUMTCB parameter.
- Specify the following parameter in the Start Parameters field of the Create An Application Environment panel when you set up a WLM application environment:

```
NUMTCB=number-of-TCBs
```

Special cases:

- For REXX stored procedures, you must set the NUMTCB parameter to 1.
- Stored procedures that invoke utilities can invoke only one utility at a time in a single address space.
 Consequently, the value of the NUMTCB parameter is forced to 1 for those procedures.

Retrieving the procedure status

When an SQL procedure returns control to the calling program, it also returns the procedure status. The status is an integer value that indicates the success of the procedure.

About this task

Db2 sets the status to 0 or -1 depending on the value of the SQLCODE. Alternatively, an SQL procedure can set the integer status value by using the RETURN statement. In this case, Db2 sets the SQLCODE in the SQLCA to 0.

Procedure

To retrieve the procedure status, perform one of the following actions in the calling program:

• Issue the GET DIAGNOSTICS statement with the DB2_RETURN_STATUS item. The specified host variable in the GET DIAGNOSTICS statement is set to one of the following values:

0

This value indicates that the procedure returned with an SQLCODE that is greater or equal to zero. You can access the value directly from the SQLCA by retrieving the value of SQLERRD(1). For C applications, retrieve SQLERRD[0].

-1

This value indicates that the procedure returned with an SQLCODE that is less than zero. In this case, the SQLERRD(1) value in the SQLCA is not set. Db2 returns -1 only.

n

Any value other than 0 or -1 is the return value that was explicitly set in the procedure with the RETURN statement.

For example, the following SQL code creates an SQL procedure that is named TESTIT, which calls another SQL procedure that is named TRYIT. The TRYIT procedure returns a status value. The TESTIT procedure retrieves that value with the DB2_RETURN_STATUS item of the GET DIAGNOSTICS statement.

```
CREATE PROCEDURE TESTIT ()

LANGUAGE SQL
A1:BEGIN

DECLARE RETVAL INTEGER DEFAULT 0;

...

CALL TRYIT;

GET DIAGNOSTICS RETVAL = DB2_RETURN_STATUS;

IF RETVAL <> 0 THEN

LEAVE A1;
ELSE

END IF;
END A1
```

• Retrieve the value of SQLERRD(1) in the SQLCA. For C applications, retrieve SQLERRD[0]. This field contains the integer value that was set by the RETURN statement in the SQL procedure. This method is not applicable if the status was set by Db2.

Writing a program to receive the result sets from a stored procedure

You can write a program to receive results set from a stored procedure for either a fixed number of result sets, for which you know the contents, or a variable number of result sets, for which you do not know the contents.

About this task

A program for a fixed number of result sets is simpler to write than a program for a variable number of result sets. However, if you write a program for a variable number of result sets, you do not need to make modifications to the program if the stored procedure changes.

If your program calls an SQL procedure that returns result sets, you must write the program for a fixed number of result sets.

In the following steps, you do not need to connect to the remote location when you execute these statements:

- DESCRIBE PROCEDURE
- ASSOCIATE LOCATORS
- ALLOCATE CURSOR
- DESCRIBE CURSOR
- FETCH
- CLOSE

Procedure

To write a program to receive the result sets from a stored procedure:

- 1. Declare a locator variable for each result set that is to be returned.
 - If you do not know how many result sets are to be returned, declare enough result set locators for the maximum number of result sets that might be returned.
- 2. Call the stored procedure and check the SQL return code.
 - If the SQLCODE from the CALL statement is +466, the stored procedure has returned result sets.
- 3. Determine how many result sets the stored procedure is returning.
 - If you already know how many result sets the stored procedure returns, skip this step.

Use the SQL statement DESCRIBE PROCEDURE to determine the number of result sets. DESCRIBE PROCEDURE places information about the result sets in an SQLDA. Make this SQLDA large enough to hold the maximum number of result sets that the stored procedure might return. When the DESCRIBE PROCEDURE statement completes, the fields in the SQLDA contain the following values:

- SQLD contains the number of result sets that are returned by the stored procedure.
- Each SQLVAR entry gives the following information about a result set:
 - The SQLNAME field contains the name of the SQL cursor that is used by the stored procedure to return the result set.
 - The SQLIND field contains the value -1, which indicates that no estimate of the number of rows in the result set is available.
 - The SQLDATA field contains the value of the result set locator, which is the address of the result
- 4. Link result set locators to result sets by performing one of the following actions:
 - Use the ASSOCIATE LOCATORS statement. You must embed this statement in an application or SQL procedure. The ASSOCIATE LOCATORS statement assigns values to the result set locator variables.

If you specify more locators than the number of result sets that are returned, Db2 ignores the extra locators.

• If you executed the DESCRIBE PROCEDURE statement previously, the result set locator values are in the SQLDATA fields of the SQLDA. You can copy the values from the SQLDATA fields to the result set locators manually, or you can execute the ASSOCIATE LOCATORS statement to do it for you.

The stored procedure name that you specify in an ASSOCIATE LOCATORS statement or DESCRIBE PROCEDURE statement must match the stored procedure name in the CALL statement as follows:

- If the name is unqualified in the CALL statement, do not qualify it.
- If the name is qualified with a schema name in the CALL statement, qualify it with the schema name.
- If the name is qualified with a location name and schema name in the CALL statement, qualify it with a location name and schema name.
- 5. Allocate cursors for fetching rows from the result sets.

Use the SQL statement ALLOCATE CURSOR to link each result set with a cursor. Execute one ALLOCATE CURSOR statement for each result set. The cursor names can differ from the cursor names in the stored procedure.

To use the ALLOCATE CURSOR statement, you must embed it in an application or SQL procedure.

6. Determine the contents of the result sets.

If you already know the format of the result set, skip this step.

Use the SQL statement DESCRIBE CURSOR to determine the format of a result set and put this information in an SQLDA. For each result set, you need an SQLDA that is big enough to hold descriptions of all columns in the result set.

You can use DESCRIBE CURSOR for only those cursors for which you executed ALLOCATE CURSOR previously.

After you execute DESCRIBE CURSOR, if the cursor for the result set is declared WITH HOLD, the high-order bit of byte 8 of field SQLDAID in the SQLDA is set to 1.

7. Fetch rows from the result sets into host variables by using the cursors that you allocated with the ALLOCATE CURSOR statements.

Fetching rows from a result set is the same as fetching rows from a table.

If you executed the DESCRIBE CURSOR statement, perform the following steps before you fetch the rows:

- a. Allocate storage for host variables and indicator variables. Use the contents of the SQLDA from the DESCRIBE CURSOR statement to determine how much storage you need for each host variable.
- b. Put the address of the storage for each host variable in the appropriate SQLDATA field of the SQLDA.
- c. Put the address of the storage for each indicator variable in the appropriate SQLIND field of the SQLDA.

Example

The following examples show C language code that accomplishes each of these steps. Coding for other languages is similar.

The following example demonstrates how to receive result sets when you know how many result sets are returned and what is in each result set.

```
/* Call stored procedure P1.
/* Check for SQLCODE +466, which indicates that result sets \star/
/* were returned.
EXEC SQL CALL P1(:parm1, :parm2, ...);
 if(SQLCODE==+466)
 /* Establish a link between each result set and its
 /* locator using the ASSOCIATE LOCATORS.
 EXEC SQL ASSOCIATE LOCATORS (:loc1, :loc2) WITH PROCEDURE P1;
 /* Associate a cursor with each result set.
 EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :loc1;
  EXEC SQL ALLOCATE C2 CURSOR FOR RESULT SET :loc2;
 /* Fetch the result set rows into host variables.
 while(SQLCODE==0)
   EXEC SQL FETCH C1 INTO :order_no, :cust_no;
  while(SQLCODE==0)
   EXEC SQL FETCH C2 :order no, :item no, :quantity;
 3
```

The following example demonstrates how to receive result sets when you do not know how many result sets are returned or what is in each result set.

```
/* Declare result set locators. For this example,
                                           */
/\star assume that no more than three result sets will be
                                           */
/* returned, so declare three locators. Also, assume
/* that you do not know the format of the result sets.
EXEC SQL BEGIN DECLARE SECTION;
 static volatile SQL TYPE IS RESULT_SET_LOCATOR *loc1, *loc2, *loc3;
 EXEC SQL END DECLARE SECTION;
/* Call stored procedure P2.
/* Check for SQLCODE +466, which indicates that result sets
/* were returned.
EXEC SQL CALL P2(:parm1, :parm2, ...);
 if(SQLCODE==+466)
 /* Determine how many result sets P2 returned, using the /* statement DESCRIBE PROCEDURE. :proc_da is an SQLDA
                                             */
 /* with enough storage to accommodate up to three SQLVAR
 /* entries.
 EXEC SQL DESCRIBE PROCEDURE P2 INTO :proc_da;
 /* Now that you know how many result sets were returned,
                                            */
 /* establish a link between each result set and its
 /* locator using the ASSOCIATE LOCATORS. For this example,
 /* we assume that three result sets are returned.
  EXEC SQL ASSOCIATE LOCATORS (:loc1, :loc2, :loc3) WITH PROCEDURE P2;
 /* Associate a cursor with each result set.
  EXEC SQL ALLOCATE C1 CURSOR FOR RESULT SET :loc1;
```

```
EXEC SQL ALLOCATE C2 CURSOR FOR RESULT SET :loc2;
EXEC SQL ALLOCATE C3 CURSOR FOR RESULT SET :loc3;
```

```
/***********************
/* Use the statement DESCRIBE CURSOR to determine the
/* format of each result set.
/**********************************
 EXEC SQL DESCRIBE CURSOR C1 INTO :res_da1; EXEC SQL DESCRIBE CURSOR C2 INTO :res_da2;
 EXEC SQL DESCRIBE CURSOR C3 INTO :res_da3;
/* Assign values to the SQLDATA and SQLIND fields of the
/\star SQLDĀs that you used in the DESCRIBE CURSOR statements.
/* These values are the addresses of the host variables and
/* indicator variables into which DB2 will put result set
/* rows.
/* Fetch the result set rows into the storage areas
/* that the SQLDAs point to.
while(SQLCODE==0)
   EXEC SQL FETCH C1 USING :res_da1;
 while(SQLCODE==0)
   EXEC SQL FETCH C2 USING :res_da2;
 while(SQLCODE==0)
  EXEC SQL FETCH C3 USING :res_da3;
7
```

The following example demonstrates how you can use an SQL procedure to receive result sets. The logic assumes that no handler exists to intercept the +466 SQLCODE, such as DECLARE CONTINUE HANDLER FOR SQLWARNING Such a handler causes SQLCODE to be reset to zero. Then the test for IF SQLCODE = 466 is never true and the statements in the IF body are never executed.

```
DECLARE RESULT1 RESULT_SET_LOCATOR VARYING;
 DECLARE RESULT2 RESULT_SET_LOCATOR VARYING;
 DECLARE AT_END, VAR1, VAR2 INT DEFAULT 0; DECLARE SQLCODE INTEGER DEFAULT 0;
 DECLARE CONTINUE HANDLER FOR NOT FOUND SET AT END = 99;
 SET TOTAL1 = 0;
 SET TOTAL2 = 0;
 CALL TARGETPROCEDURE();
 IF SQLCODE = 466 THEN
   ASSOCIATE RESULT SET LOCATORS(RESULT1, RESULT2) WITH PROCEDURE SPDG3091;
   ALLOCATE RSCUR1 CURSOR FOR RESULT1;
   ALLOCATE RSCUR2 CURSOR FOR RESULT2; WHILE AT_END = 0 DO
     FETCH RSCUR1 INTO VAR1;
     SET TOTAL1 = TOTAL1 + VAR1;
     SET VAR1 = 0;
                      /* Reset so the last value fetched is not added after AT_END
   END WHILE;
   SET AT_END = 0; /* Reset for next loop */
   WHILE \overline{A}T_{END} = 0 DO
     FETCH RSCUR2 INTO VAR2;
     SET TOTAL2 = TOTAL2 + VAR2;
     SET VAR2 = 0;
                      /* Reset so the last value fetched is not added after AT_END
   END WHILE;
 END IF;
```

Effects of distributed data on programming (Introduction to Db2 for z/OS)

Distributed data access (Introduction to Db2 for z/OS)

Three-part table names are described in <u>"Accessing distributed data by using three-part table names"</u> on page 777. Explicit connect statements are described in <u>"Accessing distributed data by using explicit CONNECT statements"</u> on page 779.

These two methods of coding applications for distributed access are illustrated by the following example.

Spiffy Computer has a main project table that supplies information about all projects that are currently active throughout the company. Spiffy has several branches in various locations around the world, each a Db2 location that maintains a copy of the project table named DSN8C10.PROJ. The main branch location occasionally inserts data into all copies of the table. The application that makes the inserts uses a table of location names. For each row that is inserted, the application executes an INSERT statement in DSN8C10.PROJ for each location.

Copying a table from a remote location

To copy a table from one location to another, you can either write your own application program or use the Db2 DataPropagator product.

Related tasks

Improving performance for applications that access distributed data (Db2 Performance)

Accessing distributed data by using three-part table names

You can use three-part table names to access data at a remote location through DRDA access.

When you use three-part table names, you must create copies of the package that you used at the local site at all possible remote locations that could be accessed by the three-part table name references. You must also explicitly or generically specify remote packages in the PKLIST of the PLAN that is used by the application.

Recommendation: Always use an alias, which resolves to a three-part table name, rather than specifying a specific three-part table name in an SQL statement. Using an alias will permit you to physically move the location of the table as needed. By using an alias, you can drop and re-create the alias by specifying the tables's new remote location and then rebind the packages of the application.

In a three-part table name, the first part denotes the location. The local Db2 makes and breaks an implicit connection to a remote server as needed.

When a three-part name is parsed and forwarded to a remote location, any special register settings are automatically propagated to remote server. This allows the SQL statements to process the same way no matter at what site a statement is run.

Example

The following example assumes that all systems involved implement two-phase commit. This example suggests updating several systems in a loop and ending the unit of work by committing only when the loop is complete. Updates are coordinated across the entire set of systems.

Spiffy's application uses a location name to construct a three-part table name in an INSERT statement. It then prepares the statement and executes it dynamically. The values to be inserted are transmitted to the remote location and substituted for the parameter markers in the INSERT statement.

The following overview shows how the application uses aliases for three-part names:

```
Read in the alias values
Do for all locations
Read location name
Set up statement to prepare
Prepare statement
a Execute statement
End loop
Commit
```

After the application obtains the next alias of a remote table to be inserted, For example, REGION1PROJ (which is the DSN8C10.PROJ table at location SAN JOSE), it creates the following character string:

```
INSERT INTO REGION1PROJ VALUES (?,?,?,?,?,?)
```

The alias is created as follows:

```
CREATE ALIAS REGION1PROJ FOR SAN_JOSE.DSN8C10.PROJ
```

The application assigns the character string to the variable INSERTX and then executes these statements:

```
EXEC SQL
PREPARE STMT1 FROM :INSERTX;
EXEC SQL
EXECUTE STMT1 USING :PROJNO, :PROJNAME, :DEPTNO, :RESPEMP,
:PRSTAFF, :PRSTDATE, :PRENDATE, :MAJPROJ;
```

The host variables for Spiffy's project table match the declaration for the sample project table.

To keep the data consistent at all locations, the application commits the work only when the loop has executed for all locations. Either every location has committed the INSERT or, if a failure has prevented any location from inserting, all other locations have rolled back the INSERT. (If a failure occurs during the commit process, the entire unit of work can be indoubt.)

Three-part names and multiple servers

Recommendation: Always use an asterisk (*) for the location name in a pklist. Never use the explicit location name unless you are sure that no other location could ever be accessed.

The following steps are recommended:

- 1. Bind the DBRM into a package at the local Db2.
- 2. Bind package copy at the first target site of the alias.
- 3. Bind package copy at the target site.

Related concepts

Considerations for binding packages at a remote location

When you bind packages at a remote location, you need to understand how the behavior of the remote packages differs from the behavior of local packages.

Accessing remote declared temporary tables by using three-part table names

You can access a remote declared temporary table by using a three-part name. However, if you combine explicit CONNECT statements and three-part names in your application, a reference to a remote declared temporary table must be a forward reference.

In a CREATE GLOBAL TEMPORARY TABLE or DECLARE GLOBAL TEMPORARY TABLE statement, you cannot specify an alias that resolves to a three-part name object at a remote location. You also cannot specify a three-part name object even if the location of the three-part name refers to the location where the object is being created or declared.

Example

You can perform the following series of actions, which includes a forward reference to a declared temporary table:

```
EXEC SQL CONNECT TO CHICAGO; /* Connect to the remote site */

EXEC SQL

DECLARE GLOBAL TEMPORARY TABLE T1 /* Define the temporary table */

(CHARCOL CHAR(6) NOT NULL) /* at the remote site */

ON COMMIT DROP TABLE;

EXEC SQL CONNECT RESET; /* Connect back to local site */

EXEC SQL INSERT INTO CHICAGO.SESSION.T1

(VALUES 'ABCDEF'); /* at the remote site (forward reference) */
```

However, you cannot perform the following series of actions, which includes a backward reference to the declared temporary table:

```
EXEC SQL

DECLARE GLOBAL TEMPORARY TABLE T1 /* Define the temporary table */

(CHARCOL CHAR(6) NOT NULL) /* at the local site (ATLANTA)*/

ON COMMIT DROP TABLE;

EXEC SQL CONNECT TO CHICAGO; /* Connect to the remote site */

EXEC SQL INSERT INTO ATLANTA.SESSION.T1

(VALUES 'ABCDEF'); /* from the remote site (backward reference)*/
```

Example using an alias

You can perform the following series of actions, which includes a forward reference to a declared temporary table using an alias. First you need to declare the alias at the requester. The name you give the alias must resolve to match the real name.

```
CREATE APPLT1 FOR CHICAGO.SESSION.T1
```

The CONNECT and DECLARE statements refer to the real declared temp table.

```
EXEC SQL CONNECT TO CHICAGO;
EXEC SQL DECLARE GLOBAL TEMPORARY TABLE T1
(CHARCOL CHAR(6) NOT NULL)
ON COMMIT DROP TABLE;
EXEC SQL CONNECT RESET;
EXEC SQL INSERT INTO APPLT1 VALUES ('ABCDEF');
```

Accessing distributed data by using explicit CONNECT statements

When you use explicit CONNECT statements to access distributed data, the application program explicitly connects to each new server.

About this task

You must bind the DBRMs for the SQL statements to be executed at the server to packages that reside at that server.

The following example assumes that all systems involved implement two-phase commit. This example suggests updating several systems in a loop and ending the unit of work by committing only when the loop is complete. Updates are coordinated across the entire set of systems.

In this example, Spiffy's application executes CONNECT for each server in turn, and the server executes INSERT. In this case, the tables to be updated each have the same name, although each table is defined at a different server. The application executes the statements in a loop, with one iteration for each server.

The application connects to each new server by means of a host variable in the CONNECT statement. CONNECT changes the special register CURRENT SERVER to show the location of the new server. The values to insert in the table are transmitted to a location as input host variables.

The following overview shows how the application uses explicit CONNECTs:

```
Read input values
Do for all locations
Read location name
Connect to location
Execute insert statement
End loop
Commit
Release all
```

For example, the application inserts a new location name into the variable LOCATION_NAME and executes the following statements:

To keep the data consistent at all locations, the application commits the work only when the loop has executed for all locations. Either every location has committed the INSERT or, if a failure has prevented any location from inserting, all other locations have rolled back the INSERT. (If a failure occurs during the commit process, the entire unit of work can be indoubt.)

The host variables for Spiffy's project table match the declaration for the sample project table. LOCATION_NAME is a character-string variable of length 16.

Project table (DSN8C10.PROJ) (Introduction to Db2 for z/OS)

Specifying a location alias name for multiple sites

You can override the location name that an application uses to access a server.

About this task

Db2 uses the DBALIAS value in the SYSIBM.LOCATIONS table to override the location name that an application uses to access a server.

For example, suppose that an employee database is deployed across two sites and that both sites make themselves known as location name EMPLOYEE. To access each site, insert a row for each site into SYSIBM.LOCATIONS with the location names SVL_EMPLOYEE and SJ_EMPLOYEE. Both rows contain EMPLOYEE as the DBALIAS value. When an application issues a CONNECT TO SVL_EMPLOYEE statement, Db2 searches the SYSIBM.LOCATIONS table to retrieve the location and network attributes of the database server. Because the DBALIAS value is not blank, Db2 uses the alias EMPLOYEE, and not the location name, to access the database.

If the application uses fully qualified object names in its SQL statements, Db2 sends the statements to the remote server without modification. For example, suppose that the application issues the statement SELECT * FROM SVL_EMPLOYEE.authid.table with the fully-qualified object name. However, Db2 accesses the remote server by using the EMPLOYEE alias. The remote server must identify itself as both SVL_EMPLOYEE and EMPLOYEE; otherwise, it rejects the SQL statement with a message indicating

that the database is not found. If the remote server is Db2, the location SVL_EMPLOYEE might be defined as a location alias for EMPLOYEE. Db2 z/OS servers are defined with this alias by using the DDF ALIAS statement of the DSNJU003 change log inventory utility. Db2 locally executes any SQL statements that contain fully qualified object names if the high-level qualifier is the location name or any of its alias names.

Related reference

LOCATIONS catalog table (Db2 SQL)
DSNJU003 (change log inventory) (Db2 Utilities)

Releasing connections

When you connect to remote locations explicitly, you must also terminate those connections explicitly.

About this task

To break the connections, you can use the RELEASE statement. The RELEASE statement differs from the CONNECT statement in the following ways:

- While the CONNECT statement makes an immediate connection, the RELEASE statement **does not** immediately break a connection. The RELEASE statement labels connections for release at the next commit point. A connection that has been labeled for release is in the *release-pending state* and can still be used before the next commit point.
- While the CONNECT statement connects to exactly one remote system, you can use the RELEASE statement to specify a single connection or a set of connections for release at the next commit point.

Example

By using the RELEASE statement, you can place any of the following connections in the release-pending state:

• A specific connection that the next unit of work does not use:

```
EXEC SQL RELEASE SPIFFY1;
```

• The current SQL connection, whatever its location name:

```
EXEC SQL RELEASE CURRENT;
```

• All connections except the local connection:

```
EXEC SQL RELEASE ALL;
```

Transmitting mixed data

Mixed data is data that contains both character and graphic data.

About this task

If you transmit mixed data between your local system and a remote system, put the data in varying-length character strings instead of fixed-length character strings.

Converting mixed data: When ASCII MIXED data or Unicode MIXED data is converted to EBCDIC MIXED, the converted string is longer than the source string. An error occurs if that conversion is performed on a fixed-length input host variable. The remedy is to use a varying-length string variable with a maximum length that is sufficient to contain the expansion.

Identifying the server at run time

You can request the location name of the system to which you are connected.

About this task

The special register CURRENT SERVER contains the location name of the system you are connected to. You can assign that name to a host variable with a statement like this:

EXEC SQL SET :CS = CURRENT SERVER;

SQL limitations at dissimilar servers

When you execute SQL statements on a remote server that is running another Db2 family product, certain limitations exist. Generally, a program that uses DRDA access can use SQL statements and clauses that are supported by a remote server, even if they are not supported by the local server.

The following examples suggest what to expect from dissimilar servers:

• They support SELECT, INSERT, UPDATE, DELETE, DECLARE CURSOR, and FETCH, but details vary.

Example: Db2 for Linux, UNIX, and Windows and Db2 for i support a form of INSERT that allows for multiple rows of input data. In this case, the VALUES clause is followed by multiple lists in parentheses. Each list represents the values to be inserted for a row of data. Db2 for z/OS does not support this form of INSERT.

· Data definition statements vary more widely.

Example: Db2 for z/OS supports ROWID columns; Db2 for Linux, UNIX, and Windows does not support ROWID columns. Any data definition statements that use ROWID columns cannot run across all platforms.

· Statements can have different limits.

Example: A query in Db2 for z/OS can have 750 columns; for other systems, the maximum is higher. But a query using 750 or fewer columns could execute in all systems.

- Some statements are not sent to the server but are processed completely by the requester. You cannot use those statements in a remote package even though the server supports them.
- In general, if a statement to be executed at a remote server contains host variables, a Db2 requester assumes them to be input host variables unless it supports the syntax of the statement and can determine otherwise. If the assumption is not valid, the server rejects the statement.

Related reference

Actions allowed on SQL statements (Db2 SQL)

Support for executing long SQL statements in a distributed environment

A distributed application can send prepared SQL statements exceed 32 KB in size. If the statements exceed 32 KB in size, the server must support these long statements.

If a distributed application assigns an SQL statement to a DBCLOB (UTF-16) variable and sends the prepared statement to a remote server, the remote Db2 server converts it to UTF-8. If the remote server does not support UTF-8, the requester converts the statement to the system EBCDIC CCSID before sending it to the remote server.

Distributed queries against ASCII or Unicode tables

When you perform a distributed query, the server determines the encoding scheme of the result table.

When a distributed query against an ASCII or Unicode table arrives at the Db2 for z/OS server, the server indicates in the reply message that the columns of the result table contain ASCII or Unicode data, rather than EBCDIC data. The reply message also includes the CCSIDs of the data to be returned. The CCSID of data from a column is the CCSID that was in effect when the column was defined.

The encoding scheme in which Db2 returns data depends on two factors:

• The encoding scheme of the requesting system.

If the requester is ASCII or Unicode, the returned data is ASCII or Unicode. If the requester is EBCDIC, the returned data is EBCDIC, even though it is stored at the server as ASCII or Unicode. However, if the SELECT statement that is used to retrieve the data contains an ORDER BY clause, the data displays in ASCII or Unicode order.

- Whether the application program overrides the CCSID for the returned data. The ways to do this are as follows:
 - For static SQL

You can bind a plan or package with the ENCODING bind option to control the CCSIDs for all static data in that plan or package. For example, if you specify ENCODING(UNICODE) when you bind a package at a remote Db2 for z/OS system, the data that is returned in host variables from the remote system is encoded in the default Unicode CCSID for that system.

- For static or dynamic SQL

An application program can specify overriding CCSIDs for individual host variables in DECLARE VARIABLE statements.

An application program that uses an SQLDA can specify an overriding CCSID for the returned data in the SQLDA. When the application program executes a FETCH statement, you receive the data in the CCSID that is specified in the SQLDA.

Related tasks

Setting the CCSID for host variables

All Db2 string data, other than binary data, has an encoding scheme and a coded character set ID (CCSID) associated with it. You can associate an encoding scheme and a CCSID with individual host variables. Any data in those host variable is then associated with that encoding scheme and CCSID.

BIND and REBIND options for packages, plans, and services (Db2 Commands)

Restrictions when using scrollable cursors to access distributed data

The restrictions that exist for scrollable cursors depend on what the requester and the server support.

If a Db2 for z/OS server processes an OPEN cursor statement for a scrollable cursor, and the OPEN cursor statement comes from a requester that does not support scrollable cursors, the Db2 for z/OS server returns an SQL error. However, if a stored procedure at the server uses a scrollable cursor to return a result set, the down-level requester can access data through that cursor. The Db2 for z/OS server converts the scrollable result set cursor to a non-scrollable cursor. The requester can retrieve the data using sequential FETCH statements.

Restrictions when using rowset-positioned cursors to access distributed data

The restrictions that exist for row-positioned cursors depend on what the requester and the server support.

If a Db2 for z/OS server processes an OPEN cursor statement for a rowset-positioned cursor, and the OPEN cursor statement comes from a requester that does not support rowset-positioned cursors, the Db2 for z/OS server returns an SQL error. However, if a stored procedure at the server uses a rowset-positioned cursor to return a result set, the down-level requester can access data through that cursor by using row-positioned FETCH statements.

IBM MQ with Db2

IBM MQ is a message handling system that enables applications to communicate in a distributed environment across different operating systems and networks.

IBM MQ handles the communication from one program to another by using application programming interfaces (APIs). You can use any of the following APIs to interact with the IBM MQ message handling system:

- Message Queue Interface (MQI)
- · IBM MQ classes for Java
- IBM MQ classes for Java Message Service (JMS)

Db2 provides its own application programming interface to the WebSphere® MQ message handling system through a set of external user-defined functions, which are called Db2 MQ functions. You can use these functions in SQL statements to combine Db2 database access with IBM MQ message handling. The Db2 MQ functions use the MQI.

Related reference

The Message Queue Interface overview

IBM MQ messages

IBM MQ uses messages to pass information between applications.

Messages consist of the following parts:

- The message attributes, which identify the message and its properties.
- The message data, which is the application data that is carried in the message.

Related concepts

Db2 MQ functions and Db2 MQ XML stored procedures

You can use the Db2 MQ functions and stored procedures to send messages to a message queue or to receive messages from the message queue.

IBM MQ message handling

Conceptually, the IBM MQ message handling system takes a piece of information (the message) and sends it to its destination. MQ guarantees delivery, despite any network disruptions that might occur.

In IBM MQ, a destination is called a message queue, and a queue resides in a queue manager. Applications can put messages on queues or get messages from them.

Db2 communicates with the WebSphere message handling system through a set of external user-defined functions, which are called Db2 MQ functions. These functions use the MQI.

When you send a message, you must specify the following three components:

message data

Defines what is sent from one program to another.

service

Defines where the message is going to or coming from. The parameters for managing a queue are defined in the service, which is typically defined by a system administrator. The complexity of the parameters in the service is hidden from the application program.

policy

Defines how the message is handled. Policies control such items as:

- The attributes of the message, for example, the priority.
- Options for send and receive operations, for example, whether an operation is part of a unit of work.

The default service and policy are set as part of defining the WebSphere MQ configuration for a particular installation of Db2. (This action is typically performed by a system administrator.) Db2 provides the default service Db2.DEFAULT.SERVICE and the default policy Db2.DEFAULT.POLICY.

Related tasks

IBM MQ home

IBM MQ message handling with the MQI

One way to send and receive IBM MQ messages from Db2 applications is to use the Db2 MQ functions that use MQI.

These MQI-based functions use the services and policies that are defined in two Db2 tables, SYSIBM.MQSERVICE_TABLE and SYSIBM.MQPOLICY_TABLE. These tables are user-managed and are typically created and maintained by a system administrator. Each table contains a row for the default service and policy that are provided by Db2.

The application program does not need know the details of the services and policies that are defined in these tables. The application need only specify which service and policy to use for each message that it sends and receives. The application specifies this information when it calls a Db2 MQ function.

Related concepts

Db2 MQ functions and Db2 MQ XML stored procedures

You can use the Db2 MQ functions and stored procedures to send messages to a message queue or to receive messages from the message queue.

Related reference

Db2 MQ tables

The Db2 MQ tables contain service and policy definitions that are used by the Message Queue Interface (MQI) based Db2 MQ functions. You must populate the Db2 MQ tables before you can use these MQI-based functions.

Db2 MQI services

A service describes a destination to which an application sends messages or from which an application receives messages. Db2 Message Queue Interface (MQI) services are defined in the Db2 table SYSIBM.MQSERVICE_TABLE.

The MQI-based Db2 MQ functions use the services that are defined in the Db2 table SYSIBM.MQSERVICE_TABLE. This table is user-managed and is typically created and maintained by a system administrator. This table contains a row for each defined service, including your customized services and the default service that is provided by Db2.

The application program does not need know the details of the defined services. When an application program calls an MQI-based Db2 MQ function, the program selects a service from SYSIBM.MQSERVICE_TABLE by specifying it as a parameter.

Related concepts

Db2 MQ functions and Db2 MQ XML stored procedures

Db2 MQ functions and Db2 MQ XML stored procedures

You can use the Db2 MQ functions and stored procedures to send messages to a message queue or to receive messages from the message queue.

The Db2 MQ functions support the following types of operations:

- Send and forget, where no reply is needed.
- Read or receive, where one or all messages are either read without removing them from the queue, or received and removed from the queue.
- Request and response, where a sending application needs a response to a request.
- Publish and subscribe, where messages are assigned to specific publisher services and are sent to queues. Applications that subscribe to the corresponding subscriber service can monitor specific messages.

You can use the Db2 MQ functions and stored procedures to send messages to a message queue or to receive messages from the message queue. You can send a request to a message queue and receive a response, and you can also publish messages to the IBM MQ publisher and subscribe to messages that have been published with specific topics. The Db2 MQ XML functions and stored procedures enable you to query XML documents and then publish the results to a message queue.

The Db2 MQ functions include scalar functions, table functions, and XML-specific functions. For each of these functions, you can call a version that uses the MQI. The function signatures are the same. However, the qualifying schema names are different. To call an MQI-based function, specify the schema name DB2MQ.

Requirement: Before you can call the version of these functions that uses MQI, you need to populate the Db2 MQ tables.

The following table describes the Db2 MQ scalar functions.

Table 123.	Dh2	MO	ccalar	functions
Table 125.	DDZ	טוייו	Scalar	TUTICLIONS

Scalar function	Description
MQREAD (receive-service, service-policy)	MQREAD returns a message in a VARCHAR variable from the MQ location specified by <i>receive-service</i> , using the policy defined in <i>service-policy</i> . This operation does not remove the message from the head of the queue but instead returns it. If no messages are available to be returned, a null value is returned.
MQREADCLOB (receive-service, service-policy)	MQREADCLOB returns a message in a CLOB variable from the MQ location specified by <i>receive-service</i> , using the policy defined in <i>service-policy</i> . This operation does not remove the message from the head of the queue but instead returns it. If no messages are available to be returned, a null value is returned.
MQRECEIVE (receive-service, service-policy, correlation-id)	MQRECEIVE returns a message in a VARCHAR variable from the MQ location specified by <i>receive-service</i> , using the policy defined in <i>service-policy</i> . This operation removes the message from the queue. If <i>correlation-id</i> is specified, the first message with a matching correlation identifier is returned; if <i>correlation-id</i> is not specified, the message at the beginning of queue is returned. If no messages are available to be returned, a null value is returned.
MQRECEIVECLOB (receive- service, service-policy, correlation-id)	MQRECEIVECLOB returns a message in a CLOB variable from the MQ location specified by <i>receive-service</i> , using the policy defined in <i>service-policy</i> . This operation removes the message from the queue. If <i>correlation-id</i> is specified, the first message with a matching correlation identifier is returned; if <i>correlation-id</i> is not specified, the message at the head of queue is returned. If no messages are available to be returned, a null value is returned.
MQSEND (send-service, service- policy, msg-data, correlation-id)	MQSEND sends the data in a VARCHAR or CLOB variable <i>msg-data</i> to the MQ location specified by <i>send-service</i> , using the policy defined in <i>service-policy</i> . An optional user-defined message correlation identifier can be specified by <i>correlation-id</i> . The return value is 1 if successful or 0 if not successful.

Notes:

1. You can send or receive messages in VARCHAR variables or CLOB variables. The maximum length for a message in a VARCHAR variable is 32 KB. The maximum length for a message in a CLOB variable is 2 MB.

The following table describes the MQ table functions that Db2 can use.

Table 124. Db2 MQ table functions		
Table function	Description	
MQREADALL (receive-service, service-policy, num-rows)	MQREADALL returns a table that contains the messages and message metadata in VARCHAR variables from the MQ location specified by <i>receive-service</i> , using the policy defined in <i>service-policy</i> . This operation does not remove the messages from the queue. If <i>num-rows</i> is specified, a maximum of <i>num-rows</i> messages is returned; if <i>num-rows</i> is not specified, all available messages are returned.	
MQREADALLCLOB (receive- service, service-policy, num-rows)	MQREADALLCLOB returns a table that contains the messages and message metadata in CLOB variables from the MQ location specified by <i>receive-service</i> , using the policy defined in <i>service-policy</i> . This operation does not remove the messages from the queue. If <i>num-rows</i> is specified, a maximum of <i>num-rows</i> messages is returned; if <i>num-rows</i> is not specified, all available messages are returned.	
MQRECEIVEALL (receive-service, service-policy, correlation-id, num-rows)	MQRECEIVEALL returns a table that contains the messages and message metadata in VARCHAR variables from the MQ location specified by <i>receive-service</i> , using the policy defined in <i>service-policy</i> . This operation removes the messages from the queue. If <i>correlation-id</i> is specified, only those messages with a matching correlation identifier are returned; if <i>correlation-id</i> is not specified, all available messages are returned. If <i>num-rows</i> is specified, a maximum of <i>num-rows</i> messages is returned; if <i>num-rows</i> is not specified, all available messages are returned.	
MQRECEIVEALLCLOB (receive- service, service-policy, correlation-id, num-rows)	MQRECEIVEALLCLOB returns a table that contains the messages and message metadata in CLOB variables from the MQ location specified by receive-service, using the policy defined in service-policy. This operation removes the messages from the queue. If correlation-id is specified, only those messages with a matching correlation identifier are returned; if correlation-id is not specified, all available messages are returned. If numrows is specified, a maximum of num-rows messages is returned; if numrows is not specified, all available messages are returned.	

Notes:

- 1. You can send or receive messages in VARCHAR variables or CLOB variables. The maximum length for a message in a VARCHAR variable is 32 KB. The maximum length for a message in a CLOB variable is 2 MB.
- 2. The first column of the result table of a Db2 MQ table function contains the message.

The Message Queue Interface overview

Generating XML documents from existing tables and sending them to an MQ message queue

You can send data from a Db2 table to the MQ message queue. First put the data in an XML document and then send that document to the message queue.

Procedure

To generate XML documents from existing tables and send them to an MQ message queue:

- 1. Compose an XML document by using the Db2 XML publishing functions.
- 2. Cast the XML document to type VARCHAR or CLOB.
- 3. Send the document to an MQ message queue by using the appropriate Db2 MQ function.

Related concepts

Db2 MQ functions and Db2 MQ XML stored procedures

You can use the Db2 MQ functions and stored procedures to send messages to a message queue or to receive messages from the message queue.

Functions for constructing XML values (Db2 Programming for XML)

Shredding XML documents from an MQ message queue

When you retrieve XML data from an MQ message queue, you can shred that data into Db2 tables for easy retrievability.

About this task

Procedure

To shred XML documents from an MQ message queue:

- 1. Retrieve the XML document from an MQ message queue by using the appropriate MQ function.
- 2. Shred the retrieved message to Db2 tables by using the XML decomposition stored procedure (XDBDECOMPXML).

Db2 MQ functions and Db2 MQ XML stored procedures

You can use the Db2 MQ functions and stored procedures to send messages to a message queue or to receive messages from the message queue.

Db2 MQ tables

The Db2 MQ tables contain service and policy definitions that are used by the Message Queue Interface (MQI) based Db2 MQ functions. You must populate the Db2 MQ tables before you can use these MQI-based functions.

The Db2 MQ tables are SYSIBM.MQSERVICE_TABLE and SYSIBM.MQPOLICY_TABLE. These tables are user-managed. You need to create them during the installation or migration process. Installation job DSNTIJRT creates these tables with one default row in each table.

If you previously used the AMI-based Db2 MQ functions, you used AMI configuration files instead of these tables. To use the MQI-based Db2 MQ functions, you need to move the data from those configuration files to the Db2 tables SYSIBM.MQSERVICE_TABLE and SYSIBM.MQPOLICY_TABLE.

The following table describes the columns for SYSIBM.MQSERVICE_TABLE.

Column name	Description
SERVICENAME	This column contains the service name, which is an optional input parameter of the MQ functions.
	This column is the primary key for the SYSIBM.MQSERVICE_TABLE table.
QUEUEMANAGER	This column contains the name of the queue manage where the MQ functions are to establish a connection
INPUTQUEUE	This column contains the name of the queue from which the MQ functions are to send and retrieve messages.
CODEDCHARSETID	This column contains the character set identifier for character data in the messages that are sent and received by the MQ functions.
	This column corresponds to the CodedCharSetId field in the message descriptor structure (MQMD). MQ functions use the value in this column to set the CodedCharSetId field.
	The default value for this column is 0, which sets the CodedCharSetId field of the MQMD to the value MQCCSI_Q_MGR.
ENCODING	This column contains the encoding value for the numeric data in the messages that are sent and received by the MQ functions.
	This column corresponds to the Encoding field in the message descriptor structure (MQMD). MQ functions use the value in this column to set the Encoding field.
	The default value for this column is 0, which sets the Encoding field in the MQMD to the value MQENC_NATIVE.
DESCRIPTION	This column contains the description of the service.
The following table describes	the columns for SYSIBM.MQPOLICY_TABLE.
Table 126. SYSIBM.MQPOLICY_TABL	E column descriptions
Column name	Description
POLICYNAME	This column contains the policy name, which is an optional input parameter of the MQ functions.
	This column is the primary key for the SYSIBM.MQPOLICY_TABLE table.

Table 126. SYSIBM.MQPOLICY_TABLE column descriptions (continued)		
Column name	Description	
SEND_PRIORITY	This column contains the priority of the message.	
	This column corresponds to the Priority field in the message descriptor structure (MQMD). MQ functions use the value in this column to set the Priority field.	
	The default value for this column is -1, which sets the Priority field in the MQMD to the value MQQPRI_PRIORITY_AS_Q_DEF.	
SEND_PERSISTENCE	This column indicates whether the message persists despite any system failures or instances of restarting the queue manager.	
	This column corresponds to the Persistence field in the message descriptor structure (MQMD). MQ functions use the value in this column to set the Persistence field.	
	This column can have the following values:	
	Sets the Persistence field in the MQMD to the value MQPER_PERSISTENCE_AS_Q_DEF. This value is the default.	
	Y Sets the Persistence field in the MQMD to the value MQPER_PERSISTENT.	
	N Sets the Persistence field in the MQMD to the value MQPER_NOT_ PERSISTENT.	
SEND_EXPIRY	This column contains the message expiration time, in tenths of a second.	
	This column corresponds to the Expiry field in the message descriptor structure (MQMD). MQ functions use the value in this column to set the Expiry field.	
	The default value is -1, which sets the Expiry field to the value MQEI_UNLIMITED.	
SEND_RETRY_COUNT	This column contains the number of times that the MQ function is to try to send a message if the procedure fails.	
	The default value is 5.	
SEND_RETRY_INTERVAL	This column contains the interval, in milliseconds, between each attempt to send a message.	
	The default value is 1000.	

Table 126. SYSIBM.MQPOLICY_TABLE column descriptions (continued)		
Column name	Description	
SEND_NEW_CORRELID	This column specifies how the correlation identifier is to be set if a correlation identifier is not passed as an input parameter in the MQ function. The correlation identifier is set in the CorrelId field in the message descriptor structure (MQMD).	
	This column can have one of the following values:	
	N Sets the CorrelId field in the MQMD to binary	
	zeros. This value is the default.	
	Specifies that the queue manager is to generate a new correlation identifier and set the CorrelId field in the MQMD to that value. This 'Y' value is equivalent to setting the MQPMO_NEW_CORREL_ID option in the Options field in the put message options structure (MQPMO).	
SEND_RESPONSE_MSGID	This column specifies how the MsgId field in the message descriptor structure (MQMD) is to be set for report and reply messages.	
	This column corresponds to the Report field in the MQMD. MQ functions use the value in this column to set the Report field.	
	This column can have one of the following values:	
	N Sets the MQRO_NEW_MSG_ID option in the Repor field in the MQMD. This value is the default.	
	P Sets the MQRO_PASS_MSG_ID option in the Report field in the MQMD.	
SEND_RESPONSE_CORRELID	This column specifies how the CorrelID field in the message descriptor structure (MQMD) is to be set for report and reply messages.	
	This column corresponds to the Report field in the MQMD. MQ functions use the value in this column to set the Report field.	
	This column can have one of the following values:	
	Sets the MQRO_COPY_MSG_ID_TO_CORREL_ID option in the Report field in the MQMD. This value is the default.	
	P Sets the MQRO_PASS_CORREL_ID option in the Report field in the MQMD.	

Table 126. SYSIBM.MQPOLICY_TABLE column descriptions (continued)		
Column name	Description	
SEND_EXCEPTION_ACTION	This column specifies what to do with the original message when it cannot be delivered to the destination queue.	
	This column corresponds to the Report field in the message descriptor structure (MQMD). MQ functions use the value in this column to set the Report field.	
	This column can have one of the following values:	
	Q Sets the MQRO_DEAD_LETTER_Q option in the Report field in the MQMD. This value is the default.	
	Sets the MQRO_DISCARD_MSG option in the Report field in the MQMD.	
	P Sets the MQRO_PASS_DISCARD_AND_EXPIRY option in the Report field in the MQMD.	
SEND_REPORT_EXCEPTION	This column specifies whether an exception report message is to be generated when a message cannot be delivered to the specified destination queue and if so, what that report message should contain.	
	This column corresponds to the Report field in the message descriptor structure (MQMD). MQ functions use the value in this column to set the Report field.	
	This column can have one of the following values:	
	N Specifies that an exception report message is not to be generated. No options in the Report field are set. This value is the default.	
	E Sets the MQRO_EXCEPTION option in the Report field in the MQMD.	
	Sets the MQRO_EXCEPTION_WITH_DATA option in the Report field in the MQMD.	
	F Sets the MQRO_EXCEPTION_WITH_FULL_DATA option in the Report field in the MQMD.	

Column name	Description	
SEND_REPORT_COA	This column specifies whether the queue manager is to send a confirm-on-arrival (COA) report message when the message is placed in the destination queue, and if so, what that COA message is to contain.	
	This column corresponds to the Report field in the message descriptor structure (MQMD). MQ functions use the value in this column to set the Report field.	
	This column can have one of the following values:	
	N	
	Specifies that a COA message is not to be sent. No options in the Report field are set. This value is the default	
	C Sets the MQRO_COA option in the Report field in the MQMD	
	Sets the MQRO_COA_WITH_DATA option in the Report field in the MQMD.	
	F Sets the MQRO_COA_WITH_FULL_DATA option in the Report field in the MQMD.	
SEND_REPORT_COD	This column specifies whether the queue manager is to send a confirm-on-delivery (COD) report message when an application retrieves and deletes a message from the destination queue, and if so, what that COD message is to contain.	
	This column corresponds to the Report field in the message descriptor structure (MQMD). MQ functions use the value in this column to set the Report field.	
	This column can have one of the following values:	
	N Specifies that a COD message is not to be sent. No options in the Report field are set. This value is the default.	
	C Sets the MQRO_COD option in the Report field in the MQMD.	
	Sets the MQRO_COD_WITH_DATA option in the Report field in the MQMD.	
	F Sets the MQRO_COD_WITH_FULL_DATA option in the Report field in the MQMD.	

Table 126. SYSIBM.MQPOLICY_TABLE column descriptions (continued)		
Column name	Description	
SEND_REPORT_EXPIRY	This column specifies whether the queue manager is to send an expiration report message if a message is discarded before it is delivered to an application, and if so, what that message is to contain.	
	This column corresponds to the Report field in the message descriptor structure (MQMD). MQ functions use the value in this column to set the Report field.	
	This column can have one of the following values:	
	Specifies that an expiration report message is not to be sent. No options in the Report field are set. This value is the default.	
	C Sets the MQRO_EXPIRATION option in the Report field in the MQMD.	
	Sets the MQRO_EXPIRATION_WITH_DATA option in the Report field in the MQMD.	
	F Sets the MQRO_EXPIRATION_WITH_FULL_DATA option in the Report field in the MQMD.	
SEND_REPORT_ACTION	This column specifies whether the receiving application sends a positive action notification (PAN), a negative action notification (NAN), or both.	
	This column corresponds to the Report field in the message descriptor structure (MQMD). MQ functions use the value in this column to set the Report field.	
	This column can have one of the following values:	
	Specifies that neither notification is to be sent. No options in the Report field are set. This value is the default.	
	P Sets the MQRO_PAN option in the Report field in the MQMD.	
	T Sets the MQRO_NAN option in the Report field in the MQMD.	
	B Sets both the MQRO_PAN and MQRO_NAN options in the Report field in the MQMD.	

Table 126. SYSIBM.MQPOLICY_TABLE column descriptions (continued)		
Column name	Description	
SEND_MSG_TYPE	This column contains the type of message.	
	This column corresponds to the MsqType field in the message descriptor structure (MQMD). MQ functions use the value in this column to set the MsqType field.	
	This column can have one of the following values:	
	DTG Sets the MsgType field in the MQMD to MQMT_DATAGRAM. This value is the default.	
	REQ Sets the MsgType field in the MQMD to MQMT_REQUEST.	
	RLY Sets the MsgType field in the MQMD to MQMT_REPLY.	
	RPT Sets the MsgType field in the MQMD to MQMT_REPORT.	
REPLY_TO_Q	This column contains the name of the message queue to which the application that issued the MQGET call is to send reply and report messages.	
	This column corresponds to the ReplyToQ field in the message descriptor structure (MQMD). MQ functions use the value in this column to set the ReplyToQ field.	
	The default value for this column is SAME AS INPUT_Q, which sets the name to the queue name that is defined in the service that was used for sending the message. If no service was specified, the name is set to DB2MQ_DEFAULT_Q, which is the name of the input queue for the default service.	
REPLY_TO_QMGR	This column contains the name of the queue manager to which the reply and report messages are to be sent.	
	This column corresponds to the ReplyToQMgr field in the message descriptor structure (MQMD). MQ functions use the value in this column to set the ReplyToQMgr field.	
	The default value for this column is SAME AS INPUT_QMGR, which sets the name to the queue manager name that is defined in the service that was used for sending the message. If no service was specified, the name is set to the name of the queue manager for the default service.	

Table 126. SYSIBM.MQPOLICY_TABLE column descriptions (continued)		
Column name	Description	
RCV_WAIT_INTERVAL	This column contains the time, in milliseconds, that Db2 is to wait for messages to arrive in the queue.	
	This column corresponds to the WaitInterval field in the get message options structure (MQGMO). MQ functions use the value in this column to set the WaitInterval field.	
	The default is 10.	
RCV_CONVERT	This column indicates whether to convert the application data in the message to conform to the CodedCharSetId and Encoding values of the specified MQ service.	
	This column corresponds to the Options field in the get message options structure (MQGMO). MQ functions use the value in this column to set the Options field.	
	This column can have one of the following values:	
	Y Sets the MQGMO_CONVERT option in the Options field in the MQGMO. This value is the default.	
	N Specifies that no data is to be converted.	
RCV_ACCEPT_TRUNC_MSG	This column specifies the behavior of the MQ function when oversized messages are retrieved.	
	This column corresponds to the Options field in the get message options structure (MQGMO). MQ functions use the value in this column to set the Options field.	
	This column can have one of the following values:	
	Υ	
	Sets the MQGMO_ACCEPT_TRUNCATED_MSG option in the Options field in the MQGMO. This value is the default.	
	N Specifies that no messages are to be truncated. If the message is too large to fit in the buffer, the MQ function terminates with an error.	
	Recommendation: Set this column to Y. In this case, if the message buffer is too small to hold the complete message, the MQ function can fill the buffer with as much of the message as the buffer can hold.	

Column name	Description
REV_OPEN_SHARED	This column specifies the input queue mode when messages are retrieved.
	This column corresponds to the Options parameter for an MQOPEN call. MQ functions use the value in this column to set the Options parameter.
	This column can have one of the following values:
	S Sets the MQOO_INPUT_SHARED option. This value is the default.
	E Sets the MQ option MQOO_INPUT_EXCLUSIVE option.
	Sets the MQ option MQOO_INPUT_AS_Q_DEF option.
SYNCPOINT	This column indicates whether the MQ function is to operate within the protocol for a normal unit of work.
	This column can have one of the following values:
	Specifies that the MQ function is to operate within the protocol for a normal unit of work. Use this value for two-phase commit environments. This value is the default. N Specifies that the MQ function is to operate outside the protocol for a normal unit of work. Use this value for one-phase commit environments.
DESC	This column contains the description of the policy.

Basic messaging with IBM MQ

The most basic form of messaging with the Db2 MQ functions occurs when all database applications connect to the same Db2 database server. Clients can be local to the database server or distributed in a network environment.

In a simple scenario, client A invokes the MQSEND function to send a user-defined string to the location that is defined by the default service. Db2 executes the MQ functions that perform this operation on the database server. At some later time, client B invokes the MQRECEIVE function to remove the message at the head of the queue that is defined by the default service, and return it to the client. Db2 executes the MQ functions that perform this operation on the database server.

Database clients can use simple messaging in a number of ways:

• Data collection

Information is received in the form of messages from one or more sources. An information source can be any application. The data is received from queues and stored in database tables for additional processing.

· Workload distribution

Work requests are posted to a queue that is shared by multiple instances of the same application. When an application instance is ready to perform some work, it receives a message that contains a work request from the head of the queue. Multiple instances of the application can share the workload that is represented by a single queue of pooled requests.

Application signaling

In a situation where several processes collaborate, messages are often used to coordinate their efforts. These messages might contain commands or requests for work that is to be performed. For more information about this technique, see "Application to application connectivity with IBM MQ" on page 801.

The following scenario extends basic messaging to incorporate remote messaging. Assume that machine A sends a message to machine B.

- 1. The Db2 client executes an MQSEND function call, specifying a target service that has been defined to be a remote queue on machine B.
- 2. The MQ functions perform the work to send the message. The WebSphere MQ server on machine A accepts the message and guarantees that it will deliver it to the destination that is defined by the service and the current MQ configuration of machine A. The server determines that the destination is a queue on machine B. The server then attempts to deliver the message to the WebSphere MQ server on machine B, trying again as needed.
- 3. The IBM MQ server on machine B accepts the message from the server on machine A and places it in the destination queue on machine B.
- 4. A IBM MQ client on machine B requests the message at the head of the queue.

Sending messages with IBM MQ

When you send messages with IBM MQ, you choose what data to send, where to send it and when to send it. This type of messaging is called *send and forget*; the sender sends a message and relies on IBM MQ to ensure that the message reaches its destination.

Procedure

To send messages with IBM MQ, use MQSEND.

Message content can be any combination of SQL statements, expressions, functions, and user-specified data. Because this MQSEND function uses two-phase commit, the COMMIT statement ensures that the message is added to the MQ queue.

Examples

If you send more than one column of information, separate the columns with the characters || ' ' ||.

MOSEND (LASTNAME || ' ' || FIRSTNAME)

The following examples use the DB2MQ schema for two-phase commit, with the default service Db2.DEFAULT.SERVICE and the default policy Db2.DEFAULT.POLICY.

The following SQL SELECT statement sends a message that consists of the string "Testing msg":

```
SELECT DB2MQ.MQSEND ('Testing msg')
FROM SYSIBM.SYSDUMMY1;
COMMIT;
```

The MQSEND function is invoked once because SYSIBM.SYSDUMMY1 has only one row. Because this MQSEND function uses two-phase commit, the COMMIT statement ensures that the message is added to the queue.

When you use single-phase commit, you do not need to use a COMMIT statement. For example:

```
SELECT DB2MQ.MQSEND ('Testing msg')
FROM SYSIBM.SYSDUMMY1;
```

The MQ operation causes the message to be added to the queue.

Assume that you have an EMPLOYEE table, with VARCHAR columns LASTNAME, FIRSTNAME, and DEPARTMENT. To send a message that contains this information for each employee in DEPARTMENT 5LGA, issue the following SQL SELECT statement:

```
SELECT DB2MQ.MQSEND (LASTNAME || ' ' || FIRSTNAME || ' ' || DEPARTMENT)
FROM EMPLOYEE WHERE DEPARTMENT = '51GA';
COMMIT;
```

MQSEND scalar function (Db2 SQL)

Retrieving messages with IBM MQ

With IBM MQ, programs can read or receive messages. Both reading and receiving operations return the message at the start of the queue. However, the reading operation does not remove the message from the queue, whereas the receiving operation does.

About this task

A message that is retrieved using a receive operation can be retrieved only once, whereas a message that is retrieved using a read operation allows the same message to be retrieved many times.

Examples

The following examples use the DB2MQ2N schema for two-phase commit, with the default service Db2.DEFAULT.SERVICE and the default policy Db2.DEFAULT.POLICY.

Example

The following SQL SELECT statement reads the message at the head of the queue that is specified by the default service and policy:

```
SELECT DB2MQ2N.MQREAD()
FROM SYSIBM.SYSDUMMY1;
```

The MQREAD function is invoked once because SYSIBM.SYSDUMMY1 has only one row. The SELECT statement returns a VARCHAR(4000) string. If no messages are available to be read, a null value is returned. Because MQREAD does not change the queue, you do not need to use a COMMIT statement.

Example

The following SQL SELECT statement causes the contents of a queue to be materialized as a Db2 table:

```
SELECT T.*
FROM TABLE(DB2MQ2N.MQREADALL()) T;
```

The result table T of the table function consists of all the messages in the queue, which is defined by the default service, and the metadata about those messages. The first column of the materialized result table is the message itself, and the remaining columns contain the metadata. The SELECT

statement returns both the messages and the metadata. To return only the messages, issue the following statement:

```
SELECT T.MSG
FROM TABLE(DB2MQ2N.MQREADALL()) T;
```

The result table T of the table function consists of all the messages in the queue, which is defined by the default service, and the metadata about those messages. This SELECT statement returns only the messages.

Example

The following SQL SELECT statement receives (removes) the message at the head of the queue:

```
SELECT DB2MQ2N.MQRECEIVE()
FROM SYSIBM.SYSDUMMY1;
COMMIT;
```

The MQRECEIVE function is invoked once because SYSIBM.SYSDUMMY1 has only one row. The SELECT statement returns a VARCHAR(4000) string. Because this MQRECEIVE function uses two-phase commit, the COMMIT statement ensures that the message is removed from the queue. If no messages are available to be retrieved, a null value is returned, and the queue does not change.

Example

Assume that you have a MESSAGES table with a single VARCHAR(2000) column. The following SQL INSERT statement inserts all of the messages from the default service queue into the MESSAGES table in your Db2 database:

```
INSERT INTO MESSAGES
  SELECT T.MSG
  FROM TABLE(DB2MQ2N.MQRECEIVEALL()) T;
COMMIT;
```

The result table T of the table function consists of all the messages in the default service queue and the metadata about those messages. The SELECT statement returns only the messages. The INSERT statement stores the messages into a table in your database.

Application to application connectivity with IBM MQ

Application-to-application connectivity is typically used when putting together a diverse set of application subsystems. To facilitate application integration, WebSphere MQ provides the means to interconnect applications.

The Request-and-reply method is very common when interconnecting applications.

Request-and-reply communication method

The request-and-reply method enables one application to request the services of another application. One way to do this is for the requester to send a message to the service provider to request that some work be performed. When the work has been completed, the provider might decide to send results, or just a confirmation of completion, back to the requester. Unless the requester waits for a reply before continuing, IBM MQ must provide a way to associate the reply with its request.

IBM MQ provides a correlation identifier to correlate messages in an exchange between a requester and a provider. The requester marks a message with a known correlation identifier. The provider marks its reply with the same correlation identifier. To retrieve the associated reply, the requester provides that correlation identifier when receiving messages from the queue. The first message with a matching correlation identifier is returned to the requester.

The following examples use the DB2MQ schema for single-phase commit.

Examples of request-and-reply communication

Example

The following SQL SELECT statement sends a message consisting of the string "Msg with corr id" to the service MYSERVICE, using the policy MYPOLICY with correlation identifier CORRID1:

```
SELECT DB2MQ.MQSEND ('MYSERVICE', 'MYPOLICY', 'Msg with corr id', 'CORRID1')
FROM SYSIBM.SYSDUMMY1;
```

The MQSEND function is invoked once because SYSIBM.SYSDUMMY1 has only one row. Because this MQSEND uses single-phase commit, IBM MQ adds the message to the queue, and you do not need to use a COMMIT statement.

Example

The following SQL SELECT statement receives the first message that matches the identifier CORRID1 from the queue that is specified by the service MYSERVICE, using the policy MYPOLICY:

```
SELECT DB2MQ.MQRECEIVE ('MYSERVICE', 'MYPOLICY', 'CORRID1')
FROM SYSIBM.SYSDUMMY1;
```

The SELECT statement returns a VARCHAR(4000) string. If no messages are available with this correlation identifier, a null value is returned, and the queue does not change.

Asynchronous messaging in Db2 for z/OS

Programs can communicate with each other by sending data in messages rather than using constructs like synchronous remote procedure calls. With asynchronous messaging, the program that sends the message proceeds with its processing after sending the message, without waiting for a reply.

If the program needs information from the reply, the program suspends processing and waits for a reply message. If the messaging programs use an intermediate queue that holds messages, the requester program and the receiver program do not need to be running at the same time. The requester program places a request message on a queue and then exits. The receiver program retrieves the request from the queue and processes the request.

Asynchronous operations require that the service provider is capable of accepting requests from clients without notice. An asynchronous listener is a program that monitors message transporters, such as WebSphere MQ, and performs actions based on the message type. An asynchronous listener can use WebSphere MQ to receive all messages that are sent to an endpoint. An asynchronous listener can also register a subscription with a publish or subscribe infrastructure to restrict the messages that are received to messages that satisfy specified constraints.

Examples: The following examples show some common uses of asynchronous messaging:

Message accumulator

You can accumulate the messages that are sent asynchronously so that the listener checks for messages and stores those messages automatically in a database. This database, which acts as a message accumulator, can save all messages for a particular endpoint, such as an audit trail. The asynchronous listener can subscribe to a subset of messages, such as save only high value stock trades. The message accumulator stores entire messages, and does not provide for selection, transformation, or mapping of message contents to database structures. The message accumulator does not reply to messages.

Message event handler

The asynchronous event handler listens for messages and invokes the appropriate handler (such as a stored procedure) for the message endpoint. You can call any arbitrary stored procedure. The asynchronous listener lets you select, map, or reformat message contents for insertion into one or more database structures.

Asynchronous messaging has the following benefits:

• The client and database do not need to be available at the same time. If the client is available intermittently, or if the client fails between the time the request is issued and the response is sent,

it is still possible for the client to receive the reply. Or, if the client is on a mobile computer and becomes disconnected from the database, and if a response is sent, the client can still receive the reply.

- The content of the messages in the database contain information about when to process particular requests. The messages in the database use priorities and the request contents to determine how to schedule the requests.
- An asynchronous message listener can delegate a request to a different node. It can forward the request to a second computer to complete the processing. When the request is complete, the second computer returns a response directly to the endpoint that is specified in the message.
- An asynchronous listener can respond to a message from a supplied client, or from a user-defined application. The number of environments that can act as a database client is greatly expanded. Clients such as factory automation equipment, pervasive devices, or embedded controllers can communicate with Db2 either directly through IBM MQ or through some gateway that supports WebSphere MQ.

MQListener in Db2 for z/OS

Db2 for z/OS provides an asynchronous listener, MQListener. MQListener is a framework for tasks that read from IBM MQ queues and call Db2 stored procedures with messages as those messages arrive.

MQListener combines messaging with database operations. You can configure the MQListener daemon to listen to the IBM MQ message queues that you specify in a configuration database. MQListener reads the messages that arrive from the queue and calls Db2 stored procedures using the messages as input parameters. If the message requires a reply, MQListener creates a reply from the output that is generated by the stored procedure. The message retrieval order is fixed at the highest priority first, and then within each priority the first message received is the first message served.

MQListener runs as a single multi-threaded process on z/OS UNIX System Services. Each thread or task establishes a connection to its configured message queue for input. Each task also connects to a Db2 database on which to run the stored procedure. The information about the queue and the stored procedure is stored in a table in the configuration database. The combination of the queue and the stored procedure is a task.

MQListener tasks are grouped together into named configurations. By default, the configuration name is empty. If you do not specify the name of a configuration for a task, MQListener uses the configuration with an empty name.

Transaction support in MQListener

There is support for both one-phase and two-phase commit environments. A one-phase commit environment is where DB interactions and MQ interactions are independent. A two-phase commit environment is where DB interactions and MQ interactions are combined in a single unit of work.

'db2mqln1' is the name of the executable for one phase and 'db2mqln2' is the name of the executable for two phase.

Logical ordering of messages in MQListener

The two-phase commit version of the MQListener stored procedure processes messages that are in a group in logical order. The single-phase commit version of the MQListener stored procedure processes messages that are in a group in physical order.

MQListener stored procedure interfaces

The MQListener interface supports two stored procedure formats: with either two or three parameters.

The data type and length of the stored procedure parameters are determined when the MQListener is started. If you change the data type or length of the parameters, the change takes effect when you restart the MQListener. You can use the following commands to restart the MQListener:

mqlistener-command mqlistener-command admin
-adminQueue adminqueue-name

MQListener stored procedure interface with two parameters

This stored procedure interface for MQListener takes the incoming message as input and returns the reply, which might be NULL, as output. For example:

```
CREATE schema.proc(
IN INMSG inMsgType,
OUT OUTMSG outMsgType)...
```

The data type for INMSG and the data type for OUTMSG can be VARCHAR, VARBINARY, CLOB, or BLOB, of any length, and are determined at startup. The input data type and output data type can be different data types. If an incoming message is a request or a datagram and has a specified reply-to queue, the message in OUTMSG is sent to the specified queue. The incoming message can be one of the following message types:

- Datagram
- Datagram with report requested
- Request message with reply
- · Request message with reply and report requested

MQListener stored procedure interface with three parameters

This stored procedure interface for MQListener has parameters with the following information:

- · An incoming message as input
- · A reply, which might be NULL, as output
- · A message header, which can be input or output

For example:

```
CREATE schema.proc(
IN INMSG inMsgType,
OUT OUTMSG outMsgType,
INOUT MSGHEADER msgHeaderType)...
```

The data type for INMSG and the data type for OUTMSG can be VARCHAR, VARBINARY, CLOB, or BLOB, of any length, and are determined at startup. The input data type and output data type can be different data types. If an incoming message is a request or a datagram and has a specified reply-to queue, the message in OUTMSG is sent to the specified queue. The incoming message can be one of the following message types:

- Datagram
- Datagram with report requested
- Request message with reply
- · Request message with reply and report requested

The data type for MSGHEADER can be VARBINARY or BLOB. The minimum length of MSGHEADER is 324, which is the size of the message queuing message descriptor (MQMD) structure for IBM MQ messages.

MQListener passes the message header to the stored procedure in the MSGHEADER parameter. The stored procedure can get the message descriptor properties from the MSGHEADER parameter. If the message is a request message, the stored procedure can specify the properties for the reply queue and reply queue manager in the MSGHEADER parameter. The output message in OUTMSG is sent to that specified queue.

Configuring MQListener in Db2 for z/OS

Before you can use MQListener, you must configure your database environment so that your applications can use messaging with database operations. You must also configure IBM MQ for MQListener.

Before you begin

Ensure that the person who runs the installation job has required authority to create the configuration table and to bind the DBRMs.

About this task

The following sample jobs for MQListener are located in the prefix.SDSNSAMP data set.

DSNTIJML

A sample job for extracting library files and configuring MQListener in z/OS UNIX System Services

DSNTEJML

A sample job that runs scripts for configuring MQListener.

DSNTEJSP

A sample job for extracting library tar files in z/OS UNIX System Services when applying PTFs for MQListener.

Procedure

To configure the environment for MQListener and to develop a simple application that receives a message, inserts the message in a table, and creates a simple response message, use these steps:

- 1. Configure MQListener to run in the Db2 environment, so that your applications can use messaging with database operations, by completing the following steps:
 - a) In z/OS UNIX System Services, the default path for MQListener in is /usr/lpp/db2c10/mq1. The mqlsn.tar.Z tar file for MQListener is located in this path. If MQListener is not installed in the default path, replace all occurrences of the default path in the samples DSNTEJML, DSNTEJSP and DSNTIJML with the path name where MQListener is installed before you run DSNTIJML.
 - b) Customize and run installation job DSNTIJML. It completes the following actions:
 - i) Extracts the necessary files and libraries to z/OS UNIX System Services under the path where MQListener is installed.
 - ii) Creates the MQListener configuration table (SYSMQL.LISTENERS) in the default database DSNDB04.
 - iii) Binds the DBRMs to the plan DB2MQLSN.

Applying PTFs:

When applying APAR PTFs for MQListener, extract the tar file and rebind the MQListener library files in z/OS UNIX System Services by running the following steps of the DSNTIJML job: COPYHFS, UNTARLN, BINDBRM. If the SYSMQL.LISTENERS table is already defined, you must skip the CREATBL step.

- c) Follow the instructions in the README file in the MQListener installation path to complete the configuration process.
- 2. Configure IBM MQ for MQListener.

You can run a simple MQListener application with a simple IBM MQ configuration. More complex applications might need a more complex configuration. Configure at least two kinds of IBM MQ entities: the queue manager and some local queues. Configure these entities for use in such instances as transaction management, deadletter queue, backout queue, and backout retry threshold.

a) Create IBM MQ QueueManager. Define the IBM MQ subsystem to z/OS and then issue the following command from a z/OS console to start the queue manager, where *command-prefix* is the command prefix for the IBM MQ subsystem.

b) Create Queues under IBM MQ QueueManager:

For example, n a simple MQListener application, you typically use the following IBM MQ queues:

Deadletter queue

The deadletter queue in IBM MQ holds messages that cannot be processed. MQListener uses this queue to hold replies that cannot be delivered, for example, because the queue to which the replies should be sent is full. A deadletter queue is useful in any MQ installation especially for recovering messages that are not sent.

Backout queue

For MQListener tasks that use two-phase commit, the backout queue serves a similar purpose as the deadletter queue. MQListener places the original request in the backout queue after the request is rolled back a specified number of times (called the backout threshold).

Administration queue

The administration queue is used for routing control messages, such as shutdown and restart, to MQListener. If you do not supply an administration queue, the only way to shut down MQListener is to issue a kill command.

Application input and output queues

The application uses input queues and output queues. The application receives messages from the input queue and sends replies and exceptions to the output queue.

Create your local queues by using CSQUTIL utility or by using IBM MQ operations and control panels from ISPF (csqorexx). The following is an example of the JCL that is used to create your local queues. In this example, MQND is the name of the queue manager:

```
//* ADMIN_Q
                    : Admin queue
     BACKOŪŤ_Q
                     : Backout queue
//* IN_0 : Input queue having a backout queue with threshold=3 //* REPLY_Q : output queue or reply queue
//* DEADLLETTER_Q: Dead letter queue
//DSNTECU
              EXEC PGM=CSQUTIL, PARM='MQND'
                   DSN=MQS.SCSQANLE,DISP=SHR
DSN=MQS.SCSQAUTH,DISP=SHR
              DD
//STEPLIB
              DD
//SYSPRINT DD
                   SYSOUT=*
//SYSIN
              DD *
  COMMAND
                DDNAME(CREATEQ)
//CREATEO DD *
     DEFINE QLOCAL('ADMIN_Q') REPLACE +
              DESCR('INPUT-OUTPUT')
              PUT(ENABLED)
              DEFPRTY(0)
              DEFPSIST(NO)
              SHARE
              DEFSOPT(SHARED)
              GET(ENABLED)
     DEFINE QLOCAL('BACKOUT_Q') REPLACE + DESCR('INPUT-OUTPUT') +
              PUT(ENABLED)
              DEFPRTY(0)
              DEFPSIST(NO)
              SHARE
              DEFSOPT(SHARED)
              GET(ENABLED)
     DEFINE QLOCAL('REPLY_Q') REPLACE + DESCR('INPUT-OUTPUT') +
              PUT(ENABLED)
              DEFPRTY(0)
              DEFPSIST(NO)
              SHARE
              DEFSOPT(SHARED)
              GET(ENABLED)
      DEFINE QLOCAL('IN_Q') REPLACE +
DESCR('INPUT-OUTPUT') +
              PUT(ENABLED)
              DEFPRTY(0)
              DEFPSIST(NO)
              SHARE
```

```
DEFSOPT(SHARED) +
GET(ENABLED) +
BOQNAME('BACKOUT_Q') +
BOTHRESH(3)

DEFINE QLOCAL('DEADLETTER_Q') REPLACE +
DESCR('INPUT-OUTPUT') +
PUT(ENABLED) +
DEFPRTY(0) +
DEFPSIST(NO) +
SHARE +
DEFSOPT(SHARED) +
GET(ENABLED)

ALTER QMGR DEADQ ('DEADLETTER_Q') REPLACE
```

- 3. Configure MQListener tasks. For more information, see "Configuring MQListener tasks" on page 808.
- 4. Create a stored procedure that MQListener uses to store messages in a table. See <u>"Creating a sample</u> stored procedure to use with MQListener" on page 811 for details.
- 5. Run a simple MQListener application.

Environment variables for logging and tracing MQListener

Several environment variables control logging and tracing for MQListener. These variables are defined in the file .profile.

MOLSNTRC

When this environment variable is set to 1, MQListener writes function entry, data, and exit points to a unique HFS or zFS file. A unique trace file is generated whenever any of the MQListener commands are run. This trace file is used by IBM Support for debugging. Do not define this variable unless IBM Support requests that you do so.

If you have enabled tracing, when the MQListener daemon is running, it writes to the trace file. Therefore, if you open the trace file while the MQListener daemon is running, you need to open it only in read mode.

MQLSNLOG

The log file contains diagnostic information about major events. This environment variable is set to the name of the file where all log information is written. All instances of the MQListener daemon running one or more tasks share the same file. For monitoring the MQListener daemon, this variable should always be set.

When the MQListener daemon is running, it writes to the log file. Therefore, if you open the log file while the MQListener daemon is running, you need to open it only in read mode.

MQLSNLWR

When MQLSNLOG specifies an HFS log file, MQLSNLWR provides the capability to limit the HFS log file size. The syntax for an MQLSNLWR export command is:

```
export MQLSNLWR=file-size,file-name
```

The meanings of the variables are:

file-size

The maximum size of the MQListener log file, in megabytes.

file-name

The name of the HFS file into which MQListener saves a copy of the MQListener log file.

When MQLSNLWR is specified, and the MQListener HFS log file reaches *file-size*, MQListener saves a copy of the log file named *file-name*, and reinitializes the HFS log file.

Important: The ID under which MQListener runs must have write access to the HFS log file and to the copy of the HFS log file that is specified by *file-name*. If MQListener cannot open or write to the copy of the HFS log file, MQListener reinitializes the HFS log file, but does not create a copy.

Refer to the README file for more details about these variables.

Configuration table: SYSMQL.LISTENERS

If you use MQListener, you must create the MQListener configuration table SYSMQL.LISTENERS by running installation job DSNTIJML.

The SYSMQL.LISTENERS table contains a row for each configuration that you create when you issue MQListener db2mqln1 or db2mqln2 configuration commands.

The following table describes each of the columns of the configuration table SYSMQL.LISTENERS.

Table 127. Description of columns in the SYSMOL.LISTENERS table

Column name	Description
CONFIGURATIONNAME	The configuration name. The configuration name enables you to group several tasks into the same configuration. A single instance of MQListener can run all of the tasks that are defined within a configuration name.
QUEUEMANAGER	The name of the IBM MQ subsystem that contains the queues that are to be used.
INPUTQUEUE	The name of the queue in the WebSphere MQ subsystem that is to be monitored for incoming messages. The combination of the input queue and the queue manager are unique within a configuration
PROCNODE	Currently unused
PROCSCHEMA	The schema name of the stored procedure that will be called by MQListener
PROCNAME	The name of the stored procedure that will be called by MQListener
PROCTYPE	Currently unused
NUMINSTANCES	The number of duplicate instances of a single task that are to run in this configuration
WAITMILLIS	The time MQListener waits (in milliseconds) after processing the current message before it looks for the next message
MINQUEUEDEPTH	Currently unused

Configuring MQListener tasks

As part of configuring MQListener in Db2 for z/OS, you must configure at least one MQListener task.

About this task

Use MQListener command **db2mqln1** or **db2mqln2** to configure MQListener tasks. Issue the command from the z/OS UNIX System Services command line in any directory. Alternatively, you can put the command in a file, grant execute permission on the file, and use the BPXBATCH utility to invoke the command using JCL. Sample script files are provided and are located in the /mqlistener-install-path/mqlsn/listener/script directory in z/OS UNIX System Services. Sample JCL is also provided in member DSNTEJML of data set prefix.SDSNSAMP. When you run MQListener commands, configuration information is stored in the Db2 table SYSMQL.LISTENERS.

The command parameters are:

-adminQueue

The queue to which MQListener listens for administration commands. If **-adminQueue** is not specified, applications do not receive any administration commands through the message queue.

-adminQMgr

The name of the IBM MQ subsystem that contains the queues that are to be used for administrative tasks. If **-adminQMgr** is not specified, the configured default queue manager is used.

-config

A name that identifies a group of tasks that run together. If -config is not specified, the default configuration is run.

-queueManager

The name of the IBM MQ subsystem that contains the queues that are to be used. If **-queueManager** is not specified, is not specified, the default queue manager is used.

-inputQueue

The name of the queue in the IBM MQ subsystem that is to be monitored for incoming messages. The combination of the -inputQueue value and the **-queueManager** value must be unique within a configuration.

-numInstances

The number of duplicate instances of a single task that are to run in a configuration.

-numMessagesCommit

The number of messages that are received before MQListener issues a COMMIT. The default is 1. This option is supported only for **db2mq1n2**.

-procName

The name of the stored procedure that MQListener calls when it detects that a message is received.

-procSchema

The schema name of the stored procedure that MQListener calls when it detects that a message is received.

-ssID

The subsystem where the MQListener daemon runs. Configuration information is stored in this subsystem.

-timeRestart

If a stored procedure that is specified by **-procSchema** and **-procName** fails at MQListener startup time, the number of seconds that threads that are running with that stored procedure suspend before repeating the setup process. MQListener continues startup for threads that do not use that stored procedure. This value must be an integer in the range 0–7200. 0 is the default.

-restartDB2

Whether MQListener automatically reconnects and resumes processing after Db2 is stopped and restarted.

ΙΥΙ

MQListener automatically reconnects and resumes processing after Db2 is stopped and restarted.

'N'

MQListener does not automatically reconnect after Db2 is stopped and restarted. 'N' is the default value.

The syntax of the commands follows. In the command syntax, mqlistener-command is db2mqln1 or db2mqln2.

• To add an MQListener configuration, issue the mqlistener-command add command:

```
mqlistener-command add
-ssID subsystem-name
-config configuration-name
-queueManager queuemanager-name
-inputQueue inputqueue-name
-procName stored-procedure-name
-procSchema stored-procedure-schema name
-numInstances number-of-instances
```

• To display information about the configuration, issue the following mqlistener-command **show** command:

```
mqlistener-command show
-ssID subsystem-name
-config configuration-name
```

To display information about all the configurations, issue the mqlistener-command show command:

```
mqlistener-command show
-ssID subsystem-name
-config all
```

• To remove the messaging tasks, issue the *mglistener-command* **remove** command:

```
mqlistener-command remove
-ssID subsystem-name
-config configuration-name
-queueManager queuemanager-name
-inputQueue inputqueue-name
```

• To run the MQListener task, issue the *mglistener-command* **run** command:

```
mqlistener-command run
-ssID subsystem-name
-config configuration-name
-adminQueue adminqueue-name
-adminQMgr adminqueuemanager-name
-numMessagesCommit number-of-messages-before-commit
-timeRestart number-of-seconds-to-suspend-before-restart
-restartDB2 y-or-n
```

• To shutdown the MQListener daemon, issue the *mglistener-command* admin command:

```
mqlistener-command admin
-adminQueue adminqueue-name
-adminQMgr adminqueuemanager-name
-adminCommand shutdown
```

• To restart the MQListener daemon, issue the following command:

```
mqlistener-command mqlistener-command admin
-adminQueue adminqueue-name
-adminQMgr adminqueuemanager-name
-adminCommand restart
```

• To get help with the command and the valid parameters, issue the *mqlistener-command* **help** command:

```
mqlistener-command help
```

• To get help for a particular parameter, issue the *mqlistener-command* **help** command, where *command* is a specific parameter:

```
mqlistener-command help command
```

Restriction:

- Use the same queue manager for the request queue and the reply queue.
- MQListener does not support logical messages that are composed of multiple physical messages. MQListener processes physical messages independently.

Creating a sample stored procedure to use with MQListener

You can create a sample stored procedure, APROC, that can be used by MQListener to store a message in a table. The stored procedure returns the string OK if the message is successfully inserted into the table.

About this task

This example assumes the following information about the environment:

- MQListener is installed and configured for subsystem DB2A.
- The IBM MQ subsystem that is defined is named CSQ1.
- The queue manager is running, and the following local queues are defined in the DB2A subsystem:
 - ADMIN_Q: The administration queue
 - BACKOUT_Q: The backout queue
 - DB2MQ_DEFAULT_Q: The input queue, which has a backout queue with a threshold of 3
 - REPLY_Q: The output queue or reply queue
 - DEADLETTER_Q: The dead letter queue
- The user who is running the MQListener daemon has the EXECUTE privilege on the DB2MQLSN plan.
- MQlistener passes the message header (MQMD structure) to the stored procedure interface for MQListener.

Procedure

The following steps create Db2 objects that you can use with MQListener applications:

1. Create a table using SPUFI, DSNTEP2, or the Db2 command line processor in the subsystem where you want to run MQListener:

```
CREATE TABLE PROCTABLE (MSG VARCHAR(25) CHECK (MSG NOT LIKE 'FAIL%'));
```

The table contains a check constraint so that messages that start with the characters FAIL cannot be inserted into the table. The check constraint is used to demonstrate the behavior of MQListener when the stored procedure fails.

2. Create the following SQL procedure, and define it to the same Db2 subsystem.

```
CREATE PROCEDURE TEST.APROC (
   IN PIN VARCHAR(25),
   OUT POUT VARCHAR(2),
   INOUT PMSGHEADER VARBINARY(500))
VERSION V1
LANGUAGE SQL
PROCEDURE1: BEGIN
   DECLARE REPLYQ VARBINARY(48);
   DECLARE REPLYQM VARBINARY(48);
   SET REPLYQ = VARBINARY(CONCAT('NEWREPLYQUEUE', X'00'));
   SET REPLYQM = VARBINARY(CONCAT('CSQ1', X'00'));
   SET PMSGHEADER = INSERT(PMSGHEADER, 101, LENGTH(REPLYQ), REPLYQ);
   SET PMSGHEADER = INSERT(PMSGHEADER, 149, LENGTH(REPLYQM), REPLYQM);
   INSERT INTO SYSADM.PROCTABLE VALUES (PIN);
   SET POUT = 'OK';
   END PROCEDURE1
```

3. Add the following configuration, named ACFG, to the configuration table by issuing this command:

```
db2mqln2 add
-ssID DB2A
-config ACFG
-queueManager CSQ1
-inputQueue DB2MQ_DEFAULT_Q
-procName APROC
-procSchema TEST
```

4. Run the MQListener daemon for two-phase commit for configuration ACFG. To run MQListener with all of the tasks that are specified in the configuration, issue the following command:

```
db2mqln2 run
-ssID DB2A
-config ACFG
-adminQueue ADMIN_Q
-adminQMgr MQND
```

- 5. Send a request to the input queue, 'DB2MQ_DEFAULT_Q', with the message 'another sample message'.
- 6. Query table PROCTABLE to verify that the sample message was inserted:

```
SELECT * FROM PROCTABLE;
```

7. Display the number of messages that remain on the input queue, to verify that the message has been removed. To do that issue the following command from a z/OS console:

```
/-CSQ1 display queue('DB2MQ_DEFAULT_Q ') curdepth
```

8. Look at the ReplytoQ name that you specified, to verify that the string 'OK' is generated by the stored procedure.

MQListener error processing

MQListener reads from IBM MQ message queues and calls Db2 stored procedures with those messages. If any errors occur during this process and the message is to be sent to the deadletter queue, MQListener returns a reason code to the deadletter queue.

Specifically, MQListener performs the following actions:

- prefixes the message with an MQ dead letter header (MQDLH) structure
- sets the reason field in the MQDLH structure to the appropriate reason code
- sends the message to the deadletter queue

The following table describes the reason codes that the MQListener daemon returns.

Table 128. Reason codes that MQListener returns	
Reason code	Explanation
900	The call to a stored procedure was successful but an error occurred during the Db2 commit process and either of the following conditions were true:
	• No exception report was requested. ¹
	An exception report was requested, but could not be delivered.
	This reason code applies only to one-phase commit environments.
901	The call to the specified stored procedure failed and the disposition of the MQ message is that an exception report be generated and the original message be sent the deadletter queue.
902	All of the following conditions occurred:
	The disposition of the MQ message is that an exception report is not to be generated. 1
	• The stored procedure was called unsuccessfully the number of times that is specified as the backout threshold.
	The name of the backout queue is the same as the deadletter queue.
	This reason code applies only to two-phase commit environments.
MQRC_TRUNCATED MSGFAILED	The size of the MQ message is greater than the input parameter of the stored procedure that is to be invoked. In one-phase commit environments, this oversized message is sent to the dead letter queue. In two-phase commit environments, this oversized message is sent to the deadletter queue only when the message cannot be delivered to the backout queue.

Note:

- 1. To specify that the receiver application generate exception reports if errors occur, set the report field in the MQMD structure that was used when sending the message to one of the following values:
 - MQRO_EXCEPTION
 - MQRO_EXCEPTION_WITH_DATA
 - MQRO_EXCEPTION_WITH_FULL_DATA

IBM MQ home

MQListener examples

The application receives a message, inserts the message into a table, and generates a simple response message.

To simulate a processing failure, the application includes a check constraint on the table that contains the message. The constraint prevents any string that begins with the characters 'fail' from being inserted into the table. If you attempt to insert a message that violates the check constraint, the example application returns an error message and re-queues the failing message to the backout queue.

In this example, the following assumptions are made:

- MQListener is installed and configured for subsystem DB7A.
- MQND is the name of IBM MQ subsystem that is defined. The Queue Manager is running, and the following local queues are defined in the DB7A subsystem:

```
ADMIN_Q : Admin queue BACKOUT_Q : Backout queue
```

IN_Q : Input queue that has a backout queue withthreshold = 3

REPLY_Q: Output queue or Reply queue DEADLLETTER_Q: Dead letter queue

• The person who is running the MQListener daemon has execute permission on the DB2MQLSN plan.

Before you run the MQListener daemon, add the following configuration, named ACFG, to the configuration table by issuing the following command:

```
db2mqln2 add
-ssID DB7A
-config ACFG
-queueManager MQND
-inputQueue IN_Q
-procName APROC
-procSchema TEST
```

Run the MQListener daemon for two-phase commit for configuration ACFG by issuing the following command:

```
db2mqln2 run
-ssID DB7A
-config ACFG
-adminQueue ADMIN_Q
-adminQMgr MQND
-numMessagesCommit 1
-timeRestart 60
```

The following examples show how to use MQListener to send a simple message and then inspect the results of the message in the IBM MQ queue manager and the database. The examples include queries to determine if the input queue contains a message or to determine if a record is placed in the table by the stored procedure.

MQListener example 1: Running a simple application:

1. Start with a clean database table by issuing the following SQL statement:

delete from PROCTABLE

- 2. Send a datagram to the input queue, 'IN_Q', with the message as 'sample message'. Refer to WebSphere MQ sample CSQ4BCK1 to send a message to the queue. Specify the MsgType option for 'Message Descriptor' as 'MQMT_DATAGRAM'.
- 3. Query the table by using the following statement to verify that the sample message is inserted:

```
select * from PROCTABLE
```

4. Display the number of messages that remain on the input queue to verify that the message has been removed. Issue the following command from a z/OS console:

```
/-MQND display queue('In_Q') curdepth
```

MQListener example 2: Sending requests to the input queue and inspecting the reply:

1. Start with a clean database table by issuing the following SQL statement:

```
delete from PROCTABLE
```

- 2. Send a request to the input queue, 'IN_Q', with the message as 'another sample message'. Refer to IBM MQ sample CSQ4BCK1 to send a message to the queue. Specify the MsgType option for 'Message Descriptor' as 'MQMT_REQUEST' and the queue name for ReplytoQ option.
- 3. Query the table by using the following statement to verify that the sample message is inserted:

```
select * from PROCTABLE
```

4. Display the number of messages that remain on the input queue to verify that the message has been removed. Issue the following command from a z/OS console:

```
/-MOND display queue('In O') curdepth
```

5. Look at the ReplytoQ name that you specified when you sent the request message for the reply by using the IBM MQ sample program CSQ4BCJ1. Verify that the string 'OK' is generated by the stored procedure.

MQListener example 3: Testing an unsuccessful insert operation: If you send a message that starts with the string 'fail', the constraint in the table definition is violated, and the stored procedure fails.

1. Start with a clean database table by issuing the following SQL statement:

```
delete from PROCTABLE
```

- 2. Send a request to the input queue, 'IN_Q', with the message as 'failing sample message'. Refer to IBM MQ sample CSQ4BCK1 to send a message to the queue. Specify the MsgType option for 'Message Descriptor' as 'MQMT_REQUEST' and the queue name for ReplytoQ option.
- 3. Query the table by using the following statement to verify that the sample message is not inserted:

```
select * from PROCTABLE
```

4. Display the number of messages that remain on the input queue to verify that the message has been removed. Issue the following command from a z/OS console:

```
/-MQND display queue('In_Q') curdepth
```

5. Look at the Backout queue and find the original message by using the WebSphere MQ sample program CSQ4BCJ1.

Note: In this example, if a request message with added options for 'exception report' is sent (the Report option is specified for 'Message Descriptor'), an exception report is sent to the reply queue and the original message is sent to the deadletter queue.

Chapter 7. Db2 as a web services consumer and provider

Web services are a set of resources and components that applications can use over HTTP. You can use Db2 as a web services provider and a web services consumer.

Db2 as a web services consumer

Db2 can act as a client for web services, which enables you to be a consumer of web services in your Db2 applications.

SOAP web services Simple Object Access Protocol (SOAP) is an XML protocol that consists of the following characteristics:

- An envelope that defines a framework for describing the contents of a message and how to process the message
- A set of encoding rules for expressing instances of application-defined data types
- A convention for representing SOAP requests and responses

A set of SOAP functions is provided by Db2 and is installed and configured when you install or migrate Db2.

REST web services The Representational State Transfer (REST) protocol provides access to web-based content directly from SQL statements through HTTP requests. A set of basic sample REST user-defined functions can be installed with Db2. These functions provide access to web-based content through the HTTP GET, POST, PUT, and DELETE methods.

Db2 as a web services provider

You can enable your Db2 data and applications as web services through the Web Services Object Runtime Framework (WORF). You can define a web service in Db2 by using a Document Access Definition Extension (DADX). In the DADX file, you can define web services based on SQL statements and stored procedures. Based on your definitions in the DADX file, WORF performs the following actions:

- Handles the connection to Db2 and the execution of the SQL and the stored procedure call
- · Converts the result to a web service
- Handles the generation of any Web Services Definition Language (WSDL) and UDDI (Universal Description, Discovery, and Integration) information that the client application needs

Related concepts

Sample REST user-defined functions (Db2 Installation and Migration)

Deprecated: The SOAPHTTPV and SOAPHTTPC user-defined functions

Db2 provides user-defined functions that allow you to work with SOAP and consume web services in SQL statements. The user-defined functions are two varieties of SOAPHTTPV for VARCHAR data and two varieties of SOAPHTTPC for CLOB data.

Restriction: SOAPHTTPV and SOAPHTTPC user-defined functions have been deprecated. Use SOAPHTTPNV and SOAPHTTPNC user-defined functions instead.

The user-defined functions perform the following actions:

- 1. Compose a SOAP request
- 2. Post the request to the service endpoint

- 3. Receive the SOAP response
- 4. Return the content of the SOAP body

When a consumer receives the result of a web services request, the SOAP envelope is stripped and the XML document is returned. An application program can process the result data and perform a variety of operations, including inserting or updating a table with the result data.

SOAPHTTPV and SOAPHTTPC are user-defined functions that enable Db2 to work with SOAP and to consume web services in SQL statements. These functions are overloaded functions that are used for VARCHAR or CLOB data of different sizes, depending on the SOAP body. Web services can be invoked in one of four ways, depending on the size of the input data and the result data. SOAPHTTPV returns VARCHAR(32672) data and SOAPHTTPC returns CLOB(1M) data. Both functions accept either VARCHAR(32672) or CLOB(1M) as the input body.

Example: The following example shows an HTTP post header that posts a SOAP request envelope to a host. The SOAP envelope body shows a temperature request for Barcelona.

```
POST /soap/servlet/rpcrouter HTTP/1.0
Host: services.xmethods.net
Connection: Keep-Alive User-Agent: DB2SOAP/1.0
Content-Type: text/xml; charset="UTF-8"
SOAPAction:
Content-Length: 410
<?xml version='1.0' encoding='UTF-8'?>
<SOAP-ENV:Envelope xmlns:SOAP-ENV=http://schemas.xmlsoap.org/soap/envelope/

```

Example: The following example shows how to insert the result from a web service into a table

The SOAPHTTPNV and SOAPHTTPNC user-defined functions

Db2 provides SOAPHTTPNV and SOAPHTTPNC user-defined functions that allow you to work with SOAP and consume web services in SQL statements. The user-defined functions are two varieties of SOAPHTTPNV for VARCHAR data and two varieties of SOAPHTTPNC for CLOB data.

The user-defined functions perform the following actions:

- 1. Post the input SOAP request to the service endpoint
- 2. Receive and return the SOAP response

SOAPHTTPNV and SOAPHTTPNC allow you to specify a complete SOAP message as input and return complete SOAP messages from the specified web service as a CLOB or VARCHAR representation of the returned XML data. . SOAPHTTPNV returns VARCHAR(32672) data and SOAPHTTPNC returns CLOB(1M) data. Both functions accept either VARCHAR(32672) or CLOB(1M) as the input body.

SOAPHTTPNV and SOAPHTTPNC user-defined functions can support SOAP 1.1 or SOAP 1.2. Check with your system administrator to determine which levels of SOAP are supported by the user-defined functions in your environment.

Example

The following example shows how to insert the complete result from a web service into a table using SOAPHTTPNC.

SQLSTATEs for **Db2** as a web services consumer

Db2 returns SQLSTATE values for error conditions that are related to using Db2 as a web services consumer.

The following tables show possible SQLSTATE values.

Table 129. SQLSTATE values for SOAPHTTPV and SOAPHTTPC user-defined functions

SQLSTATE	Description
38301	An unexpected NULL value was pass as input to the function.
38302	The function was unable to allocate space.
38304	An unknown protocol was specified ion the endpoint URL.
38305	An invalid URL was specified on the endpoint URL.
38306	An error occurred while attempting to create a TCP/IP socket.
38307	An error occurred while attempting to bind a TCP/IP socket.

Table 129. SQ	LSTATE values for SOAPHTTPV and SOAPHTTPC user-defined functions (continued)	
SQLSTATE	Description	
38308	The function could not resolve the specified hostname.	
38309	An error occurred while attempting to connect to the specified server.	
38310	An error occurred while attempting to retrieve information from the protocol.	
38311	An error occurred while attempting to set socket options.	
38312	The function received unexpected data returned for the web service.	
38313	The web service did not return data of the proper content type.	
38314	An error occurred while initializing the XML parser.	
38315	An error occurred while creating the XML parser.	
38316	An error occurred while establishing a handler for the XML parser.	
38317	The XML parser encountered an error while parsing the result data.	
38318	The XML parser could not convert the result data to the database code page.	
38319	The function could not allocate memory when creating a TCP/IP socket.	
38320	An error occurred while attempting to send the request to the specified server.	
38321	The function was unable to send the entire request to the specified server.	
38322	An error occurred while attempting to read the result data from the specified server.	
38323	An error occurred while waiting for data to be returned from the specified server.	
38324	The function encountered an internal error while attempting to format the input message.	
38325	The function encountered an internal error while attempting to add namespace information to the input message.	
38327	The XML parser could not strip the SOAP envelope from the result message.	
38328	An error occurred while processing an SSL connection.	
Table 130. SQI	LSTATE values for SOAPHTTPNV and SOAPHTTPNC user-defined functions	
SQLSTATE	Description	
38350	An unexpected NULL value was specified for the endpoint, action, or SOAP input.	
38351	A dynamic memory allocation error.	
38352	An unknown or unsupported transport protocol.	
38353	An invalid URL was specified.	
38354	An error occurred while resolving the hostname.	
38355	A memory exception for socket.	
38356	An error occurred during socket connect.	
38357	An error occurred while setting socket options.	
38358	An error occurred during input/output control (ioctl) to verify HTTPS enablement.	
38359	An error occurred while reading from the socket.	

Table 130. SQLSTATE values for SOAPHTTPNV and SOAPHTTPNC user-defined functions (continued)		
SQLSTATE	Description	
38360	An error occurred due to socket timeout.	
38361	No response from the specified host.	
38362	An error occurred due to an unexpected HTTP return or content type	
38363	The TCP/IP stack was not enabled for HTTPS.

Additional steps for enabling web service user-defined functions (Db2 Installation and Migration)

Chapter 8. APPLCOMPAT levels in Db2 12

The application compatibility (APPLCOMAPT) level of your applications controls the adoption and use of new capabilities and enhancements, and sometimes reduces the impact of incompatible changes. The advantage is that you can complete the Db2 12 migration process without the need to update your applications immediately.

After function level 500 or higher is activated, you can continue run applications with the features and behavior of previous versions or specific Db2 12 function levels.

You can change the APPLCOMPAT level for each application when you are ready for it to run with the features and behavior of a higher Db2 version or function level. The application compatibility level applies to most SQL statements, including data definition statements (such as CREATE and ALTER statements) and data control statements (such as GRANT and REVOKE statements).

The application compatibility of a package is initially set when you bind a package, based on the following values:

- 1. The APPLCOMPAT bind option value, if specified.
- 2. If the bind option is omitted, the APPLCOMPAT subsystem parameter.

For static SQL statements, the APPLCOMPAT column of the SYSIBM.SYSPACKAGE catalog table stores the application compatibility setting. This setting changes for the following reasons:

- You issue a REBIND command for the package and specify a different value for the APPLCOMPAT
 option. If you omit this option, the previous value for the package is used. If no previous value is
 available (such as for packages last bound before the introduction of application compatibility) the
 APPLCOMPAT subsystem parameter value is used.
- An automatic bind of the package occurs. The application compatibility is set to the previous value. If no previous value is available, the APPLCOMPAT subsystem parameter value is used.

For dynamic SQL statements, the CURRENT APPLICATION COMPATIBILITY special register stores the application compatibility setting. This setting changes for the following reasons:

- The special register is initialized to the application compatibility of the package, as described above.
- During execution of the package, SET CURRENT APPLICATION COMPATIBILITY statements can change the special register. The value must be equivalent to the APPLCOMPAT bind option for the package or lower. if the value is V12R1M500 or above.

For new installations, the default APPLCOMPAT subsystem parameter value is V12R1M500. However, you can specify a higher value. For migrated environments, the default value is the value from the migration input member.

Tip: When you migrate to Db2 12, or activate any higher function level, change the APPLCOMPAT subsystem parameter value only after all applications can use the SQL capabilities of Db2 12 or the higher function level. For details, see "Enabling default application compatibility with function level 500 or higher" on page 848.

Supported application compatibility levels in Db2 12

Db2 12 supports the following application compatibility levels in most contexts.

Tip: For best results, configure your development environment to use the lowest application compatibility level that the application will run at in the production environment. For dynamic SQL, remember to consider the application compatibility levels of client and NULLID packages. If you develop and test applications at a higher application compatibility level and try to run them at a lower level in production, you are likely to encounter SQL code -4743 and other errors when you deploy the applications to production.

VvvRrMmmm

Compatibility with the behavior of the identified Db2 function level. For example, V12R1M510 specifies compatibility with the highest available Db2 12 function level. The equivalent function level or higher must be activated.

For the new capabilities that become available in each application compatibility level, see:

- SQL changes in Db2 13 application compatibility levels
- SQL changes in Db2 12 application compatibility levels

Tip: Extra program preparation steps might be required to increase the application compatibility level for applications that use data server clients or drivers to access Db2 for z/OS. For more information, see "Setting application compatibility levels for data server clients and drivers" on page 830.

V12R1

Compatibility with the behavior of Db2 12 function level 500. This value has the same result as specifying V12R1M500.

V11R1

Compatibility with the behavior of Db2 11 new-function mode. After migration to Db2 12, this value has the same result as specifying V12R1M100. For more information, see "V11R1 application compatibility level" on page 838

V10R1

Compatibility with the behavior of DB2 10 new-function mode. For more information, see <u>"V10R1"</u> application compatibility level" on page 843.

Example: V10R1 application compatibility

The following example shows the results of using a capability that is introduced in the application compatibility level V11R1, with application compatibility level set to V10R1. Assume that the APPLCOMPAT subsystem parameter value is V10R1. The example CREATE PROCEDURE statement does not specify the APPLCOMPAT keyword. In this example the CREATE TYPE statement is successful but the CREATE PROCEDURE statement results in SQL code -4743.

```
CREATE TYPE PHONENUMBERS AS VARCHAR(12) ARRAY ??(1000000??)

DSNT400I SQLCODE = 000, SUCCESSFUL EXECUTION

CREATE PROCEDURE FIND_CUSTOMERS(
   IN NUMBERS_IN KRAMSC01.PHONENUMBERS,
   IN AREA_CODE CHAR(3),
   OUT NUMBERS_OUT KRAMSC01.PHONENUMBERS)
   BEGIN
   SET NUMBERS_OUT = (SELECT ARRAY_AGG(T.NUM)
        FROM UNNEST(NUMBERS_IN) AS T(NUM)
        WHERE SUBSTR(T.NUM, 1, 3) = AREA_CODE);
   END

DSNT408I SQLCODE = -4743, ERROR: ATTEMPT TO USE A FUNCTION WHEN THE APPLICATION COMPATIBILITY SETTING IS SET FOR A PREVIOUS LEVEL
```

The APPLCOMPAT bind option value for the CREATE PROCEDURE statement is then set to V11R1 or higher and result of the statement is then successful.

```
CREATE PROCEDURE FIND_CUSTOMERS(
IN NUMBERS_IN KRAMSC01.PHONENUMBERS,
IN AREA_CODE CHAR(3),
OUT NUMBERS_OUT KRAMSC01.PHONENUMBERS)
APPLCOMPAT V11R1
BEGIN
SET NUMBERS_OUT =
(SELECT ARRAY_AGG(T.NUM)
```

```
FROM UNNEST(NUMBERS_IN) AS T(NUM)
WHERE SUBSTR(T.NUM, 1, 3) = AREA_CODE);
FND
```

DSNT400I SQLCODE = 000, SUCCESSFUL EXECUTION

Incompatible changes for APPLCOMPAT levels in Db2 12

Before you start running applications at higher application compatibility (APPCLOMPAT) levels in Db2 12, you might need to adjust your applications for certain behavior changes that are unrelated to use of new SQL capabilities.

Identifying potential incompatible changes in APPLCOMPAT levels with the IFCID 0376 trace

You can run package level accounting or monitor traces with IFCID 0239 and review the QPACFLGS field, which indicates an SQL incompatible change. If a trace is started for IFCID 0376, and the application runs at a lower APPLCOMPAT level, details about features and functions that have a change in behavior at higher APPLCOMPAT levels are written in field QW0376FN.

Descriptions of potential incompatible changes that for SQL statements that start running at higher APPLCOMPAT levels are also available in the IFCID 0376 section of the DSNWMSGS flat file. The most current version of DSNWMSGS is available only for clients who have Db2 12 for z/OS licenses. The information is in a PDF file. To locate this information, see Db2 12 for z/OS IFCID flat file (DSNWMSGS)

Incompatible change details for APPLCOMPAT levels in Db2 12

The following entries provide more details for incompatible changes that applications might encounter when you first run them at higher APPLCOMAPT levels in Db2 13.

New built-in function names supported by pass-through to IBM Db2 Analytics Accelerator

Starting in APPPLCOMPAT level V12R1M507 or higher, the following built-in functions are supported passthrough-only built-in functions through IBM Db2 Analytics Accelerator. If your Db2 applications have unqualified references to existing user-defined functions with these names, they might start invoking new built-in functions instead if the names and signatures match, in certain situations.

- ADD_DAYS scalar function (Db2 SQL)
- BTRIM scalar function (Db2 SQL)
- DAYS_BETWEEN scalar function (Db2 SQL)
- NEXT_MONTH scalar function (Db2 SQL)
- Regression functions (REGR_AVGX, REGR_AVGY, REGR_COUNT, ...) (Db2 SQL)

ROUND_TIMESTAMP scalar function (Db2 SQL) if invoked with a date expression

Actions to take: See "Ensuring that Db2 executes the intended user-defined function" on page 455.

New built-in function names supported by pass-through to IBM Db2 Analytics Accelerator

Starting in APPPLCOMPAT level V12R1M504 or higher, the following built-in functions are supported passthrough-only built-in functions through IBM Db2 Analytics Accelerator. If your Db2 applications have unqualified references to existing user-defined functions with these names, they might start invoking new built-in functions instead if the names and signatures match, in certain situations.

- CUME_DIST
- CUME_DIST aggregate function (Db2 SQL)
- FIRST_VALUE
- LAG
- LAST_VALUE
- LEAD
- NTH_VALUE
- NTILE
- PERCENT_RANK
- PERCENT_RANK aggregate function (Db2 SQL)
- RATIO TO REPORT
- REGEXP_COUNT scalar function (Db2 SQL)
- REGEXP_INSTR scalar function (Db2 SQL)
- REGEXP_LIKE scalar function (Db2 SQL)
- REGEXP_REPLACE scalar function (Db2 SQL)
- REGEXP_SUBSTR scalar function (Db2 SQL)

Actions to take: "Ensuring that Db2 executes the intended user-defined function" on page 455.

CURRENT_TIMEZONE and **CURRENT_SERVER** in column names

Starting in APPPLCOMPAT level V12R1M504 or higher, if your Db2 environment contains existing columns or variables with names such as CURRENT_TIMEZONE or CURRENT_SERVER, you must modify your applications to delimit these column names.

Actions to take: You can use the following queries to identify columns and variables with the names.

Object type	Example query
Columns	SELECT * FROM SYSIBM.SYSCOLUMNS WHERE NAME IN('CURRENT_SERVER','CURRENT_TIMEZONE');
Variables	SELECT * FROM SYSIBM.SYSVARIABLES WHERE NAME IN('CURRENT_SERVER','CURRENT_TIMEZONE');

Based on the result, you can then check for dependencies, for example by querying the SYSIBM.SYSPACKDEP catalog table, to identify any static applications that depend on the nondelimited forms of these names.

Creation of deprecated objects prevented

Starting with APPPLCOMPAT level V12R1M504 or higher, SQL statements that explicitly or implicitly create table spaces for base tables always create always create universal table spaces (UTS), which are either partition-by-growth (PBG) or partition-by-range (PBR) table spaces. Also, errors can be returned for certain SQL statements that previously succeeded, as side effects of base tables always being created in a UTS.

- CREATE AUX TABLE statements for LOB columns can start failing with the SQLCODE -769 error because the PART clause is required when the base table resides in a PBG table space.
- DROP TABLE statements can fail with the SQLCODE -669 error because the DROP TABLE statement is not supported for tables in PBG table spaces. The DROP TABLESPACE statement must be used instead. (APPLCOMPAT level V12R1M506 resolves this situation. For more information, see <u>Function</u> level 506 (PH16829 October 2019) (Db2 for z/OS What's New?).)
- CREATE TABLE statements can start failing with the SQLCODE -646 error if they attempt to create more than one table in a the same table space. Each UTS contains only a single table.

Starting in APPLCOMPAT level 504 or higher, the following SQL statements return errors instead of creating deprecated objects:

- CREATE SYNONYM statements
- CREATE TABLE statements that specify existing non-UTS table spaces
- CREATE TABLE and ALTER TABLE statements that specify ORGANIZE BY HASH

Actions to take: Update your applications to use non-deprecated object types.

Tip: Although it is best to use non-deprecated types for all new database objects, you can still use a lower APPLCOMPAT level to create the deprecated table spaces if necessary, such as for recovery situations. For more information, see <u>Creating non-UTS table spaces</u> (deprecated) (Db2 Administration Guide).

Result change for system-period temporal tables defined with ON DELETE ADD EXTRA ROW

Starting at application compatibility level V12R1M503 or higher, rows that contain a null value in the history table column that corresponds to a DATA CHANGE OPERATION column in a system-period temporal table are considered part of the intermediate result of a query that contains a period specification, even if the system-period temporal table is defined with the ON DELETE ADD EXTRA ROW attribute. Queries that run at lower application compatibility levels continue to omit the rows that contain null values from the intermediate result set and might return the incomplete results.

The behavior change occurs for queries that run at application compatibility level V12R1M503 or higher if all the following conditions are met:

- The query references a system-period temporal table (STT) with FOR SYSTEM_TIME FROM *value1* TO *value2* (or BETWEEN *value1* AND *value2*) period specification. The STT can be directly referenced or indirectly referenced through views.
- The STT is defined with the ON DELETE ADD EXTRA ROW clause.
- The STT is defined with the DATA CHANGE OPERATION column.
- During migration to use the temporal auditing feature, the altered table contains existing rows.
- The DATA CHANGE OPERATION column is populated with the default NULL value for the existing rows.
- When the query is executed, the historical table contains records with NULL values in the column associated with a DATA CHANGE OPERATION column in the STT.

Actions to take: Start a trace for IFCID 0376. In the trace output, function code 1215031 or 1202 identifies the affected queries.

The SET_MAINT_MODE_RECORD_NO_TEMPORALHISTORY stored procedure is not supported when APPLCOMPAT is V12R1M503 or higher

Starting at application compatibility level V12R1M503 or higher, Db2 returns an error for any user or application that invokes the SYSPROC.SET_MAINT_MODE_RECORD_NO_TEMPORALHISTORY stored procedure.

Actions to take: Start a trace for IFCID 0376. In the trace output, function code 1215032 or 1203 identifies applications that use the SYSPROC.SET_MAINT_MODE_RECORD_NO_TEMPORALHISTORY stored procedure. Modify such applications to set value of the SYSIBMADM.REPLICATION_OVERRIDE built-in global variable to 'Y' instead. For more information, see SYSIBMADM.REPLICATION_OVERRIDE built-in global variable.

GRAPHIC and VARGRAPHIC supported as built-in functions

Starting at APPLCOMPAT level V12R1M502 or higher, if your environment contains existing user-defined functions named GRAPHIC or VARGRAPHIC, applications with unqualified references to the existing user-defined functions might start invoking the built-in function instead of the user-defined function in certain situations.

Actions to take: See "Ensuring that Db2 executes the intended user-defined function" on page 455.

SUBSTR built-in function change for invalid input and the SQLCODE -138 error

Starting in function level V12R1M500 or higher (and not controlled by the APPLCOMPAT level), the SUBSTR_COMPATIBILITY subsystem parameter specifies whether calls to the SUBSTR built-in function consistently return the SQLCODE -138 error for invalid arguments that do not meet the requirements described in SUBSTR scalar function (Db2 SQL). That is, if SUBSTR_COMPATIBILITY is set to CURRENT, Db2 always enforces the documented rules for the SUBSTR built-in function and returns an SQL error code for invalid input. For more information about rules for valid input the SUBSTR built-in function, see . The behavior with the CURRENT setting improves compatibility with Db2 on other platforms.

With the default SUBSTR_COMPATIBILITY set to PREVIOUS, Db2 sometimes incorrectly returns a result for invalid input instead of issuing an appropriate error message. The default value is PREVIOUS. For more information, see <u>SUBSTR COMPATIBILITY</u> field (<u>SUBSTR_COMPATIBILITY</u> subsystem parameter) (Db2 Installation and Migration).

For more information about the introduction of this change in Db2 12, see the APAR closing text for PH36071.

Actions to take: Before you set the SUBSTR_COMPATIBILITY subsystem parameter to CURRENT, you might need to modify some of your applications to handle this change. If you enable a trace for IFCID 0376, the function identifier '14' value in the QW0376FN field of the trace output identifies applications that might be affected by this change.

KEEPDYNAMIC(YES) bind option support for ROLLBACK

Starting at APPLCOMPAT level V12R1M500 or higher, the KEEPDYNAMIC(YES) bind option affects both COMMIT and ROLLBACK statements. With KEEPDYNAMIC(YES), the dynamic SQL statements in the package are retained after COMMIT or ROLLBACK, and those statements can run again without another PREPARE. This changes introduces the following differences:

- An OPEN statement without a preceding PREPARE statement does not receive the SQLCODE -514 error.
- An EXECUTE statement without a preceding PREPARE statement does not receive the SQLCODE
 -518 error.

At lower APPLCOMPAT levels, the KEEPDYNAMIC(YES) bind option applies only to COMMIT statements. After a ROLLBACK statement, another PREPARE is required so that the dynamic SQL statements can run. That is, a package that was bound with KEEPDYNAMIC(YES) was required to prepare dynamic SQL statements again after a ROLLBACK was issued.

Actions to take: Review packages that use the KEEPDYNAMIC(YES) bind option. You can make dynamic SQL programs that are bound with KEEPDYNAMIC(YES) run more efficiently by removing PREPARE statements that prepare SQL statements again following execution of ROLLBACK statements. Do not take this action until you are certain that you no longer need to run the programs at APPLCOMPAT level V11R1 or earlier. For more information, see: Methods for keeping prepared statements after the point of commit or rollback (Db2 Performance) and KEEPDYNAMIC bind option (Db2 Commands).

POWER built-in function returns a warning SQLCODE for out of range DOUBLE results

Starting at APPLCOMPAT level V12R1M500 or higher, calls to the POWER built-in function with DOUBLE arguments with results that are out of range return the SQLCODE +802 warning in some cases. For example, the following query returns the SQLCODE +802 warning:

```
SELECT POWER(DOUBLE(2.0E38), DOUBLE(2.0))
FROM SYSIBM.SYSDUMMY1;
```

In lower APPLCOMPAT levels, Db2 issues -802 in these situations.

Actions to take: Adjust error processing to account for the change in the returned SQLCODE from an error to a warning. If you enable a trace for IFCID 0376, the function identifier '1201' value in the QW0376FN field of the trace output identifies applications that might be affected by this change.

CAST(string AS TIMESTAMP) result changes

Starting with APPLCOMPAT level V11R1 or higher, the result of CAST(*string* AS TIMESTAMP) is changed in some cases. That is, when an 8-byte string or a 13-byte string is input to CAST(*string* AS TIMESTAMP), Db2 interprets the input strings as string representations of TIMESTAMP values. An invalid representation of an 8-byte or 13-byte string in CAST(*string* AS TIMESTAMP) results in the SQLCODE -180 error. For example, the result of the first following SELECT statement is 2013-01-01-00.00.00.000000, which is the correct result. The result of the second SELECT statement is the SQLCODE -180 error, because a Store Clock value is not valid input to CAST(*string* AS TIMESTAMP).

```
-- SET APPLICATION COMPATIBILITY TO V11R1
SET CURRENT APPLICATION COMPATIBILITY='V11R1';
-- CAST AN 8-BYTE STRING REPRESENTATION OF A DATETIME VALUE
-- TO TIMESTAMP
SELECT CAST('1/1/2013' AS TIMESTAMP) FROM SYSIBM.SYSDUMMY1;
-- CAST AN 8-BYTE STRING REPRESENTATION OF A STORE CLOCK VALUE
-- TO TIMESTAMP
SELECT CAST(X'CAB5060708090100' AS TIMESTAMP) FROM SYSIBM.SYSDUMMY1;
```

In lower APPLCOMPAT levels, when Db2 executed CAST(string AS TIMESTAMP), Db2 interprets an 8-byte string as a Store Clock value and a 13-byte string as a GENERATE_UNIQUE value. This interpretation might result in an incorrect result from the CAST specification. For example, the result of the first SELECT statement is 2034-07-25-16.43.41.599503, which is an incorrect result. The result of the second SELECT statement is 2013-01-01-20.37.04.246928, which is the correct result if the input string is interpreted as a Store Clock value.

```
-- SET APPLICATION COMPATIBILITY TO V10R1
SET CURRENT APPLICATION COMPATIBILITY='V10R1';
-- CAST AN 8-BYTE STRING REPRESENTATION OF A DATETIME VALUE
-- TO TIMESTAMP
SELECT CAST('1/1/2013' AS TIMESTAMP) FROM SYSIBM.SYSDUMMY1;
-- CAST AN 8-BYTE STRING REPRESENTATION OF A STORE CLOCK VALUE
-- TO TIMESTAMP
SELECT CAST(X'CAB5060708090100' AS TIMESTAMP) FROM SYSIBM.SYSDUMMY1;
```

Actions to take: If you enable a trace for IFCID 0376, the function identifier '1109' value in the QW0376FN field of the trace output identifies applications that might be affected by this change.

If you need to convert Store Clock values to the TIMESTAMP data type, use the TIMESTAMP built-in function instead of CAST(*string* AS TIMESTAMP). For example, the following statements return the correct result, 2013-01-01-20.37.04.246928.

```
-- SET APPLICATION COMPATIBILITY TO V11R1
SET CURRENT APPLICATION COMPATIBILITY='V11R1';
-- CONVERT AN 8-BYTE STRING REPRESENTATION OF A STORE CLOCK VALUE
-- TO TIMESTAMP
SELECT TIMESTAMP(X'CAB5060708090100') FROM SYSIBM.SYSDUMMY1;
```

CURRENT CLIENT special register lengths increased

Starting with APPLCOMPAT level V11R1 or higher, the following special register values might return values of greater length, the values are not padded to the supported maximum length, and any trailing blanks are removed.

Special register	New maximum length	Previous maximum length	QW0376FN function code
CURRENT CLIENT_ACCTNG	255 bytes	200 bytes	'1104'
CURRENT CLIENT_APPLNAM	255 bytes	32 bytes	'1105'
CURRENT CLIENT_USERID	128 bytes	16 bytes	'1106'
CURRENT CLIENT_WKSTNAME	255 bytes	18 bytes	'1107'

Actions to take: If you enable a trace for IFCID 0376, the following function level identifier values in the QW0376FN field of the trace output identify applications that might be affected by this change, as shown in the preceding table: '1104', '1105', '1106', or '1107'.

ASUTIME limit changes for RLF enforcement of dynamic SQL

Starting with APPLCOMPAT level V11R1 or higher, the resource limit facility (RLF) enforces the ASUTIME limit that is specified for each package when multiple packages are called in the same thread, and the ASUTIME limit that is specified for the top-level calling package is not considered. If the dynamic SQL statements in a package use more ASUTIME than the limit specified for that package, Db2 returns the SQLCODE -905 error. Because the limit is enforced for each package, applications might return more the SQLCODE -905 errors more often.

Also, the APPLCOMPAT level of each package controls the new behavior regardless of the APPLCPOMPAT level of a calling package. That is, the RLF enforces the ASUTIME limit specified for the dynamic SQL statements in any package that is itself bound out APPLCOMPAT level V11R1 or higher, even if it was called by a package that was bound at V10R1.

At lower APPLCOMPAT level V10R, Db2 issues the SQLCODE -905 error only when the limit of the top-level calling package for the entire threads is encountered.

Actions to take: Review ASUTIME limits on routines and packages that use dynamic SQL and adjust as necessary. If you enable a trace for IFCID 0376, the function identifier '1103' value in the QW0376FN field of the trace output identifies applications that might be affected by this change.

XPath processing continues with errors on filtered results

Starting with APPLCOMPAT level V11R1 or higher, XPath processing might return fewer errors on predicate expressions with an explicit cast or an operation with an invalid value. Examples of XPath expressions that are likely to return fewer errors include the following situations:

- Data is filtered from the result by the predicate before an invalid operation such as division of a number by zero
- · Data is explicitly cast to an incompatible data type

For more information about using XPath expressions, see <u>XPath expressions for filtering output (Db2</u> Administration Guide) and "Selecting XML data" on page 362.

Actions to take: Review error processing for applications that use XPath processing. If you enable a trace for IFCID 0376, the function identifier '1102' value in the QW0376FN field of the trace output identifies applications that might be affected by this change.

XML document nodes implicitly added for insert and update of XML columns

Starting with APPLCOMPAT V11R1 or higher, when an application inserts or updates an XML column, Db2 implicitly adds an XML document node if the XML document does not already contain one.

At lower function levels, Db2 issues the SQLCODE -20345 error in this situation, unless the application also invokes the XMLDOCUMENT function before the insert or update.

Actions to take: Review your applications for use of the XMLDOCUMENT function. If you enable a trace for IFCID 0376, the function identifier '1101' value in the QW0376FN field of the trace output identifies applications that might be affected by this change.

Incompatible changes for Db2 12 migration or function level activation (Db2 for z/OS What's New?)

Related tasks

Managing incompatible changes for applications

Before you move an application to a new application compatibility (APPLCOMPT) level, you might need to adjust your applications for certain incompatible changes that are unrelated to use of new SQL function, and verify that they are resolved.

V12R1Mnnn application compatibility levels

In Db2 12, you can use the application compatibility level to control the adoption of new SQL capabilities and enhancements of particular function levels.

You can use the *application compatibility (APLCOMPAT)* level of applications, and objects such as routines or triggers, to control the adoption and use of SQL capabilities that are introduced in function levels. Generally, applications, and routines or triggers, cannot use new or changed SQL capabilities unless the effective application compatibility level is equivalent to or higher than the function level that introduced the changes. The application compatibility level applies to most SQL statements, including data definition statements (such as CREATE and ALTER statements) and data control statements (such as GRANT and REVOKE statements).

Important: Before you start running applications at higher application compatibility (APPCLOMPAT) levels in Db2 12, you might need to make adjustments for certain behavior changes that are unrelated to use of new SQL capabilities. You can use a trace for IFCID 0376 to identify these incompatible changes. For more information, see <u>Incompatible changes for APPLCOMPAT levels in Db2 12 (Db2 for z/OS What's New?)</u>.

The corresponding function level or higher must be activated when you bind packages at an application compatibility level. However, if you activate a lower function level (or * function level), applications can continue to run with the higher application compatibility level. To prevent the continued use of SQL capabilities introduced in the higher function level, you must also modify the application and change the effective application compatibility level to the lower level.

Tip: Extra program preparation steps might be required to increase the application compatibility level for applications that use data server clients or drivers to access Db2 for z/OS. For more information, see "Setting application compatibility levels for data server clients and drivers" on page 830.

Tip: Do not raise the default application compatibility level of the Db2 subsystem immediately after migrating or activating a new function level. Instead, wait until applications have been verified to work correctly at the higher function level, and any incompatibilities have been resolved. For details, see "Enabling default application compatibility with function level 500 or higher" on page 848.

Application compatibility levels are specified by nine-character strings that correspond to the Db2 function level that introudces them. See the activation details for each function level for a summary the new features that are controlled by the corresponding application compatibility level. For example, V12R1M510 specifies compatibility with the highest available Db2 12 function level. The equivalent function level or higher must be activated.

Setting application compatibility levels for data server clients and drivers

IBM data server clients and drivers that use Db2 for z/OS capabilities with a function level requirement of greater than V12R1M500 require extra program preparation steps.

Before you begin

Take these actions on the clients that connect to your Db2 for z/OS system:

- Determine whether you need to upgrade the data server clients or drivers to support V12R1M501 application compatibility:
 - If your applications include function that requires a minimum application compatibility level of V12R1M501, you need to upgrade to Db2 Connect Version 11.1 Modification 2 Fix Pack 2 or later.
 - If your applications include function that requires a minimum application compatibility level of V12R1M500 or earlier, you can use any Db2 Connect version.

The minimum data server client or driver levels for exploitation of application compatibility of V12R1M501 or later are:

- IBM Data Server Driver for JDBC and SQLJ: Versions 3.72 and 4.22, or later. For information on the
 driver versions that are delivered with each Db2 Connect version, see <u>IBM Data Server Driver for</u>
 JDBC and SQLJ versions and Db2 or Db2 Connect levels (Db2 Application Programming for Java).
- Other IBM data server clients and drivers: Db2 for Linux, UNIX, and Windows, Version 11.1
 Modification 2 Fix Pack 2, or later.
- Run the db2connectactivate utility to activate the Version 11.1 license certificate file for Db2 Connect Unlimited Edition on Db2 for z/OS. Specify the options to bind the driver and client packages into the NULLID collection, with APPLCOMPAT V12R1M500. For example:

```
db2connectactivate.sh -host sys1.svl.ibm.com -port 5021 -database STLEC1 -user dbadm -password dbadmpass -bindoptions "APPLCOMPAT V12R1M500" -collection NULLID
```

For more information, see:

Activating the license key for Db2 Connect Unlimited Edition (IBM Z) db2connectactivate - Server license activation utility

About this task

This procedure sets the V12R1Mnnn application compatibility for a client or driver that needs to utilize server capabilities that require an application compatibility of greater than V12R1M500. If the client or driver does not utilize the capabilities of a new function level, you do not need to update its application compatibility settings.

Procedure

- 1. Set the Db2 for z/OS server application compatibility (APPLCOMPAT) level.
 - a) For client applications that contain static SQL statements, rebind the static application packages with the new APPLCOMPAT value, on the client and on the server.
 - b) For client applications that contain only dynamic SQL statements, bind or rebind the client or driver packages with the new APPLCOMPAT value, on the server.

Tip: Binding package copies and keeping the original driver packages lets you access new capabilities for applications that need them, while ensuring stability for applications that should not be exposed to incompatibilities.

For drivers only, you can use jobs that are provided with Db2 for z/OS, in data set *prefix*.SDSNSAMP, to bind or rebind the driver packages on the server. To run those jobs, follow these steps:

- i) Customize jobs DSNTIJLC and DSNTIJLR, using the instructions in the job prologs.
- ii) If there is a possibility that you still need to run applications under a driver that is at the old application compatibility level, run DSNTIJLC to bind copies of the driver packages at the new application compatibility level, while leaving the packages in the NULLID collection at the old application compatibility level. In most cases, you should do this.
 - If you are sure that you do not need to run applications under a driver at the old application compatibility level, run job DSNTIJLR to rebind the client or driver packages at the new application compatibility level.
- iii) If you bound copies of the driver packages for the new function level, switch the drivers to the new function level by modifying the property that controls the current package set to match the collection ID of the new package copies.
 - For CLI or ODBC drivers, change the CLI/ODBC CurrentPackageSet configuration keyword value.
 - For the IBM Data Server Driver for JDBC and SQLJ, change the DB2BaseDataSource.currentPackageSet Connection or DataSource property value.
- 2. Set the client application compatibility value to control the capabilities of client applications when a client or driver contains changes that enable new server capabilities. If you set the client application compatibility level, its value must be less than or equal to the server application compatibility level.

Take one of the following actions to set the client application compatibility value.

• For CLI or ODBC drivers or IBM Data Server clients, change the CLI/ODBC ClientApplCompat configuration keyword value.

Do this by adding a line similar to this example to the <databases> section or the <dsn> section in the db2dsdriver.cfg file.

```
<parameter name="clientApplCompat" value="V12R1M501"/>
```

For more information, see:

- IBM data server driver configuration file
- Installing the IBM Data Server Driver Package software on the Linux and UNIX operating systems (includes information on creating and populating the db2dsdriver.cfg file)
- ClientApplCompat IBM data server driver configuration keyword
- For the IBM Data Server Driver for JDBC and SQLJ, change the DB2BaseDataSource.clientApplcompat Connection or DataSource property value.

        DSNTIRU STEP
                                 Bind Copy the IBM JDBC and CLI standard
//*
//*
                                 set of packages to a new collection in
                                 order to override the APPLCOMPAT package
//*
//*
                                 option.
//* NOTES =
//*
//*
        (1) This job includes an in-stream data set having
DB2 bind statements that contain substitution
//*
             symbols. For example:
                BIND PACKAGE (&TGTCOLID)
                      COPY(&SRCCOLID..SYSLH100) +
//*
//*
                      APPLCOMPAT(&APPLCMPT)
             where
                &TGTCOLID is the name of the collection-ID to
                             bind from copy. The DB2-supplied setting is 'NULLID_V12R1M500'. Use the
//*
//*
                             SET TGTCOLID statement in job step
                             DSNTIRU to specify a different setting.
//*
                &SRCCOLID is the name of the collection-ID to copy
                             from. The DB2-supplied setting is 'NULLID'. Use the SET SRCCOLID
//*
//*
//*
                             statement in job step DSNTIRU to
               specify a different setting.
&APPLCMPT is the DB2 application compatibility
                             level. The DB2-supplied setting is 'V12R1M500'. Use the SET APPLCMPT
//*
//*
                             statement in job step DSNTIRU to
                             specify a different setting.
//*
//*
//*
//*
             Attention JES3 users: Symbolic substitution within in-stream data sets in JES3 requires z/OS 2.2 or \,
             above. In order to run this job on JES2 using z/OS
             2.1, you need to make the following manual changes:
(a) Remove the EXPORT SYMLIST and all SET statements
//*
//*
//*
             (b) Change all occurrences of &TGTCOLID to the name
of the collection-ID to bind from copy.
             (c) Change all occurrences of &SRCCOLID to the name
             of the collection-ID to copy from.

(d) Change all occurrences of &APPLCMPT to the DB2
//*
//*
                  application compatibility setting.
//*
        (2) Before running this job, customize it as follows:
             (a) Add a valid job card.
(b) Locate and change all occurrences of the
//*
//*
                  following strings as indicated:
- '!DSN!' to the name of the DB2 subsystem.
- 'DSN!!O' to the prefix of the DB2 target
             libraries for the DB2 subsystem.
(c) Set TGTCOLID, SRCCOLID, and APPLCMPT as
//*
                  described above.
//*
//* CHANGE LOG =
       11/08/2016 Job created
                                                                            S28617 PI74456
//*
//JOBLIB DD DISP=SHR,
// DSN=DSN!!0.SDSNLOAD
//*
//* Symbolic substitution requires z/OS 2.2, or z/OS 2.1 with JES2. // EXPORT SYMLIST=(TGTCOLID, SRCCOLID, APPLCMPT)

```
//* FUNCTION = Migrate DB2 Connect packages to support a new
                 function level.
//* PSEUDOCODE =
       DSNTIRU STEP
                             Rebind the IBM JDBC and CLI standard
//*
                             set of packages to a new collection in
//*
//*
                             order to override the APPLCOMPAT package
                             option.
//* NOTES =
       (1) This job includes an in-stream data set having
//*
//*
           DB2 bind statements that contain substitution
            symbols.
                      For example:
              REBIND PACKAGE (&SRCCOLID..SYSLH100) +
                      APPLCOMPAT(&APPLCMPT)
//*
//*
//*
             &SRCCOLID is the name of the collection-ID owning the package to be rebound.
//*
                          The DB2-supplied setting is
                          'NULLID V12R1M500'. Use the SET
                          SRCCOLID statement in job step
                          DSNTIRU to specify a different
                          setting
              &APPLCMPT is the DB2 application compatibility
                         level. The DB2-supplied setting is 'V12R1M500'. Use the SET APPLCMPT statement in job step DSNTIRU to
                          specify a different setting.
Attention JES3 users: Symbolic substitution within in-stream data sets in JES3 requires \rm z/OS~2.2~or
           above. In order to run this job on JES2 using z/OS 2.1, you need to make the following manual changes: (a) Remove the EXPORT SYMLIST and all SET statements
            (b) Change all occurrences of &SRCCOLID to the name
                of the collection-ID owning the package to be
                rebound
            (c) Change all occurrences of &APPLCMPT to the DB2
                application compatibility setting.
//*
//*
//*
       (2) Before running this job, customize it as follows:
            (a) Add a valid job card.
            (b) Locate and change all occurrences of the
                following strings as indicated:
- '!DSN!' to the name of the DB2 subsystem.
- 'DSN!!O' to the prefix of the DB2 target
//*
                  libraries for the DB2 subsystem.
            (c) Set SRCCOLID and APPLCMPT as described above.

Using profile tables to control which Db2 for z/OS application compatibility levels to use for specific data server client applications

Profiles can be used to control which client applications use features that are associated with a specific Db2 for z/OS application compatibility level. This capability allows client applications that do not need to use new features to continue to connect to a Db2 for z/OS server at an earlier application compatibility level.

About this task

In this example procedure, client application ACCTG_APP501 needs to use Db2 for z/OS capabilities that are available at application compatibility level V12R1M501. All other client applications need to use capabilities that are available at application compatibility level V12R1M500 or lower.

Procedure

- 1. On the client operating system, bind the client driver packages into two collections:
 - One collection with the default collection name NULLID, and with the APPLCOMPAT option set to V12R1M500. If you have already bound the client driver packages into collection NULLID with APPLCOMPAT set to V12R1M500, you do not need to bind them again.
 - Another collection with a different name, such as NULLID_NF, and with the APPLCOMPAT option set to V12R1M501.
 - For the IBM Data Server Driver for JDBC and SQLJ, follow these steps to bind the driver packages:
 - If you have not already done so, invoke the DB2Binder utility with a control statement like this
 one to create a collection with the default name NULLID, and with application compatibility set to
 V12R1M500:

```
java com.ibm.db2.jcc.DB2Binder -url jdbc:db2://sys1.svl.ibm.com:5021/STLEC1 \
-user user -password password \
-bindoptions "APPLCOMPAT V12R1M500" -action REPLACE
```

 Invoke the DB2Binder utility with a control statement like this one to create a collection named NULLID_NF, with application compatibility set to V12R1M501:

```
java com.ibm.db2.jcc.DB2Binder -url jdbc:db2://sys1.svl.ibm.com:5021/STLEC1 \
-collection NULLID_NF \
-user user -password password \
-bindoptions "APPLCOMPAT V12R1M501" -action REPLACE
```

- For the IBM Data Server Driver for ODBC and CLI, follow these steps to bind the driver packages:
 - If CLI/ODBC configuration keyword OnlyUseBigPackages=1, you do not need to bind the driver packages.
 - If CLI/ODBC configuration keyword OnlyUseBigPackages=0, you need to bind small packages with application compatibility set to V12R1M501:

```
db2 bind '%DB2PATH%\bnd\@ddcsmvs.lst' blocking all sqlerror continue \
grant public action replace collection NULLID_NF \
generic \"APPLCOMPAT V12R1M501\"
```

2. In Db2 for z/OS, create a profile for client application ACCTG_APP501 by inserting rows into tables SYSIBM.DSN_PROFILE_TABLE and SYSIBM.DSN_PROFILE_ATTRIBUTES. The profile directs Db2 to use the driver with packages in collection NULLID_NF when application ACCTG_APP501 runs. Because the driver packages in the NULLID_NF collection are bound with option APPLCOMPAT V12R1M501, ACCTG_APP501 can use capabilities that are available at application compatibility level V12R1M501.

```
INSERT INTO SYSIBM.DSN_PROFILE_TABLE
  (PROFILEID, CLIENT_APPLNAME, PROFILE_ENABLED)
  VALUES (1002, 'ACCTG_APP501', 'Y');
INSERT INTO SYSIBM.DSN_PROFILE_ATTRIBUTES
  (PROFILEID, KEYWORDS, ATTRIBUTE1)
  VALUES (1002, 'SPECIAL_REGISTER', 'SET CURRENT PACKAGE PATH=NULLID_NF');
```

Important: Although PKGNAME can be used as a filtering category for profile table rows that use the 'SPECIAL_REGISTER' value for KEYWORDS, when client drivers are used, you should not use PKGNAME alone or in combination with COLLID.

3. On Db2 for z/OS, issue the -START PROFILE command to load the updated profile tables into memory.

Results

Application ACCTG_APP501 can now successfully connect to Db2 for z/OS and use data server driver packages in collection NULLID_NF. All other applications can connect to Db2 for z/OS and use data server driver packages in collection NULLID.

You can verify the application compatibility level and collection that are being used for your client application by adding code to execute a query like this to your application.

```
SELECT CURRENT APPLICATION COMPATIBILITY,
GETVARIABLE('SYSIBM.PACKAGE_SCHEMA')
FROM SYSIBM.SYSDUMMY1
```

For example, you might add code like this to a Java application:

```
String currApplcompat, appCollection;
Connection con;
Statement stmt;
ResultSet rs;
" FROM SYSIBM.SYSDUMMY1");
                                       // Get the result table from the query
while (rs.next()) {
                                       // Position the cursor
 currApplcompat = rs.getString(1);  // Retrieve the a
System.out.println("APPLCOMPAT = " + currApplcompat);
                                       // Retrieve the application compatibility
                                       // Print the application compatibility
appCollection = rs.getString(1);
System.out.println("COLLID = " +
                                       // Retrieve the collection name
                                 + appCollection);
                                       // Print the collection name
```

For application ACCTG_APP501, the query should return a value of V12R1M501 for the current application compatibility, and NULLID_NF for the collection name.

V11R1 application compatibility level

When you set the application compatibility level to V11R1, applications that attempt to use functions and features that are introduced in Db2 12 or later might behave differently or receive an error.

When new function is activated in your Db2 12 environment, you can run individual applications with some of the features and behavior of Db2 11. That is, your applications can continue to experience V11R1 behavior after new function is activated in Db2 12 or later. Then, you can migrate each application to a new application compatibility value separately until all are migrated. If application compatibility level is set to V11R1 and you attempt to use the new functions of a later version, SQL might behave differently or result in a negative SQL codes, such as -4743.

For examples of newer SQL capabilities that cannot be used at application compatibility V11R1, see the following topics:

- SQL changes in Db2 13
- SQL changes in Db2 12

Tip: For best results, configure your development environment to use the lowest application compatibility level that the application will run at in the production environment. For dynamic SQL, remember to consider the application compatibility levels of client and NULLID packages. If you develop and test applications at a higher application compatibility level and try to run them at a lower level in production, you are likely to encounter SQL code -4743 and other errors when you deploy the applications to production.

Important: Before you start running applications at higher application compatibility (APPCLOMPAT) levels in Db2 12, you might need to make adjustments for certain behavior changes that are unrelated to use of new SQL capabilities. You can use a trace for IFCID 0376 to identify these incompatible changes. For more information, see <u>Incompatible changes for APPLCOMPAT levels in Db2 12 (Db2 for z/OS What's New?)</u>.

A migrated Db2 12 environment behaves with V11R1 application compatibility until function level 500 or higher is activated.

The following table shows some features and functions that are controlled by application compatibility, and the results if you specify V11R1. If a behavior difference is traced, then the IFCID trace function code is shown.

Table 131. Behavior of V11R1 application compatibility

Feature or Function	Result with V11R1 application compatibility	IFCID 0376 trace function code
The POWER built-in function returns a result with the DOUBLE data type. The result is out of range.	SQLCODE -802	1201

Table 131. Behavior of V11R1 application compatibility (continued)		
Feature or Function	Result with V11R1 application compatibility	IFCID 0376 trace function code
CURRENT_SERVER or CURRENT_TIMEZONE is used as a column name or variable name.	SQLCODE -206	1204

SQL changes in application compatibility level V11R1

The following SQL capabilities are available in Db2 11 new-function mode or later for applications that run at application compatibility level V11R1 or higher.

Any attempt to use the capabilities in the following table at a lower application compatibility level than V11R1 results in an error condition, such as SQL code -4743 or others. For more restrictions that apply at lower application compatibility levels, see "V11R1 application compatibility level" on page 838.

New SQL statements in Db2 11

GUPI

Table 132. New SQL statements in Db2 11	
SQL statement	Description
CREATE	The CREATE TYPE (array) SQL statement defines an array type at the current server.
CREATE VARIABLE statement (Db2 SQL)	The CREATE VARIABLE statement creates a global variable at the current server.
SET CURRENT ACCELERATOR statement (Db2 SQL)	The SET CURRENT ACCELERATOR changes the value of the CURRENT ACCELERATOR special register.
SET CURRENT APPLICATION COMPATIBILITY statement (Db2 SQL)	The SET CURRENT APPLICATION COMPATIBILITY statement changes the value of the CURRENT APPLICATION COMPATIBILITY special register.
SET CURRENT TEMPORAL BUSINESS_TIME statement (Db2 SQL)	The SET CURRENT TEMPORAL BUSINESS_TIME statement changes the value of the CURRENT TEMPORAL BUSINESS_TIME special register.
SET CURRENT TEMPORAL SYSTEM_TIME statement (Db2 SQL)	The SET CURRENT TEMPORAL SYSTEM_TIME statement changes the value of the CURRENT TEMPORAL SYSTEM_TIME special register.
SET assignment-statement statement (Db2 SQL)	The SET assignment-statement statement is a reclassification of the documentation of the SET host-variable and SET transition-variable statements into a single statement.

SQL statement changes in Db2 11

The following table shows the changes to existing SQL statements that applications can use in application compatibility level V11R1 or higher.

GUPI

Table 133. Changes to exist	ing SQL statements in Db2 11
SQL statement	Description of enhancements and notes
ALTER FUNCTION (SQL	New clauses:
<u>scalar)</u>	BUSINESS_TIME SENSITIVE SYSTEM_TIME SENSITIVE ARCHIVE SENSITIVE APPLCOMPAT
	Changed clauses:
	data-type, data-type2 can include array-type-name.

REVOKE (type or JAR	Changed clauses:
privileges)	The object of the TYPE clause can be a distinct type or an array type.
SELECT INTO	Changed clauses:
	The object of the INTO clause can be a host variable, a global variable, an SQL parameter, an SQL variable, a transition variable, or an array element.

Table 133. Changes to existing SQL statements in Db2 11 (continued)		
SQL statement	Description of enhancements and notes	
SET PATH	Changed clauses:	
	The SYSTEM PATH now includes the schemas "SYSIBM", "SYSFUN", "SYSPROC", "SYSIBMADM".	
SQL statement with	Changed clauses:	
<u>subselect</u>	collection-derived-table is added to table-reference in the FROM clause of a subselect.	
	Other changes: A user-defined function that is defined with MODIFIES SQL DATA can be invoked in a subselect.	
VALUES INTO	Changed clauses:	
	The object of the INTO clause can be a host variable, a global variable, an SQL parameter, an SQL variable, a transition variable, or an array element.	

New built-in functions in Db2 11

Db2 11 introduces new built-in functions that improve the power of the SQL language. The following table shows the new built-in functions.

GUPI

Table 134. New built-in functions in Db2 11	
Function name	Description
ARRAY_AGG aggregate function (Db2 SQL)	The ARRAY_AGG function returns an array in which each value of the input set is assigned to an element of the array.
ARRAY_DELETE scalar function (Db2 SQL)	The ARRAY_DELETE function deletes elements from an array.
ARRAY_FIRST scalar function (Db2 SQL)	The ARRAY_FIRST function returns the minimum array index value of an array.
ARRAY_LAST scalar function (Db2 SQL)	The ARRAY_LAST function returns the maximum array index value of an array.
ARRAY_NEXT scalar function (Db2 SQL)	The ARRAY_NEXT function returns the next larger array index value, relative to a specified array index value.
ARRAY_PRIOR scalar function (Db2 SQL)	The ARRAY_PRIOR function returns the next smaller array index value, relative to a specified array index value.
BLOCKING_THREADS table function (Db2 SQL)	The BLOCKING_THREADS function returns a table that contains one row for each lock or claim that threads hold against specified databases.
CARDINALITY scalar function (Db2 SQL)	The CARDINALITY function returns the number of elements in an array.

Table 134. New built-in functions in Db2 11 (continued)		
Function name	Description	
CHAR9 scalar function (Db2 SQL)	The CHAR9 function returns a fixed-length character string representation of the argument. The CHAR9 function is intended for compatibility with previous releases of Db2 for z/OS that depend on the result format that is returned for decimal input values in Version 9 and earlier.	
	Important: For portable applications that might run on platforms other than Db2 for z/OS, use the <u>CHAR</u> function instead. Other Db2 family products do not support the CHAR9 function.	
MAX_CARDINALITY scalar function (Db2 SQL)	The MAX_CARDINALITY function returns the maximum number of elements that an array can contain.	
MEDIAN	The MEDIAN function returns the median of a set of numbers. This function can run only on an accelerator server.	
TRIM_ARRAY scalar function (Db2 SQL)	The TRIM_ARRAY function deletes elements from the end can ordinary array.	
VARCHAR9 scalar function (Db2 SQL)	The VARCHAR9 function returns a fixed-length character string representation of the argument. The VARCHAR9 function is intended for compatibility with previous releases of Db2 for z/OS that depend on the result format that is returned for decimal input values in Version 9 and earlier.	
	Important: For portable applications that might run on platforms other than Db2 for z/OS, use the <u>VARCHAR</u> function instead. Other Db2 family products do not support the VARCHAR9 function.

Application Programming and SQL Guide (Db2 11 for z/OS)

V10R1 application compatibility level

When you set the application compatibility level to V10R1, applications that attempt to use functions and features that are introduced in Db2 11 or later might behave differently or receive an error.

In Db2 12, you can continue to run individual applications with some of the features and behavior of DB2 10. That is, your applications can continue to experience V10R1 behavior while in Db2 12, regardless of whether new function is activated. Then, you can migrate each application to a new application compatibility value separately until all are migrated. If application compatibility is set to V10R1 and you attempt to use the new functions of a later version, SQL might behave differently or result in a negative SQL codes, such as -4743 and others.

Important: Before you start running applications at higher application compatibility (APPCLOMPAT) levels in Db2 12, you might need to make adjustments for certain behavior changes that are unrelated to use of new SQL capabilities. You can use a trace for IFCID 0376 to identify these incompatible changes. For more information, see <u>Incompatible changes</u> for <u>APPLCOMPAT levels</u> in Db2 12 (Db2 for z/OS What's New?).

A migrated Db2 12 environment behaves with V11R1 application compatibility until function level 500 or higher is activated. Application and SQL incompatibilities are described in the migration information for each version.

The following table shows examples of many of the new capabilities of Db2 11 features and functions that are controlled by application compatibility, and the results if you specify V10R1. If a behavior difference is traced, then the IFCID trace function code is shown.

Also, the new SQL capabilities of later Db2 releases cannot be used at application compatibility level V10R1. For lists of these SQL capabilities see:

- SQL changes in Db2 13
- SQL changes in Db2 12

Tip: For best results, configure your development environment to use the lowest application compatibility level that the application will run at in the production environment. For dynamic SQL, remember to consider the application compatibility levels of client and NULLID packages. If you develop and test applications at a higher application compatibility level and try to run them at a lower level in production, you are likely to encounter SQL code -4743 and other errors when you deploy the applications to production.

Table 135. Behavior of V10R1 application compatibility

Feature or Function	Result with V10R1 application compatibility	IFCID 0376 trace function code
An SQL statement in a client application includes an unsupported conversion (from a string type to a numeric type or from a numeric type to a string type), and implicit casting is disabled (DDF_COMPATIBILITY is set to SP_PARMS_NJV or to DISABLE_IMPCAST_NJV).	SQLCODE -301	7 <u>"1" on page 846</u>
A client application executes an SQL CALL statement to execute a Db2 for z/OS stored procedure. The DDF_COMPATIBILITY subsystem parameter is set to SP_PARMS_NJV for client applications other than Java applications, or SP_PARMS_JV for Java applications.	The data types of the data that is returned from the SQL CALL statement match the data types of the CALL statement arguments. This behavior is compatible with the behavior before Version 10.	8 <u>"1" on page 846</u>
A client application accesses Db2 11 from an IBM Data Server Driver for JDBC and SQLJ client. The DDF_COMPATIBILITY subsystem parameter is set to IGNORE_TZ for Java applications.	The Db2 server ignores the TIMEZONE portion, appended by the IBM Data Server Driver for JDBC and SQLJ, of the value in the TIMESTAMP WITH TIMEZONE input to a TIMESTAMP target. This behavior is compatible with the behavior before DB2 10.	9
BIF_COMPATIBILITY is set to V9_TRIM, and input <i>string-expression</i> is EBCDIC mixed data for the RTRIM, LTRIM, or STRIP built-in function.	The DB2 9 version of SYSIBM.LTRIM(string-expression), SYSIBM.RTRIM(string-expression), or SYSIBM.STRIP(string-expression) is executed.	10
An implicit insert or update of an XML document node	SQLCODE -20345	1101

Table 135. Behavior of V10R1 application compatibility (continued)				
Feature or Function	Result with V10R1 application compatibility	IFCID 0376 trace function code		
A predicate expression with an explicit cast or an operation with an invalid value that does not affect the results of XPath processing	SQLCODE -20345	1102		
How the resource limit facility uses ASUTIME value for nested routines	SQLCODE -905 is issued only when the ASUTIME limit of the top-level calling package is encountered.	1103		
The lengths of values that are returned from CURRENT CLIENT_USERID, CURRENT CLIENT_WRKSTNNAME, CURRENT CLIENT_APPLNAME, or CURRENT CLIENT_ACCTNG special register are longer than the DB2 10 limits.	The special register values are truncated to the DB2 10 maximum lengths and padded with blanks	1104, 1105, 1106, 1107		
A CAST(string as TIMESTAMP) specification with an input string of length of 8 or an input string of length 13	An explicit cast specification from string as TIMESTAMP interprets an 8-byte character string as a Store Clock value and a 13-byte string as a GENERATE_UNIQUE value. CAST result might be incorrect.	1109		
Invocation of the SPACE or VARCHAR built- in function when the result is defined as VARCHAR(32765), VARCHAR(32766), or VARCHAR(32767)	No error	1110, 1111		
Subsystem parameter XML_RESTRICT_EMPTY_TAG is set to YES, and an empty XML element is serialized as <emptyelement></emptyelement>	No error	1112		
Specification of bind option DBPROTOCOL(DRDACBF)	DSNT298I			
A period specification that follows the name of a view in the FROM clause of a query	SQLCODE -4743			
A period clause that follows the name of a target view in an UPDATE or DELETE statement	SQLCODE -4743			
A SET CURRENT TEMPORAL SYSTEM_TIME statement	SQLCODE -4743			
A SET CURRENT TEMPORAL BUSINESS_TIME statement	SQLCODE -4743			
A reference to a global variable	SQLCODE -4743			

Table 135. Behavior of V10R1 application compatibility (continued)			
Feature or Function	Result with V10R1 application compatibility	IFCID 0376 trace function code	
Use of array operations and built-in functions such as	SQLCODE -4743		
• Use of the UNNEST collection-derived-table			
 Use of the ARRAY_FIRST, ARRAY_LAST, ARRAY_NEXT, ARRAY_PRIOR, ARRAY_AGG, TRIM_ARRAY, CARDINALITY, MAX_CARDINALITY built-in functions 			
 A SET assignment-statement of an array element as a target table 			
 A CAST specification with a parameter marker as the source and an array as the data type 			
An aggregate function that contains the keyword DISTINCT and references a column that is defined with a column mask	SQLCODE -20478		
An SQL statement contains the GROUP BY clause and references a column that is defined with a column mask	SQLCODE -20478		
An SQL statement contains the set operator UNION ALL or UNION DISTINCT and references a column that is defined with a column mask	SQLCODE -20478		
A reference to an alias for a sequence object	SQLCODE -4743		
A reference to an unqualified sequence that is not resolved to a public alias	SQLCODE -204		
A SELECT with a table function reference that includes a typed correlation clause	SQLCODE -4743		
A table-reference, collection-derived-table, or xmltable-expression that does not include a correlation-clause.	SQLCODE -4743		
A CALL statement that specifies an autonomous procedure	SQLCODE -4743		
The following datetime assignments:	SQLCODE -180		
 A valid string representation of a timestamp to a date column 			
 A valid string representation of a timestamp to a time column 			
 A valid string representation of a date to a timestamp column 			
Notors			

Notes:

1. PSPI To find details about the incompatible parameters, examine the contents of fields QW0376SC_Var, QW0376PR_Var, and QW0376INC_Var. See the DSNWMSGS file for more information. PSPI

Managing incompatible changes for applications

Before you move an application to a new application compatibility (APPLCOMPT) level, you might need to adjust your applications for certain incompatible changes that are unrelated to use of new SQL function, and verify that they are resolved.

Procedure

1. Start a trace that includes IFCID 0239 to capture package information. For example, issue the following START TRACE command: GUPI

```
-START TRACE(ACCTG) CLASS(7,8,10)
```

GUPI

2. Examine the trace output.

PSPI IFCID 0239 field QPACFLGS contains a bit that is on if a package contains incompatibilities. If this bit is off, no incompatibilities were detected, and you can skip the rest of the steps. If this bit is on, proceed to step 3. PSPI

3. Start a trace for IFCID 0376 to report incompatibility information about the packages. For example, issue the following START TRACE command: GUPI

```
-START TRACE(PERFM) CLASS(32) IFCID(376)
```

GUPI

- 4. Run the application.
- 5. Examine the trace output.

record for each SQL statement that is incompatible with the subsequent Db2 function level. See file prefix.SDSNIVPD(DSNWMSGS) for listings of the IFCID 0239 and 0376 trace records.

- 6. Revise the application to avoid any application incompatibilities.
- 7. Prepare the application for execution. When you bind the packages for the application, use the old APPLCOMPAT value.
- 8. Run the application.
- 9. Examine the trace output again to verify that the incompatibilities no longer exist.

What to do next

When the application runs at the old level with no application incompatibilities, rebind the package with the APPLCOMPAT value for the new function level.

Incompatible changes for APPLCOMPAT levels in Db2 12 (Db2 for z/OS What's New?)

Enabling default application compatibility with function level 500 or higher

The APPLCOMPAT subsystem parameter specifies the default value of the APPLCOMPAT bind option. Before function level 500 or higher is activated, the APPLCOMPAT subsystem parameter must be set to V11R1 or V10R1. These settings ensure that existing SQL applications are bound for compatibility with the earlier release by default.

Before you begin

- 1. Activate function level 500 or higher, as described in <u>Activating Db2 12 new function at migration (Db2 Installation and Migration)</u>.
- 2. For any packages that need to continue running at a lower level, bind or rebind them and explicitly specify the APPLCOMPAT bind option. For more information, see <u>Controlling the Db2 application</u> compatibility level (Db2 for z/OS What's New?).
- 3. Take the following precautions to ensure that applications are ready to run at the higher application compatibility level by default.
 - Identify and resolve all application incompatibilities of the higher level, as described in <u>"Managing</u> incompatible changes for applications" on page 847.
 - Rebind any packages that must continue to run at the lower application compatibility level and explicitly specify the APPLCOMPAT bind option for that level.

About this task

After all applications are ready to run at a higher application compatibility level or explicitly bound at a lower level, you can increase the APPLCOMPAT subsystem parameter value to bind packages at a higher application compatibility level by default.

The APPLCOMPAT subsystem parameter specifies the default value to use when the APPLCOMPAT bind option is not specified in a BIND command, or the APPLCOMPAT value is not specified or stored in the Db2 catalog for a REBIND command. Its value does not prevent specific applications from running at higher application compatibility levels. For more information, see APPL COMPAT LEVEL field (APPLCOMPAT subsystem parameter) (Db2 Installation and Migration).

Procedure

To enable default application compatibility with the current function level:

- 1. Change the APPLCOMPAT subsystem parameter setting. Set the value to V12R1M500 or the equivalent higher active *function-level* value.
 - You can complete this step as described in <u>Updating subsystem parameter and application default</u> values (Db2 Installation and Migration), or by modifying your customized copy of the DSNTIJUZ job.
 - The format is VvvRrMmmm, where vv is the version, r is the release, and mmm is the modification level. For example, V12R1M510 identifies function level 510. For a list of all available function levels in Db2 12, see Db2 12 function levels (Db2 for z/OS What's New?). See the activation details for each function level for a summary the new features that are controlled by the corresponding application compatibility level.
- 2. Run the first two job steps of DSNTIJUZ to rebuild your subsystem parameter (DSNZPxxx) module.
- 3. Use the -SET SYSPARM command or restart Db2.

Results

Future bind and rebind operations set the application compatibility level of the package to the APPLCOMPAT subsystem parameter value, if the APPLCOMPAT bind option is not specified. Packages that are bound or rebound at the higher level can begin use of SQL capabilities introduced at that level.

Chapter 9. Preparing an application to run on Db2 for z/OS

To prepare and run applications that contain embedded static SQL statements or dynamic SQL statements, you must process, compile, link-edit, and bind the SQL statements.

Before you begin

To avoid rework, follow these steps:

- 1. Test your SQL statements by using SPUFI.
- 2. Compile your program with no SQL statements, and resolve all compiler errors.
- 3. Proceed with the preparation and the Db2 precompiler or with the host compiler that supports that Db2 coprocessor.

The following types of applications require different methods of program preparation:

- Applications that contain ODBC calls
- Applications in interpreted languages, such as REXX. For information about running REXX programs, which you do not prepare for execution, see "Running a Db2 REXX application" on page 956.
- Java applications, which can contain JDBC calls or embedded SQL statements

About this task

Before you can run an application program on Db2 for z/OS, you need to prepare it. To prepare the program, you create a load module, possibly one or more packages, and an application plan.

If your application program includes SQL statements, you need to process those SQL statements by using either the Db2 coprocessor that is provided with a compiler or the Db2 precompiler.

Tip: The Db2 coprocessor is the recommended method for processing SQL statements in application programs. Compared to the Db2 precompiler, the Db2 coprocessor has fewer restrictions on SQL programs, and more fully supports the latest SQL and programming language enhancements. See "Processing SQL statements by using the Db2 coprocessor" on page 857.

Both the Db2 coprocessor and the Db2 precompiler perform the following actions:

- Replace the SQL statements in your source programs with calls to Db2 language interface modules
- Create a database request module (DBRM), which communicates your SQL requests to Db2 during the bind process

Db2 coprocessor

The following figure illustrates the program preparation process when you use the Db2 coprocessor. The process is similar to the process with the Db2 precompiler, except that the Db2 coprocessor does not create modified source for your application program. For more information, see "Processing SQL statements by using the Db2 coprocessor" on page 857.

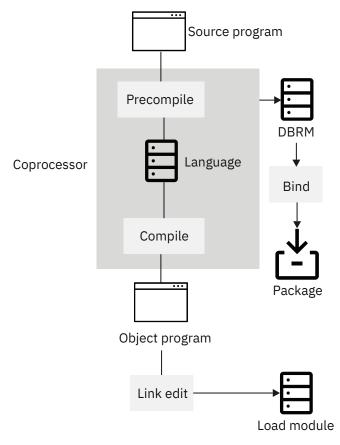

Figure 43. Overview of the program preparation process for applications that contain embedded SQL. The Db2 coprocessor can combine the precompile and compile steps for certain languages.

Db2 precompiler

After you process SQL statements in your source program by using the Db2 precompiler, you create a load module, possibly one or more packages, and an application plan. Creating a load module involves compiling the modified source code that is produced by the precompiler into an object program, and link-editing the object program to create a load module. Creating a package or an application plan, a process unique to Db2, involves binding one or more DBRMs, which are created by the Db2 precompiler, by using the BIND PACKAGE command. For more information, see "Processing SQL statements by using the Db2 precompiler" on page 861.

Procedure

- Complete the tasks by using one of the methods described below:
 - a) "Processing SQL statements for program preparation" on page 856
 - b) "Compiling and link-editing an application" on page 883
 - c) "Binding application packages and plans" on page 884
 - d) Chapter 10, "Running an application on Db2 for z/OS," on page 953

Binding a package is not necessary in all cases. These instructions assume that you bind some of your DBRMs into packages and include a package list in your plan.

If you use CICS, you might need to complete additional steps. For more information, see:

- "Translating command-level statements in a CICS program" on page 870
- "Example of calling applications in a command procedure" on page 965

You can use the following methods to complete the program preparation tasks:

Preparing applications by using JCL procedures

A number of methods are available for preparing an application to run. You can:

- Use Db2 interactive (DB2I) panels, which lead you step by step through the preparation process.
- Submit a background job using JCL (which the program preparation panels can create for you).
- Start the DSNH CLIST in TSO foreground or background.
- Use TSO prompters and the DSN command processor.
- Use JCL procedures added to your SYS1.PROCLIB (or equivalent) at Db2 installation time.
- You can invoke the coprocessor from UNIX System Services. If the DBRM is generated in a HFS file, you can also use the Db2 command line processor to bind the resulting DBRM. Optionally, you can also copy the DBRM into a partitioned data set member by using the oput and oget commands and then bind it by using conventional JCL.

This topic describes how to use JCL procedures to prepare a program. For information about using the DB2I panels, see Chapter 9, "Preparing an application to run on Db2 for z/OS," on page 851.

Preparing applications by the Db2 Program Preparation panels

If you develop programs using TSO and ISPF, you can prepare them to run by using the Db2 Program Preparation panels. These panels guide you step by step through the process of preparing your application to run. Other ways of preparing a program to run are available, but using Db2 Interactive (DB2I) is the easiest because it leads you automatically from task to task.

Important: If your C++ program satisfies both of the following conditions, you must use a JCL procedure to prepare it:

- The program consists of more than one data set or member.
- More than one data set or member contains SQL statements.

To prepare an application by using the Db2 Program Preparation panels:

1. If you want to display or suppress message IDs during program preparation, specify one of the following commands on the ISPF command line:

TSO PROFILE MSGID

Message IDs are displayed

TSO PROFILE NOMSGID

Message IDs are supressed

- 2. Open the DB2I Primary Option Menu.
- 3. Select the option that corresponds to the Program Preparation panel.
- 4. Complete the Program Preparation panel and any subsequent panels. After you complete each panel, DB2I automatically displays the next appropriate panel.

Preparation guidelines for DL/I batch programs

Use the following guidelines when you prepare a program to access Db2 and DL/I in a batch program:

- "Processing SQL statements by using the Db2 precompiler" on page 861
- "Binding a batch program" on page 897
- "Compiling and link-editing an application" on page 883
- "Loading and running a batch program" on page 959

Setting the DB2I defaults

When you use the Db2 Interactive (DB2I) panels to prepare an application, you can specify the default values that DB2I is to use. These defaults values can include the default application language and default JCL JOB statement. Otherwise, DB2I uses the system default values that were set at installation time.

Procedure

As DB2I leads you through a series a panels, enter the default values that you want on the following panels when they are displayed.

Table 136. DB2I panels to use to set default values	
If you want to set the following default values	Use this panel
subsystem ID	DB2I Defaults Panel 1 panel
 number of additional times to attempt to connect to Db2 	
 programming language 	
 number of lines on each page of listing or SPUFI output 	
• lowest level of message to return to you during the BIND phase	
 SQL string delimiter for COBOL programs 	
 how to represent decimal separators 	
 smallest value of the return code (from precompile, compile, link-edit, or bind) that prevents later steps from running 	
 default number of input entry rows to generate on the initial display of ISPF panels 	
 user ID to associate with the trusted connection for the current DB2I session 	
default JOB statement	DB2I Defaults Panel 2 panel
 symbol used to delimit a string in a COBOL statement in a COBOL application 	
 whether DCLGEN generates a picture clause that has the form PIC G(n) DISPLAY-1 or PIC N(n). 	

Table 136. DB2I panels to use to set default values (continued)	
If you want to set the following default values	Use this panel
The following package and plan characteristics	Defaults for Bind Package panel
• isolation level	Defaults for Bind Plan panel
 whether to check authorization at run time or at bind time 	
when to release locks on resources	
 whether to obtain EXPLAIN information about how SQL statements in the plan or package execute 	
 whether you need data currency for ambiguous cursors opened at remote locations 	
 whether to use parallel processing 	
 whether Db2 determines access paths at bind time and again at execution time 	
 whether to defer preparation of dynamic SQL statements 	
 whether Db2 keeps dynamic SQL statements after commit points 	
the application encoding scheme	
 whether you want to use optimization hints to determine access paths 	
 when Db2 writes the changes for updated group buffer pool- dependent pages 	
 whether run time (RUN) or bind time (BIND) rules apply to dynamic SQL statements at run time 	
 whether to continue to create a package after finding SQL errors (packages only) 	
 when to acquire locks on resources (plans only) 	
 whether a CONNECT (Type 2) statement executes according to Db2 rules (Db2) or the SQL standard (STD). (plans only) 	
which remote connections end during a commit or a rollback

DB2I Defaults Panel 1

DB2I Defaults Panel 1 lets you change many of the system default values that were set at Db2 installation time.

DB2I Defaults Panel 2

After you press Enter on the DB2I Defaults Panel 1, the DB2I Defaults Panel 2 is displayed. If you chose IBMCOB as the language on the DB2I Defaults Panel 1, three fields are displayed. Otherwise, only the first field is displayed.

Defaults for Bind Package and Defaults for Rebind Package panels

These DB2I panels lets you change your defaults for BIND PACKAGE and REBIND PACKAGE options.

Defaults for Bind Plan and Defaults for Rebind Plan panels

These DB2I panels let you change your defaults for BIND PLAN and REBIND PLAN options.

Processing SQL statements for program preparation

The first step in preparing an SQL application to run is to process the SQL statements in the program. To process the statements, use the Db2 coprocessor or the Db2 precompiler. During this step, the SQL statements are replaced with calls to Db2 language interface modules, and a DBRM is created.

Before you begin

Ensure that your application development programming languages meet the minimum requirements listed in "Programming Languages" in *Db2 12 Program Directory*. See <u>Program directories for Db2 12 (Db2 for z/OS in IBM Documentation)</u>.

About this task

Because most compilers do not recognize SQL statements, you can prevent compiler errors by using either the Db2 coprocessor or the Db2 precompiler.

You can use the Db2 coprocessor for the host language. When you use the Db2 coprocessor, the compiler (rather than the Db2 precompiler) scans the program and returns the modified source code. The Db2 coprocessor also produces a DBRM.

Tip: The Db2 coprocessor is the recommended method for processing SQL statements in application programs. Compared to the Db2 precompiler, the Db2 coprocessor has fewer restrictions on SQL programs, and more fully supports the latest SQL and programming language enhancements. See "Processing SQL statements by using the Db2 coprocessor" on page 857.

The Db2 precompiler scans the program and returns modified source code, which you can then compile and link edit. The precompiler also produces a DBRM (database request module). You can bind this DBRM to a package using the BIND subcommand. When you complete these steps, you can run your Db2 application.

Db2 version in DSNHDECP module

When you process SQL statements in your program, if the Db2 version in DSNHDECP is the default system-provided version, Db2 issues a warning and processing continues. In this case, ensure that the information in DSNHDECP that Db2 uses accurately reflects your environment.

Procedure

To process SQL statements in application programs, use one of the following methods:

- Invoke the Db2 coprocessor for the host language that you are using as you compile your program. You can use the Db2 coprocessor with C, C++, COBOL, and PL/I host compilers.
 - To invoke the Db2 coprocessor, specify the SQL compiler option followed by its suboptions, which are those options that are defined for the Db2 precompiler. Some Db2 precompiler options are ignored. You can also invoke the Db2 coprocessor from UNIX System Services on z/OS to generate a DBRM in either a partitioned data set or an HFS file.
 - For more information, see "Processing SQL statements by using the Db2 coprocessor" on page 857.
- Use the Db2 precompiler before you compile your program. For more information, see <u>"Processing SQL</u> statements by using the Db2 precompiler" on page 861.
 - For assembler or Fortran applications, use the Db2 precompiler to prepare the SQL statements.

Results

The main output from the Db2 coprocessor or Db2 precompiler is a database request module (DBRM). However, the Db2 coprocessor or Db2 precompiler also produces modified source statements, a list of source statements, a list of statements that refer to host names and columns, and diagnostics. For more information, see "Output from the Db2 precompiler" on page 867.

What to do next

If the application contains CICS® commands, you must translate the program before you compile it. For more information, see "Translating command-level statements in a CICS program" on page 870.

Related concepts

Using the Db2 C/C++ precompiler (XL C/C++ Programming Guide)

Db2 coprocessor (Enterprise COBOL for z/OS Programming Guide)

Output from the Db2 precompiler

The main output from the Db2 precompiler is a database request module (DBRM). However, the Db2 precompiler also produces modified source statements, a list of source statements, a list of statements that refer to host names and columns, and diagnostics.

Differences between the Db2 coprocessor and the Db2 precompiler

The Db2 coprocessor and the Db2 precompiler have architectural differences. You cannot switch from one to the other without considering those differences and adjusting your program accordingly.

Enterprise COBOL for z/OS

Processing SQL statements by using the Db2 coprocessor

You can use the Db2 coprocessor for processing SQL statements at compile time. With the Db2 coprocessor, the compiler scans a program and copies all of the SQL statements and host variable information into a database request module (DBRM). The Db2 coprocessor is the recommended method for processing SQL statements in application programs. Compared to the Db2 precompiler, the Db2 coprocessor has fewer restrictions on SQL programs, and more fully supports the latest SQL and programming language enhancements.

Before you begin

Ensure that your application development programming languages meet the minimum requirements listed in "Building applications by using the Db2 coprocessor" in *Db2 12 Program Directory*. See <u>Program directories</u> for Db2 12 (Db2 for z/OS in IBM Documentation).

About this task

The Db2 coprocessor processes SQL statements at compile time.

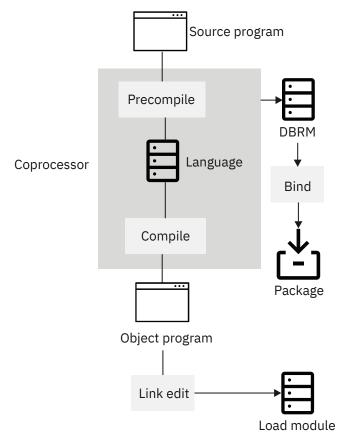

Figure 44. Overview of the program preparation process for applications that contain embedded SQL. The Db2 coprocessor can combine the precompile and compile steps for certain languages.

Exception: For PL/I, the Db2 coprocessor is called from the PL/I preprocessor instead of the compiler.

The Db2 coprocessor is the recommended method for processing SQL statements in application programs. Compared to the Db2 precompiler, the Db2 coprocessor has fewer restrictions on SQL programs, and more fully supports the latest SQL and programming language enhancements.

For example, when you process SQL statements with the Db2 coprocessor, you can do the following things in your program:

- Use fully qualified names for structured host variables.
- Include SQL statements at any level of a nested program, instead of in only the top-level source file. (Although you can include SQL statements at any level of a nested program, you must compile the entire program as one unit.)
- Use nested SQL INCLUDE statements.
- For C or C++ programs only, write applications with variable length format.
- For C or C++ programs only, use codepage-dependent characters, such as left and right brackets, without using tri-graph notation when the programs use different code pages.

Procedure

To process SQL statements by using the Db2 coprocessor, take one of the following actions:

- Submit a JCL job to process that SQL statement. Include the following information:
 - Specify the SQL compiler option when you compile your program:

The SQL compiler option indicates that you want the compiler to invoke the Db2 coprocessor. Specify a list of SQL processing options in parentheses after the SQL keyword. <u>Table 140 on page</u> 872 lists the options that you can specify.

For COBOL and PL/I, enclose the list of SQL processing options in single or double quotation marks. For PL/I, separate options in the list by a comma, blank, or both, as shown in the following examples:

C/C++	SQL(APOSTSQL STDSQL(NO))
COBOL	SQL("APOSTSQL STDSQL(NO)")
PL/I	PP(SQL("APOSTSQL,STDSQL(NO)")

 For PL/I programs that use BIGINT or LOB data types, specify the following compiler options when you compile your program:

```
LIMITS(FIXEDBIN(63), FIXEDDEC(31))
```

- If needed, increase the user's region size so that it can accommodate more memory for the Db2 coprocessor.
- Include DD statements for the following data sets in the JCL for your compile step:

Db2 load library (prefix.SDSNLOAD)

The Db2 coprocessor calls Db2 modules to process the SQL statements. You therefore need to include the name of the Db2 load library data set in the STEPLIB concatenation for the compiler step.

DBRM library

The Db2 coprocessor produces a DBRM. DBRMs and the DBRM library are described in <u>"Output from the Db2 coprocessor" on page 860</u>. You need to include a DBRMLIB DD statement that specifies the DBRM library data set.

Library for SQL INCLUDE statements

If your program contains SQL INCLUDE *member-name* statements that specify secondary input to the source program, you need to also specify the data set for *member-name*. Include the name of the data set that contains *member-name* in the SYSLIB concatenation for the compiler step.

• Invoke the Db2 coprocessor from z/OS UNIX System Services.

If you invoke the Db2 coprocessor from z/OS UNIX System Services, you can choose to have the DBRM generated in a partitioned data set or an HFS file.

When you invoke the Db2 coprocessor, specify the SQL compiler option. The SQL compiler option indicates that you want the compiler to invoke the Db2 coprocessor. Specify a list of SQL processing options in parentheses after the SQL keyword. For the list of options that you can specify, see <u>SQL processing options</u>.

The file name for the DBRM is determined as described in <u>DRBMLIB</u>. For host languages other than C and C++, the DBRMLIB option is not supported and the file name is always generated. For C and C++, you can specify one of the following items:

- The name of a partitioned data set. The following example invokes the C/C++ Db2 coprocessor to compile (with the c89 compiler) a sample C program and requests that the resulting DBRM is stored in the test member of the userid.dbrmlib.data data set:

```
c89 -Wc, "sql, dbrmlib(//'userid.dbrmlib.data(test)'), langlvl(extended)" -c t.c
```

The name of an HFS file. The name can be qualified, partially qualified, or unqualified. The file
path can contain a maximum of 1024 characters, and the file name can contain a maximum of 255
characters. The first 8 characters of the file name, not including the file extension, must be unique
within the file system.

For example, assume that your directory structure is /u/USR001/c/example and that your current working directory is /u/USR001/c. The following table shows examples of how to specify the HFS file names with the DBRMLIB option and how the file names are resolved.

Table 137. How to specify HFS files to store DBRMs		
If you specify	The DBRM is generated in	
dbrmlib(/u/USR001/sample.dbrm)	/u/USR001/sample.dbrm	
dbrmlib(example/sample.dbrm)	/u/USR001/c/example/sample.dbrm	
dbrmlib(/sample.dbrm)	/u/USR001/sample.dbrm	
dbrmlib(sample.dbrm)	/u/USR001/c/sample.dbrm	

The following example invokes the Db2 coprocessor to compile (with the c89 compiler) a sample C program and requests that the resulting DBRM is stored in the file test.dbrm in the tmp directory:

```
c89 -Wc, "sql, dbrmlib(/tmp/test.dbrm), langlvl(extended)" -c t.c
```

The following example invokes the Db2 coprocessor to compile a sample COBOL program with the Enterprise COBOL for z/OS 6.2 or later compilers:

```
cob2 myprogram.cbl -c myprogram -dbrmlib -qsql
```

The following example invokes the Db2 coprocessor to compile a sample PL/I program from Enterprise PL/I for z/OS 5.2 or later compilers:

```
pli -c -qpp=sql -qdbrmlib -qrent myprogram.pli
```

If you request that the DBRM be generated in an HFS file, you can bind the resulting DBRM by using the Db2 command line processor BIND command. For more information about using the Db2 command line processor BIND command, see "Binding a DBRM that is in an HFS file to a package or collection" on page 886. Optionally, you can also copy the DBRM into a partitioned data set member by using the oput and oget commands and then bind the DBRM by using conventional JCL.

Results

The main output from the Db2 coprocessor is a database request module (DBRM). However, the Db2 coprocessor also produces modified source statements, a list of source statements, a list of statements that refer to host names and columns, and diagnostics. For more information, see "Output from the Db2 coprocessor" on page 860.

Support for compiling a COBOL program that includes SQL from an assembler program

The COBOL compiler provides a facility that enables you to invoke the COBOL compiler by using an assembler program.

If you intend to use the Db2 coprocessor and start the COBOL compiler from an assembler program as part of your Db2 application preparation, you can use the SQL compiler option and provide the alternate DBRMLIB DD name the same way that you can specify other alternate DD names. The Db2 coprocessor creates the DBRM member according to your DBRM PDS library and the DBRM member that you specified using the alternate DBRMLIB DD name.

Starting the compiler from an assembler program

Output from the Db2 coprocessor

The output from the Db2 coprocessor is a database request module (DBRM).

Tip: The Db2 coprocessor is the recommended method for processing SQL statements in application programs. Compared to the Db2 precompiler, the Db2 coprocessor has fewer restrictions on SQL

programs, and more fully supports the latest SQL and programming language enhancements. See "Processing SQL statements by using the Db2 coprocessor" on page 857.

The Db2 coprocessor produces a *database request module (DBRM)*. The DBRM is a data set that contains the SQL statements and host variable information that is extracted from the source program, along with information that identifies the program and ties the DBRM to the translated source statements. The DBRM becomes the input to the bind process.

The data set requires space to hold all the SQL statements plus space for each host variable name and some header information. The header information alone requires approximately two records for each DBRM, 20 bytes for each SQL record, and 6 bytes for each host variable.

For an exact format of the DBRM, see the DBRM mapping macros, DSNXDBRM and DSNXNBRM, in library *prefix*.SDSNMACS. The DCB attributes of the data set are RECFM FB, LRECL 80. The precompiler sets the characteristics. You can use IEBCOPY, IEHPROGM, TSOCOPY and DELETE commands, or other PDS management tools for maintaining these data sets.

Important: Do not modify the contents of the DBRM. If you do, unpredictable results can occur. Db2 does not support modified DBRMs.

All other character fields in a DBRM use EBCDIC. The current release marker (DBRMMRIC) in the header of a DBRM is marked according to the release of the precompiler, regardless of the value of NEWFUN.

In a DBRM, the SQL statements and the list of host variable names use the UTF-8 character encoding scheme.

Processing SQL statements by using the Db2 precompiler

The Db2 precompiler scans a program and copies all of the SQL statements and host variable information into a database request module (DBRM). The Db2 precompiler also returns source code that has been modified so that the SQL statements do not cause errors when you compile the program.

Before you begin

Ensure that your application development programming languages meet the minimum requirements listed in "Building applications by using the Db2 precompiler" in *Db2 12 Program Directory*. See <u>Program directories</u> for Db2 12 (Db2 for z/OS in IBM Documentation).

Tip: The Db2 coprocessor is the recommended method for processing SQL statements in application programs. Compared to the Db2 precompiler, the Db2 coprocessor has fewer restrictions on SQL programs, and more fully supports the latest SQL and programming language enhancements. See "Processing SQL statements by using the Db2 coprocessor" on page 857.

If you are using the Db2 precompiler, ensure that the names of host variables and host-variable arrays are unique within the program, even if the variables and variable arrays are in different blocks, classes, procedures, functions, or subroutines. You can qualify the names with a structure name to make them unique.

About this task

After the SQL statements and host variable information are copied into a DBRM and the modified source code is returned, you can compile and link-edit this modified source code.

The following figure illustrates the program preparation process when you use the Db2 precompiler. After you process SQL statements in your source program by using the Db2 precompiler, you create a load module, possibly one or more packages, and an application plan. Creating a load module involves compiling the modified source code that is produced by the precompiler into an object program, and link-editing the object program to create a load module. Creating a package or an application plan, a process unique to Db2, involves binding one or more DBRMs, which are created by the Db2 precompiler, using the BIND PACKAGE command.

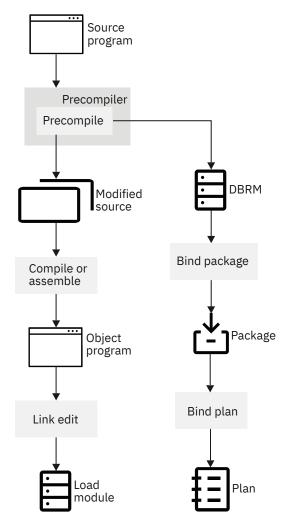

Figure 45. Program preparation with the Db2 precompiler

Before you run the Db2 precompiler, use DCLGEN to obtain accurate SQL DECLARE TABLE statements. Db2 precompiler checks table and column references against SQL DECLARE TABLE statements in the program, not the actual tables and columns.

Db2 does not need to be active when you precompile your program.

You do not need to precompile the program on the same Db2 subsystem on which you bind the DBRM and run the program. You can bind a DBRM and run it on a Db2 subsystem at the previous release level, if the original program does not use any properties of Db2 that are unique to the current release. You can also run applications on the current release that were previously bound on subsystems at the previous release level.

Procedure

To process SQL statements by using the Db2 precompiler:

- 1. Ensure that your program is ready to be processed by the Db2 precompiler by performing the following actions.
 - For information about the criteria for programs that are passed to the Db2 precompiler, see <u>"Input to</u> the Db2 precompiler" on page 865.
- 2. If you plan to run multiple precompilation jobs and are not using the DFSMSdfp partitioned data set extended (PDSE), change the Db2 language preparation procedures (DSNHCOB, DSNHCOB2, DSNHICOB, DSNHFOR, DSNHC, DSNHPLI, DSNHASM, DSNHSQL) to specify the DISP=OLD parameter instead of the DISP=SHR parameter.

The Db2 language preparation procedures in job DSNTIJMV use the DISP=OLD parameter to enforce data integrity. However, the installation process converts the DISP=OLD parameter for the DBRM library data set to DISP=SHR, which can cause data integrity problems when you run multiple precompilation jobs.

- 3. Start the precompile process by using one of the following methods:
 - DB2I panels. Use the **Precompile** panel or the Db2 **Program Preparation** panels. For details, see "DB2I panels that are used for program preparation" on page 920.
 - The DSNH command procedure (a TSO CLIST). For details, see <u>DSNH command procedure (TSO CLIST)</u> (Db2 Commands).
 - JCL procedures that are supplied with Db2. For details, see "Db2-supplied JCL procedures for preparing an application" on page 917.

Recommendation: Specify the SOURCE and XREF precompiler options to get complete diagnostic output from the Db2 precompiler. This output is useful if you need to precompile and compile program source statements several times before they are error-free and ready to link-edit.

Results

The main output from the Db2 precompiler is a database request module (DBRM). However, the Db2 precompiler also produces modified source statements, a list of source statements, a list of statements that refer to host names and columns, and diagnostics. For more information, see "Output from the Db2 precompiler" on page 867.

What to do next

Preparing a program with object-oriented extensions by using JCL

If your C++ or Enterprise COBOL for z/OS program satisfies both of these conditions, you need special JCL to prepare it:

- The program consists of more than one data set or member.
- More than one data set or member contains SQL statements.

You must precompile the contents of each data set or member separately, but the prelinker must receive all of the compiler output together.

JCL procedure DSNHCPP2, which is in member DSNTIJMV of data set DSN1210.SDSNSAMP, shows you one way to do this for C++.

Precompiling a batch program

When you add SQL statements to an application program, you must precompile the application program and bind the resulting DBRM into a package, as described in Chapter 9, "Preparing an application to run on Db2 for z/OS," on page 851.

Related concepts

DCLGEN (declarations generator)

Your program should declare the tables and views that it accesses. The Db2 declarations generator, DCLGEN, produces these DECLARE statements for C, COBOL, and PL/I programs, so that you do not need to code the statements yourself. DCLGEN also generates corresponding host variable structures.

Output from the Db2 precompiler

The main output from the Db2 precompiler is a database request module (DBRM). However, the Db2 precompiler also produces modified source statements, a list of source statements, a list of statements that refer to host names and columns, and diagnostics.

Related reference

DSNH command procedure (TSO CLIST) (Db2 Commands)

Data sets that the precompiler uses

When you invoke the precompiler you need to provide data sets that contain input for the precompiler, such as the host programming statements and SQL statements. You also need to provide data sets where the precompiler can store its output, such as the modified source code and diagnostics messages.

Table 138. DD statements and data sets that the Db2 precompiler uses

DD statement	Data set description	Required?
DBRMLIB	Output data set, which contains the SQL statements and host variable information that the Db2 precompiler extracted from the source program. It is called Database Request Module (DBRM). This data set becomes the input to the Db2 bind process. The DCB attributes of the data set are RECFM FB, LRECL 80. DBRMLIB has to be a PDS and a member name must be specified. You can use IEBCOPY, IEHPROGM, TSO commands, COPY and DELETE, or PDS management tools for maintaining the data set.	Yes
STEPLIB	Step library for the job step. In this DD statement, you can specify the name of the library for the precompiler load module, DSNHPC, and the name of the library for your Db2 application programming defaults member, DSNHDECP.	No, but recommended
	Recommendation: Always use the STEPLIB DD statement to specify the library where your Db2 DSNHDECP module resides to ensure that the proper application defaults are used by the Db2 precompiler. The library that contains your Db2 DSNHDECP module needs to be allocated ahead of the prefix.SDSNLOAD library.	
SYSCIN	Output data set, which contains the modified source that the Db2 precompiler writes out. This data set becomes the input data set to the compiler or assembler. This data set must have attributes RECFM F or FB, and LRECL 80. SYSCIN can be a PDS or a sequential data set. If a PDS is used, the member name must be specified.	Yes
SYSIN	Input data set, which contains statements in the host programming language and embedded SQL statements. This data set must have the attributes RECFM F or FB, LRECL 80. SYSIN can be a PDS or a sequential data set. If a PDS is used, the member name must be specified.	Yes

Table 138. DD statements and data sets that the Db2 precompiler uses (continued)		
DD statement	Data set description	Required?
SYSLIB	INCLUDE library, which contains additional SQL and host language statements. The Db2 precompiler includes the member or members that are referenced by SQL INCLUDE statements in the SYSIN input from this DD statement. Multiple data sets can be specified, but they must be partitioned data sets with attributes RECFM F or FB, LRECL 80. SQL INCLUDE statements cannot be nested.	No
SYSPRINT	Output data set, which contains the output listing from the Db2 precompiler. This data set must have an LRECL of 133 and a RECFM of FBA. SYSPRINT must be a sequential data set	Yes
SYSTERM	Terminal output file, which contains diagnostic messages from the Db2 precompiler. The DCB attributes of the data set are determined by the z/OS system. SYSTERM must be a sequential data set.	No
SYSUT1 and SYSUT2	Internal work files that the precompiler uses to store temporary information as it converts embedded SQL statements to host language statements. Precompilation of assembler and PL/I source code uses only the SYSUT1 data set. The default SPACE parameter values in the Db2-supplied program preparation procedures (DSNHASM, DSNHC, DSNHCPP, DSNHCPP2, DSNHICOB, DSNHPLI, and DSNHFOR) are adequate in most cases. If your application program contains a large number of embedded SQL statements, you might need to increase those values.	No, unless you need to override the default SPACE parameter values.

Related reference

SPACE Parameter (MVS JCL Reference)

Input to the Db2 precompiler

The primary input for the precompiler consists of statements in the host programming language and embedded SQL statements.

You can use the SQL INCLUDE statement to get secondary input from the include library, SYSLIB. The SQL INCLUDE statement reads input from the specified member of SYSLIB until it reaches the end of the member.

Another preprocessor, such as the PL/I macro preprocessor, can generate source statements for the precompiler. Any preprocessor that runs before the precompiler must be able to pass on SQL statements. Similarly, other preprocessors can process the source code, after you precompile and before you compile or assemble.

Input to the Db2 precompiler has the following restrictions:

• The size of a source program that Db2 can precompile is limited by the region size and the virtual memory available to the precompiler. These amounts vary with each system installation.

- The forms of source statements that can pass through the precompiler are limited. For example, constants, comments, and other source syntax that are not accepted by the host compilers (such as a missing right brace in C) can interfere with precompiler source scanning and cause errors. To check for such unacceptable source statements, run the host compiler before the precompiler. You can ignore the compiler error messages for SQL statements or comment out the SQL statements. After the source statements are free of unacceptable compiler errors, you can then uncomment any SQL statements that you previously commented out and continue with the normal Db2 program preparation process for that host language.
- You must write host language statements and SQL statements using the same margins, as specified in the precompiler option MARGINS.
- The input data set, SYSIN, must have the attributes RECFM F or FB, LRECL 80.
- SYSLIB must be a partitioned data set, with attributes RECFM F or FB, LRECL 80.
- Input from the INCLUDE library cannot contain other precompiler INCLUDE statements.

Starting the precompiler dynamically when using JCL procedures

You can call the precompiler from an assembler program by using a macro.

About this task

You can call the precompiler from an assembler program by using one of the macro instructions ATTACH, CALL, LINK, or XCTL.

To call the precompiler, specify DSNHPC as the entry point name. You can pass three address options to the precompiler; the following topics describe their formats. The options are addresses of:

- A precompiler option list
- A list of alternative DD names for the data sets that the precompiler uses
- A page number to use for the first page of the compiler listing on SYSPRINT

Related reference

Using X-macros (MVS Assembler Services Reference)

Precompiler option list format

When you call the precompiler, you can specify a number of options, in a list, for SQL statement processing. You must specify that option list in a particular format.

The option list must begin on a 2-byte boundary. The first 2 bytes contain a binary count of the number of bytes in the list (excluding the count field). The remainder of the list is EBCDIC and can contain precompiler option keywords, separated by one or more blanks, a comma, or both.

DD name list format

When you call the precompiler, you can specify a list of alternative DD names for the data sets that the precompiler uses. You must specify this list in a particular format.

The DD name list must begin on a 2-byte boundary. The first 2 bytes contain a binary count of the number of bytes in the list (excluding the count field). Each entry in the list is an 8-byte field, left-justified, and padded with blanks if needed.

The following table gives the following sequence of entries:

Table 139. DDNAME list entries			
Entry	Standard ddname	Usage	
1	Not applicable		
2	Not applicable		
3	Not applicable		

Table 139. DDNAME list entries (continued)		
Entry	Standard ddname	Usage
4	SYSLIB	Library input
5	SYSIN	Source input
6	SYSPRINT	Diagnostic listing
7	Not applicable	
8	SYSUT1	Work data
9	SYSUT2	Work data
10	Not applicable	
11	Not applicable	
12	SYSTERM	Diagnostic listing
13	Not applicable	
14	SYSCIN	Changed source output
15	Not applicable	
16	DBRMLIB	DBRM output

Page number format

When you call the precompiler, you can specify a page number to use for the first page of the compiler listing on SYSPRINT. You must specify this page number in a particular format.

A 6-byte field beginning on a 2-byte boundary contains the page number. The first 2 bytes must contain the binary value 4 (the length of the remainder of the field). The last 4 bytes contain the page number in character or zoned-decimal format.

The precompiler adds 1 to the last page number that is used in the precompiler listing and puts this value into the page-number field before returning control to the calling routine. Thus, if you call the precompiler again, page numbering is continuous.

Output from the Db2 precompiler

The main output from the Db2 precompiler is a database request module (DBRM). However, the Db2 precompiler also produces modified source statements, a list of source statements, a list of statements that refer to host names and columns, and diagnostics.

Tip: The Db2 coprocessor is the recommended method for processing SQL statements in application programs. Compared to the Db2 precompiler, the Db2 coprocessor has fewer restrictions on SQL programs, and more fully supports the latest SQL and programming language enhancements. See "Processing SQL statements by using the Db2 coprocessor" on page 857.

Specifically, the Db2 coprocessor or Db2 precompiler produces the following types of output:

Listing output

The Db2 precompiler writes the following information in the SYSPRINT data set:

- Precompiler source listing
 - If the Db2 precompiler option SOURCE is specified, a source listing is produced. The source listing includes precompiler source statements, with line numbers that are assigned by the precompiler.
- Precompiler diagnostics

The precompiler produces diagnostic messages that include precompiler line numbers of statements that have errors.

· Precompiler cross-reference listing

If the Db2 precompiler option XREF is specified, a cross-reference listing is produced. The cross-reference listing shows the precompiler line numbers of SQL statements that refer to host names and columns.

The SYSPRINT data set has an LRECL of 133 and a RECFM of FBA. This data set uses the CCSID of the source program. Statement numbers in the output of the precompiler listing are displayed as they appear in the listing.

Terminal diagnostics

If a terminal output file, SYSTERM, exists, the Db2 precompiler writes diagnostic messages to it. A portion of the source statement accompanies the messages in this file. You can often use the SYSTERM file instead of the SYSPRINT file to find errors. This data set uses EBCDIC.

Modified source statements

The Db2 precompiler writes the source statements that it processes to SYSCIN, the input data set to the compiler or assembler. This data set must have attributes RECFM F or FB, and LRECL 80. The modified source code contains calls to the Db2 language interface. The SQL statements that the calls replace appear as comments. This data set uses the CCSID of the source program.

Database request modules

The database request module (DBRM) is a data set that contains the SQL statements and host variable information that is extracted from the source program, along with information that identifies the program and ties the DBRM to the translated source statements. It becomes the input to the bind process.

The data set requires space to hold all the SQL statements plus space for each host variable name and some header information. The header information alone requires approximately two records for each DBRM, 20 bytes for each SQL record, and 6 bytes for each host variable.

For an exact format of the DBRM, see the DBRM mapping macros, DSNXDBRM and DSNXNBRM, in library *prefix*.SDSNMACS. The DCB attributes of the data set are RECFM FB, LRECL 80. The precompiler sets the characteristics. You can use IEBCOPY, IEHPROGM, TSOCOPY and DELETE commands, or other PDS management tools for maintaining these data sets.

Important: Do not modify the contents of the DBRM. If you do, unpredictable results can occur. Db2 does not support modified DBRMs.

In a DBRM, the SQL statements and the list of host variable names use the UTF-8 character encoding scheme.

All other character fields in a DBRM use EBCDIC. The current release marker (DBRMMRIC) in the header of a DBRM is marked according to the release of the precompiler, regardless of the value of NEWFUN.

Related tasks

Processing SQL statements by using the Db2 coprocessor

You can use the Db2 coprocessor for processing SQL statements at compile time. With the Db2 coprocessor, the compiler scans a program and copies all of the SQL statements and host variable information into a database request module (DBRM). The Db2 coprocessor is the recommended method for processing SQL statements in application programs. Compared to the Db2 precompiler, the Db2 coprocessor has fewer restrictions on SQL programs, and more fully supports the latest SQL and programming language enhancements.

Processing SQL statements by using the Db2 precompiler

The Db2 precompiler scans a program and copies all of the SQL statements and host variable information into a database request module (DBRM). The Db2 precompiler also returns source code that has been modified so that the SQL statements do not cause errors when you compile the program.

Differences between the Db2 coprocessor and the Db2 precompiler

The Db2 coprocessor and the Db2 precompiler have architectural differences. You cannot switch from one to the other without considering those differences and adjusting your program accordingly.

Tip: The Db2 coprocessor is the recommended method for processing SQL statements in application programs. Compared to the Db2 precompiler, the Db2 coprocessor has fewer restrictions on SQL programs, and more fully supports the latest SQL and programming language enhancements. See "Processing SQL statements by using the Db2 coprocessor" on page 857.

Recommendation: Use the Db2 coprocessor instead of the precompiler when using Unicode variables in COBOL or PL/I applications.

Depending on whether you use the Db2 coprocessor which is recommended in most cases, or the Db2 precompiler, ensure that you account for the following differences:

• Differences in handling source CCSIDs:

The Db2 coprocessor and Db2 precompiler both convert the SQL statements of your source program to UTF-8 for parsing.

The Db2 coprocessor or Db2 precompiler uses the source CCSID(n) value to convert from that CCSID to CCSID 1208 (UTF-8). The CCSID value must be an EBCDIC CCSID. If you want to prepare a source program that is written in a CCSID that cannot be directly converted to or from CCSID 1208, you must create an indirect conversion.

• Differences in handling host variable CCSIDs:

- COBOL:

Db2 coprocessor

The COBOL compiler with National Character Support always sets CCSIDs for alphanumeric variables, including host variables that are used within SQL, to the source CCSID. Alternatively, you can specify that you want the COBOL Db2 coprocessor to handle CCSIDs the same way as the Db2 precompiler.

Db2 precompiler:

The Db2 precompiler sets CCSIDs for alphanumeric host variables only when the program includes an explicit DECLARE :hv VARIABLE statement.

Recommendation: If you have problems with host variable CCSIDs, change your application to include the DECLARE :hv VARIABLE statement to overwrite the CCSID that is specified by the COBOL compiler, or use the Db2 precompiler.

For example, assume that Db2 has mapped a FOR BIT DATA column to a host variable in the following way:

```
01 hv1 pic x(5).

01 hv2 pic x(5).

EXEC SQL CREATE TABLE T1 (colwbit char(5) for bit data, rowid char(5)) END-EXEC.

EXEC SQL INSERT INTO T1 VALUES (:hv1, :hv2) END-EXEC.
```

Db2 coprocessor: In the modified source from the Db2 coprocessor with the National Character Support for COBOL, hv1 and hv2 are represented to Db2 in the following way, with CCSIDs: (Assume that the source CCSID is 1140.)

```
for hv1 and hv2, the value for CCSID is set to '1140' ('474'x) in input SQLDA of the INSERT statement.
```

```
'7F00000474000000007F'x
```

To ensure that no discrepancy exists between the column with FOR BIT DATA and the host variable with CCSID 1140, add the following statement for :hv1 or use the Db2 precompiler:

```
EXEC SQL DECLARE: hv1 VARIABLE FOR BIT DATA END-EXEC.

for hv1 declared with for bit data. The value in SQL---AVAR-NAME-DATA is set to 'FFFF'x for CCSID instead of '474x'.

'7F0000FFFF0000000007F'x <<= with DECLARE:hv1 VARIABLE FOR BIT DATA vs.
'7F00000474000000007F'x <<= without
```

Db2 precompiler: In the modified source from the Db2 precompiler, hv1 and hv2 are represented to Db2 through SQLDA in the following way, without CCSIDs:

```
for hv1: NO CCSID

20 SQL-PVAR-NAMEL1 PIC S9(4) COMP-4 VALUE +0.
20 SQL-PVAR-NAMEC1 PIC X(30) VALUE ''.

for hv2: NO CCSID

20 SQL-PVAR-NAMEL2 PIC S9(4) COMP-4 VALUE +0.
20 SQL-PVAR-NAMEC2 PIC X(30) VALUE ''
```

- PL/I

Db2 coprocessor:

You can specify whether CCSIDs are to be associated with host variables by using the following PL/I SQL preprocessor options:

CCSIDO

Specifies that the PL/I SQL preprocessor is not to set the CCSIDs for all host variables unless they are defined with the SQL DECLARE :hv VARIABLE statement.

NOCCSIDO

Specifies that the PL/I SQL preprocessor is to set the CCSIDs for all host variables.

Descriptions of SQL processing options

You can specify any SQL processing options regardless of whether you use the Db2 precompiler or the Db2 coprocessor. However, the Db2 coprocessor might ignore certain options because host language compiler options exist that provide the same information.

Enterprise COBOL for z/OS

SQL preprocessor options (PL/I) (Enterprise PL/I for z/OS Programming Guide:)

Translating command-level statements in a CICS program

You can translate CICS applications with the CICS command language translator as a part of the program preparation process. CICS command language translators are available only for assembler, C, COBOL, and PL/I languages.

Procedure

Prepare your CICS program in either of these sequences:

Sequence	Remarks
a. Db2 precompiler	This sequence is the preferred method of program preparation and the one that the DB2I Program Preparation panels support. If you use the DB2I panels for program preparation, you can specify

Sequence	Remarks
b. CICS Command Language Translator.	translator options automatically, rather than needing to provide a separate option string.
a. CICS command language translator b. Db2 precompiler	This sequence results in a warning message from the CICS translator for each EXEC SQL statement that it encounters. The warning messages have no effect on the result. If you are using double-byte character sets (DBCS), precompiling is recommended before translating, as described previously.

Use the Db2 precompiler before the CICS translator to prevent the precompiler from mistaking CICS translator output for graphic data.

If your source program is in COBOL, you must specify a string delimiter that is the same for the Db2 precompiler, COBOL compiler, and CICS translator. The defaults for the Db2 precompiler and COBOL compiler are not compatible with the default for the CICS translator.

If the SQL statements in your source program refer to host variables that a pointer stored in the CICS TWA addresses, you must make the host variables addressable to the TWA before you execute those statements. For example, a COBOL application can issue the following statement to establish addressability to the TWA:

```
EXEC CICS ADDRESS
TWA (address-of-twa-area)
END-EXEC
```

You can run CICS applications only from CICS address spaces. This restriction applies to the RUN option on the second program DSN command processor. All of those possibilities occur in TSO.

To prepare an application program, you can append JCL from a job that is created by the Db2 Program Preparation panels to the JCL for the CICS command language translator. To run the prepared program under CICS, you might need to define programs and transactions to CICS. Your system programmer must make the appropriate CICS resource or table entries.

prefix.SDSNSAMP contains examples of the JCL that is used to prepare and run a CICS program that includes SQL statements. The set of JCL includes:

- PL/I macro phase
- · Db2 precompiling
- CICS Command Language Translation
- Compiling of the host language source statements
- · Link-editing of the compiler output
- · Binding of the DBRM
- Running of the prepared application.

Options for SQL statement processing

Use SQL processing options to specify how the Db2 precompiler and the Db2 coprocessor interpret and process input, and how they present output.

Tip: The Db2 coprocessor is the recommended method for processing SQL statements in application programs. Compared to the Db2 precompiler, the Db2 coprocessor has fewer restrictions on SQL

programs, and more fully supports the latest SQL and programming language enhancements. See "Processing SQL statements by using the Db2 coprocessor" on page 857.

Db2 coprocessor

If you are using the Db2 coprocessor, specify SQL processing options in one of the following ways:

- For C or C++, specify the options as the argument of the SQL compiler option.
- For COBOL, specify the options as the argument of the SQL compiler option.
- For PL/I, specify the options as the argument of the PP(SQL('option,...')) compiler option.

For examples of how to specify the Db2 coprocessoroptions, see $\frac{\text{"Processing SQL statements by using the Db2 coprocessor"}}{\text{"Processor"}}$ on page 857

Db2 precompiler

If you are using the Db2 precompiler, specify SQL processing options in one of the following ways:

- With DSNH operands
- With the PARM option of the EXEC JCL statement
- · On DB2I panels

Db2 assigns default values for any SQL processing options for which you do not explicitly specify a value. Those defaults are the values that are specified on the APPLICATION PROGRAMMING DEFAULTS installation panels.

Descriptions of SQL processing options

You can specify any SQL processing options regardless of whether you use the Db2 precompiler or the Db2 coprocessor. However, the Db2 coprocessor might ignore certain options because host language compiler options exist that provide the same information.

The following table shows the options that you can specify when you use the Db2 precompiler or Db2 coprocessor. The table also includes abbreviations for those options and indicates which options are ignored for a particular host language or by the Db2 coprocessor. This table uses a vertical bar (|) to separate mutually exclusive options, and brackets ([]) to indicate that you can sometimes omit the enclosed option.

Table 140. SQL processing	options
---------------------------	---------

Option keyword	Meaning
APOST ¹	Indicates that the Db2 precompiler is to use the apostrophe (') as the string delimiter in host language statements that it generates.
	This option is not available in all languages.
	APOST and QUOTE are mutually exclusive options. The default is in the field STRING DELIMITER on Application Programming Defaults Panel 1 during installation. If STRING DELIMITER is the apostrophe ('), APOST is the default.
APOSTSQL	Recognizes the apostrophe (') as the string delimiter and the double quotation mark (") as the SQL escape character within SQL statements.
	APOSTSQL and QUOTESQL are mutually exclusive options. The default is in the field SQL STRING DELIMITER on Application Programming Defaults Panel 1 during installation. If SQL STRING DELIMITER is the apostrophe ('), APOSTSQL is the default.

Table 140. SQL processing options (continued)			
Option keyword	Meaning		
ATTACH(TSO CAF RRSAF ULI)	Specifies the attachment facility that the application uses to access Db2 TSO, CAF, RRSAF, or DSNULI applications that load the attachment facility can use this option to specify the correct attachment facility, instead of coding a dummy DSNHLI entry point.		
	You can specify ATTACH(ULI) only when you use the Db2 coprocessor.		
	This option is not available for Fortran applications.		
	The default is ATTACH(TSO).		
CCSID(n)	Specifies the numeric value n of the CCSID in which the source program is written. The number n must be an EBCDIC CCSID.		
	The default setting is the EBCDIC system CCSID as specified on the panel DSNTIPF during installation.		
	The Db2 coprocessor uses the following process to determine the CCSID of the source statements:		
	1. If the CCSID of the source program is specified by a compiler option, such as the COBOL CODEPAGE compiler option, the Db2 coprocessor uses that CCSID. If you also specify the CCSID suboption of the SQL compiler option that is different from the CCSID compiler option, a warning is returned, and the CCSID suboption value is not used.		
	2. If the CCSID is not specified by a compiler option:		
	 a. If the CCSID suboption of the SQL compiler option is specified and contains a valid EBCDIC CCSID, that CCSID is used. 		
	b. If the CCSID suboption of the SQL compiler option is not specified, and the compiler supports an option for specifying the CCSID, such as the COBOL CODEPAGE compiler option, the default for the CCSID compiler option is used.		
	c. If the CCSID suboption of the SQL compiler option is not specified, and the compiler does not support an option for specifying the CCSID, the default CCSID from DSNHDECP or a user-specified application defaults module is used.		
	 d. If the CCSID suboption of the SQL option is specified and contains an invalid CCSID, compilation terminates. 		
	CCSID supersedes the GRAPHIC and NOGRAPHIC SQL processing options.		
	If you specify CCSID(1026) or CCSID(1155), the Db2 coprocessor does not support the code point 'FC'X for the double quotation mark (").		
COMMA	Recognizes the comma (,) as the decimal point indicator in decimal or floating point literals in the following cases:		
	 For static SQL statements in COBOL programs 		
	 For dynamic SQL statements, when the value of installation parameter DYNRULS is NO and the package or plan that contains the SQL statements has DYNAMICRULES bind, define, or invoke behavior. 		
	COMMA and PERIOD are mutually exclusive options. The default (COMMA or PERIOD) is chosen under DECIMAL POINT IS on Application Programming Defaults Panel 1 during installation.		

Table 140. SQL processing options (continued)		
Option keyword	Meaning	
CONNECT(2 1) CT(2 1)	Determines whether to apply type 1 or type 2 CONNECT statement rules.	
	CONNECT(2) Default: Apply rules for the CONNECT (Type 2) statement CONNECT(1) Apply rules for the CONNECT (Type 1) statement	
	If you do not specify the CONNECT option when you precompile a program, the rules of the CONNECT (Type 2) statement apply.	
DATE(ISO USA EUR JIS LOCAL)	Specifies that date output should always be returned in a particular format, regardless of the format that is specified as the location default.	
	The default is specified in the field DATE FORMAT on Application Programming Defaults Panel 2 during installation.	
	The default format is determined by the installation defaults of the system where the program is bound, not by the installation defaults of the system where the program is precompiled.	
	You cannot use the LOCAL option unless you have a date exit routine.	
DEC(15 31)	Specifies the maximum precision for decimal arithmetic operations.	
DEC(15 51) DEC15 DEC31 D15.s D31.s	The default is in the field DECIMAL ARITHMETIC on Application Programming Defaults Panel 1 during installation.	
	If the form Dpp.s is specified, pp must be either 15 or 31, and s, which represents the minimum scale to be used for division, must be a number between 1 and 9.	
DECP(name)	name represents the 1 to 8 character name of the application defaults data-only load module that is to be used.	
	The default name DSNHDECP is used if this parameter is omitted.	
FLAG(I W E S) ¹	Suppresses diagnostic messages below the specified severity level (Informational, Warning, Error, and Severe error for severity codes 0, 4, 8, and 12 respectively).	
	The default setting is FLAG(I).	
FLOAT(S390 IEEE)	Determines whether the contents of floating-point host variables in assembler, C, C++, or PL/I programs are in IEEE floating-point format or z/Architecture hexadecimal floating-point format. Db2 ignores this option if the value of HOST is anything other than ASM, C, CPP, or PLI.	
	The default setting is FLOAT(S390).	
GRAPHIC	This option is no longer used for SQL statement processing. Use the CCSID option instead.	
	Indicates that the source code might use mixed data, and that X'0E'and X'0F' are special control characters (shift-out and shift-in) for EBCDIC data.	
	GRAPHIC and NOGRAPHIC are mutually exclusive options. The default (GRAPHIC or NOGRAPHIC) is specified in the field MIXED DATA on Application Programming Defaults Panel 1 during installation.	

Table 140. SQL processing	options (continued)		
Option keyword	Meaning		
HOST¹(ASM C[(FOLD)] CPP[(FOLD)] IBMCOB PLI	Defines the host language that contains the SQL statements.		
	Use IBMCOB for Enterprise COBOL for z/OS.		
	For C, specify:		
FORTRAN SQL	 C if you do not want Db2 to fold lowercase letters in SBCS SQL ordinary identifiers to uppercase 		
SQLPL)	 C(FOLD) if you want Db2 to fold lowercase letters in SBCS SQL ordinary identifiers to uppercase 		
	For C++, specify:		
	 CPP if you do not want Db2 to fold lowercase letters in SBCS SQL ordinary identifiers to uppercase 		
	 CPP(FOLD) if you want Db2 to fold lowercase letters in SBCS SQL ordinary identifiers to uppercase 		
	For SQL procedural language, specify:		
	 SQL, to perform syntax checking and conversion to a generated C program for an external SQL procedure. 		
	 SQLPL, to perform syntax checking for a native SQL procedure. 		
	If you omit the HOST option, the Db2 precompiler issues a level-4 diagnostic message and uses the default value for this option.		
	The default is in the field LANGUAGE DEFAULT on Application Programming Defaults Panel 1 during installation.		
	This option also sets the language-dependent defaults.		
LEVEL[(aaaa)] L	Defines the level of a module, where $aaaa$ is any alphanumeric value of up to seven characters. This option is not recommended for general use, and the DSNH CLIST and the DB2I panels do not support it.		
	For assembler, C, C++, Fortran, and PL/I, you can omit the suboption (aaaa). The resulting consistency token is blank. For COBOL, you need to specify the suboption.		
LINECOUNT ¹ (n) LC	Defines the number of lines per page to be <i>n</i> for the Db2 precompiler listing. This includes header lines that are inserted by the Db2 precompiler. The default setting is LINECOUNT(60).		
MARGINS ¹ (m,n[,c]) MAR	Specifies what part of each source record contains host language or SQL statements. For assembler, this option also specifies where column continuations begin. The first option (m) is the beginning column for statements. The second option (n) is the ending column for statements. The third option (c) specifies where assembler continuations begin. Otherwise, the Db2 precompiler places a continuation indicator in the column immediately following the ending column. Margin values can range 1–80.		
	Default values depend on the HOST option that you specify.		
	The DSNH CLIST and the DB2I panels do not support this option. In assembler, the margin option must agree with the ICTL instruction, if presented in the source.		

Option keyword	Meaning	
NEWFUN(Vn)	Deprecated function: The NEWFUN processing option is deprecated. Use the SQLLEVEL option instead.	
	Indicates whether to accept the function syntax that is new for Db2 12.	
	NEWFUN(V12) Specifies that any syntax up to Db2 12 is allowed. This value is equivalent to function level V12R1M501.	
	NEWFUN(V11) Specifies that any syntax up to Db2 11 is allowed.	
	NEWFUN(V10) Specifies that any syntax up to DB2 10 is allowed.	
	NEWFUN(V9) Specifies that any syntax up to DB2 9 is allowed. DB2 9 is supported, but causes the precompilation process to support only a DB2 9 level of function	
	NEWFUN(V8) Specifies that any syntax up to DB2 version 8 is allowed. V8 is supported, b causes the precompilation process to support only a V8 level of function.	
	The NEWFUN option applies only to the precompilation process by either the precompiler or the Db2 coprocessor, regardless of whether new functions are activated on the subsystem. You are responsible for ensuring that you bind the resulting DBRM on a subsystem in the correct migration mode.	
NOFOR	In static SQL, eliminates the need for the FOR UPDATE or FOR UPDATE OF clause in DECLARE CURSOR statements. When you use NOFOR, your program can make positioned updates to any columns that the program has Db2 authorito update.	
	When you do not use NOFOR, if you want to make positioned updates to any columns that the program has Db2 authority to update, you need to specify FOI UPDATE with no column list in your DECLARE CURSOR statements. The FOR UPDATE clause with no column list applies to static or dynamic SQL statements	
	Regardless of whether you use NOFOR, you can specify FOR UPDATE OF with a column list to restrict updates to only the columns that are named in the clause and you can specify the acquisition of update locks.	
	You imply NOFOR when you use the option STDSQL(YES).	
	If the resulting DBRM is very large, you might need extra storage when you specify NOFOR or use the FOR UPDATE clause with no column list.	
NOGRAPHIC	This option is no longer used for SQL statement processing. Use the CCSID option instead.	
	Indicates the use of X'0E'and X'0F' in a string, but not as control characters.	
	GRAPHIC and NOGRAPHIC are mutually exclusive options. The default (GRAPHIC or NOGRAPHIC) is specified in the field MIXED DATA on Application Programming Defaults Panel 1 during installation.	
	The NOGRAPHIC option applies to only EBCDIC data.	
NOOPTIONS NOOPTN	Suppresses the Db2 precompiler options listing.	

Table 140. SQL processing options (continued)		
Option keyword	Meaning	
NOPADNTSTR	Indicates that output host variables that are NUL-terminated strings are not padded with blanks. That is, additional blanks are not inserted before the NUL-terminator is placed at the end of the string.	
	PADNTSTR and NOPADNTSTR are mutually exclusive options. The default (PADNTSTR or NOPADNTSTR) is specified in the field PAD NUL-TERMINATED on Application Programming Defaults Panel 2 during installation.	
	This option applies to only C and C++ applications.	
NOSOURCE ² NOS	Suppresses the Db2 precompiler source listing. This is the default.	
NOXREF	Suppresses the Db2 precompiler cross-reference listing. This is the default.	
ONEPASS ON	Processes in one pass, to avoid the additional processing time for making two passes. Declarations must appear before SQL references.	
	Default values depend on the HOST option specified.	
	ONEPASS and TWOPASS are mutually exclusive options.	
OPTIONS ¹ OPTN	Lists Db2 precompiler options. This is the default.	
PADNTSTR	Indicates that output host variables that are NUL-terminated strings are padded with blanks with the NUL-terminator placed at the end of the string.	
	PADNTSTR and NOPADNTSTR are mutually exclusive options. The default (PADNTSTR or NOPADNTSTR) is specified in the field PAD NUL-TERMINATED on Application Programming Defaults Panel 2 during installation.	
	This option applies to only C and C++ applications.	
PERIOD	Recognizes the period (.) as the decimal point indicator in decimal or floating point literals in the following cases:	
	 For static SQL statements in COBOL programs 	
	 For dynamic SQL statements, when the value of installation parameter DYNRULS is NO and the package or plan that contains the SQL statements has DYNAMICRULES bind, define, or invoke behavior. 	
	COMMA and PERIOD are mutually exclusive options. The default (COMMA or PERIOD) is specified in the field DECIMAL POINT IS on Application Programming Defaults Panel 1 during installation.	

Table 140. SQL process	ing options (continued)		
Option keyword	Meaning		
QUOTE ¹ Q	Indicates that the Db2 precompiler is to use the quotation mark (") as the string delimiter in host language statements that it generates.		
	QUOTE is valid only for COBOL applications. QUOTE is not valid for either of the following combinations of precompiler options:		
	CCSID(1026) and HOST(IBMCOB)		
	 CCSID(1155) and HOST(IBMCOB) 		
	The default is specified in the field STRING DELIMITER on Application Programming Defaults Panel 1 during installation. If STRING DELIMITER is the double quotation mark (") or DEFAULT, QUOTE is the default.		
	APOST and QUOTE are mutually exclusive options.		
QUOTESQL	Recognizes the double quotation mark (") as the string delimiter and the apostrophe (') as the SQL escape character within SQL statements. This option applies only to COBOL.		
	The default is specified in the field SQL STRING DELIMITER on Application Programming Defaults Panel 1 during installation. If SQL STRING DELIMITER is the double quotation mark (") or DEFAULT, QUOTESQL is the default.		
	APOSTSQL and QUOTESQL are mutually exclusive options.		
SOURCE ¹	Lists Db2 precompiler source and diagnostics.		
SQL(ALL DB2)	Indicates whether the source contains SQL statements other than those recognized by Db2 for z/OS.		
	SQL(ALL) is recommended for application programs whose SQL statements must execute on a server other that Db2 for z/OS using DRDA access. SQL(ALL) indicates that the SQL statements in the program are not necessarily for Db2 for z/OS. Accordingly, the SQL statement processor then accepts statements that do not conform to the Db2 syntax rules. The SQL statement processor interprets and processes SQL statements according to distributed relational database architecture (DRDA) rules. The SQL statement processor also issues an informational message if the program attempts to use IBM SQL reserved words as ordinary identifiers. SQL(ALL) does not affect the limits of the SQL statement processor.		
	SQL(Db2), the default, means to interpret SQL statements and check syntax for use by Db2 for z/OS. SQL(Db2) is recommended when the database server is Db2 for z/OS.		

Table 140. SQL processing o	ptions (continued)
Option keyword	Meaning
SQLLEVEL(V10R1 V11R1 function-level)	Indicates whether to accept the SQL syntax that is new in Db2 12 function levels.
	SQLLEVEL (function-level) Specifies the function level allowed by the precompilation process. The format is $V \nu \nu R r M m m m$, where $v v$ is the version, r is the release, and $m m m m m$ is the modification level. SQLLEVEL V12R1M100 is equivalent to V11R1.
	SQLLEVEL(V11R1) Specifies that any SQL syntax up to Db2 11 is allowed.
	SQLLEVEL(V10R1) Specifies that any SQL syntax up to DB2 10 is allowed.
	SQLLEVEL(V9R1) Specifies that any SQL syntax up to DB2 9 is allowed. DB2 9 is supported, but causes the precompilation process to support only a DB2 9 level of SQL syntax.
	SQLLEVEL(V8R1) Specifies that any SQL syntax up to DB2 version 8 is allowed. DB2 version 8 is supported, but causes the precompilation process to support only a DB2 version 8 level of SQL syntax.
	The function level activated on the Db2 subsystem does not restrict the SQLLEVEL value. However, you must ensure that you bind the resulting DBRM with the correct application compatibility level on a Db2 subsystem with the correct function level activated.
STDSQL(NO YES)3	Indicates to which rules the output statements should conform.
	STDSQL(YES) ³ indicates that the precompiled SQL statements in the source program conform to certain rules of the SQL standard. STDSQL(NO) indicates conformance to Db2 rules.
	The default is specified in the field STD SQL LANGUAGE on Application Programming Defaults Panel 2 during installation.
	STDSQL(YES) automatically implies the NOFOR option.
TIME(ISO USA EUR JIS LOCAL)	Specifies that time output always return in a particular format, regardless of the format that is specified as the location default.
	The default is specified in the field TIME FORMAT on Application Programming Defaults Panel 2 during installation.
	The default format is determined by the installation defaults of the system where the program is bound, not by the installation defaults of the system where the program is precompiled.
	You cannot use the LOCAL option unless you have a time exit routine.
TWOPASS TW	Processes in two passes, so that declarations need not precede references. Default values depend on the HOST option that is specified.
	ONEPASS and TWOPASS are mutually exclusive options.
	For the Db2 coprocessor, you can specify the TWOPASS option for only PL/I applications. For C/C++ and COBOL applications, the Db2 coprocessor uses the ONEPASS option.

Table 140. SQL processing options (continued)	
Option keyword	Meaning
VERSION(aaaa AUTO)	Defines the version identifier of a package, program, and the resulting DBRM. A version identifier is an SQL identifier of up to 64 EBCDIC bytes.
	When you specify VERSION, the SQL statement processor creates a version identifier in the program and DBRM. This affects the size of the load module and DBRM. Db2 uses the version identifier when you bind the DBRM to a package.
	If you do not specify a version at precompile time, an empty string is the default version identifier. If you specify AUTO, the SQL statement processor uses the consistency token to generate the version identifier. If the consistency token is a timestamp, the timestamp is converted into ISO character format and is used as the version identifier. The timestamp that is used is based on the store clock value.
XREF ⁵	Includes a sorted cross-reference listing of symbols that are used in SQL statements in the listing output.

Notes:

- 1. The Db2 coprocessor ignores this option when the Db2 coprocessor is invoked by the compiler to prepare the application.
- 2. This option is always in effect when the Db2 coprocessor is invoked by the compiler to prepare the application.
- 3. You can use STDSQL(86) as in prior releases of Db2. The SQL statement processor treats it the same as STDSQL(YES).
- 4. Precompiler options do not affect ODBC behavior.
- 5. The Db2 coprocessor ignores this option when the Db2 coprocessor is invoked by the compiler to prepare the application. However, if you are using PL/I V4.1 or later, it is supported.

Related concepts

Precision for operations with decimal numbers

Db2 accepts two sets of rules for determining the precision and scale of the result of an operation with decimal numbers.

Datetime values (Db2 SQL)

Related tasks

Creating a package version

If you want to run different versions of a program without needing to make changes to the associated application plan, use package versions. This technique is useful if you need to make changes to your program without causing an interruption to the availability of the program.

Setting the program level

The program level defines the level for a particular module. This information is stored in the consistency token, which is in an internal Db2 format. Overriding the program level in the consistency token is possible, if needed, but generally not recommended.

Related reference

Defaults for SQL processing options

Some SQL statement processing options have default values that are based on values that are specified on the DB2I Application Programming Defaults panels.

Defaults for SQL processing options

Some SQL statement processing options have default values that are based on values that are specified on the DB2I Application Programming Defaults panels.

The following table shows those options and defaults.

Table 141. IBM-supplied installation default SQL statement processing options. The installer can change these defaults.

Tooks II subtices	Tuestall default	Equivalent SQL statement processing	Available SQL statement
Install option	Install default	option	processing options
STRING DELIMITER	quotation mark (")	QUOTE	APOSTQUOTE
SQL STRING DELIMITER	quotation mark (")	QUOTESQL	APOSTSQLQUOTESQL
DECIMAL POINT IS	PERIOD	PERIOD	COMMAPERIOD
DATE FORMAT	ISO	DATE(ISO)	DATE(ISO USA EUR JIS LOCAL)
DECIMAL ARITHMETIC	DEC15	DEC(15)	DEC(15 31)
MIXED DATA	NO	CCSID(n)	CCSID(n)
LANGUAGE DEFAULT	COBOL	HOST(COBOL)	HOST(ASM C[(FOLD)] CPP[(FOLD)] IBMCOB FORTRAN PLI)
STD SQL LANGUAGE	NO	STDSQL(NO)	STDSQL(YES NO 86)
TIME FORMAT	ISO	TIME(ISO)	TIME(IS USA EUR JIS LOCAL)

Notes: For dynamic SQL statements, another application programming default, USE FOR DYNAMICRULES, determines whether Db2 uses the application programming default or the SQL statement processor option for the following installation options:

- STRING DELIMITER
- SQL STRING DELIMITER
- DECIMAL POINT IS
- DECIMAL ARITHMETIC

If the value of USE FOR DYNAMICRULES is YES, dynamic SQL statements use the application programming defaults. If the value of USE FOR DYNAMICRULES is NO, dynamic SQL statements in packages or plans with bind, define, and invoke behavior use the SQL statement processor options.

Some SQL statement processor options have default values based on the host language. Some options do not apply to some languages. The following table shows the language-dependent options and defaults.

Table 142. Language-dependent Db2 precompiler options and defaults

HOST value	Defaults
ASM	APOST ¹ , APOSTSQL ¹ , PERIOD ¹ , TWOPASS, MARGINS(1,71,16)
C or CPP	APOST ¹ , APOSTSQL ¹ , PERIOD ¹ , ONEPASS, MARGINS(1,72)
IBMCOB	QUOTE ² , QUOTESQL ² , PERIOD, ONEPASS ¹ , MARGINS(8,72) ¹

Table 142. Language-dependent Db2 precompiler options and defaults (continued)		
HOST value	Defaults	
FORTRAN	APOST ¹ , APOSTSQL ¹ , PERIOD ¹ , ONEPASS ¹ , MARGINS(1,72) ¹	
PLI	APOST ¹ , APOSTSQL ¹ , PERIOD ¹ , ONEPASS, MARGINS(2,72)	
SQL or SQLPL	APOST ¹ , APOSTSQL ¹ , PERIOD ¹ , ONEPASS, MARGINS(1,72)	

Notes:

- 1. Forced for this language; no alternative is allowed.
- 2. The default is chosen on Application Programming Defaults Panel 1 during installation. The IBM-supplied installation defaults for string delimiters are QUOTE (host language delimiter) and QUOTESQL (SQL escape character). The installer can replace the IBM-supplied defaults with other defaults. The precompiler options that you specify override any defaults that are in effect.

SQL statement processing defaults for dynamic statements

Generally, dynamic statements use the defaults that are specified during installation. However, if the value of application defaults module parameter DYNRULS is NO, you can use these options for dynamic SQL statements in packages or plans with bind, define, or invoke behavior:

- COMMA or PERIOD
- APOST or QUOTE
- APOSTSQL or QUOTESQL
- DEC(15) or DEC(31)

Related concepts

Dynamic rules options for dynamic SQL statements

The DYNAMICRULES bind option and the runtime environment determine the rules for the dynamic SQL attributes.

SQL options for DRDA access

Certain SQL statement processing options are relevant when you prepare a package to be run with DRDA access.

The following SQL statement processing options are relevant for DRDA access:

CONNECT

Use CONNECT(2), explicitly or by default.

CONNECT(1) causes your CONNECT statements to allow only the restricted function known as "remote unit of work". Be particularly careful to avoid CONNECT(1) if your application updates more than one DBMS in a single unit of work.

SOL

Use SQL(ALL) explicitly for a package that runs on a server that *is not* Db2 for z/OS. The precompiler then accepts any statement that obeys DRDA rules.

Use SQL (DB2), explicitly or by default, if the server is Db2 for z/OS only. The precompiler then rejects any statement that does not obey the rules of Db2 for z/OS.

Compiling and link-editing an application

If you use the Db2 coprocessor, you process SQL statements as you compile your program, and the next step is the link edit the program. The purpose of the link-edit step is to produce an executable load module.

About this task

For programs other than C and C++ programs, you must use JCL procedures when you use the Db2 coprocessor. For C and C++ programs, you can use either JCL procedures or UNIX System Services on z/OS to invoke the Db2 coprocessor.

For more information, see "Processing SQL statements by using the Db2 coprocessor" on page 857.

Tip: The Db2 coprocessor is the recommended method for processing SQL statements in application programs. Compared to the Db2 precompiler, the Db2 coprocessor has fewer restrictions on SQL programs, and more fully supports the latest SQL and programming language enhancements. See "Processing SQL statements by using the Db2 coprocessor" on page 857.

If you use the Db2 precompiler precompiler, as described in <u>"Processing SQL statements by using the Db2 precompiler"</u> on page 861, your next step in the program preparation process is to compile and link-edit your program.

Procedure

- You can use one of the following methods to compile and link-edit an application:
 - DB2I panels. For details, see "DB2I panels that are used for program preparation" on page 920.
 - The DSNH command procedure (a TSO CLIST). For details, see <u>DSNH command procedure (TSO CLIST)</u> (Db2 Commands).
 - JCL procedures supplied with Db2. For details, see <u>"Db2-supplied JCL procedures for preparing an</u> application" on page 917.
 - JCL procedures supplied with a host language compiler.
- Use a link-edit procedure that builds a load module that satisfies the environment-specific requirements of the program.

TSO and batch

Include the Db2 TSO attachment facility language interface module (DSNELI) or Db2 call attachment facility language interface module (DSNALI) or the Universal Language Interface module (DSNULI).

IMS

Include the Db2 IMS language interface module (DFSLI000), which contains the DSNHLI entry point. Also, the IMS RESLIB must precede the SDSNLOAD library in the link list, JOBLIB, or STEPLIB concatenations.

IMS and Db2 share a common alias name, DSNHLI, for the language interface module. You must do the following when you concatenate your libraries:

- If you use IMS, be sure to concatenate the IMS library first so that the application program compiles with the correct IMS version of DSNHLI.
- If you run your application program only under Db2, be sure to concatenate the Db2 library first.

CICS

Include the Db2 CICS language interface module (DSNCLI) or the Universal Language Interface module (DSNULI). You can link DSNCLI with your program in either 24-bit or 31-bit addressing mode (AMODE=31), but DSNULI must be linked with your program in 31-bit addressing mode (AMODE=31). If your application runs in 31-bit addressing mode, you should link-edit the DSNCLI or DSNULI stub to your application with the attributes AMODE=31 and RMODE=ANY so that your application can run above the 16-MB line.

You also need the CICS EXEC interface module that is appropriate for the programming language. CICS requires that this module be the first control section (CSECT) in the final load module.

The size of the executable load module that is produced by the link-edit step varies depending on the values that the SQL statement processor inserts into the source code of the program.

Link-editing a batch program

Db2 has language interface routines for each unique supported environment. Db2 requires the IMS language interface routine for DL/I batch. You need to have DFSLI000 link-edited with the application program.

Related concepts

Universal language interface (DSNULI)

The universal language interface (DSNULI) subcomponent determines the runtime environment and dynamically loads and branches to the appropriate language interface module.

Related tasks

Binding application packages and plans

You must bind the DBRM that is produced by the SQL statement processor to a package before your Db2 application can run. The bind process establishes a relationship between an application program and its relational data.

Before you begin

You must have appropriate privileges. For more information, see <u>Privileges required for handling plans</u> and packages (Managing Security)

About this task

During the precompilation process, the Db2 precompiler produces both modified source code and a database request module (DBRM) for each application program. The modified source code must be compiled and link-edited before the program can be run. DBRMs must be bound to a package. You can then associate that package with a particular application plan.

During the bind process, Db2 also completes the following actions:

- Validates object references in the SQL statements of the program, such as table, view, and column names, against the Db2 catalog. Because the bind process occurs before program execution, errors are detected and can be corrected before the program is executed.
- Verifies the authorization of the bind process to specify the program owner and the authorization of the specified owner to access data that is requested by SOL statements in the program.
- Selects the access paths that Db2 uses to access data for the program. Db2 considers factors such as table size, available indexes, and others, when selecting the access paths.

When determining the maximum size of a plan, you must consider several physical limitations, including the time required to bind the plan, the size of the EDM pool, and fragmentation. As a general rule, the EDM pool should be at least 10 times the size of the largest DBD or plan, whichever is greater.

Each package that you bind can contain only one DBRM.

Exception: You do not need to bind a DBRM if the only SQL statement in the program is SET CURRENT PACKAGESET.

Because you do not need a plan or package to execute the SET CURRENT PACKAGESET statement, the ENCODING bind option does not affect the SET CURRENT PACKAGESET statement. An application that needs to provide a host variable value in an encoding scheme other than the system default encoding scheme must use the DECLARE VARIABLE statement to specify the encoding scheme of the host variable.

You must bind plans locally, regardless of whether they reference packages that run remotely. However, you must bind the packages that run at remote locations at those remote locations.

From a Db2 requester, you can run a plan by specifying it in the RUN subcommand, but you cannot run a package directly. You must include the package in a plan and then run the plan.

Tip: Develop a naming convention and strategy for the most effective and efficient use of your plans and packages.

Procedure

To bind application programs, take the following actions.

- 1. To bind individual DBRMs into packages, use BIND PACKAGE commands with ACTION(REPLACE). Packages provide the flexibility for you to test different versions of a program without having to rebind everything in the application plan.
 - For programs whose corresponding DBRMs are in HFS files, you can use the Db2 command line processor to bind the DBRMs to packages. Optionally, you can also copy the DBRM into a partitioned data set member by using the **oput** and **oget** commands and then bind it by using conventional JCL.
 - To create new trigger packages for existing triggers, you must re-create the trigger that is associated with the package. For more information, see "Trigger packages" on page 163.
- 2. To designate packages in application plans, use the BIND PLAN command with ACTION(REPLACE). Plans can specify packages, collections of packages, or a combination of these elements. If you specify one or more DBRMs to include in the plan (by using the MEMBER option of BIND PLAN), Db2 automatically binds those DBRMs into packages and then binds those packages into the plan. The plan contains information about the designated packages and about the data that the application programs intend to use. The plan is stored in the Db2 catalog.

Related concepts

Package copies for plan management (Db2 Performance)

Automatic rebinds

Automatic rebinds (sometimes called "autobinds") occur when an authorized user runs a package or plan and the runtime structures in the plan or package cannot be used. This situation usually results from changes to the attributes of the data on which the package or plan depends, or changes to the environment in which the package or plan runs.

Related tasks

Binding a DBRM that is in an HFS file to a package or collection

If DBRMs are in z/OS UNIX HFS files, you can use the Db2 command line processor to bind the DBRMs to packages at the target Db2 server. Optionally, you can also copy the DBRM into a partitioned data set member by using the TSO/E oput and oget commands and then bind the DBRM by using conventional JCL.

BIND and REBIND options for packages, plans, and services (Db2 Commands)

Creating a package version

If you want to run different versions of a program without needing to make changes to the associated application plan, use package versions. This technique is useful if you need to make changes to your program without causing an interruption to the availability of the program.

About this task

You can create a different package version for each version of the program. Each package has the same package name and collection name, but a different version number is associated with each package. The plan that includes that package includes all versions of that package. Thus, you can run a program that is associated with any one of the package versions without having to rebind the application plan, rename the plan, or change any RUN subcommands that use it.

Procedure

To create a package version:

- 1. Precompile your program with the option VERSION(version-identifier).
- 2. Bind the resulting DBRM with the same collection name and package name as any existing versions of that package. When you run the program, Db2 uses the package version that you specified when you precompiled it.

Example

Suppose that you bound a plan with the following statement:

BIND PLAN (PLAN1) PKLIST (COLLECT.*)

The following steps show how to create two versions of a package, one for each of two programs.

Step number	For package version 1	For package version 2
1	Precompile program 1. Specify VERSION(1).	Precompile program version 2. Specify VERSION(2).
2	Bind the DBRM with the collection name COLLECT and the package name PACKA.	Bind the DBRM with the collection name COLLECT and package name PACKA.
3	Link-edit program 1 into your application.	Link-edit program 2 into your application.
4	Run the application; it uses program 1 and PACKA, VERSION 1.	Run the application; it uses program 2 and PACKA, VERSION 2.

Binding a DBRM that is in an HFS file to a package or collection

If DBRMs are in z/OS UNIX HFS files, you can use the Db2 command line processor to bind the DBRMs to packages at the target Db2 server. Optionally, you can also copy the DBRM into a partitioned data set member by using the TSO/E oput and oget commands and then bind the DBRM by using conventional JCL.

About this task

Restrictions:

You cannot specify the REBIND command with the Db2 command line processor. Alternatively, specify the BIND command with the ACTION(REPLACE) option.

You cannot specify the FREE PACKAGE command with the Db2 command line processor. Alternatively, specify the DROP PACKAGE statement to drop the existing packages.

Procedure

To bind a DBRM that is in an HFS file to a package or collection:

- 1. Invoke the Db2 command line processor and connect to the target Db2 server.
- 2. Specify the BIND command with the appropriate options.

Processing SQL statements by using the Db2 coprocessor

You can use the Db2 coprocessor for processing SQL statements at compile time. With the Db2 coprocessor, the compiler scans a program and copies all of the SQL statements and host variable information into a database request module (DBRM). The Db2 coprocessor is the recommended method for processing SQL statements in application programs. Compared to the Db2 precompiler, the Db2 coprocessor has fewer restrictions on SQL programs, and more fully supports the latest SQL and programming language enhancements.

BIND and REBIND options for packages, plans, and services (Db2 Commands)

Binding an application plan

An application plan can include package lists.

Procedure

To bind an application plan, use the BIND PLAN subcommand with at least one of the following options:

MEMBER

Specify this option to bind DBRMs to a package and then bind the package list to a plan. After the keyword MEMBER, specify the member names of the DBRMS.

PKLIST

Specify this option to include package lists in the plan. After the keyword PKLIST, specify the names of the packages to include in the package list. To include an entire collection of packages in the list, use an asterisk after the collection name. For example, PKLIST(GROUP1.*).

Specifying the package list for the PKLIST option of BIND PLAN

The order in which you specify packages in a package list can affect run time performance. Searching for the specific package involves searching the Db2 directory, which can be costly. When you use *collection-id.** with the PKLIST keyword, you should specify first the collections in which Db2 is most likely to find a package.

For example, assume that you perform the following bind:

```
BIND PLAN (PLAN1) PKLIST (COLL1.*, COLL2.*, COLL3.*, COLL4.*)
```

Then you execute program PROG1. Db2 does the following package search:

- a. Checks to see if program PROG1 is bound as part of the plan
- b. Searches for COLL1.PROG1.timestamp
- c. If it does not find COLL1.PROG1.timestamp, searches for COLL2.PROG1.timestamp
- d. If it does not find COLL2.PROG1.timestamp, searches for COLL3.PROG1.timestamp

e. If it does not find COLL3.PROG1.timestamp, searches for COLL4.PROG1.timestamp.

When both special registers CURRENT PACKAGE PATH and CURRENT PACKAGESET contain an empty string

If you do not set these special registers, Db2 searches for a DBRM or a package in one of these sequences:

- At the local location (if CURRENT SERVER is blank or specifies that location explicitly), the order is:
 - a. All packages that are already allocated to the plan while the plan is running.
 - b. All unallocated packages that are explicitly specified in, and all collections that are completely included in, the package list of the plan. Db2 searches for packages in the order that they appear in the package list.
- At a remote location, the order is:
 - a. All packages that are already allocated to the plan at that location while the plan is running.
 - b. All unallocated packages that are explicitly specified in, and all collections that are completely included in, the package list of the plan, whose locations match the value of CURRENT SERVER. Db2 searches for packages in the order that they appear in the package list.

If you use the BIND PLAN option DEFER(PREPARE), Db2 does not search all collections in the package list.

If the order of search is not important

In many cases, the order in which Db2 searches the packages is not important to you and does not affect performance. For an application that runs only at your local Db2 system, you can name every package differently and include them all in the same collection. The package list on your BIND PLAN subcommand can read:

```
PKLIST (collection.*)
```

The resulting plan consists of the following information:

- Any programs that are associated with DBRMs in the MEMBER list
- Any programs that are associated with packages and collections that are identified in PKLIST

You can add packages to the collection even after binding the plan. Db2 lets you bind packages having the same package name into the same collection only if their version IDs are different.

If your application uses DRDA access, you must bind some packages at remote locations. Use the same collection name at each location, and identify your package list as:

```
PKLIST (*.collection.*)
```

If you use an asterisk for part of a name in a package list, Db2 checks the authorization for the package to which the name resolves at run time. To avoid the checking at run time in the preceding example, you can grant EXECUTE authority for the entire collection to the owner of the plan before you bind the plan.

CURRENT PACKAGE PATH special register (Db2 SQL)
CURRENT PACKAGESET special register (Db2 SQL)

How Db2 identifies packages at run time

The Db2 precompiler or Db2 coprocessor identifies each call to Db2 with a consistency token. The same consistency token identifies the DBRM that the SQL statement processor produces and the package to which you bound the DBRM.

When you run the program, Db2 uses the consistency token in matching the call to Db2 to the correct DBRM. Usually, the consistency token is in an internal Db2 format. You can override that token if you want.

You also need other identifiers. The consistency token alone does not necessarily identify a unique package. You can bind the same DBRM to many packages, at different locations and in different collections, and you can include all those packages in the package list of the same plan. All those packages will have the same consistency token. You can specify a particular location or a particular collection at run time.

Related tasks

Setting the program level

The program level defines the level for a particular module. This information is stored in the consistency token, which is in an internal Db2 format. Overriding the program level in the consistency token is possible, if needed, but generally not recommended.

Specifying the location of the package that Db2 is to use

When your program executes SQL statements, Db2 uses the value in the CURRENT SERVER special register to determine the location of the necessary package. If the current server is your local Db2 subsystem and it does not have a location name, the value in the special register is blank.

About this task

You can change the value of CURRENT SERVER by using the SQL CONNECT statement in your program. If you do not use CONNECT, the value of CURRENT SERVER is the location name of your local Db2 subsystem (or blank, if your Db2 subsystem has no location name).

Specifying the package collection that Db2 uses for applications

You can ensure that Db2 uses the intended package collection and does not waste time searching by explicitly specify the package collection that you want Db2 to use.

About this task

You can use the CURRENT PACKAGE PATH special register or CURRENT PACKAGESET (if CURRENT PACKAGE PATH is not set) to specify the collections that Db2 uses for package resolution. The CURRENT PACKAGESET special register contains the name of a single collection, and the CURRENT PACKAGE PATH special register contains a list of collection names.

If you do not set these special registers, they contain an empty string when your application begins to run, and they remain as an empty string. In this case, Db2 searches the available package collections.

However, explicitly specifying the intended collection by using the special registers can avoid a potentially costly search through a package list that has many qualifying entries. In addition, Db2 uses the values in these special registers for applications that do not run under a plan.

When you call an external stored procedure, the CURRENT PACKAGESET special register contains the value that you specified for the COLLID parameter when you defined the stored procedure. If the routine was defined without a value for the COLLID parameter, the value for the special register is inherited from the calling program.

If the external stored procedure is not defined with a specified COLLID value and the calling program package does not have the same collection ID as the package for the stored procedure, you might receive SQLCODE -805. In this situation, you can issue an ALTER PROCEDURE statement with the COLLID clause to fix the problem.

Also, the CURRENT PACKAGE PATH special register contains the value that you specified for the PACKAGE PATH parameter when you defined the stored procedure. When the stored procedure returns control to the calling program, Db2 restores this register to the value that it contained before the call.

Specifying the package collection for a Java routine in a JAR file that is installed in the Db2 catalog: If the Java routine definition specifies a COLLID value that is different from the collection into which the IBM Data Server Driver for JDBC and SQLJ packages are bound, you need to run the DB2Binder utility with the -collection option to bind the driver packages into the collection that is specified by the COLLID value in the Java routine definition. If you do not do so, you might receive SQLCODE -805.

Related tasks

Binding an application plan

An application plan can include package lists.

Overriding the values that Db2 uses to resolve package lists

Db2 resolves package lists by searching the available collections in a particular order. To avoid this search, you can specify the values that Db2 should use for package resolution.

Related information

-805 (Db2 Codes)

Overriding the values that Db2 uses to resolve package lists

Db2 resolves package lists by searching the available collections in a particular order. To avoid this search, you can specify the values that Db2 should use for package resolution.

About this task

If you set the special register CURRENT PACKAGE PATH or CURRENT PACKAGESET, Db2 skips the check for programs that are part of a plan and uses the values in these registers for package resolution.

If you set CURRENT PACKAGE PATH, Db2 uses the value of CURRENT PACKAGE PATH as the collection name list for package resolution. For example, if CURRENT PACKAGE PATH contains the list COLL1, COLL2, COLL3, COLL4, Db2 searches for the first package that exists in the following order:

COLL1.PROG1.timestamp

COLL2.PROG1.timestamp

COLL3.PROG1.timestamp

COLL4.PROG1.timestamp

If you set CURRENT PACKAGESET and **not** CURRENT PACKAGE PATH, Db2 uses the value of CURRENT PACKAGESET as the collection for package resolution. For example, if CURRENT PACKAGESET contains COLL5, Db2 uses COLL5.PROG1.timestamp for the package search.

When CURRENT PACKAGE PATH is set, the server that receives the request ignores the collection that is specified by the request and instead uses the value of CURRENT PACKAGE PATH at the server to resolve the package. Specifying a collection list with the CURRENT PACKAGE PATH special register can avoid the need to issue multiple SET CURRENT PACKAGESET statements to switch collections for the package search.

The following table shows examples of the relationship between the CURRENT PACKAGE PATH special register and the CURRENT PACKAGESET special register.

Table 143. Scope of CURRENT PACKAGE PATH			
Example	What happens		
SET CURRENT PACKAGESET SELECT FROM T1	The collection in PACKAGESET determines which package is invoked.		
SET CURRENT PACKAGE PATH SELECT FROM T1	The collections in PACKAGE PATH determine which package is invoked.		
SET CURRENT PACKAGESET SET CURRENT PACKAGE PATH SELECT FROM T1	The collections in PACKAGE PATH determine which package is invoked.		
SET CURRENT PACKAGE PATH CONNECT TO S2 SELECT FROM T1	PACKAGE PATH at server S2 is an empty string because it has not been explicitly set. The values from the PKLIST bind option of the plan that is at the requester determine which package is invoked. ¹		
SET CURRENT PACKAGE PATH = 'A,B' CONNECT TO S2 SET CURRENT PACKAGE PATH = 'X,Y' SELECT FROM T1	The collections in PACKAGE PATH that are set at server S2 determine which package is invoked.		
SET CURRENT PACKAGE PATH SELECT FROM S2.QUAL.T1	Three-part table name. On implicit connection to server S2, PACKAGE PATH at server S2 is inherited from the local server. The collections in PACKAGE PATH at server S2 determine which package is invoked.		

Notes:

1. When CURRENT PACKAGE PATH is set at the requester (and not at the remote server), Db2 passes one collection at a time from the list of collections to the remote server until a package is found or until the end of the list. Each time a package is not found at the server, Db2 returns an error to the requester. The requester then sends the next collection in the list to the remote server.

Bind process for remote access

You can use several different bind processes to enable access to data at a remote server.

These processes work when the remote server is a Db2 for z/OS system or another type of database system that uses DRDA access.

Bind a package at the local site and the remote site

If you have not yet bound a local package, use this technique.

- 1. Bind the DBRM into a package at the local site.
- 2. Bind the DBRM into a package at the remote site.
- 3. Bind a plan with a package list that includes the local package and the remote package.

Example: Bind a package at the local site and the remote site

Suppose that you precompiled program MYPROG to generate DBRM MYPROG, and compiled and linkedited program MYPROG. You want to run MYPROG to access tables at site CHICAGO from your local site.

Use commands like these to bind local and remote packages and a plan. The number at the end of each line corresponds to a previously described step.

```
BIND PACKAGE(LOCALCOLLID) MEMBER(MYPROG) other bind options
BIND PACKAGE (CHICAGO.REMOTECOLLID) MEMBER(MYPROG) other bind options
BIND PLAN (MYPLAN) PKLIST(LOCALCOLLID.* ,*.REMOTECOLLID.*)
```

Bind a copy of an existing local package at the remote site

If you have already bound a local package, you can use this technique.

- 1. Issue the BIND command with COPY and OPTIONS to create a copy of the local package at the remote site.
 - OPTIONS controls the option values for bind options that you do not specify.
- 2. Bind a plan with a package list that includes the local package and the remote package.

Example: Bind a copy of an existing local package at the remote site

Suppose that you previously prepared program MYPROG for execution at the local site. As part of program preparation, you bound package LOCALCOLLID.MYPROG at the local site. Now you want to run MYPROG to access tables at site CHICAGO from your local site. Use commands like these to bind a copy of the local package at site CHICAGO, and then bind a plan. The number at the end of each line corresponds to a previously described step.

```
BIND PACKAGE(CHICAGO.REMOTECOLLID) COPY(LOCALCOLLID.MYPROG) -
OPTIONS(COMPOSITE|COMMAND) -
other bind options
BIND PLAN (MYPLAN) PKLIST(LOCALCOLLID.* ,*.REMOTECOLLID.*)
```

Bind options for remote access

Binding a package to run at a remote location is like binding a package to run at your local Db2 subsystem. Binding a plan to run the package is like binding any other plan. However, a few differences exist.

For the general instructions, see Chapter 9, "Preparing an application to run on Db2 for z/OS," on page 851.

BIND PLAN options for DRDA access

The following options of BIND PLAN are particularly relevant to binding a plan that uses DRDA access:

DISCONNECT

For most flexibility, use DISCONNECT(EXPLICIT), explicitly or by default. That requires you to use RELEASE statements in your program to explicitly end connections.

The other values of the option are also useful.

DISCONNECT(AUTOMATIC) ends all remote connections during a commit operation, without the need for RELEASE statements in your program.

DISCONNECT(CONDITIONAL) ends remote connections during a commit operation except when an open cursor defined as WITH HOLD is associated with the connection.

SQLRULES

Use **SQLRULES(Db2)**, explicitly or by default.

SQLRULES(STD) applies the rules of the SQL standard to your CONNECT statements, so that CONNECT TO x is an error if you are already connected to x. Use STD only if you want that statement to return an error code.

If your program selects LOB data from a remote location, and you bind the plan for the program with SQLRULES(Db2), the format in which you retrieve the LOB data with a cursor is restricted. After you open the cursor to retrieve the LOB data, you must retrieve all of the data using a LOB variable, or

retrieve all of the data using a LOB locator variable. If the value of SQLRULES is STD, this restriction does not exist.

If you intend to switch between LOB variables and LOB locators to retrieve data from a cursor, execute the SET SOLRULES=STD statement before you connect to the remote location.

CURRENTDATA

Use **CURRENTDATA(NO)** to force block fetch for ambiguous cursors.

ENCODING

Use this option to control the encoding scheme that is used for static SQL statements in the plan and to set the initial value of the CURRENT APPLICATION ENCODING SCHEME special register.

For applications that execute remotely and use explicit CONNECT statements, Db2 uses the ENCODING value for the plan. For applications that execute remotely and use implicit CONNECT statements, Db2 uses the ENCODING value for the package that is at the site where a statement executes.

BIND PACKAGE options for DRDA access

The following options of BIND PACKAGE are relevant to binding a package to be run using DRDA access:

location-name

Name the location of the server at which the package runs.

The privileges needed to run the package must be granted to the owner of the package at the server. If you are not the owner, you must also have SYSCTRL authority or the BINDAGENT privilege that is granted locally.

SQLERROR

Use **SQLERROR(CONTINUE)** if you used SQL(ALL) when precompiling. That creates a package even if the bind process finds SQL errors, such as statements that are valid on the remote server but that the precompiler did not recognize. Otherwise, use SQLERROR(NOPACKAGE), explicitly or by default.

COPY

If you bind with the COPY option to copy a local package to a remote site, Db2 performs authorization checking, reads and updates the catalog, and creates the package at the remote site. Db2 reads the catalog records that are related to the copied package at the local site. Db2 converts values that are returned from the remote site in ISO format if all of the following conditions are true:

- If the local site is installed with time or date format LOCAL
- A package is created at a remote site with the COPY option
- The SQL statement does not specify a different format.

CURRENTDATA

Use **CURRENTDATA(NO)** to force block fetch for ambiguous cursors.

OPTIONS

When you make a remote copy of a package using BIND PACKAGE with the COPY option, use this option to control the default bind options that Db2 uses. Specify:

COMPOSITE to cause Db2 to use any options you specify in the BIND PACKAGE command. For all other options, Db2 uses the options of the copied package. COMPOSITE is the default.

COMMAND to cause Db2 to use the options you specify in the BIND PACKAGE command. For all other options, Db2 uses the defaults for the server on which the package is bound. This helps ensure that the server supports the options with which the package is bound.

ENCODING

Use this option to control the encoding scheme that is used for static SQL statements in the package and to set the initial value of the CURRENT APPLICATION ENCODING SCHEME special register.

When you bind the same package locally and remotely, and you specify the ENCODING bind option for the package, the ENCODING bind option for the local package applies to the remote application. The default ENCODING value for a package that is bound at a remote Db2 for z/OS server is the

system default for that server. The system default is specified at installation time in the APPLICATION ENCODING field of panel DSNTIPF, which is the APPENSCH DECP value.

EXPLAIN

If you specify the option EXPLAIN(YES) or EXPLAIN(ONLY), and you do not specify the option SQLERROR(CONTINUE), PLAN_TABLE must exist at the remote location at which the package is bound.

BIND and REBIND options for packages, plans, and services (Db2 Commands)

Considerations for binding packages at a remote location

When you bind packages at a remote location, you need to understand how the behavior of the remote packages differs from the behavior of local packages.

Scope of a remote bind

When you bind or rebind a package at a remote site, Db2 checks authorizations, reads and updates the catalog, and creates the package in the directory at the remote site. Db2 does not read or update catalogs or check authorizations at the local site.

After you bind a remote package, you can bind, rebind, or free the remote package from the local site or at the remote site.

Authorization for binding and running packages at a remote location

To bind a package at a remote Db2 system, you must have all the privileges or authority there that you would need to bind the package on your local system. To bind a package at another type of a system, such as Db2 for Linux, UNIX, and Windows, you need all privileges that the other system requires to execute the SQL statements in the package, and to access the data objects to which the package refers.

Communications database requirements for binding packages at a remote location

When you bind a package at a remote site, the local communications database must be able to resolve the location name in the package to a remote location.

Remote access through a stored procedure

If a local stored procedure uses a cursor to access data, and the cursor-related statement is bound in a separate package under the stored procedure, you must bind this separate package both locally and remotely. In addition, the invoker or owner of the stored procedure must be authorized to execute both local and remote packages. At your local requesting system, you must bind a plan whose package list includes all of those local and remote packages.

Checking which BIND PACKAGE options a particular server supports

You can request only the options of the BIND PACKAGE command that are supported by the server by specifying those options at the requester.

About this task

To find out which options are supported by a specific server DBMS, refer to the documentation provided for that server.

For specific Db2 bind information, refer to the following documentation:

- For guidance in using Db2 bind options and performing a bind process, see Chapter 9, "Preparing an application to run on Db2 for z/OS," on page 851.
- For the syntax of Db2 BIND command, see the topics BIND PACKAGE subcommand (DSN) (Db2 Commands) and BIND PLAN subcommand (DSN) (Db2 Commands).
- For the syntax of Db2 REBIND command, see the topics REBIND PACKAGE subcommand (DSN) (Db2 Commands) and REBIND PLAN command (DSN) (Db2 Commands).

Binding a batch program

Before a batch program can issue SQL statements, a Db2 plan must exist.

About this task

The owner of the plan or package must have all the privileges that are required to execute the SQL statements embedded in it.

You can specify the plan name to Db2 in one of the following ways:

- In the DDITV02 input data set.
- In subsystem member specification.
- By default; the plan name is then the application load module name that is specified in DDITV02.

Db2 passes the plan name to the IMS attach package. If you do not specify a plan name in DDITV02, and a resource translation table (RTT) does not exist or the name is not in the RTT, Db2 uses the passed name as the plan name. If the name exists in the RTT, the name translates to the plan that is specified for the RTT.

Recommendation: Give the Db2 plan the same name as that of the application load module, which is the IMS attachment facility default. The plan name must be the same as the program name.

Conversion of DBRMs that are bound to a plan to DBRMs that are bound to a package

You must bind all DBRMs into a package, and bind the packages into a plan. One package can have only one DBRM.

The default REBIND PLAN COLLID (*) option converts all plans with DBRMs into plans with a package list. You can use this technique for local applications only. If the plan that you specify already contains both DBRMs and package lists, the newly converted package entries will be inserted into the front of the existing package list.

Important: If the same DBRM is in multiple plans, and you run REBIND PLAN with the same COLLID option value on more than one of those plans, Db2 overlays the previously created package in the collection each time you run REBIND with COLLID. To avoid overlaying packages, specify a different COLLID value for each plan that contains DBRMs that are also in other plans.

For more information on developing a strategy for converting your plans to include only packages, see DB2 9 for z/OS: Packages Revisited (IBM Redbooks).

Example: converting all plans

The following examples converts all DBRMs that are bound with plan X into packages under collection ID: DSN_DEFAULT_COLLID_X.

REBIND PLAN(X) COLLID(*);

Example: specifying a collection ID

The following examples converts DBRMs that are bound with plan X into packages under the *my_collection* collection ID.

```
REBIND PLAN(x) COLLID('my_collection');
```

Example: rebinding multiple plans which may contain DBRMs

In the following example, BIND will traverse through each plan that is specified in the REBIND PLAN command statement and will convert the DBRMs accordingly, and until none of the DBRMs are bound with plans.

```
REBIND PLAN (X1, X2, X3) COLLID (collection_id|*);
```

Example: rebinding all plans which may contain DBRMs

In the following example, BIND will traverse through all plans that are specified in the SYSPLAN table and will convert the DBRMs accordingly, and until none of the DBRMs are bound with plans.

```
REBIND PLAN (*) COLLID (collection_id|*);
```

Example: specifying a package list

The following examples converts all DBRMs that are bound with plan X into packages under collection ID: DSN_DEFAULT_COLLID_X.

- If plan X does not have a package list, the newly converted package entries will be appended to the front of package list Z and then package list Z will be added to plan X.
- If plan X has both a package list and DBRMs, the newly converted package entries will be appended to the front of package list Z and then package list Z will replace the existing package list.
- If plan X has only a package list, then package list Z will replace the existing package list.

```
REBIND PLAN (x) COLLID (collection_id|*) PKLIST(Z);
```

Example: specifying no package list

The following examples converts all DBRMs that are bound with plan X into packages under collection ID: DSN_DEFAULT_COLLID_X.

- If plan X has both a package list and DBRMs, the existing package list will be deleted, and the new package list will be bound into plan X.
- If plan X has only DBRMs, the DBRMs will be converted into packages accordingly and added to plan X. The NOPKLIST option will be ignored.
- If plan X does not have DBRMs, then the existing package list, if any, will be deleted.

```
REBIND PLAN (x) COLLID (collection id|*) NOPKLIST;
```

Converting an existing plan into packages to run remotely

If you have an existing application that you want to run at a remote location by using remote access, you need a new plan that includes those remote packages in its package list.

Procedure

To turn an existing plan with member DBRMs into packages to run remotely, perform the following actions for each remote location:

1. Choose a name for a collection to contain member DBRMs, such as REMOTE1.

2. Convert the plan into a plan with a package list of packages.

```
REBIND PLAN(REMOTE1)COLLID(*)
```

Specifying COLLID(*) produces the packages under the collection of DSN_DEFAULT_COLLID_planname.

- 3. Query SYSIBM.SYSPACKDEP, to see if any of the packages have a dependency on an alias. That alias is a definition for a 3-part name.
 - a) For each of the packages that have a dependency on an alias:

```
BIND PACKAGE(location.remote_server_collid)
COPY(DSN_DEFAULT_COLLID_planname.pgkid)
COPYVER(...) OPTIONS(COMPOSITE)
```

4. Adjust the location's package list. If prior to this process, the plan had no package list, after <u>"2" on</u> page 899 it will have a package list containing DSN_DEFAULT_COLLID_planname.pgkid.

```
REBIND PLAN PKLIST
(*.DSN_DEFAULT_COLLID_planname.pgkid* *.remote_server_collid.*)
```

Results

When you now run the existing application at your local Db2 system using the new application plan, these things happen:

- You connect immediately to the remote location that is named in the CURRENTSERVER option.
- Db2 searches for the package in the collection REMOTE1 at the remote location.
- Any UPDATE, DELETE, or INSERT statements in your application affect tables at the remote location.
- Any results from SELECT statements are returned to your existing application program, which processes them as though they came from your local Db2 system.

Setting the program level

The program level defines the level for a particular module. This information is stored in the consistency token, which is in an internal Db2 format. Overriding the program level in the consistency token is possible, if needed, but generally not recommended.

Procedure

Use the LEVEL (aaaa) option.

Db2 uses the value that you choose for aaaa to generate the consistency token. Although this method is not recommended for general use and the DSNH CLIST or the Db2 Program Preparation panels do not support it, this method enables you to perform the following actions:

- a. Change the source code (but not the SQL statements) in the Db2 precompiler output of a bound program.
- b. Compile and link-edit the changed program.
- c. Run the application without rebinding a plan or package.

Dynamic rules options for dynamic SQL statements

The DYNAMICRULES bind option and the runtime environment determine the rules for the dynamic SQL attributes.

The BIND or REBIND option DYNAMICRULES determines what values apply at run time for the following dynamic SQL attributes:

- The authorization ID that is used to check authorization
- · The qualifier that is used for unqualified objects

- The source for application programming options that Db2 uses to parse and semantically verify dynamic SOL statements
- Whether dynamic SQL statements can include GRANT, REVOKE, ALTER, CREATE, DROP, and RENAME statements

In addition, the runtime environment of a package controls how dynamic SQL statements behave at run time. The two possible runtime environments are:

- The package runs as part of a stand-alone program.
- The package runs as a stored procedure or user-defined function package, or it runs under a stored procedure or user-defined function.

A package that runs under a stored procedure or user-defined function is a package whose associated program meets one of the following conditions:

- The program is called by a stored procedure or user-defined function.
- The program is in a series of nested calls that start with a stored procedure or user-defined function.

Dynamic SQL statement behavior

The dynamic SQL attributes that are determined by the value of the DYNAMICRULES bind option and the runtime environment are collectively called the *dynamic SQL statement behavior* or the *dynamic rules behavior*. The four dynamic rules behaviors are: run, bind, define, and invoke.

The following table shows the combination of DYNAMICRULES value and runtime environment that yield each dynamic SQL behavior.

Table 144. How DYNAMICRULES and the runtime environment determine dynamic SQL statement behavior

	Behavior of dynamic SQL statements		
DYNAMICRULES value	Stand-alone program environment	User-defined function or stored procedure environment	
RUN	Run	Run	
BIND	Bind	Bind	
DEFINERUN	Run	Define	
DEFINEBIND	Bind	Define	
INVOKERUN	Run	Invoke	
INVOKEBIND	Bind	Invoke	

Note: BIND and RUN values can be specified for packages, plans, and native SQL procedures. The other values can be specified for packages and native SQL procedures but not for plans.

The following table shows the dynamic SQL attribute values for each type of dynamic SQL behavior.

Table 145. Definitions of dynamic SQL statement behaviors

Dynamic SQL attribute	Setting for dynamic SQL behavior attributes			
	Bind	Run	Define	Invoke
Authorization ID	Plan or package owner	Current SQLID	User-defined function or stored procedure owner	Authorization ID of invoker ¹

Table 145. Definitions of dynamic SQL statement behaviors (continued)

Dynamic SQL attribute	Setting for dynamic SQL behavior attributes			
	Bind	Run	Define	Invoke
Default qualifier for unqualified objects	Bind OWNER or QUALIFIER value	CURRENT SCHEMA	User-defined function or stored procedure owner	Authorization ID of invoker
CURRENT SQLID ²	Not applicable	Applies	Not applicable	Not applicable
Source for application programming options	Determined by DSNHDECP or a user-specified application defaults module parameter DYNRULS ³	Install panel DSNTIP4	Determined by DSNHDECP or a user-specified application defaults module parameter DYNRULS ³	Determined by DSNHDECP or a user-specified application defaults module parameter DYNRULS ³
Can execute GRANT, REVOKE, CREATE, ALTER, DROP, RENAME?	No	Yes	No	No

Notes:

- 1. If the invoker is the primary authorization ID of the process or the CURRENT SQLID value, secondary authorization IDs are also checked if they are needed for the required authorization. Otherwise, only one ID, the ID of the invoker, is checked for the required authorization.
- 2. Db2 uses the value of CURRENT SQLID as the authorization ID for dynamic SQL statements only for plans and packages that have run behavior. For the other dynamic SQL behaviors, Db2 uses the authorization ID that is associated with each dynamic SQL behavior, as shown in this table.

The value to which CURRENT SQLID is initialized is independent of the dynamic SQL behavior. For standalone programs, CURRENT SQLID is initialized to the primary authorization ID.

You can execute the SET CURRENT SQLID statement to change the value of CURRENT SQLID for packages with any dynamic SQL behavior, but Db2 uses the CURRENT SQLID value only for plans and packages with run behavior.

3. The value of DSNHDECP or a user-specified application defaults module parameter DYNRULS, which you specify in field USE FOR DYNAMICRULES in installation panel DSNTIP4, determines whether Db2 uses the SQL statement processing options or the application programming defaults for dynamic SQL statements. See "Options for SQL statement processing" on page 871 for more information.

Dynamic plan selection

It is beneficial to use dynamic plan selection and packages together. You can convert individual programs in an application that contains many programs and plans, one at a time, to use a combination of plans and packages. This process reduces the number of plans per application; having fewer plans reduces the effort that is needed to maintain the dynamic plan exit routine.

CICSYou can use packages and dynamic plan selection together, but when you dynamically switch plans, the following conditions must exist:

- All special registers, including CURRENT PACKAGESET, must contain their initial values.
- The value in the CURRENT DEGREE special register cannot have changed during the current transaction.

Assume that you develop the following programs and DBRMs:

Table 146. Example programs and DBRMs

Program Name	DBRM Name
MAIN	MAIN
PROGA	PLANA
PROGB	PKGB
PROGC	PLANC

You could create packages using the following bind statement:

BIND PACKAGE(PKGB) MEMBER(PKGB)

The following scenario illustrates thread association for a task that runs program MAIN. Suppose that you execute the following SQL statements in the indicated order. For each SQL statement, the resulting event is described.

1. EXEC CICS START TRANSID(MAIN)

TRANSID (MAIN) executes program MAIN.

2. EXEC SQL SELECT...

Program MAIN issues an SQL SELECT statement. The default dynamic plan exit routine selects plan MAIN.

3. EXEC CICS LINK PROGRAM(PROGA)

Program PROGA is invoked.

4. EXEC SQL SELECT...

Db2 does not call the default dynamic plan exit routine, because the program does not issue a sync point. The plan is MAIN.

5. EXEC CICS LINK PROGRAM(PROGB)

Program PROGB is invoked.

6. EXEC SOL SELECT...

Db2 does not call the default dynamic plan exit routine, because the program does not issue a sync point. The plan is MAIN and the program uses package PKGB.

7. EXEC CICS SYNCPOINT

Db2 calls the dynamic plan exit routine when the next SQL statement executes.

8. EXEC CICS LINK PROGRAM(PROGC)

Program PROGC is invoked.

9. EXEC SQL SELECT...

Db2 calls the default dynamic plan exit routine and selects PLANC.

10. EXEC SQL SET CURRENT SQLID = 'ABC'

The CURRENT SQLID special register is assigned the value 'ABC.'

11. EXEC CICS SYNCPOINT

Db2 does not call the dynamic plan exit routine when the next SQL statement executes because the previous statement modifies the special register CURRENT SQLID.

12. EXEC CICS RETURN

Control returns to program PROGB.

13. EXEC SQL SELECT...

CICS With packages, you probably do not need dynamic plan selection and its accompanying exit routine. A package that is listed within a plan is not accessed until it is executed. However, you can use dynamic plan selection and packages together, which can reduce the number of plans in an application and the effort to maintain the dynamic plan exit routine.

Rebinding applications

You must rebind applications to change bind options. You also need to rebind applications when you make changes that affect the plan or package, such as creating an index, but you have not changed the SQL statements.

About this task

In some cases, Db2 automatically rebinds plans or packages for you, depending on the value of the ABIND subsystem parameter. For details, see "Automatic rebinds" on page 912.

The following actions might require that you rebind a package:

- Changing the host language or SQL statements in the application. You must replace the package. Precompile, compile, and link the application program. Then issue a BIND command with the ACTION(REPLACE) option.
- Changing your data attributes in ways that invalidate the package. For details, see <u>"Changes that</u> invalidate packages" on page 15.
- Improving access paths selection after reorganizing data with the REORG utility or collecting database statistics with RUNSTATS or other utilities. For more information, see <u>Maintaining data organization and</u> statistics (Db2 Performance).
- Enabling Db2 to select an access path that uses a newly created index for access to a table.
- Changing the bind options for a package. If an option that you want to change is not available for the REBIND command, issue the BIND command with ACTION(REPLACE) instead.
- Preparing for migration to a new Db2 release. For more information, see Rebind old plans and packages in Db2 11 to avoid disruptive autobinds in Db2 12 (Db2 Installation and Migration).

FL 505 With rebind-phase in, Db2 can rebind a package concurrently with its execution. A rebind operation creates a new copy of the package. When the rebind operation finishes, new threads can use the new package copy immediately, and existing threads can continue to use the copy that was in use prior to the rebind (the phased-out copy) without disruption. For more information, see "Phase-in of package rebinds" on page 905.

BIND PACKAGE subcommand (DSN) (Db2 Commands)

BIND and REBIND options for packages, plans, and services (Db2 Commands)

Rebinding a package

You need to rebind a package when you make changes that affect the package but that do not involve changes to the SQL statements. For example, if you create a new index, you need to rebind the package. If you change the SQL, you need to use the BIND PACKAGE command with the ACTION(REPLACE) option.

Before you begin

For a trigger package, use the REBIND TRIGGER PACAKGE subcommand. For more information, see "Trigger packages" on page 163.

Procedure

Use the REBIND PACKAGE subcommand.

You can change any of the bind options for a package when you rebind it.

The following table clarifies which packages are bound, depending on how you specify *collection-id* (coll-id), *package-id* (pkg-id), and *version-id* (ver-id) on the REBIND PACKAGE subcommand.

REBIND PACKAGE does not apply to packages for which you do not have the BIND privilege. An asterisk (*) used as an identifier for collections, packages, or versions does not apply to packages at remote sites.

Table 147. Behavior of REBIND PACKAGE specification. "All" means all collections, packages, or versions at the local Db2 server for which the authorization ID that issues the command has the BIND privilege.

Input	Collections affected	Packages affected	Versions affected
*	all	all	all
..(*)	all	all	all
.	all	all	all
..(ver-id)	all	all	ver-id
..()	all	all	empty string
coll-id.*	coll-id	all	all
coll-id.*.(*)	coll-id	all	all
coll-id.*.(ver-id)	coll-id	all	ver-id
coll-id.*.()	coll-id	all	empty string
coll-id.pkg-id.(*)	coll-id	pkg-id	all
coll-id.pkg-id	coll-id	pkg-id	empty string
coll-id.pkg-id.()	coll-id	pkg-id	empty string
coll-id.pkg-id.(ver-id)	coll-id	pkg-id	ver-id
.pkg-id.()	all	pkg-id	all
*.pkg-id	all	pkg-id	empty string
*.pkg-id.()	all	pkg-id	empty string

Table 147. Behavior of REBIND PACKAGE specification. "All" means all collections, packages, or versions at the local Db2 server for which the authorization ID that issues the command has the BIND privilege. (continued)

Input	Collections affected	Packages affected	Versions affected
*.pkg-id.(ver-id)	all	pkg-id	ver-id

Examples

Example: Rebinding a package at a remote location

The following example shows the options for rebinding a package at the remote location. The location name is SNTERSA. The collection is GROUP1, the package ID is PROGA, and the version ID is V1. The connection types shown in the REBIND subcommand replace connection types that are specified on the original BIND subcommand.

```
REBIND PACKAGE(SNTERSA.GROUP1.PROGA.(V1)) ENABLE(CICS,REMOTE)
```

Example: Rebinding all local packages

You can use the asterisk on the REBIND subcommand for local packages, but not for packages at remote sites. Any of the following commands rebinds all versions of all packages in all collections, at the local Db2 system, for which you have the BIND privilege.

```
REBIND PACKAGE (*)
REBIND PACKAGE (*.*)
REBIND PACKAGE (*.*.(*))
```

Example: Rebinding all versions of all local packages

Either of the following commands rebinds all versions of all packages in the local collection LEDGER for which you have the BIND privilege.

```
REBIND PACKAGE (LEDGER.*)

REBIND PACKAGE (LEDGER.*.(*))
```

Example: Rebinding local packages in all collections

Either of the following commands rebinds the empty string version of the package DEBIT in all collections, at the local Db2 system, for which you have the BIND privilege.

```
REBIND PACKAGE (*.DEBIT.())

REBIND PACKAGE (*.DEBIT.())
```

Related tasks

Reusing and comparing access paths at bind and rebind (Db2 Performance)

Related reference

BIND and REBIND options for packages, plans, and services (Db2 Commands)

REBIND PACKAGE subcommand (DSN) (Db2 Commands)

Phase-in of package rebinds

With rebind-phase in, Db2 can rebind a package concurrently with its execution. A rebind operation creates a new copy of the package. When the rebind operation finishes, new threads can use the new package copy immediately, and existing threads can continue to use the copy that was in use prior to the rebind (the phased-out copy) without disruption.

FL 505

With rebind phase-in, a REBIND PACKAGE operation generates a new copy, while existing threads continue to execute the current copy of the package, which becomes the phased-out copy. When the new copy is committed by the REBIND command, that copy becomes the current copy and is immediately available for the next execution by a new thread. Threads that existed prior to the REBIND can also use the new current copy when they release the phased-out copy (based on the RELEASE(COMMIT) or RELEASE(DEALLOCATION) option).

Tip: <u>APAR PH28693</u> (January 2021) improves concurrency for REBIND commands in Db2 12 at function level 505 or higher. With this APAR, a REBIND command now always obtains a U lock, allowing subsequent transactions that are executing a package to run in parallel. For more information, see Improved transaction execution times and concurrency for REBIND PACKAGE.

Db2 can generate as many as 14 copies to phase in new package copies at REBIND. Only one is the current copy, and its copy ID is in the catalog table SYSPACKAGE. All phased-out copies, and the original and previous copies, are stored in SYSPACKCOPY and other catalog tables until they are deleted. However, copyID 3 is for internal use only, and is not stored in the SYSPACKCOPY or SYSPACKAGE catalog tables.

On subsequent executions of the REBIND PACKAGE command, Db2 detects when a phased-out copy can be safely deleted, and its copy ID can be reused. The maximum copy ID is 16.

When all available copy IDs are in use, a subsequent REBIND command might fail and issue the DSNT500I message, with reason code 00E30307. This failed command indicates a thread which prevents one or more phased-out copies from being reused.

You can use the PLANMGMTSCOPE(PHASEOUT) option on the FREE PACKAGE subcommand to free unused phased-out copies, which could be created when a package is rebound. It is recommended that phased-out package copies be freed in order to reduce space in the Db2 directory and catalog. The subcommand will free the phased-out copies that are not currently used by an executing thread. The SYSPACKCOPY.TIMESTAMP column value can be used to determine when a copy becomes phased-out. In addition, the PLANMGMTSCOPE(INACTIVE) option on the FREE PACKAGE subcommand also addresses the phased-out copies.

Rebind phase-in is supported with the following options:

- APREUSE(NONE) PLANMGMT(EXTENDED)
- APREUSE(WARN) PLANMGMT(EXTENDED) APREUSESOURCE(CURRENT)
- APREUSE(ERROR) PLANMGMT(EXTENDED) APREUSESOURCE(CURRENT)

Rebind phase-in is not supported for any REBIND PACKAGE command that also specifies changes to any bind options that prevent use of the PLANMGMT(EXTENDED) option. For more information, see PLANMGMT bind option (Db2 Commands).

The package must not be a generated package for a trigger or SQL routine, such as a procedure or user-defined function.

When PLANMGMTSCOPE(PHASEOUT) is specified, phased-out package copies are freed regardless of whether the INVALIDONLY(YES) option is also specified.

Package copies for plan management (Db2 Performance)

Automatic rebinds

Automatic rebinds (sometimes called "autobinds") occur when an authorized user runs a package or plan and the runtime structures in the plan or package cannot be used. This situation usually results from changes to the attributes of the data on which the package or plan depends, or changes to the environment in which the package or plan runs.

Related tasks

Rebinding applications

You must rebind applications to change bind options. You also need to rebind applications when you make changes that affect the plan or package, such as creating an index, but you have not changed the SQL statements.

Related reference

REBIND PACKAGE subcommand (DSN) (Db2 Commands)

Rebinding a plan

You need to rebind a plan when you make a change to one of the attributes of the plan, such as the package list.

Procedure

Use the REBIND PLAN subcommand.

You can change any of bind options for that plan.

When you rebind a plan, use the PKLIST keyword to replace any previously specified package list. Omit the PKLIST keyword to use of the previous package list for rebinding. Use the NOPKLIST keyword to delete any package list that was specified when the plan was previously bound.

Examples

Example

The following command rebinds PLANA and changes the package list:

REBIND PLAN(PLANA) PKLIST(GROUP1.*) MEMBER(ABC)

Example

The following command rebinds the plan and drops the entire package list:

REBIND PLAN(PLANA) NOPKLIST

Related reference

BIND and REBIND options for packages, plans, and services (Db2 Commands) REBIND PLAN command (DSN) (Db2 Commands)

Rebinding lists of plans and packages

In some situations, you need to rebind a set of plans or packages that cannot be described by using asterisks. For example, if a rebind operation terminates, you can generate a rebind subcommand for each object that was not bound.

About this task

One situation in which this technique is useful is to complete a rebind operation that has terminated due to lack of resources. A rebind for many objects, such as REBIND PACKAGE (*) for an ID with SYSADM authority, terminates if a needed resource becomes unavailable. As a result, some objects are successfully rebound and others are not. If you repeat the subcommand, Db2 attempts to rebind all the objects again. But if you generate a rebind subcommand for each object that was not rebound, and issue those subcommands, Db2 does not repeat any work that was already done and is not likely to run out of resources.

For a description of the technique and several examples of its use, see <u>"Sample program to create REBIND subcommands for lists of plans and packages"</u> on page 908.

Generating lists of REBIND commands

To generate a list of REBIND subcommands for a set of packages that cannot be described, use asterisks, and use information in the Db2 catalog. You can then issue the list of subcommands through DSN.

About this task

The following list is an overview of the procedures for REBIND PACKAGE:

- 1. Use DSNTIAUL to generate the REBIND PACKAGE subcommands for the selected packages.
- 2. Use DSNTEDIT CLIST to delete extraneous blanks from the REBIND PACKAGE subcommands.
- 3. Use TSO edit commands to add DSN commands to the sequential data set.
- 4. Use DSN to execute the REBIND PACKAGE subcommands for the selected packages.

Sample program to create REBIND subcommands for lists of plans and packages

If you cannot use asterisks to identify a list of packages or plans that you want to rebind, you might be able to create the needed REBIND subcommands automatically, by using the sample program DSNTIAUL.

One situation in which this technique might be useful is when a resource becomes unavailable during a rebind of many plans or packages. Db2 normally terminates the rebind and does not rebind the remaining plans or packages. Later, however, you might want to rebind only the objects that remain to be rebound. You can build REBIND subcommands for the remaining plans or packages by using DSNTIAUL to select the plans or packages from the Db2 catalog and to create the REBIND subcommands. You can then submit the subcommands through the DSN command processor, as usual.

You might first need to edit the output from DSNTIAUL so that DSN can accept it as input. The CLIST DSNTEDIT can perform much of that task for you.

This section contains the following topics:

- "Generating lists of REBIND commands" on page 908
- "Sample SELECT statements for generating REBIND commands" on page 908
- "Sample JCL for running lists of REBIND commands" on page 910

Sample SELECT statements for generating REBIND commands

You can select specific plans or packages to be rebound and concatenate the REBIND subcommand syntax around the plan or package names. You can also convert a varying-length string to a fixed-length string, and append additional blanks to the REBIND PLAN and REBIND PACKAGE subcommands, so that the DSN command processor can accept the record length as valid input.

Building REBIND subcommands: The examples that follow illustrate the following techniques:

- Using SELECT to select specific packages or plans to be rebound
- Using the CONCAT operator to concatenate the REBIND subcommand syntax around the plan or package names
- Using the SUBSTR function to convert a varying-length string to a fixed-length string
- Appending additional blanks to the REBIND PLAN and REBIND PACKAGE subcommands, so that the DSN command processor can accept the record length as valid input

If the SELECT statement returns rows, then DSNTIAUL generates REBIND subcommands for the plans or packages identified in the returned rows. Put those subcommands in a sequential data set, where you can then edit them.

For REBIND PACKAGE subcommands, delete any extraneous blanks in the package name, using either TSO edit commands or the Db2 CLIST DSNTEDIT.

For both REBIND PLAN and REBIND PACKAGE subcommands, add the DSN command that the statement needs as the first line in the sequential data set, and add END as the last line, using TSO edit commands. When you have edited the sequential data set, you can run it to rebind the selected plans or packages.

If the SELECT statement returns no qualifying rows, then DSNTIAUL does not generate REBIND subcommands.

The examples in this topic generate REBIND subcommands that work in Db2 for z/OS Db2 12. You might need to modify the examples for prior releases of Db2 that do not allow all of the same syntax.

Example: REBIND all plans without terminating because of unavailable resources.

```
SELECT SUBSTR('REBIND PLAN('CONCAT NAME CONCAT') ',1,45)
FROM SYSIBM.SYSPLAN;
```

Example: REBIND all versions of all packages without terminating because of unavailable resources.

```
SELECT SUBSTR('REBIND PACKAGE('CONCAT COLLID CONCAT'.'
CONCAT NAME CONCAT'.(*)) ',1,55)
FROM SYSIBM.SYSPACKAGE;
```

Example: REBIND all plans bound before a given date and time.

```
SELECT SUBSTR('REBIND PLAN('CONCAT NAME
CONCAT') ',1,45)
FROM SYSIBM.SYSPLAN
WHERE BINDDATE <= 'yymmdd' OR
(BINDDATE <= 'yymmdd' AND
BINDTIME <= 'hhmmssth');
```

where *yymmdd* represents the date portion and *hhmmssth* represents the time portion of the timestamp string.

If the date specified is after 2000, you need to include another condition that includes plans that were bound before year 2000:

```
WHERE

BINDDATE >= '830101' OR

BINDDATE <= 'yymmdd' OR

(BINDDATE <= 'yymmdd' AND

BINDTIME <= 'hhmmssth');
```

Example: REBIND all versions of all packages bound before a given date and time.

```
SELECT SUBSTR('REBIND PACKAGE('CONCAT COLLID CONCAT'.'

CONCAT NAME CONCAT'.(*)) ',1,55)

FROM SYSIBM.SYSPACKAGE

WHERE BINDTIME <= 'timestamp';
```

where timestamp is an ISO timestamp string.

Example: REBIND all plans bound since a given date and time.

```
SELECT SUBSTR('REBIND PLAN('CONCAT NAME
CONCAT') ',1,45)
FROM SYSIBM.SYSPLAN
WHERE BINDDATE >= 'yymmdd' AND
BINDTIME >= 'hhmmssth';
```

where *yymmdd* represents the date portion and *hhmmssth* represents the time portion of the timestamp string.

Example: REBIND all versions of all packages bound since a given date and time.

```
SELECT SUBSTR('REBIND PACKAGE('CONCAT COLLID CONCAT'.'CONCAT NAME CONCAT'.(*)) ',1,55)
FROM SYSIBM.SYSPACKAGE
WHERE BINDTIME >= 'timestamp';
```

where timestamp is an ISO timestamp string.

Example: REBIND all plans bound within a given date and time range.

```
SELECT SUBSTR('REBIND PLAN('CONCAT NAME
CONCAT') ',1,45)
FROM SYSIBM.SYSPLAN
WHERE
(BINDDATE >= 'yymmdd' AND
BINDTIME >= 'hhmmssth') AND
BINDDATE <= 'yymmdd' AND
BINDDATE <= 'yymmdd' AND
BINDTIME <= 'hhmmssth');
```

where *yymmdd* represents the date portion and *hhmmssth* represents the time portion of the timestamp string.

Example: REBIND all versions of all packages bound within a given date and time range.

```
SELECT SUBSTR('REBIND PACKAGE('CONCAT COLLID CONCAT'.'
  CONCAT NAME CONCAT'.(*)) ',1,55)
FROM SYSIBM.SYSPACKAGE
WHERE BINDTIME >= 'timestamp1' AND
BINDTIME <= 'timestamp2';</pre>
```

where timestamp1 and timestamp2 are ISO timestamp strings.

Example: REBIND all invalid versions of all packages.

```
SELECT SUBSTR('REBIND PACKAGE('CONCAT COLLID CONCAT'.'
  CONCAT NAME CONCAT'.(*)) ',1,55)
FROM SYSIBM.SYSPACKAGE
WHERE VALID = 'N';
```

Example: REBIND all plans bound with ISOLATION level of cursor stability.

```
SELECT SUBSTR('REBIND PLAN('CONCAT NAME
CONCAT') ',1,45)
FROM SYSIBM.SYSPLAN
WHERE ISOLATION = 'S';
```

Example: REBIND all versions of all packages that allow CPU and/or I/O parallelism.

```
SELECT SUBSTR('REBIND PACKAGE('CONCAT COLLID CONCAT'.'
CONCAT NAME CONCAT'.(*)) ',1,55)
FROM SYSIBM.SYSPACKAGE
WHERE DEGREE='ANY';
```

Sample JCL for running lists of REBIND commands

You can use JCL to rebind all versions of all packages that are bound within a specified date and time period.

You specify the date and time period for which you want packages to be rebound in a WHERE clause of the SELECT statement that contains the REBIND command. In The following example, the WHERE clause looks like the following clause:

```
WHERE BINDTIME >= 'YYYY-MM-DD-hh.mm.ss' AND
BINDTIME <= 'YYYY-MM-DD-hh.mm.ss'
```

The date and time period has the following format:

YYYY

The four-digit year. For example: 2008.

MM

The two-digit month, which can be a value between 01 and 12.

DD

The two-digit day, which can be a value between 01 and 31.

hh

The two-digit hour, which can be a value between 01 and 24.

mm

The two-digit minute, which can be a value between 00 and 59.

SS

The two-digit second, which can be a value between 00 and 59.

Automatic rebinds

Automatic rebinds (sometimes called "autobinds") occur when an authorized user runs a package or plan and the runtime structures in the plan or package cannot be used. This situation usually results from changes to the attributes of the data on which the package or plan depends, or changes to the environment in which the package or plan runs.

For a list of actions that might cause Db2 to mark packages invalid, see <u>"Changes that invalidate packages"</u> on page 15.

In most cases, Db2 marks a package that must be automatically rebound as *invalid* by setting VALID='N' in the SYSIBM.SYSPLAN and SYSIBM.SYSPACKAGE catalog tables.

If an automatic rebind fails, Db2 marks a package as *inoperative* in the OPERATIVE column of SYSIBM.SYSPLAN and SYSIBM.SYSPACKAGE catalog tables. However, if autobind phase-in fails for a package that is invalidated at the statement level, OPERATIVE='R' is used in the SYSPACKAGE table only.

Controls for automatic binds

Db2 uses automatic binds only when the ABIND subsystem parameter is set to YES or COEXIST (Db2 12 uses the same behavior is used for both settings.). If ABIND is set to NO when an invalid package runs, Db2 returns an error. For details, see <u>AUTO BIND field (ABIND subsystem parameter) (Db2 Installation and Migration)</u>.

You can also use resource limit tables to control automatic binds. For details, see <u>Restricting bind</u> operations (Db2 Performance).

Bind options for automatic binds

In general, Db2 uses the same bind options from the most recent bind process for automatic binds. The exceptions are:

- If an option is no longer supported, the automatic rebind option process substitutes a supported option.
- If an option does not have an existing value, the default bind option is used.
- The automatic rebind value for APCOMPARE is NONE.
- The automatic rebind value for APREUSE is WARN, and the automatic rebind value for APREUSESOURCE is CURRENT.
- If there is no existing value for the APPLCOMPAT bind option, the APPLCOMPAT subsystem parameter is used.
- If there is no existing value for the DESCSTAT bind option, the DESCSTAT subsystem parameter is used.

Automatic binds with package copies

If a package has previous or original copies as a result of rebinding with the PLANMGMT(BASIC) or PLANMGMT(EXTENDED) options or having the PLANMGMT subsystem parameter set to BASIC or EXTENDED, those copies are not affected by automatic rebind. Automatic rebind replaces only the current copy.

A situation can occur in which automatic rebind causes the previous or original copy to be at a newer Db2 version than the current copy. Suppose that copy A is the current copy, and copy B is the previous copy. Copy A is at a previous and supported version for Db2 packages, but copy B is at an older Db2 version than the minimum supported version. When you switch the packages so that copy B becomes the current copy, and run copy B, Db2 automatically rebinds copy B. Now, copy B is at a newer Db2 version than copy A.

When automatic binds fail

When an automatic bind fails, Db2 issues message DSNT500I to the console with reason '00E30305'x, resource type '804'x, and resource name collection.package. (version).

If EXPLAIN(YES) was specified for the previous rebind operation, the ABEXP subsystem parameter controls whether Db2 captures EXPLAIN information during automatic rebinds. For details, see EXPLAIN PROCESSING field (ABEXP subsystem parameter) (Db2 Installation and Migration). Automatic rebinds fail for most EXPLAIN errors.

If an automatic bind occurs while running in ACCESS(MAINT) mode the automatic bind is run under the authorization id of SYSOPR. If SYSOPR is not defined as an installation SYSOPR the automatic bind fails.

Specifying the rules that apply to SQL behavior at run time

You can specify whether Db2 rules or SQL standard rules apply to SQL behavior at run time.

About this task

Not only does SQLRULES specify the rules under which a type 2 CONNECT statement executes, but it also sets the initial value of the special register CURRENT RULES when the database server is the local Db2 system. When the server is not the local Db2 system, the initial value of CURRENT RULES is DB2. After binding a plan, you can change the value in CURRENT RULES in an application program by using the statement SET CURRENT RULES.

CURRENT RULES determines the SQL rules, Db2 or SQL standard, that apply to SQL behavior at run time. For example, the value in CURRENT RULES affects the behavior of defining check constraints by issuing the ALTER TABLE statement on a populated table:

• If CURRENT RULES has a value of STD and no existing rows in the table violate the check constraint, Db2 adds the constraint to the table definition. Otherwise, an error occurs and Db2 does not add the check constraint to the table definition.

If the table contains data and is already in a check pending status, the ALTER TABLE statement fails.

• If CURRENT RULES has a value of DB2, Db2 adds the constraint to the table definition, defers the enforcing of the check constraints, and places the table space or partition in CHECK-pending status.

You can use the statement SET CURRENT RULES to control the action that the statement ALTER TABLE takes. Assuming that the value of CURRENT RULES is initially STD, the following SQL statements change the SQL rules to DB2, add a check constraint, defer validation of that constraint, place the table in CHECK-pending status, and restore the rules to STD.

```
EXEC SQL
SET CURRENT RULES = 'DB2';
EXEC SQL
ALTER TABLE DSN8C10.EMP
ADD CONSTRAINT C1 CHECK (BONUS <= 1000.0);
EXEC SQL
SET CURRENT RULES = 'STD';
```

See "Check constraints" on page 131 for information about check constraints.

You can also use CURRENT RULES in host variable assignments. For example, if you want to store the value of the CURRENT RULES special register at a particular point in time, you can use assign the value to a host variable, as in the following statement:

```
SET :XRULE = CURRENT RULES;
```

You can also use CURRENT RULES as the argument of a search-condition. For example, the following statement retrieves rows where the COL1 column contains the same value as the CURRENT RULES special register.

SELECT * FROM SAMPTBL WHERE COL1 = CURRENT RULES;

Input and output data sets for DL/I batch jobs

DL/I batch jobs require an input data set with DD name DDITV02 and an output data set with DD name DDOTV02.

Db2 DL/I batch input:

Before you can run a DL/I batch job, you need to provide values for a number of input parameters. The input parameters are positional and delimited by commas.

You can specify values for the following parameters using a DDITV02 data set or a subsystem member:

SSN, LIT, ESMT, RTT, REO, CRC

You can specify values for the following parameters **only** in a DDITV02 data set:

CONNECTION_NAME, PLAN, PROG

If you use the DDITV02 data set and specify a subsystem member, the values in the DDITV02 DD statement override the values in the specified subsystem member. If you provide neither, Db2 abnormally terminates the application program with system abend code X'04E' and a unique reason code in register 15.

DDITV02 is the DD name for a data set that has DCB options of LRECL=80 and RECFM=F or FB.

A subsystem member is a member in the IMS procedure library. Its name is derived by concatenating the value of the SSM parameter to the value of the IMSID parameter. You specify the SSM parameter and the IMSID parameter when you invoke the DLIBATCH procedure, which starts the DL/I batch processing environment.

The meanings of the input parameters are:

SSN

Specifies the name of the Db2 subsystem. This value is required. You must specify a name in order to make a connection to Db2.

The SSN value can be from one to four characters long.

If the value in the SSN parameter is the name of an active subsystem in the data sharing group, the application attaches to that subsystem. If the SSN parameter value is not the name of an active subsystem, but the value is a group attachment name, the application attaches to an active Db2 subsystem in the data sharing group.

LIT

Specifies a language interface token. Db2 requires a language interface token to route SQL statements when operating in the online IMS environment. Because a batch application program can connect to only one Db2 system, Db2 does not use the LIT value.

The LIT value can be from zero to four characters long.

Recommendation: Specify the LIT value as SYS1.

You can omit the LIT value by entering SSN,, ESMT.

ESMT

Specifies the name of the Db2 initialization module, DSNMIN10. This value is required.

The ESMT value must be eight characters long.

RTT

Specifies the resource translation table. This value is optional.

The RTT can be from zero to eight characters long.

REO

Specifies the region error option. This option determines what to do if Db2 is not operational or the plan is not available. The three options are:

- R, the default, results in returning an SQL return code to the application program. The most common SQLCODE issued in this case is -923 (SQLSTATE '57015').
- *Q* results in an abend in the batch environment; however, in the online environment, this value places the input message in the queue again.
- A results in an abend in both the batch environment and the online environment.

If the application program uses the XRST call, and if coordinated recovery is required on the XRST call, REO is ignored. In that case, the application program terminates abnormally if Db2 is not operational.

The REO value can be from zero to one character long.

CRC

Specifies the command recognition character. Because Db2 commands are not supported in the DL/I batch environment, the command recognition character is not used at this time.

The CRC value can be from zero to one character long.

CONNECTION_NAME

Represents the name of the job step that coordinates Db2 activities. This value is optional. If you do not specify this option, the connection name defaults are:

Type of application

Default connection name

Batch job

Job name

Started task

Started task name

TSO user

TSO authorization ID

If a batch update job fails, you must use a separate job to restart the batch job. The connection name used in the restart job must be the same as the name that is used in the batch job that failed. Alternatively, if the default connection name is used, the restart job must have the same job name as the batch update job that failed.

Db2 requires unique connection names. If two applications try to connect with the same connection name, the second application program fails to connect to Db2.

The CONNECTION_NAME value can be from one to eight characters long.

PLAN

Specifies the Db2 plan name. This value is optional. If you do not specify the plan name, the application program module name is checked against the optional resource translation table. If the resource translation table has a match, the translated name is used as the Db2 plan name. If no match exists in the resource translation table, the application program module name is used as the plan name.

The PLAN value can be from zero to eight characters long.

PROG

Specifies the application program name. This value is required. It identifies the application program that is to be loaded and to receive control.

The PROG value can be from one to eight characters long.

Example: An example of the fields in the record is shown below:

DSN, SYS1, DSNMIN10,, R, -, BATCH001, DB2PLAN, PROGA

Db2 DL/I batch output:

In an online IMS environment, Db2 sends unsolicited status messages to the master terminal operator (MTO) and records on indoubt processing and diagnostic information to the IMS log. In a batch environment, Db2 sends this information to the output data set that is specified in the DDOTV02 DD statement. Ensure that the output data set has DCB options of RECFM=V or VB, LRECL=4092, and BLKSIZE of at least LRECL + 4. If the DD statement is missing, Db2 issues the message IEC130I and continues processing without any output.

You might want to save and print the data set, as the information is useful for diagnostic purposes. You can use the IMS module, DFSERA10, to print the variable-length data set records in both hexadecimal and character format.

Db2-supplied JCL procedures for preparing an application

You can precompile and prepare an application program using a Db2-supplied JCL procedure.

Db2 has a unique JCL procedure for each supported language, with appropriate defaults for starting the Db2 precompiler and host language compiler or assembler. The procedures are in *prefix*.SDSNSAMP member DSNTIJMP, which installs the procedures.

Table 146. Frocedures for precomplining programs			
Language	Procedure	Invocation included in	
High-level assembler	DSNHASM	DSNTEJ2A	
С	DSNHC	DSNTEJ2D	
C++	DSNHCPP	DSNTEJ2E	
C++	DSNHCPP2 ²	DSNTEJ6V	
Enterprise COBOL	DSNHICOB	DSNTEJ2C ¹	
Fortran	DSNHFOR	DSNTEJ2F	
PL/I	DSNHPLI	DSNTEJ2P	
SQL	DSNHSQL	DSNTEJ63	
	'	'	

Table 148. Procedures for precompiling programs

Notes:

- 1. You must customize these programs to invoke the procedures that are listed in this table.
- 2. This procedure demonstrates how you can prepare an object-oriented program that consists of two data sets or members, both of which contain SQL.

If you use the PL/I macro processor, you must not use the PL/I *PROCESS statement in the source to pass options to the PL/I compiler. You can specify the needed options on the PARM.PLI= parameter of the EXEC statement in the DSNHPLI procedure.

JCL to include the appropriate interface code when using the Db2-supplied JCL procedures

To include the proper interface code when you submit the JCL procedures, use an INCLUDE SYSLIB statement in your link-edit JCL. The statement should specify the correct language interface module for the environment.

TSO, batch

```
//LKED.SYSIN DD *
  INCLUDE SYSLIB(member)
/*
```

member must be DSNELI or DSNULI, except for FORTRAN, in which case member must be DSNHFT.

IMS

```
//LKED.SYSIN DD *
INCLUDE SYSLIB(DFSLI000)
ENTRY (specification)
/*
```

DFSLI000 is the module for DL/I batch attach.

ENTRY specification varies depending on the host language. Include one of the following:

DLITCBL, for COBOL applications PLICALLA, for PL/I applications

The program name, for assembler language applications.

Recommendation: For COBOL applications, specify the PSB linkage directly on the PROCEDURE DIVISION statement instead of on a DLITCBL entry point. When you specify the PSB linkage directly on the PROCEDURE DIVISION statement, you can either omit the ENTRY specification or specify the application program name instead of the DLITCBL entry point.

CICS

```
//LKED.SYSIN DD *
INCLUDE SYSLIB(member)
/*
```

member must be DSNCLI or DSNULI.

Related concepts

"Universal language interface (DSNULI)" on page 115

The universal language interface (DSNULI) subcomponent determines the runtime environment and dynamically loads and branches to the appropriate language interface module.

Related tasks

Making the CAF language interface (DSNALI) available

Before you can invoke the call attachment facility (CAF), you must first make DSNALI available.

Compiling and link-editing an application

If you use the Db2 coprocessor, you process SQL statements as you compile your program, and the next step is the link edit the program. The purpose of the link-edit step is to produce an executable load module.

Tailoring Db2-supplied JCL procedures for preparing CICS programs

Instead of using the Db2 Program Preparation panels to prepare your CICS program, you can tailor CICS-supplied JCL procedures to do that. To tailor a CICS procedure, you need to add some steps and change some DD statements.

About this task

Make changes as needed to perform the following actions:

- Process the program with the Db2 precompiler.
- Bind the application plan. You can do this any time after you precompile the program. You can bind the program either online by the DB2I panels or as a batch step in this or another z/OS job.
- Include a DD statement in the linkage editor step to access the Db2 load library.
- Be sure the linkage editor control statements contain an INCLUDE statement for the Db2 language interface module.

The following example illustrates the necessary changes. This example assumes the use of a COBOL program. For any other programming language, change the CICS procedure name and the Db2 precompiler options.

```
//************************
             BIND THIS PROGRAM.
       (2)
(2)
(2)
(2)
(2)
(2)
(2)
(2)
(2)
(2)
           COND=((4,LT,PC))
       //STEPLIB DD DISP=SHR, DSN=prefix.SDSNEXIT
       // DD DISP=SHR,DSN=prefix.SDSNLOAD
//DBRMLIB DD DISP=OLD,DSN=USER.DBRMLIB.DATA(TESTCO1)
       //SYSPRINT DD SYSOUT=*
//SYSTSPRT DD SYSOUT=*
       //SYSUDUMP DD SYSOUT=*
       //SYSTSIN DD *
DSN S(DSN)
       BIND PLAN(TESTCO1) MEMBER(TESTCO1) ACTION(REP) RETAIN ISOLATION(CS)
        END
       //************************
       //*
                    COMPILE THE COBOL PROGRAM
       //***********************
       //CICS EXEC DFHEITVL
(3)
       //TRN.SYSIN DD DSN=&&DSNHOUT,DISP=(OLD,DELETE)
//LKED.SYSLMOD DD DSN=USER.RUNLIB.LOAD
(4)
(5)
       //LKED.CICSLOAD DD DISP=SHR,DSN=prefix.SDFHLOAD
(6)
       //LKED.SYSIN DD *
(7)
       INCLUDE CICSLOAD(DSNCLI)
```

The procedure accounts for these steps:

- **Step 1.** Precompile the program. The output of the Db2 precompiler becomes the input to the CICS command language translator.
- **Step 2.** Bind the application plan.
- **Step 3.** Call the CICS procedure to translate, compile, and link-edit a COBOL program. This procedure has several options that you need to consider.
- **Step 4.** Reflect an application load library in the data set name of the SYSLMOD DD statement. You must include the name of this load library in the DFHRPL DD statement of the CICS run time JCL.
- **Step 5.** Name the CICS load library that contains the module DSNCLI.
- **Step 6.** Direct the linkage editor to include the CICS-Db2 language interface module (DSNCLI). In this example, the order of the various control sections (CSECTs) is of no concern because the structure of the procedure automatically satisfies any order requirements.

For more information about the procedure DFHEITVL, other CICS procedures, or CICS requirements for application programs, please see the appropriate CICS manual.

If you are preparing a particularly large or complex application, you can use another preparation method. For example, if your program requires four of your own link-edit include libraries, you cannot prepare the program with DB2I, because DB2I limits the number of include libraries to three, plus language, IMS or CICS, and Db2 libraries. Therefore, you would need another preparation method. **Be careful to use the correct language interface.**

Related reference

Data sets that the precompiler uses

When you invoke the precompiler you need to provide data sets that contain input for the precompiler, such as the host programming statements and SQL statements. You also need to provide data sets where the precompiler can store its output, such as the modified source code and diagnostics messages.

DB2I panels that are used for program preparation

DB2I contains a set of panels that let you prepare an application for execution.

The following table describes each of the panels that you need to use to prepare an application.

Table 149. DB2.	I panels used	for program	preparation

Panel name	Panel description
"Db2 Program Preparation panel" on page 921	Lets you choose specific program preparation functions to perform. For the functions that you choose, you can also display the associated panels to specify options for performing those functions.
	This panel also lets you change the DB2I default values and perform other precompile and prelink functions.
"DB2I Defaults Panel 1" on page 925	Lets you change many of the system defaults that are set at Db2 installation time.
"DB2I Defaults Panel 2" on page 927	Lets you change your default job statement and set additional COBOL options.
"Precompile panel" on page	Lets you specify values for precompile functions.
928	You can reach this panel directly from the DB2I Primary Option Menu or from the Db2 Program Preparation panel. If you reach this panel from the Program Preparation panel, many of the fields contain values from the Primary and Precompile panels.

Table 149. DB2I panels used for program preparation (continued)		
Panel name	Panel description	
"Bind Package panel" on page	Lets you change many options when you bind a package.	
930	You can reach this panel directly from the DB2I Primary Option Menu or from the Db2 Program Preparation panel. If you reach this panel from the Db2 Program Preparation panel, many of the fields contain values from the Primary and Precompile panels.	
"Bind Plan panel" on page	Lets you change options when you bind an application plan.	
932	You can reach this panel directly from the DB2I Primary Option Menu or as a part of the program preparation process. This panel also follows the Bind Package panels.	
"Defaults for Bind Package and Defaults for Rebind Package panels" on page 935	Let you change the defaults for BIND or REBIND PACKAGE or PLAN.	
"System Connection Types	Lets you specify a system connection type.	
panel" on page 939	This panel displays if you choose to enable or disable connections on the Bind or Rebind Package or Plan panels.	
"Panels for entering lists of values" on page 941	Let you enter or modify an unlimited number of values. A list panel looks similar to an ISPF edit session and lets you scroll and use a limited set of commands.	
"Program Preparation: Compile, Link, and Run panel" on page 942	Lets you perform the last two steps in the program preparation process (compile and link-edit).	
	This panel also lets you do the PL/I MACRO PHASE for programs that require this option.	
	For TSO programs, the panel also lets you run programs.

The DB2I primary option menu (Introduction to Db2 for z/OS)

DB2I panels that are used to rebind and free plans and packages

A set of DB2I panels lets you bind, rebind, or free packages.

Db2 Program Preparation panel

The Db2 Program Preparation panel lets you choose which specific program preparation function to perform.

For the functions you choose, you can also choose to display the associated panels to specify options for performing those functions. Some of the functions you can select are:

Precompile

The panel for this function lets you control the Db2 precompiler.

Bind a package

The panel for this function lets you bind your program's DBRM to a package and change your defaults for binding the packages.

Bind a plan

The panel for this function lets you create your program's application plan and change your defaults for binding the plans.

Compile, link, and run

The panel for these functions let you control the compiler or assembler and the linkage editor.

TSO and batch: For TSO programs, you can use the program preparation programs to control the host language run time processor and the program itself.

The Program Preparation panel also lets you change the DB2I default values, and perform other precompile and prelink functions.

On the Db2 Program Preparation panel, shown in the following figure, enter the name of the source program data set (this example uses SAMPLEPG.COBOL) and specify the other options you want to include. When finished, press ENTER to view the next panel.

                                          (Y/N)
                                                         ===> N
                                                                   (Y/N)
                                          (Y/N)
                                                         ===> Y
14 LINK.... ===> N
                                                                   (Y/N)
15 RUN..... ===> N
                                                         ===> Y
```

Figure 46. The Db2 Program Preparation panel

The following explains the functions on the Db2 Program Preparation panel and how to complete the necessary fields in order to start program preparation.

1 INPUT DATA SET NAME

Lets you specify the input data set name. The input data set name can be a PDS or a sequential data set, and can also include a member name. If you do not enclose the data set name in apostrophes, a standard TSO prefix (user ID) qualifies the data set name.

The input data set name you specify is used to precompile, bind, link-edit, and run the program.

2 DATA SET NAME QUALIFIER

Lets you qualify temporary data set names involved in the program preparation process. Use any character string 1–8 characters that conforms to normal TSO naming conventions. (The default is TEMP.)

For programs that you prepare in the background or that use EDITJCL for the PREPARATION ENVIRONMENT option, Db2 creates a data set named *tsoprefix.qualifier*.CNTL to contain the program preparation JCL. The name *tsoprefix* represents the prefix TSO assigns, and *qualifier* represents the value you enter in the DATA SET NAME QUALIFIER field. If a data set with this name already exists, Db2 deletes it.

3 PREPARATION ENVIRONMENT

Lets you specify whether program preparation occurs in the foreground or background. You can also specify EDITJCL, in which case you are able to edit and then submit the job. Use:

FOREGROUND to use the values you specify on the Program Preparation panel and to run immediately.

BACKGROUND to create and submit a file containing a DSNH CLIST that runs immediately using the JOB control statement from either the DB2I Defaults panel or your site's SUBMIT exit. The file is saved.

EDITJCL to create and open a file containing a DSNH CLIST in edit mode. You can then submit the CLIST or save it.

4 RUN TIME ENVIRONMENT

Lets you specify the environment (TSO, CAF, CICS, IMS, RRSAF) in which your program runs.

All programs are prepared under TSO, but can run in any of the environments. If you specify CICS, IMS, or RRSAF, then you must set the RUN field to NO because you cannot run such programs from the Program Preparation panel. If you set the RUN field to YES, you can specify only TSO or CAF.

(Batch programs also run under the TSO Terminal Monitor Program. You therefore need to specify TSO in this field for batch programs.)

5 OTHER DSNH OPTIONS

Lets you specify a list of DSNH options that affect the program preparation process, and that override options specified on other panels. If you are using CICS, these can include options you want to specify to the CICS command translator.

If you specify options in this field, separate them by commas. You can continue listing options on the next line, but the total length of the option list can be no more than 70 bytes.

Fields 6 through 15 let you select the function to perform and to choose whether to show the DB2I panels for the functions you select. Use Y for YES, or N for NO.

If you are willing to accept default values for all the steps, enter N under Display panel? for all the other preparation panels listed.

To make changes to the default values, entering Y under Display panel? for any panel you want to see. DB2I then displays each of the panels that you request. After all the panels display, Db2 proceeds with the steps involved in preparing your program to run.

Variables for all functions used during program preparation are maintained separately from variables entered from the DB2I Primary Option Menu. For example, the bind plan variables you enter on the Program Preparation panel are saved separately from those on any Bind Plan panel that you reach from the Primary Option Menu.

6 CHANGE DEFAULTS

Lets you specify whether to change the DB2I defaults. Enter Y in the Display panel? field next to this option; otherwise enter N. Minimally, you should specify your subsystem identifier and programming language on the Defaults panel.

7 PL/I MACRO PHASE

Lets you specify whether to display the "Program Preparation: Compile, Link, and Run" panel to control the PL/I macro phase by entering PL/I options in the OPTIONS field of that panel. That panel also displays for options COMPILE OR ASSEMBLE, LINK, and RUN.

This field applies to PL/I programs only. If your program is not a PL/I program or does not use the PL/I macro processor, specify N in the Perform function field for this option, which sets the Display panel? field to the default N.

8 PRECOMPILE

Lets you specify whether to display the Precompile panel. To see this panel enter Y in the Display panel? field next to this option; otherwise enter N.

9 CICS COMMAND TRANSLATION

Lets you specify whether to use the CICS command translator. This field applies to CICS programs only.

IMS and TSO: If you run under TSO or IMS, ignore this step; this allows the Perform function field to default to N.

CICS: If you are using CICS and have precompiled your program, you must translate your program using the CICS command translator.

The command translator does not have a separate DB2I panel. You can specify translation options on the Other Options field of the Db2 Program Preparation panel, or in your source program if it is not an assembler program.

Because you specified a CICS run time environment, the Perform function column defaults to Y. Command translation takes place automatically after you precompile the program.

10 BIND PACKAGE

Lets you specify whether to display the Bind Package panel. To see it, enter Y in the Display panel? field next to this option; otherwise, enter N.

11 BIND PLAN

Lets you specify whether to display the Bind Plan panel. To see it, enter Y in the Display panel? field next to this option; otherwise, enter N.

12 COMPILE OR ASSEMBLE

Lets you specify whether to display the "Program Preparation: Compile, Link, and Run" panel. To see this panel enter Y in the Display panel? field next to this option; otherwise, enter N.

13 PRELINK

Lets you use the prelink utility to make your C, C++, or Enterprise COBOL for z/OS program reentrant. This utility concatenates compile-time initialization information from one or more text decks into a single initialization unit. To use the utility, enter Y in the Display panel? field next to this option; otherwise, enter N. If you request this step, then you must also request the compiler step and the link-edit step.

14 LINK

Lets you specify whether to display the "Program Preparation: Compile, Link, and Run" panel. To see it, enter Y in the Display panel? field next to this option; otherwise, enter N. If you specify Y in the Display panel? field for the COMPILE OR ASSEMBLE option, you do not need to make any changes to this field; the panel displayed for COMPILE OR ASSEMBLE is the same as the panel displayed for LINK. You can make the changes you want to affect the link-edit step at the same time you make the changes to the compiler step.

15 RUN

Lets you specify whether to run your program. The RUN option is available only if you specify TSO or CAF for RUN TIME ENVIRONMENT.

If you specify Y in the Display panel? field for the COMPILE OR ASSEMBLE or LINK option, you can specify N in this field, because the panel displayed for COMPILE OR ASSEMBLE and for LINK is the same as the panel displayed for RUN.

IMS and CICS: IMS and CICS programs cannot run using DB2I. If you are using IMS or CICS, use N in these fields.

TSO and batch: If you are using TSO and want to run your program, you must enter Y in the Perform function column next to this option. You can also indicate that you want to specify options and values to affect the running of your program, by entering Y in the Display panel column.

Pressing ENTER takes you to the first panel in the series you specified, in this example to the DB2I Defaults panel. If, at any point in your progress from panel to panel, you press the END key, you return to this first panel, from which you can change your processing specifications. Asterisks (*) in the Display panel? column of rows 7 through 14 indicate which panels you have already examined. You can see a panel again by writing a Y over an asterisk.

Related reference

Bind Package panel

The Bind Package panel is the first of two DB2I panels that request information about how you want to bind a package.

Bind Plan panel

The Bind Plan panel is the first of two DB2I panels that request information about how you want to bind an application plan.

DB2I Defaults Panel 1

DB2I Defaults Panel 1 lets you change many of the system default values that were set at Db2 installation time.

Defaults for Bind Package and Defaults for Rebind Package panels

These DB2I panels lets you change your defaults for BIND PACKAGE and REBIND PACKAGE options.

Defaults for Bind Plan and Defaults for Rebind Plan panels

These DB2I panels let you change your defaults for BIND PLAN and REBIND PLAN options.

Precompile panel

After you set the DB2I defaults, you can precompile your application. You can reach the Precompile panel by specifying it as a part of the program preparation process from the Db2 Program Preparation panel. Or you can reach it directly from the DB2I Primary Option Menu.

Program Preparation: Compile, Link, and Run panel

The Compile, Link, and Run panel lets you perform the last two steps in the program preparation process (compile and link-edit). This panel also lets you perform the PL/I MACRO PHASE for programs that require this option.

DSNH command procedure (TSO CLIST) (Db2 Commands)

Prelinking an application (z/OS Language Environment Programming Guide)

DB2I Defaults Panel 1

DB2I Defaults Panel 1 lets you change many of the system default values that were set at Db2 installation time.

The following figure shows the fields that affect the processing of the other DB2I panels.

```
DB2I DEFAULTS PANEL 1
DSNEOP01
COMMAND ===>_
Change defaults as desired:
                                . ===> DSN
     DB2 NAME
                                                      (Subsystem identifier)
 2 DB2 CONNECTION RETRIES ===> 0
                                                     (How many retries for DB2 connection)
 3 APPLICATION LANGUAGE ===> IBMCOB
4 LINES/PAGE OF LISTING ===> 6
                                                     (ASM, C, CPP, IBMCOB, FORTRAN, PLI)
                                                     (A number from 5 to 999)
    MESSAGE LEVEL ..... ===> I (Informati SQL STRING DELIMITER ===> DEFAULT (DEFAULT,
                                                     (Information, Warning, Error, Severe)
 5 MESSAGE LEVEL
6 SQL STRING DELIMITER --- SETTING DECIMAL POINT ..... ===> .

                                                                   or ")
                                                      (. or ,)
                                                     (Lowest terminating return code)
                                                      (For ISPF Tables)
10 AS USER
                                                     (User ID to associate with trusted connection)
```

Figure 47. DB2I Defaults Panel 1

The following explains the fields on DB2I Defaults Panel 1.

1 Db2 NAME

Lets you specify the Db2 subsystem that processes your DB2I requests. If you specify a different Db2 subsystem, its identifier displays in the SSID (subsystem identifier) field located at the top, right side of your screen. The default is DSN.

2 Db2 CONNECTION RETRIES

Lets you specify the number of additional times to attempt to connect to Db2, if Db2 is not up when the program issues the DSN command. The program preparation process does not use this option.

Use a number from 0 to 120. The default is 0. Connections are attempted at 30-second intervals.

3 APPLICATION LANGUAGE

Lets you specify the default programming language for your application program. You can specify any of the following languages:

ASM

For High Level Assembler/z/OS

C

For C language

CPP

For C++

IBMCOB

For Enterprise COBOL for z/OS. This option is the default.

FORTRAN

For VS Fortran

PLI

For PL/I

If you specify IBMCOB, Db2 prompts you for more COBOL defaults on panel DSNEOP02. See <u>"DB2I"</u> Defaults Panel 2" on page 927.

You cannot specify FORTRAN for IMS or CICS programs.

4 LINES/PAGE OF LISTING

Lets you specify the number of lines to print on each page of listing or SPUFI output. The default is 60.

5 MESSAGE LEVEL

Lets you specify the lowest level of message to return to you during the BIND phase of the preparation process. Use:

Ι

For all information, warning, error, and severe error messages

W

For warning, error, and severe error messages

Ε

For error and severe error messages

S

For severe error messages only

6 SQL STRING DELIMITER

Lets you specify the symbol used to delimit a string in SQL statements in COBOL programs. This option is valid only when the application language is IBMCOB. Use:

DEFAULT

To use the default defined at installation time

•

For an apostrophe

п

For a quotation mark

7 DECIMAL POINT

Lets you specify how your host language source program represents decimal separators and how SPUFI displays decimal separators in its output. Use a comma (,) or a period (.). The default is a period (.).

8 STOP IF RETURN CODE >=

Lets you specify the smallest value of the return code (from precompile, compile, link-edit, or bind) that will prevent later steps from running. Use:

4

To stop on warnings and more severe errors.

8

To stop on errors and more severe errors. The default is 8.

9 NUMBER OF ROWS

Lets you specify the default number of input entry rows to generate on the initial display of ISPF panels. The number of rows with non-blank entries determines the number of rows that appear on later displays.

10 AS USER

Lets you specify a user ID to associate with the trusted connection for the current DB2I session.

Db2 establishes the trusted connection for the user that you specify if the following conditions are true:

- The primary authorization ID that Db2 obtains after running the connection exit is allowed to use the trusted connection without authentication.
- The security label, if defined either implicitly or explicitly in the trusted context for the user, is defined in RACF for the user.

After Db2 establishes the trusted connection, the primary authorization ID, any secondary authorization IDs, any role, and any security label that is associated with the user ID that is specified in the AS USER field are used for the trusted connection. Db2 uses this security label to verify multilevel security for the user.

If the primary authorization ID that is associated with the user ID that is specified in the AS USER field is not allowed to use the trusted connection or requires authentication information, the connection request fails. If Db2 cannot verify the security label, the connection request also fails.

The value that you enter in this field is retained only for the length of the DB2I session. The field is reset to blank when you exit DB2I.

Suppose that the default programming language is PL/I and the default number of lines per page of program listing is 60. Your program is in COBOL, so you want to change field 3, APPLICATION LANGUAGE. You also want to print 80 lines to the page, so you need to change field 4, LINES/PAGE OF LISTING, as well. Figure 47 on page 925 shows the entries that you make in DB2I Defaults Panel 1 to make these changes. In this case, pressing ENTER takes you to Db2 Defaults Panel 2.

DB2I Defaults Panel 2

After you press Enter on the DB2I Defaults Panel 1, the DB2I Defaults Panel 2 is displayed. If you chose IBMCOB as the language on the DB2I Defaults Panel 1, three fields are displayed. Otherwise, only the first field is displayed.

The following figure shows the DB2I Defaults Panel 2 when IBMCOB is selected.

```
DSNEOPO2
COMMAND ===>_

Change defaults as desired:

1 DB2I JOB STATEMENT: (Optional if your site has a SUBMIT exit)
===> //USRT001A JOB (ACCOUNT),'NAME'
===> //*
===> //*
===> //*

COBOL DEFAULTS: (For IBMCOB)
2 COBOL STRING DELIMITER ===> DEFAULT (DEFAULT, ' or ")
3 DBCS SYMBOL FOR DCLGEN ===> G (G/N - Character in PIC clause)
```

Figure 48. DB2I Defaults Panel 2

1 DB2I JOB STATEMENT

Lets you change your default job statement. Specify a job control statement, and optionally, a JOBLIB statement to use either in the background or the EDITJCL program preparation environment. Use a JOBLIB statement to specify run time libraries that your application requires. If your program has a SUBMIT exit routine, Db2 uses that routine. If that routine builds a job control statement, you can leave this field blank.

2 COBOL STRING DELIMITER

Lets you specify the symbol used to delimit a string in a COBOL statement in a COBOL application. Use:

DEFAULT

To use the default defined at installation time

For an apostrophe

For a quotation mark

Leave this field blank to accept the default value.

3 DBCS SYMBOL FOR DCLGEN

Lets you enter either G (the default) or N, to specify whether DCLGEN generates a picture clause that has the form PIC G(n) DISPLAY-1 or PIC N(n).

Leave this field blank to accept the default value.

Pressing ENTER takes you to the next panel you specified on the Db2 Program Preparation panel, in this case, to the Precompile panel.

Precompile panel

After you set the DB2I defaults, you can precompile your application. You can reach the Precompile panel by specifying it as a part of the program preparation process from the Db2 Program Preparation panel. Or you can reach it directly from the DB2I Primary Option Menu.

The way you choose to reach the panel determines the default values of the fields it contains. The following figure shows the Precompile panel.

```
DSNETP01
COMMAND ===>_

Enter precompiler data sets:

1 INPUT DATA SET ... ===> SAMPLEPG.COBOL
2 INCLUDE LIBRARY .. ===> SRCLIB.DATA

3 DSNAME QUALIFIER .. ===> TEMP (For building data set names)
4 DBRM DATA SET ... ===>

Enter processing options as desired:
5 WHERE TO PRECOMPILE ===> FOREGROUND
6 VERSION ... ===>

(Blank, VERSION, or AUTO)

7 OTHER OPTIONS ... ===>
```

Figure 49. The Precompile panel

The following explains the functions on the Precompile panel, and how to enter the fields for preparing to precompile.

1 INPUT DATA SET

Lets you specify the data set name of the source program and SQL statements to precompile.

If you reached this panel through the Db2 Program Preparation panel, this field contains the data set name specified there. You can override it on this panel.

If you reached this panel directly from the DB2I Primary Option Menu, you must enter the data set name of the program you want to precompile. The data set name can include a member name. If you do not enclose the data set name with apostrophes, a standard TSO prefix (user ID) qualifies the data set name.

2 INCLUDE LIBRARY

Lets you enter the name of a library containing members that the precompiler should include. These members can contain output from DCLGEN. If you do not enclose the name in apostrophes, a standard TSO prefix (user ID) qualifies the name.

You can request additional INCLUDE libraries by entering DSNH CLIST parameters of the form PnLIB(dsname), where n is 2, 3, or 4) on the OTHER OPTIONS field of this panel or on the OTHER DSNH OPTIONS field of the Program Preparation panel.

3 DSNAME QUALIFIER

Lets you specify a character string that qualifies temporary data set names during precompile. Use any character string from 1 to 8 characters in length that conforms to normal TSO naming conventions.

If you reached this panel through the Db2 Program Preparation panel, this field contains the data set name qualifier specified there. You can override it on this panel.

If you reached this panel from the DB2I Primary Option Menu, you can either specify a DSNAME QUALIFIER or let the field take its default value, TEMP.

IMS and TSO: For IMS and TSO programs, Db2 stores the precompiled source statements (to pass to the compiler or assemble step) in a data set named *tsoprefix.qualifier.suffix*. A data set named *tsoprefix.qualifier.*PCLIST contains the precompiler print listing.

For programs prepared in the background or that use the PREPARATION ENVIRONMENT option EDITJCL (on the Db2 Program Preparation panel), a data set named *tsoprefix.qualifier*.CNTL contains the program preparation JCL.

In these examples, *tsoprefix* represents the prefix TSO assigns, often the same as the authorization ID. *qualifier* represents the value entered in the DSNAME QUALIFIER field. *suffix* represents the output name, which is one of the following: COBOL, FORTRAN, C, PLI, ASM, DECK, CICSIN, OBJ, or DATA. In the Precompile Panel that is shown above, the data set *tsoprefix*.TEMP.COBOL contains the precompiled source statements, and *tsoprefix*.TEMP.PCLIST contains the precompiler print listing. If data sets with these names already exist, then Db2 deletes them.

CICS: For CICS programs, the data set *tsoprefix.qualifier.suffix* receives the precompiled source statements in preparation for CICS command translation.

If you do not plan to do CICS command translation, the source statements in *tsoprefix.qualifier.suffix*, are ready to compile. The data set *tsoprefix.qualifier*.PCLIST contains the precompiler print listing.

When the precompiler completes its work, control passes to the CICS command translator. Because there is no panel for the translator, translation takes place automatically. The data set *tsoprefix.qualifier*.CXLIST contains the output from the command translator.

4 DBRM DATA SET

Lets you name the DBRM library data set for the precompiler output. The data set can also include a member name.

When you reach this panel, the field is blank. When you press ENTER, however, the value contained in the DSNAME QUALIFIER field of the panel, concatenated with *DBRM*, specifies the DBRM data set: *qualifier*.DBRM.

You can enter another data set name in this field only if you allocate and catalog the data set before doing so. This is true even if the data set name that you enter corresponds to what is otherwise the default value of this field.

The precompiler sends modified source code to the data set *qualifier.host*, where *host* is the language specified in the APPLICATION LANGUAGE field of DB2I Defaults panel 1.

5 WHERE TO PRECOMPILE

Lets you indicate whether to precompile in the foreground or background. You can also specify EDITJCL, in which case you are able to edit and then submit the job.

If you reached this panel from the Db2 Program Preparation panel, the field contains the preparation environment specified there. You can override that value if you want.

If you reached this panel directly from the DB2I Primary Option Menu, you can either specify a processing environment or allow this field to take its default value. Use:

FOREGROUND to immediately precompile the program with the values you specify in these panels. BACKGROUND to create and immediately submit to run a file containing a DSNH CLIST using the JOB control statement from either DB2I Defaults Panel 2 or your site's SUBMIT exit. The file is saved.

EDITJCL to create and open a file containing a DSNH CLIST in edit mode. You can then submit the CLIST or save it.

6 VERSION

Lets you specify the version of the program and its DBRM. If the version contains the maximum number of characters permitted (64), you must enter each character with no intervening blanks from one line to the next. This field is optional.

7 OTHER OPTIONS

Lets you enter any option that the DSNH CLIST accepts, which gives you greater control over your program. The DSNH options you specify in this field override options specified on other panels. The option list can continue to the next line, but the total length of the list can be no more than 70 bytes.

DSNH command procedure (TSO CLIST) (Db2 Commands)

Bind Package panel

The Bind Package panel is the first of two DB2I panels that request information about how you want to bind a package.

You can reach the Bind Package panel either directly from the DB2I Primary Option Menu, or as a part of the program preparation process. If you enter the Bind Package panel from the Program Preparation panel, many of the Bind Package entries contain values from the Primary and Precompile panels. Figure 50 on page 930 shows the Bind Package panel.

```
DSNEBP07
                              BIND PACKAGE
                                                                        SSID: DSN
 COMMAND ===>_
 Specify output location and collection names:
  1 LOCATION NAME ..... ===>
                                                               (Defaults to local)
  2 COLLECTION-ID ..... ===>
                                                            > (Required)
Specify package source (DBRM or COPY):

3 DBRM: COPY: ===> DBRM

4 MEMBER or COLLECTION-ID ===>
5 PASSWORD or PACKAGE-ID .. ===>
6 LIBRARY or VERSION .... ===>
                                                        (Specify DBRM or COPY)
                                                        (Blank, or COPY version-id)
     ..... -- OPTIONS .... ===>
                                                        (COMPOSITE or COMMAND)
 Enter options as desired:
  8 CHANGE CURRENT DEFAULTS? ===> NO
                                                        (NO or YES)
  9 ENABLE/DISABLE CONNECTIONS? ===> NO
                                                        (NO or YES)
 10 OWNER OF PACKAGE (AUTHID).. ===> > (Leave blank for primary ID)
11 QUALIFIER ..... ===> >
12 ACTION ON PACKAGE .... ===> REPLACE
13 INCLUDE PATH? .... ===> NO
                                                     > (Leave blank for OWNER)
                                                        (ADD or REPLACE)
                                                        (NO or YES)
 14 REPLACE VERSION ..... ===>
                                                        (Replacement version-id)
```

Figure 50. The Bind Package panel

The following information explains the functions on the Bind Package panel and how to fill the necessary fields in order to bind your program.

1 LOCATION NAME

Lets you specify the system at which to bind the package. You can use 1–16 characters to specify the location name. The location name must be defined in the catalog table SYSIBM.LOCATIONS. The default is the local DBMS.

2 COLLECTION-ID

Lets you specify the collection the package is in. You can use 1–128 characters to specify the collection, and the first character must be alphabetic. This field is scrollable.

3 DBRM: COPY:

Lets you specify whether you are creating a new package (DBRM) or making a copy of a package that already exists (COPY). Use:

DBRM

To create a new package. You must specify values in the LIBRARY, PASSWORD, and MEMBER fields.

COPY

To copy an existing package. You must specify values in the COLLECTION-ID and PACKAGE-ID fields. (The VERSION field is optional.)

4 MEMBER or COLLECTION-ID

MEMBER (for new packages): If you are creating a new package, this option lets you specify the DBRM to bind. You can specify a member name of 1–128 characters. This field is scrollable. The default name depends on the input data set name.

- If the input data set is partitioned, the default name is the member name of the input data set specified in the INPUT DATA SET NAME field of the Db2 Program Preparation panel.
- If the input data set is sequential, the default name is the second qualifier of this input data set.

COLLECTION-ID (for copying a package): If you are copying a package, this option specifies the collection ID that contains the original package. You can specify a collection ID of 1–128 characters, which must be different from the collection ID specified on the PACKAGE ID field. This field is scrollable.

5 PASSWORD or PACKAGE-ID

PASSWORD (for new packages): If you are creating a new package, this lets you enter password for the library you list in the LIBRARY field. You can use this field only if you reached the Bind Package panel directly from the Db2 Primary Option Menu. This field is scrollable.

PACKAGE-ID (for copying packages): If you are copying a package, this option lets you specify the name of the original package. You can enter a package ID of 1–128 characters. This field is scrollable.

6 LIBRARY or VERSION

LIBRARY (for new packages): If you are creating a new package, this lets you specify the names of the libraries that contain the DBRMs specified on the MEMBER field for the bind process. Libraries are searched in the order specified and must in the catalog tables.

VERSION (for copying packages): If you are copying a package, this option lets you specify the version of the original package. You can specify a version ID of 1–64 characters.

7 OPTIONS

Lets you specify which bind options Db2 uses when you issue BIND PACKAGE with the COPY option. Specify:

- **COMPOSITE (default)** to cause Db2 to use any options you specify in the BIND PACKAGE command. For all other options, Db2 uses the options of the copied package.
- **COMMAND** to cause Db2 to use the options you specify in the BIND PACKAGE command. For all other options, Db2 uses the following values:
 - For a local copy of a package, Db2 uses the defaults for the local Db2 subsystem.
 - For a remote copy of a package, Db2 uses the defaults for the server on which the package is bound.

8 CHANGE CURRENT DEFAULTS?

Lets you specify whether to change the current defaults for binding packages. If you enter YES in this field, you see the Defaults for Bind Package panel as your next step. You can enter your new preferences there; for instructions, see "Defaults for Bind Package and Defaults for Rebind Package panels" on page 935.

9 ENABLE/DISABLE CONNECTIONS?

Lets you specify whether you want to enable and disable system connections types to use with this package. This is valid only if the LOCATION NAME field names your local Db2 system.

Placing YES in this field displays a panel (shown in <u>Figure 56 on page 940</u>) that lets you specify whether various system connections are valid for this application. You can specify connection names

to further identify enabled connections within a connection type. A connection name is valid only when you also specify its corresponding connection type.

The default enables all connection types.

10 OWNER OF PACKAGE (AUTHID)

Lets you specify the primary authorization ID of the owner of the new package. That ID is the name owning the package, and the name associated with all accounting and trace records produced by the package.

The owner must have the privileges required to run SQL statements contained in the package.

The default is the primary authorization ID of the bind process.

The field is scrollable, and the maximum field length is 128.

11 QUALIFIER

Lets you specify the default schema for unqualified tables, views, indexes, and aliases. You can specify a schema name of 1–128 characters. The default is the authorization ID of the package owner. This field is scrollable.

12 ACTION ON PACKAGE

Lets you specify whether to replace an existing package or create a new one. Use:

REPLACE (default) to replace the package named in the PACKAGE-ID field if it already exists, and add it if it does not. (Use this option if you are changing the package because the SQL statements in the program changed. If only the SQL environment changes but not the SQL statements, you can use REBIND PACKAGE.)

ADD to add the package named in the PACKAGE-ID field, only if it does not already exist.

13 INCLUDE PATH?

Indicates whether you will supply a list of schema names that Db2 searches when it resolves unqualified distinct type, user-defined function, and stored procedure names in SQL statements. The default is NO. If you specify YES, Db2 displays a panel in which you specify the names of schemas for Db2 to search.

14 REPLACE VERSION

Lets you specify whether to replace a specific version of an existing package or create a new one. If the package and the version named in the PACKAGE-ID and VERSION fields already exist, you must specify REPLACE. You can specify a version ID of 1–64 characters. The default version ID is that specified in the VERSION field.

Bind Plan panel

The Bind Plan panel is the first of two DB2I panels that request information about how you want to bind an application plan.

Like the Precompile panel, you can reach the Bind Plan panel either directly from the DB2I Primary Option Menu, or as a part of the program preparation process. You must have an application plan, even if you bind your application to packages; this panel also follows the Bind Package panels.

If you enter the Bind Plan panel from the Program Preparation panel, many of the Bind Plan entries contain values from the Primary and Precompile panels.

```
DSNEBP02
                         BIND PLAN
                                                              SSID: DSN
COMMAND ===>_
Enter primary package list:
  1 LOCATION NAME ..... ===>
                                                 (Defaults to local)
    COLLECTION ID ..... ===>
                                              > (Required)
  3 PACKAGE ID ..... ===>
                                                 (Package ID or *)
  4 ADDITIONAL PACKAGE LISTS .. ===> NO
                                                 (YES to include more packages)
Enter options as desired:
    PLAN NAME ..... ===>
CHANGE CURRENT DEFAULTS?.. ===> NO
                                                 (Required to create a plan)
                                                (NO or YES)
    ENABLE/DISABLE CONNECTIONS? ===> NO
                                                 (NO or YES)
    OWNER OF PLAN (AUTHID).... ===>
                                              > (Leave blank for your primary ID)
     QUALIFIER .... ===>
                                             > (For tables, views, and aliases)
10 CACHESIZE .... ===> 0
11 ACTION ON PLAN .... ===> REPLACE
                                                (Blank, or value 0-4096)
(REPLACE or ADD)
12 RETAIN EXECUTION AUTHORITY. ===> NO
                                                 (YES to retain user list)
13 CURRENT SERVER ..... ===>
                                                 (Location name)
14 INCLUDE PATH? ..... ===> NO
                                                 (NO or YES)
```

Figure 51. The Bind Plan panel

The following explains the functions on the Bind Plan panel and how to fill the necessary fields in order to bind your program.

1 LOCATION NAME

Lets you specify the remote system where the package that is named in the PACKAGE ID field is bound. The location name must be defined in the catalog table SYSIBM.LOCATIONS. The default is the local DBMS.

2 COLLECTION ID

Lets you specify the collection that includes the package that is to be bound into the plan.

The field is scrollable, and the maximum field length is 128.

3 PACKAGE ID

Lets you specify the name of the package that is to be bound into the plan.

4 ADDITIONAL PACKAGE LISTS

Lets you include a list of additional packages in the plan. If you specify YES, a separate panel displays, where you must enter the package location, collection name, and package name for each package to include in the plan. This list is optional.

5 PLAN NAME

Lets you name the application plan to create. You can specify a name of 1–8 characters, and the first character must be alphabetic. If there are no errors, the bind process prepares the plan and enters its description into the EXPLAIN table.

If you reached this panel through the Db2 Program Preparation panel, the default for this field depends on the value you entered in the INPUT DATA SET NAME field of that panel.

If you reached this panel directly from the Db2 Primary Option Menu, you must include a plan name if you want to create an application plan. The default name for this field depends on the input data set:

- If the input data set is partitioned, the default name is the member name.
- If the input data set is sequential, the default name is the second qualifier of the data set name.

6 CHANGE CURRENT DEFAULTS?

Lets you specify whether to change the current defaults for binding plans. If you enter YES in this field, you see the Defaults for Bind Plan panel as your next step. You can enter your new preferences there.

7 ENABLE/DISABLE CONNECTIONS?

Lets you specify whether you want to enable and disable system connections types to use with this package. This is valid only if the LOCATION NAME field names your local Db2 system.

Placing YES in this field displays a panel (shown in <u>Figure 56 on page 940</u>) that lets you specify whether various system connections are valid for this application. You can specify connection names

to further identify enabled connections within a connection type. A connection name is valid only when you also specify its corresponding connection type.

The default enables all connection types.

8 OWNER OF PLAN (AUTHID)

Lets you specify the primary authorization ID of the owner of the new plan. That ID is the name owning the plan, and the name associated with all accounting and trace records produced by the plan.

The owner must have the privileges required to run SQL statements contained in the plan.

The field is scrollable, and the maximum field length is 128.

9 QUALIFIER

Lets you specify the default schema for unqualified tables, views, and aliases. You can specify a schema name of 1–128 characters, which must conform to the rules for SQL identifiers. If you leave this field blank, the default qualifier is the authorization ID of the plan owner. This field is scrollable.

Lets you specify the default schema for unqualified tables, views, and aliases. You can specify a schema name from 1 to 8 characters, which must conform to the rules for SQL identifiers. If you leave this field blank, the default qualifier is the authorization ID of the plan owner.

10 CACHESIZE

Lets you specify the size (in bytes) of the authorization cache. Valid values are in the range 0 to 4096. Values that are not multiples of 256 round up to the next highest multiple of 256. A value of 0 indicates that Db2 does not use an authorization cache. The default is 1024.

Each concurrent user of a plan requires 8 bytes of storage, with an additional 32 bytes for overhead.

11 ACTION ON PLAN

Lets you specify whether this is a new or changed application plan. Use:

REPLACE (default) to replace the plan named in the PLAN NAME field if it already exists, and add the plan if it does not exist.

ADD to add the plan named in the PLAN NAME field, only if it does not already exist.

12 RETAIN EXECUTION AUTHORITY

Lets you choose whether or not those users with the authority to bind or run the existing plan are to keep that authority over the changed plan. This applies only when you are replacing an existing plan.

If the plan ownership changes and you specify YES, the new owner grants BIND and EXECUTE authority to the previous plan owner.

If the plan ownership changes and you do not specify YES, then everyone but the new plan owner loses EXECUTE authority (but not BIND authority), and the new plan owner grants BIND authority to the previous plan owner.

13 CURRENT SERVER

Lets you specify the initial server to receive and process SQL statements in this plan. You can specify a name of 1–16 characters, which you must previously define in the catalog table SYSIBM.LOCATIONS.

If you specify a remote server, Db2 connects to that server when the first SQL statement executes. The default is the name of the local Db2 subsystem.

14 INCLUDE PATH?

Indicates whether you will supply a list of schema names that Db2 searches when it resolves unqualified distinct type, user-defined function, and stored procedure names in SQL statements. The default is NO. If you specify YES, Db2 displays a panel in which you specify the names of schemas for Db2 to search.

When you finish making changes to this panel, press ENTER to go to the second of the program preparation panels, Program Prep: Compile, Link, and Run.

Figure 53. The Defaults for Rebind Package panel

The following table lists the fields on the Defaults for Bind Package and Defaults for Rebind Package panels, and the corresponding bind and rebind options.

Table 150. Defaults for Bind Package and Defaults for Rebind Package panel fields and corresponding bind or rebind options

Field name	Bind or rebind option
ACCESS PATH COMPARISON	APCOMPARE
ACCESS PATH RETAIN DUPS	APRETAINDUP
ACCESS PATH REUSE	APREUSE
APPLICATION COMPATIBILITY	APPLCOMPAT
APPLICATION ENCODING	ENCODING
ARCHIVE SENSITIVE	ARCHIVESENSITIVE
BUSINESS_TIME SENSITIVE	BUSTINESENSITIVE
DATA CURRENCY	CURRENTDATA
DBPROTOCOL	DBPROTOCOL
DEFER PREPARE	DEFER and NODEFER
DYNAMIC RULES	DYNAMICRULES
EXPLAIN PATH SELECTION	EXPLAIN
IMMEDIATE WRITE	IMMEDWRITE

Field name	Bind or rebind option
ISOLATION LEVEL	ISOLATION
KEEP DYNAMIC SQL PAST COMMIT OR ROLLBACK	KEEPDYNAMIC
OPTIMIZATION HINT	OPTHINT
PARALLEL DEGREE	DEGREE
PLAN MANAGEMENT	PLANMGMT
REOPTIMIZE FOR INPUT VARS	REOPT
RESOURCE RELEASE TIME	RELEASE
SQLERROR PROCESSING	SQLERROR
SYSTEM_TIME SENSITIVE	SYSTIMESENSITIVE
VALIDATION TIME and PLAN VALIDATION TIME	VALIDATE

REOPTIMIZE FOR INPUT VARS	REOPT
RESOURCE ACQUISITION TIME	ACQUIRE
RESOURCE RELEASE TIME	RELEASE
VALIDATION TIME and PLAN VALIDATION TIME	VALIDATE

Related concepts

I

Dynamic rules options for dynamic SQL statements

The DYNAMICRULES bind option and the runtime environment determine the rules for the dynamic SQL attributes.

Parallel processing (Db2 Performance)

Investigating SQL performance by using EXPLAIN (Db2 Performance)

Related tasks

Caching authorization IDs for plans (Managing Security)

Setting the isolation level of SQL statements in a REXX program

Isolation levels specify the locking behavior for SQL statements. You can set the isolation level for SQL statements in your REXX program to repeatable read (RR), read stability (RS), cursor stability (CS), or uncommitted read (UR).

Specifying the rules that apply to SQL behavior at run time

You can specify whether Db2 rules or SQL standard rules apply to SQL behavior at run time.

System Connection Types panel

The System Connection Types panel lets you specify which types of connections can use a plan or package.

This panel displays if you enter YES for ENABLE/DISABLE CONNECTIONS? on the Bind or Rebind Package or Plan panels. For the Bind or Rebind Package panel, the REMOTE option does not display as it does in the following panel.

```
DSNEBP13
          SYSTEM CONNECTION TYPES FOR BIND ...
                                                             SSID: DSN
COMMAND ===>
Select system connection types to be Enabled/Disabled:
 1 ENABLE ALL CONNECTION TYPES? ===>
                                         (* to enable all types)
 2 ENABLE/DISABLE SPECIFIC CONNECTION TYPES ===>
                                                     (E/D)
    BATCH ..... ===>
                                         SPECIFY CONNECTION NAMES?
     DB2CALL .... ===>
                           (Y/N)
    RRSAF ..... ===>
                           (Y/N)
    CICS ..... ===>
                           (Y/N)
                                         ==> N (Y/N)
            ..... ===>
    IMS
                           (Y/N)
     DLIBATCH .... ===>
                                         ===> N
                           (Y/N)
                                                 (Y/N)
    IMSBMP .... ===>
                           (Y/N)
                                         ===> N
                                                 (Y/N)
                           (Y/N)
                                         ===> N
                                                 (Y/N)
     REMOTE ..... ===>
                           (Y/N)
```

Figure 56. The System Connection Types panel

To enable or disable connection types (that is, allow or prevent the connection from running the package or plan), enter the following information.

1 ENABLE ALL CONNECTION TYPES?

Lets you enter an asterisk (*) to enable all connections. After that entry, you can ignore the rest of the panel.

2 ENABLE/DISABLE SPECIFIC CONNECTION TYPES

Lets you specify a list of types to enable or disable; you cannot enable some types and disable others in the same operation. If you list types to enable, enter E; that disables all other connection types. If you list types to disable, enter D; that enables all other connection types.

For each connection type that follows, enter Y (yes) if it is on your list, N (no) if it is not. The connection types are:

- **BATCH** for a TSO connection
- DB2CALL for a CAF connection
- RRSAF for an RRSAF connection
- CICS for a CICS connection
- IMS for all IMS connections: DLIBATCH, IMSBMP, and IMSMPP
- **DLIBATCH** for a DL/I Batch Support Facility connection
- **IMSBMP** for an IMS connection to a BMP region
- IMSMPP for an IMS connection to an MPP or IFP region
- REMOTE for all remote locations or no remote locations

For each connection type that has a second arrow, under SPECIFY CONNECTION NAMES?, enter Y if you want to list specific connection names of that type. Leave N (the default) if you do not. If you use Y in any of those fields, you see another panel on which you can enter the connection names.

If you use the DISPLAY command under TSO on this panel, you can determine what you have currently defined as "enabled" or "disabled" in your ISPF DSNSPFT library (member DSNCONNS). The information does not reflect the current state of the Db2 Catalog.

If you type DISPLAY ENABLED on the command line, you get the connection names that are currently enabled for your TSO connection types. For example:

```
Display OF ALL connection name(s) to be ENABLED
       CONNECTION
                            SUBSYSTEM
       CICS1
                            ENABLED
       CICS2
                            ENABLED
       CICS3
                            ENABLED
       CTCS4
                            ENABLED
       DI T1
                            ENABLED
       DLI2
                            ENABLED
       DLI3
                            ENABLED
```

DLI4	ENABLED	
DLI5	ENABLED

Panels for entering lists of values

Some fields in DB2I panels are associated with command keywords that accept multiple values. Those fields lead you to a list panel that lets you enter or modify multiple values.

BIND and REBIND options for packages, plans, and services (Db2 Commands)

Panels for entering lists of values

Some fields in DB2I panels are associated with command keywords that accept multiple values. Those fields lead you to a list panel that lets you enter or modify multiple values.

A list panel looks like an ISPF edit session and lets you scroll and use a limited set of commands.

The format of each list panel varies, depending on the content and purpose for the panel. The following figure shows a generic sample of a list panel:

```
panelid Specific subcommand function SSID: DSN

COMMAND ===>_ SCROLL ===>

Subcommand operand values:

CMD

""""

value ...

""""

""""

""""
```

Figure 57. Generic example of a DB2I list panel

All of the list panels let you enter limited commands in two places:

- On the system command line, prefixed by ====>
- In a special command area, identified by """"

On the system command line, you can use:

END

Saves all entered variables, exits the table, and continues to process.

CANCEL

Discards all entered variables, terminates processing, and returns to the previous panel.

SAVE

Saves all entered variables and remains in the table.

In the special command area, you can use:

Inn

Insert nn lines after this one.

Dnn

Delete this and the following lines for *nn* lines.

Rnn

Repeat this line *nn* number of times.

The default for nn is 1.

When you finish with a list panel, specify END to same the current panel values and continue processing.

Program Preparation: Compile, Link, and Run panel

The Compile, Link, and Run panel lets you perform the last two steps in the program preparation process (compile and link-edit). This panel also lets you perform the PL/I MACRO PHASE for programs that require this option.

For TSO programs, the panel also lets you run programs.

```
DSNEPPO2 PROGRAM PREP: COMPILE, PRELINK, LINK, AND RUN

COMMAND ===>_

Enter compiler or assembler options:

1 INCLUDE LIBRARY ===> SRCLIB.DATA

2 INCLUDE LIBRARY ===> NUM, OPTIMIZE, ADV

Enter linkage editor options:

4 INCLUDE LIBRARY ===> SAMPLIB.COBOL

5 INCLUDE LIBRARY ===>
6 INCLUDE LIBRARY ===>
7 LOAD LIBRARY ===> RUNLIB.LOAD
8 PRELINK OPTIONS ===>
9 LINK OPTIONS... ===>
Enter run options:
10 PARAMETERS ... ===> D01, D02, D03/
11 SYSIN DATA SET ===> TERM
12 SYSPRINT DS ... ===> TERM
```

Figure 58. The Program Preparation: Compile, Link, and Run panel

1,2 INCLUDE LIBRARY

Lets you specify up to two libraries containing members for the compiler to include. The members can also be output from DCLGEN. You can leave these fields blank. There is no default.

3 OPTIONS

Lets you specify compiler, assembler, or PL/I macro processor options. You can also enter a list of compiler or assembler options by separating entries with commas, blanks, or both. You can leave these fields blank. There is no default.

4,5,6 INCLUDE LIBRARY

Lets you enter the names of up to three libraries containing members for the linkage editor to include. You can leave these fields blank. There is no default.

7 LOAD LIBRARY

Lets you specify the name of the library to hold the load module. The default value is RUNLIB.LOAD.

If the load library specified is a PDS, and the input data set is a PDS, the member name specified in INPUT DATA SET NAME field of the Program Preparation panel is the load module name. If the input data set is sequential, the second qualifier of the input data set is the load module name.

You must complete this field if you request LINK or RUN on the Program Preparation panel.

8 PRELINK OPTIONS

Lets you enter a list of prelinker options. Separate items in the list with commas, blanks, or both. You can leave this field blank. There is no default.

The prelink utility applies only to programs using C, C++, and Enterprise COBOL for z/OS.

9 LINK OPTIONS

Lets you enter a list of link-edit options. Separate items in the list with commas, blanks, or both.

To prepare a program that uses 31-bit addressing and runs above the 16-megabyte line, specify the following link-edit options: AMODE=31, RMODE=ANY.

10 PARAMETERS

Lets you specify a list of parameters you want to pass either to your host language run time processor, or to your application. Separate items in the list with commas, blanks, or both. You can leave this field blank.

If you are preparing an IMS or CICS program, you must leave this field blank; you cannot use DB2I to run IMS and CICS programs.

Use a slash (/) to separate the options for your run time processor from those for your program.

• For PL/I and Fortran, run time processor parameters must appear on the left of the slash, and the application parameters must appear on the right.

```
run time processor parameters / application parameters
```

- For COBOL, reverse this order. run time processor parameters must appear on the right of the slash, and the application parameters must appear on the left.
- For assembler and C, there is no supported run time environment, and you need not use a slash to pass parameters to the application program.

11 SYSIN DATA SET

Lets you specify the name of a SYSIN (or in Fortran, FT05F001) data set for your application program, if it needs one. If you do not enclose the data set name in apostrophes, a standard TSO prefix (user ID) and suffix is added to it. The default for this field is TERM.

If you are preparing an IMS or CICS program, you must leave this field blank; you cannot use DB2I to run IMS and CICS programs.

12 SYSPRINT DS

Lets you specify the names of a SYSPRINT (or in Fortran, FT06F001) data set for your application program, if it needs one. If you do not enclose the data set name in apostrophes, a standard TSO prefix (user ID) and suffix is added to it. The default for this field is TERM.

If you are preparing an IMS or CICS program, you must leave this field blank; you cannot use DB2I to run IMS and CICS programs.

Your application could need other data sets besides SYSIN and SYSPRINT. If so, remember to catalog and allocate them before you run your program.

When you press ENTER after entering values in this panel, Db2 compiles and link-edits the application. If you specified in the Db2 Program Preparation panel that you want to run the application, Db2 also runs the application.

The DB2I primary option menu (Introduction to Db2 for z/OS)

Bind/Rebind/Free Selection panel

The Bind/Rebind/Free selection panel lets choose whether to bind, rebind, or free plans and packages.

DSNEBP01 COMMAND ===>_	BIND/REBIND/FREE	SSID: DSN		
Select one of the fol	Select one of the following and press ENTER:			
1 BIND PLAN	(Add or replace an app	lication plan)		
2 REBIND PLAN	(Rebind existing appli	cation plan or plans)		
3 FREE PLAN	(Erase application plan	n or plans)		
4 BIND PACKAGE	(Add or replace a pack	age)		
5 REBIND PACKAGE	(Rebind existing packa	ge or packages)		
6 REBIND TRIGGER PA	CKAGE (Rebind existing packa	ge or packages)		
7 FREE PACKAGE (Erase a package or packages)			

Figure 59. The Bind/Rebind/Free selection panel

This panel lets you select the process you need.

1 BIND PLAN

Lets you build an application plan. You must have an application plan to allocate Db2 resources and support SQL requests during run time. If you select this option, the Bind Plan panel displays. For more information, see "Bind Plan panel" on page 932.

2 REBIND PLAN

Lets you rebuild an application plan when changes to it affect the plan but the SQL statements in the program are the same. For example, you should rebind when you change authorizations, create a new index that the plan uses, or use RUNSTATS. If you select this option, the Rebind Plan panel displays. For more information, see "Rebind Plan panel" on page 948.

3 FREE PLAN

Lets you delete plans from Db2. If you select this option, the Free Plan panel displays. For more information, see "Free Plan panel" on page 951.

4 BIND PACKAGE

Lets you build a package. If you select this option, the Bind Package panel displays. For more information, see "Bind Package panel" on page 930.

5 REBIND PACKAGE

Lets you rebuild a package when changes to it affect the package but the SQL statements in the program are the same. For example, you should rebind when you change authorizations, create a new index that the package uses, or use RUNSTATS. If you select this option, the Rebind Package panel displays. For more information, see "Rebind Package panel" on page 945.

6 REBIND TRIGGER PACKAGE

Lets you rebuild a trigger package when you need to change options for the package. When you execute CREATE TRIGGER, Db2 binds a trigger package using a set of default options. You can use REBIND TRIGGER PACKAGE to change those options. For example, you can use REBIND TRIGGER PACKAGE to change the isolation level for the trigger package. If you select this option, the Rebind Trigger Package panel displays. For more information, see "Rebind Trigger Package panel" on page 947.

7 FREE PACKAGE

Lets you delete a specific version of a package, all versions of a package, or whole collections of packages from Db2. If you select this option, the Free Package panel displays. For more information, see "Free Package panel" on page 950.

Rebind Package panel

The Rebind Package panel is the first of two panels that you use to rebind a package. This panel lets you specify options for rebinding the package.

The following figure shows the rebind package options.

```
DSNEBP08
                            REBIND PACKAGE
                                                                    SSID: DSN
 COMMAND ===>_
  1 Rebind all local packages ===>
                                                    (* to rebind all packages)
 or
   Enter package name(s) to be rebound: LOCATION NAME ..... ===>
                                                              (Defaults to local)
  3 COLLECTION-ID ..... ===>
                                                          > (Required)
 4 PACKAGE-ID ... ===>
5 VERSION-ID ... ===>
                                                             (Required)
                                                      (*, Blank, (), or version-id)
  6 ADDITIONAL PACKAGES? ..... ===>
                                                     (Yes to include more packages)
 Enter options as desired ..... ===>
7 CHANGE CURRENT DEFAULTS?... ===>
                                                     (NO or YES)
                                                   > (SAME, new OWNER)
> (SAME, new QUALIFIER)
  8 OWNER OF PACKAGE (AUTHID).. ===>
     QUALIFIER ..
 10 ENABLE/DISABLE CONNECTIONS? ===>
                                                      (NO or YES)
 11 INCLUDE PATH? ..... ===>
                                                      (SAME, DEFAULT, or YES)
```

Figure 60. The Rebind Package panel

This panel lets you choose options for rebinding a package.

1 Rebind all local packages

Lets you rebind all packages on the local DBMS. To do so, place an asterisk (*) in this field; otherwise, leave it blank.

2 LOCATION NAME

Lets you specify where to bind the package. If you specify a location name, you should use 1–16 characters, and you must have defined it in the catalog table SYSIBM.LOCATIONS.

3 COLLECTION-ID

Lets you specify the collection of the package to rebind. You must specify a collection ID from 1 to 128 characters, or an asterisk (*) to rebind all collections in the local Db2 system. You cannot use the asterisk to rebind a remote collection. This field is scrollable.

4 PACKAGE-ID

Lets you specify the name of the package to rebind. You must specify a package ID of 1–8 characters, or an asterisk (*) to rebind all packages in the specified collections in the local Db2 system. You cannot use the asterisk to rebind a remote package.

The field is scrollable, and the maximum field length is 128.

5 VERSION-ID

Lets you specify the version of the package to rebind. You must specify a version ID of 1–64 characters, or an asterisk (*) to rebind all versions in the specified collections and packages in the local Db2 system. You cannot use the asterisk to rebind a remote version.

6 ADDITIONAL PACKAGES?

Lets you indicate whether to name more packages to rebind. Use YES to specify more packages on an additional panel, described on "Panels for entering lists of values" on page 941. The default is NO.

7 CHANGE CURRENT DEFAULTS?

Lets you indicate whether to change the binding defaults. Use:

NO (default) to retain the binding defaults of the previous package.

YES to change the binding defaults from the previous package. For information about the defaults for binding packages, see "Defaults for Bind Package and Defaults for Rebind Package panels" on page 935.

8 OWNER OF PACKAGE (AUTHID)

Lets you change the authorization ID for the package owner. The owner must have the required privileges to execute the SQL statements in the package. The default is the existing package owner.

The field is scrollable, and the maximum field length is 128.

9 QUALIFIER

Lets you specify the default schema for all unqualified table names, views, indexes, and aliases in the package. You can specify a schema name of 1–8 characters, which must conform to the rules for the SQL short identifier. The default is the existing qualifier name.

The field is scrollable, and the maximum field length is 128.

10 ENABLE/DISABLE CONNECTIONS?

Lets you specify whether you want to enable and disable system connections types to use with this package. This is valid only if the LOCATION NAME field names your local Db2 system.

Placing YES in this field displays a panel (shown in Figure 56 on page 940) that lets you specify whether various system connections are valid for this application.

The default is the values used for the previous package.

11 INCLUDE PATH?

Indicates which one of the following actions you want to perform:

- Request that Db2 uses the same schema names as when the package was bound for resolving unqualified distinct type, user-defined function, and stored procedure names in SQL statements. Choose SAME to perform this action. This is the default.
- Supply a list of schema names that Db2 searches when it resolves unqualified distinct type, userdefined function, and stored procedure names in SQL statements. Choose YES to perform this action.
- Request that Db2 resets the SQL path to SYSIBM, SYSFUN, SYSPROC, and the package owner.
 Choose DEFAULT to perform this action.

If you specify YES, Db2 displays a panel in which you specify the names of schemas for Db2 to search.

```

Figure 61. The Rebind Trigger Package panel

This panel lets you choose options for rebinding a trigger package.

1 Rebind all trigger packages

Lets you rebind all packages on the local DBMS. To do so, place an asterisk (*) in this field; otherwise, leave it blank.

2 LOCATION NAME

Lets you specify where to bind the trigger package. If you specify a location name, you should use of 1–16 characters, and you must have defined it in the catalog table SYSIBM.LOCATIONS.

3 COLLECTION-ID (SCHEMA NAME)

Lets you specify the collection of the trigger package to rebind. You must specify a collection ID of 1–128 characters, or an asterisk (*) to rebind all collections in the local Db2 system. You cannot use the asterisk to rebind a remote collection. This field is scrollable.

4 PACKAGE-ID

Lets you specify the name of the trigger package to rebind. You must specify a package ID from 1 to 128 characters, or an asterisk (*) to rebind all trigger packages in the specified collections in the local Db2 system. You cannot use the asterisk to rebind a remote trigger package. This field is scrollable.

5 ISOLATION LEVEL

Lets you specify how far to isolate your application from the effects of other running applications. The default is the value used for the old trigger package.

6 RESOURCE RELEASE TIME

Lets you specify COMMIT or DEALLOCATE to tell when to release locks on resources. The default is that used for the old trigger package.

7 EXPLAIN PATH SELECTION

Lets you specify YES or NO for whether to obtain EXPLAIN information about how SQL statements in the package execute. The default is the value used for the old trigger package.

The bind process inserts information into the table *owner*.PLAN_TABLE, where *owner* is the authorization ID of the plan or package owner. If you defined *owner*.DSN_STATEMNT_TABLE, Db2 also inserts information about the cost of statement execution into that table. If you specify YES in

this field and BIND in the VALIDATION TIME field, and if you do not correctly define PLAN_TABLE, the bind fails.

8 DATA CURRENCY

Lets you specify YES or NO for whether you need data currency for ambiguous cursors opened at remote locations. The default is the value used for the old trigger package.

Data is current if the data within the host structure is identical to the data within the base table. Data is always current for local processing.

9 IMMEDIATE WRITE OPTION

Specifies when Db2 writes the changes for updated group buffer pool-dependent pages. This field applies only to a data sharing environment. The values that you can specify are:

SAME

Choose the value of IMMEDIATE WRITE that you specified when you bound the trigger package. SAME is the default.

NO

Write the changes at or before phase 1 of the commit process. If the transaction is rolled back later, write the additional changes that are caused by the rollback at the end of the abort process.

PH1 is equivalent to NO.

YES

Write the changes immediately after group buffer pool-dependent pages are updated.

10 PLAN MANAGEMENT

Specifies the PLANMGMT option to use for rebinding the trigger. DEFAULT means to take the default setting for this option when rebinding for the old trigger package.

11 ACCESS PATH REUSE

Specifies the APREUSE option to use for rebinding the trigger. DEFAULT means to take the default setting for this option when rebinding for the old trigger package.

12 ACCESS PATH COMPARISON

Specifies the APCOMPARE option to use for rebinding the trigger. DEFAULT means to take the default setting for this option when rebinding for the old trigger package.

13 ACCESS PATH RETAIN DUPS

Specifies the APRETAINDUP option to use for rebinding the trigger. DEFAULT means to take the default setting for this option when rebinding for the old trigger package.

14 SYSTEM_TIME SENSITIVE

Specifies the SYSTIMESENSITIVE option to use for rebinding the trigger. SAME means to take the previous setting for this option when rebinding the old trigger package.

15 BUSINESS TIME SENSITIVE

Specifies the BUSTIMESENSITIVE option to use for rebinding the trigger. SAME means to take the previous setting for this option when rebinding the old trigger package.

16 ARCHIVE SENSITIVE

Specifies the ARCHIVESENSITIVE option to use for rebinding the trigger. SAME means to take the previous setting for this option when rebinding the old trigger package.

17 APPLICATION COMPATIBILITY

Specifies the APPLCOMPAT option to use for rebinding the trigger. SAME means to take the previous setting for this option when rebinding the old trigger package.

BIND and REBIND options for packages, plans, and services (Db2 Commands)

Rebind Plan panel

The Rebind Plan panel is the first of two panels that you use to rebind a plan. This panel lets you specify options for rebinding the plan.

The following figure shows the rebind plan options.

```
DSNEBP03
                                  REBIND PLAN
                                                                                  SSID: DSN
 COMMAND ===>_
 Enter plan name(s) to be rebound:
  1 PLAN NAME ..... ===>
2 ADDITIONAL PLANS? .... ===> NO
                                                                (* to rebind all plans)
                                                               (Yes to include more plans)
 Enter options as desired:
   3 CHANGE CURRENT DEFAULTS?... ===> NO
                                                               (NO or YES)
                                                           > (SAME, new OWNER)
> (SAME, new QUALIFIER)
(SAME, or value 0-4096)
  4 OWNER OF PLAN (AUTHID).... ===> SAME
  5 QUALIFIER ... ==> SAME
6 CACHESIZE ... ==> SAME
  7 ENABLE/DISABLE CONNECTIONS? ===> NO
8 INCLUDE PACKAGE LIST?.... ===> SAME
                                                                (NO or YES)
                                                               (SAME, NO, or YES)
 9 CURRENT SERVER .... ===>
10 INCLUDE PATH? .... ===> SAME
                                                                             (Location name)
                                                               (SAME, DEFAULT, or YES)
```

Figure 62. The Rebind Plan panel

This panel lets you specify options for rebinding your plan.

1 PLAN NAME

Lets you name the application plan to rebind. You can specify a name of 1–8 characters, and the first character must be alphabetic. Do not begin the name with DSN, because it could create name conflicts with Db2. If there are no errors, the bind process prepares the plan and enters its description into the EXPLAIN table.

If you leave this field blank, the bind process occurs but produces no plan.

2 ADDITIONAL PLANS?

Lets you indicate whether to name more plans to rebind. Use YES to specify more plans on an additional panel, described at "Panels for entering lists of values" on page 941. The default is NO.

3 CHANGE CURRENT DEFAULTS?

Lets you indicate whether to change the binding defaults. Use:

NO (default) to retain the binding defaults of the previous plan.

YES to change the binding defaults from the previous plan.

4 OWNER OF PLAN (AUTHID)

Lets you change the authorization ID for the plan owner. The owner must have the required privileges to execute the SQL statements in the plan. The default is the existing plan owner.

The field is scrollable, and the maximum field length is 128.

5 QUALIFIER

Lets you specify the default schema for all unqualified table names, views, indexes, and aliases in the plan. You can specify a schema name of 1–128 characters, which must conform to the rules for the SQL identifier. The default is the authorization ID. This field is scrollable.

6 CACHESIZE

Lets you specify the size (in bytes) of the authorization cache. Valid values are in the range 0 to 4096. Values that are not multiples of 256 round up to the next highest multiple of 256. A value of 0 indicates that Db2 does not use an authorization cache. The default is the cache size specified for the previous plan.

Each concurrent user of a plan requires 8 bytes of storage, with an additional 32 bytes for overhead.

7 ENABLE/DISABLE CONNECTIONS?

Lets you specify whether you want to enable and disable system connections types to use with this plan. This is valid only for rebinding on your local Db2 system.

Placing YES in this field displays a panel (shown in <u>Figure 56 on page 940</u>) that lets you specify whether various system connections are valid for this application.

The default is the values used for the previous plan.

8 INCLUDE PACKAGE LIST?

Lets you include a list of collections and packages in the plan. If you specify YES, a separate panel displays on which you must enter the package location, collection name, and package name for each package to include in the plan (see "Panels for entering lists of values" on page 941). This field can either add a package list to a plan that did not have one, or replace an existing package list.

You can specify a location name of 1–16 characters, a collection ID of 1–18 characters, and a package ID from 1 to 8 characters. Separate two or more package list parameters with a comma. If you specify a location name, it must be in the catalog table SYSIBM.LOCATIONS. The default location is the package list used for the previous plan.

9 CURRENT SERVER

Lets you specify the initial server to receive and process SQL statements in this plan. You can specify a name of 1–16 characters, which you must previously define in the catalog table SYSIBM.LOCATIONS.

If you specify a remote server, Db2 connects to that server when the first SQL statement executes. The default is the name of the local Db2 subsystem.

10 INCLUDE PATH?

Indicates which one of the following actions you want to perform:

- Request that Db2 uses the same schema names as when the plan was bound for resolving unqualified distinct type, user-defined function, and stored procedure names in SQL statements. Choose SAME to perform this action. This is the default.
- Supply a list of schema names that Db2 searches when it resolves unqualified distinct type, userdefined function, and stored procedure names in SQL statements. Choose YES to perform this action.
- Request that Db2 resets the SQL path to SYSIBM, SYSFUN, SYSPROC, and the plan owner. Choose DEFAULT to perform this action.

If you specify YES, Db2 displays a panel in which you specify the names of schemas for Db2 to search.

Defaults for Bind Plan and Defaults for Rebind Plan panels

These DB2I panels let you change your defaults for BIND PLAN and REBIND PLAN options.

BIND and REBIND options for packages, plans, and services (Db2 Commands)

Free Package panel

The DB2I Free Package panel is the first of two panels through which you can specify options for freeing an application package.

The following figure shows the free package options.

```
DSNFRP18
                           FREE PACKAGE
                                                                SSID: DSN
COMMAND ===>_
 1 Free ALL packages ..... ===>
                                            (* to free authorized packages)
or
     Enter package name(s) to be freed:
     LOCATION NAME .... ===>
  2
                                                    (Defaults to local)
 3 COLLECTION-ID ..... ===>
                                                     > (Required)
                                           >(* to free all packages)
    PACKAGE-ID ..... ===>
    VERSION-ID ..... ===>
                                            (*, Blank, (), or version-id)
(Yes to include more packages)
   ADDITIONAL PACKAGES?.... ===>
PLAN MANAGEMENT SCOPE .... ===> ALL
                                                   (ALL or INACTIVE)
```

Figure 63. The Free Package panel

This panel lets you specify options for erasing packages.

1 Free ALL packages

Lets you free (erase) all packages for which you have authorization or to which you have BINDAGENT authority. To do so, place an asterisk (*) in this field; otherwise, leave it blank.

2 LOCATION NAME

Lets you specify the location name of the DBMS to free the package. You can specify a name of 1–16 characters.

3 COLLECTION-ID

Lets you specify the collection from which you want to delete packages for which you own or have BINDAGENT privileges. You can specify a name of 1–128 characters, or an asterisk (*) to free all collections in the local Db2 system. You cannot use the asterisk to free a remote collection. This field is scrollable.

4 PACKAGE-ID

Lets you specify the name of the package to free. You can specify a name of 1–128 characters, or an asterisk (*) to free all packages in the specified collections in the local Db2 system. You cannot use the asterisk to free a remote package. The name you specify must be in the Db2 catalog tables. This field is scrollable.

5 VERSION-ID

Lets you specify the version of the package to free. You can specify an identifier 1–64 characters, or an asterisk (*) to free all versions of the specified collections and packages in the local Db2 system. You cannot use the asterisk to free a remote version.

6 ADDITIONAL PACKAGES?

Lets you indicate whether to name more packages to free. Use YES to specify more packages on an additional panel, described in "Panels for entering lists of values" on page 941. The default is NO.

7 PLAN MANAGEMENT SCOPE

Specifies whether Db2 frees all copies of the package, or only the inactive previous and original copies. This value corresponds to the PLANMGMTSCOPE option. The default value is ALL.

Free Plan panel

The DB2I Free Plan panel is the first of two panels through which you can specify options for freeing an application plan.

Figure 64 on page 951 shows the free plan options.

```
DSNEBP09 FREE PLAN SSID: DSN

COMMAND ===>_

Enter plan name(s) to be freed:

1 PLAN NAME ..... ===> (* to free all authorized plans)

2 ADDITIONAL PLANS? ... ===> (Yes to include more plans)
```

Figure 64. The Free Plan panel

This panel lets you specify options for freeing plans.

1 PLAN NAME

Lets you name the application plan to delete from Db2. Use an asterisk to free all plans for which you have BIND authority. You can specify a name of 1–8 characters, and the first character must be alphabetic.

If there are errors, the free process terminates for that plan and continues with the next plan.

2 ADDITIONAL PLANS?

Lets you indicate whether to name more plans to free. Use YES to specify more plans on an additional panel, described in "Panels for entering lists of values" on page 941. The default is NO.

Chapter 10. Running an application on Db2 for z/OS

You can run your application after you have processed the SQL statements, compiled and link-edited the application, and bound the application.

About this task

At run time, Db2 verifies that the information in the application plan and its associated packages is consistent with the corresponding information in the Db2 catalog. If any destructive changes, such as DROP or REVOKE, occur (either to the data structures that your application accesses or to the binder's authority to access those data structures), Db2 automatically rebinds packages or the plan as needed.

Establishing a test environment: This topic describes how to design a test data structure and how to fill tables with test data.

CICSBefore you run an application, ensure that the following two conditions are met:

- The corresponding entries in the SNT and RACF control areas authorize your application to run.
- The program and its transaction code are defined in the CICS CSD.

The system administrator is responsible for these functions.

DSN command processor

The DSN command processor is a TSO command processor that runs in TSO foreground or under TSO in a JES-initiated batch environment.

It uses the TSO attachment facility to access Db2. The DSN command processor provides an alternative method for running programs that access Db2 in a TSO environment.

When you run an application by using the DSN command processor, that application can run in a trusted connection if Db2 finds a matching trusted context.

You can use the DSN command processor implicitly during program development for functions such as:

- Using the declarations generator (DCLGEN)
- Running the BIND, REBIND, and FREE subcommands on Db2 plans and packages for your program
- · Using SPUFI (SQL Processor Using File Input) to test some of the SQL functions in the program

The DSN command processor runs with the TSO terminal monitor program (TMP). Because the TMP runs in either foreground or background, DSN applications run interactively or as batch jobs.

The DSN command processor can provide these services to a program that runs under it:

- Automatic connection to Db2
- Attention key support
- Translation of return codes into error messages

Limitations of the DSN command processor

When using DSN services, your application runs under the control of DSN. Because TSO executes the ATTACH macro to start DSN, and DSN executes the ATTACH macro to start a part of itself, your application gains control that is two task levels below TSO.

Because your program depends on DSN to manage your connection to Db2:

- If Db2 is down, your application cannot begin to run.
- If Db2 terminates, your application also terminates.
- An application can use only one plan.

If these limitations are too severe, consider having your application use the call attachment facility or Resource Recovery Services attachment facility. For more information about these attachment facilities, see "Call attachment facility" on page 40 and "Resource Recovery Services attachment facility" on page 70.

DSN return code processing

At the end of a DSN session, register 15 contains the highest value that is placed there by any DSN subcommand that is used in the session or by any program that is run by the RUN subcommand. Your run time environment might format that value as a return code. However, the value does not originate in DSN.

Command types for Db2 for z/OS (Db2 Commands)

DB2I Run panel

The DB2I Run panel lets you start an application program that can contain SQL statements.

You can reach the Run panel only through the DB2I Primary Options Menu. You can accomplish the same task using the "Program Preparation: Compile, Link, and Run" panel. You should use this panel if you have already prepared the program and simply want to run it. Figure 65 on page 954 shows the run options.

```
DSNERP01 RUN SSID: DSN

COMMAND ===>_

Enter the name of the program you want to run:

1 DATA SET NAME ===>
2 PASSWORD.... ===> (Required if data set is password protected)

Enter the following as desired:
3 PARAMETERS .. ===>
4 PLAN NAME ... ===> (Required if different from program name)
5 WHERE TO RUN ===> (FOREGROUND, BACKGROUND, or EDITJCL)
```

Figure 65. The Run panel

This panel lets you run existing application programs.

1 DATA SET NAME

Lets you specify the name of the partitioned data set that contains the load module. If the module is in a data set that the operating system can find, you can specify the member name only. There is no default.

If you do not enclose the name in apostrophes, a standard TSO prefix (user ID) and suffix (.LOAD) is added.

2 PASSWORD

Lets you specify the data set password if needed. The RUN processor does not check whether you need a password. If you do not enter a required password, your program does not run.

3 PARAMETERS

Lets you specify a list of parameters you want to pass either to your host language run time processor, or to your application. You should separate items in the list with commas, blanks, or both. You can leave this field blank.

Use a slash (/) to separate the options for your run time processor from those for your program.

• For PL/I and Fortran, run time processor parameters must appear on the left of the slash, and the application parameters must appear on the right.

```
run time processor parameters / application parameters
```

- For COBOL, reverse this order. run time processor parameters must appear on the right of the slash, and the application parameters must appear on the left.
- For assembler and C, there is no supported run time environment, and you need not use the slash to pass parameters to the application program.

4 PLAN NAME

Lets you specify the name of the plan to which the program is bound. The default is the member name of the program.

5 WHERE TO RUN

Lets you indicate whether to run in the foreground or background. You can also specify EDITJCL, in which case you are able to edit the job control statement before you run the program. Use:

FOREGROUND to immediately run the program in the foreground with the specified values. BACKGROUND to create and immediately submit to run a file containing a DSNH CLIST using the JOB control statement from either DB2I Defaults Panel 2 or your site's SUBMIT exit. The program runs in the background.

EDITJCL to create and open a file containing a DSNH CLIST in edit mode. You can then submit the CLIST or save it. The program runs in the background.

Running command processors

To run a command processor (CP), use the following commands from the TSO ready prompt or as a TSO TMP:

```
DSN SYSTEM (Db2-subsystem-name)
RUN CP PLAN (plan-name)
```

The RUN subcommand prompts you for more input. The end the DSN processor, use the END command.

Running a program in TSO foreground

Use the DB2I RUN panel to run a program in TSO foreground. Alternatively, you can issue the DSN command, followed by the RUN subcommand of DSN.

About this task

Before running the program, be sure to allocate any data sets that your program needs.

The following example shows how to start a TSO foreground application. The name of the application is SAMPPGM, and *ssid* is the system ID:

```
TSO Prompt:
               READY
               DSN SYSTEM(ssid)
Enter:
DSN Prompt:
               DSN
               RUN PROGRAM(SAMPPGM) -
Enter:
               PLAN(SAMPLAN)
               LIB(SAMPPROJ.SAMPLIB) -
               PARMS('/D01 D02 D03')
: (Here the program runs and might prompt you for input)
DSN Prompt:
               DSN
               END
Enter:
TSO Prompt:
               READY
```

This sequence also works in ISPF option 6. You can package this sequence in a CLIST. Db2 does not support access to multiple Db2 subsystems from a single address space.

The PARMS keyword of the RUN subcommand enables you to pass parameters to the run time processor and to your application program:

```
PARMS ('/D01, D02, D03')
```

The slash (/) indicates that you are passing parameters. For some languages, you pass parameters and run time options in the form PARMS('parameters/run time-options). An example of the PARMS keyword might be:

```
PARMS ('D01, D02, D03/')
```

Check your host language publications for the correct form of the PARMS option.

Running a Db2 REXX application

You run Db2 REXX applications under TSO. You do not precompile, compile, link-edit, or bind Db2 REXX applications before you run them.

About this task

In a batch environment, you might use statements like these to invoke application REXXPROG:

```
//RUNREXX EXEC PGM=IKJEFT01, DYNAMNBR=20
//SYSEXEC DD DISP=SHR, DSN=SYSADM.REXX.EXEC
//SYSTSPRT DD SYSOUT=*
//SYSTSIN DD *
%REXXPROG parameters
```

The SYSEXEC data set contains your REXX application, and the SYSTSIN data set contains the command that you use to invoke the application.

Invoking programs through the Interactive System Productivity Facility

You can use ISPF to invoke programs that connect to Db2 through the call attachment facility (CAF).

About this task

The ISPF/CAF sample connection manager programs (DSN8SPM and DSN8SCM) take advantage of the ISPLINK SELECT services, letting each routine make its own connection to Db2 and establish its own thread and plan.

With the same modular structure as in the previous example, using CAF is likely to provide greater efficiency by reducing the number of CLISTs. This does not mean, however, that any Db2 function executes more quickly.

Disadvantages: Compared to the modular structure using DSN, the structure using CAF is likely to require a more complex program, which in turn might require assembler language subroutines. For more information, see "Call attachment facility" on page 40.

ISPF

The Interactive System Productivity Facility (ISPF) helps you to construct and execute dialogs. Db2 includes a sample application that illustrates how to use ISPF through the call attachment facility (CAF).

Each scenario has advantages and disadvantages in terms of efficiency, ease of coding, ease of maintenance, and overall flexibility.

Using ISPF and the DSN command processor

There are some restrictions on how you make and break connections to Db2 in any structure. If you use the PGM option of ISPF SELECT, ISPF passes control to your load module by the LINK macro; if you use CMD, ISPF passes control by the ATTACH macro.

The DSN command processor permits only single task control block (TCB) connections. Take care not to change the TCB after the first SQL statement. ISPF SELECT services change the TCB if you started DSN

under ISPF, so you cannot use these to pass control from load module to load module. Instead, use LINK, XCTL, or LOAD.

The following figure shows the task control blocks that result from attaching the DSN command processor below TSO or ISPF.

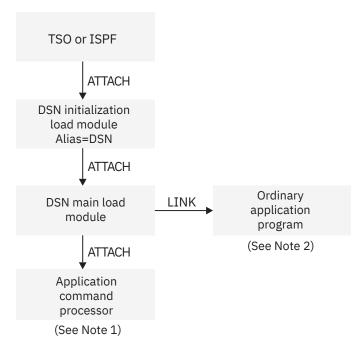

Figure 66. DSN task structure

Notes:

- 1. The RUN command with the CP option causes DSN to attach your program and create a new TCB.
- 2. The RUN command without the CP option causes DSN to link to your program.

If you are in ISPF and running under DSN, you can perform an ISPLINK to another program, which calls a CLIST. In turn, the CLIST uses DSN and another application. Each such use of DSN creates a separate unit of recovery (process or transaction) in Db2.

All such initiated DSN work units are unrelated, with regard to isolation (locking) and recovery (commit). It is possible to deadlock with yourself; that is, one unit (DSN) can request a serialized resource (a data page, for example) that another unit (DSN) holds incompatibly.

A COMMIT in one program applies only to that process. There is no facility for coordinating the processes.

Related concepts

Dynamic SQL and the ISPF/CAF application (Db2 Installation and Migration)

Printing options for the sample application listings (Db2 Installation and Migration)

Sample applications supplied with Db2 for z/OS

Db2 provides sample applications to help you with Db2 programming techniques and coding practices within each of the four environments: batch, TSO, IMS, and CICS. The sample applications contain various applications that might apply to managing a company.

DSN command processor

The DSN command processor is a TSO command processor that runs in TSO foreground or under TSO in a JES-initiated batch environment.

Invoking a single SQL program through ISPF and DSN

When you invoke a single SQL program through ISPF and DSN, you should first invoke ISPF, which displays the data and selection panels. When you select the program on the selection panel, ISPF calls a CLIST that runs the program.

About this task

A corresponding CLIST might contain:

```
DSN RUN PROGRAM(MYPROG) PLAN(MYPLAN)
END
```

The application has one large load module and one plan.

Disadvantages: For large programs of this type, you want a more modular design, making the plan more flexible and easier to maintain. If you have one large plan, you must rebind the entire plan whenever you change a module that includes SQL statements. To achieve a more modular construction when all parts of the program use SQL, consider using packages. See Chapter 9, "Preparing an application to run on Db2 for z/OS," on page 851. You cannot pass control to another load module that makes SQL calls by using ISPLINK; rather, you must use LINK, XCTL, or LOAD and BALR.

If you want to use ISPLINK, then call ISPF to run under DSN:

```
DSN
RUN PROGRAM(ISPF) PLAN(MYPLAN)
END
```

You then need to leave ISPF before you can start your application.

Furthermore, the entire program is dependent on Db2; if Db2 is not running, no part of the program can begin or continue to run.

Invoking multiple SQL programs through ISPF and DSN

You can break a large application into several different functions. Each function communicates through a common pool of shared variables, which is controlled by ISPF.

About this task

You might write some functions as separately compiled and loaded programs, others as EXECs or CLISTs. You can start any of those programs or functions through the ISPF SELECT service, and you can start that from a program, a CLIST, or an ISPF selection panel.

When you use the ISPF SELECT service, you can specify whether ISPF should create a new ISPF variable pool before calling the function. You can also break a large application into several independent parts, each with its own ISPF variable pool.

You can call different parts of the program in different ways. For example, you can use the PGM option of ISPF SELECT:

```
PGM(program-name) PARM(parameters)
```

Alternatively, you can use the CMD option:

```
CMD(command)
```

For a part that accesses Db2, the command can name a CLIST that starts DSN:

```
DSN RUN PROGRAM(PART1) PLAN(PLAN1) PARM(input from panel)
END
```

Breaking the application into separate modules makes it more flexible and easier to maintain. Furthermore, some of the application might be independent of Db2; portions of the application that do not call Db2 can run, even if Db2 is not running. A stopped Db2 database does not interfere with parts of the program that refer only to other databases.

Disadvantages: The modular application, on the whole, has to do more work. It calls several CLISTs, and each one must be located, loaded, parsed, interpreted, and executed. It also makes and breaks connections to Db2 more often than the single load module. As a result, you might lose some efficiency.

Loading and running a batch program

You can run a DL/I batch program by running module DSNMTV01, which loads your application, or by running the application program directly.

Procedure

To run a program using Db2, you need a Db2 plan.

The bind process creates the Db2 plan. Db2 first verifies whether the DL/I batch job step can connect to Db2. Then Db2 verifies whether the application program can access Db2 and enforce user identification of batch jobs accessing Db2.

The two ways to submit DL/I batch applications to Db2 are:

- DSNMTV01 can be specified as the application program name for the batch region. When this method is used, control is given to DSNMTV01. When the Db2 environment is established, control is passed to the application program.
- The application program name can be specified for the batch region. Control is given to DSNMTV01 directly to establish the external subsystem environment for Db2. When the Db2 environment is established, control is passed to the application program that is specified in the batch region. To accomplish this, in the batch region startup procedure in your application JCL, specify the following information:
 - MBR=application-name
 - SSM=DB2-subsystem-name

Examples

Example: Submitting a DL/I batch application without using DSNMTV01

The skeleton JCL in the following example illustrates a COBOL application program, IVP8CP22, that runs using Db2 DL/I batch support.

Example: Submitting a DL/I batch application using DSNMTV01

The following skeleton JCL example illustrates a COBOL application program, IVP8CP22, that runs using Db2 DL/I batch support.

- The first step uses the standard DLIBATCH IMS procedure.
- The second step shows how to use the DFSERA10 IMS program to print the contents of the DDOTV02 output data set.

```
//ISOCS04 JOB 3000, ISOIR, MSGLEVEL=(1,1), NOTIFY=ISOIR,
        MSGCLASS=T,CLASS=A
//JOBLIB DD DISP=SHR,
             DSN=prefix.SDSNLOAD
//* THE FOLLOWING STEP SUBMITS COBOL JOB IVP8CP22, WHICH UPDATES
//* BOTH DB2 AND DL/I DATABASES.
//* ********************************
//UPDTE
          EXEC DLIBATCH, DBRC=Y, LOGT=SYSDA, COND=EVEN,
// MBR=DSNMTV01,PSB=IVP8CA,BK0=Y,IRLM=N
//G.STEPLIB DD
            DD DSN=prefix.SDSNLOAD,DISP=SHR
           DD DSN=prefix.RUNLIB.LOAD,DISP=SHR
DD DSN=CEE.SCEERUN,DISP=SHR
DD DSN=IMS.PGMLIB,DISP=SHR
//G.DDOTV02 DD DSN=&TEMP1,DISP=(NEW,PASS,DELETE),
// SPACE=(TRK,(1,1),RLSE),UNIT=SYSDA,
          DCB=(RECFM=VB, BLKSIZE=4096, LRECL=4092)
//G.DDITV02 DD *
SSDQ,SYS1,DSNMIN10,,A,-,BATCH001,,IVP8CP22
//********************
//*** ALWAYS ATTEMPT TO PRINT OUT THE DDOTVO2 DATA SET ***
//*********************************
//STEP3 EXEC PGM=DFSERA10,COND=EVEN
//STEPLIB DD DSN=IMS.RESLIB,DISP=SHR
//SYSPRINT DD SYSOUT=A
//SYSUT1 DD DSNAME=&TEMP1,DISP=(OLD,DELETE)
//SYSUT1
//SYSIN DD *
CONTROL CNTL K=000,H=8000
OPTION PRINT
```

Related concepts

Input and output data sets for DL/I batch jobs

DL/I batch jobs require an input data set with DD name DDITV02 and an output data set with DD name DDOTV02.

Authorization for running a batch DL/I program

When a DL/I batch application tries to run the first SQL statement, Db2 checks whether the authorization ID has the EXECUTE privilege for the plan. Db2 uses the same ID for subsequent authorization checks and also identifies records from the accounting and performance traces.

The primary authorization ID is the value of the USER parameter on the job statement, if that is available. If that parameter is not available, the primary authorization ID is the TSO logon name if the job is submitted. Otherwise, the primary authorization ID is the IMS PSB name. In that case, however, the ID must not begin with the string "SYSADM" because this string causes the job to abnormally terminate. The batch job is rejected if you try to change the authorization ID in an exit routine.

Restarting a batch program

To restart a batch program that updates data, first run the IMS Batch Backout utility, followed by a restart job indicating the last successful checkpoint ID.

About this task

For guidelines on finding the last successful checkpoint, see <u>"Finding the DL/I batch checkpoint ID" on page 962.</u>

Examples

Example: Batch checkout with JCL

The skeleton JCL example that follows illustrates a batch backout for PSB=IVP8CA.

```
//ISOCS04 JOB 3000, ISOIR, MSGLEVEL=(1,1), NOTIFY=ISOIR,
        MSGCLASS=T,CLASS=A
//* BACKOUT TO LAST CHKPT.
                IF RC=0028 LOG WITH NO-UPDATE
,,
//*
//* - - -
---> DBRC ON
//STEPLIB DD DSN=IMS.RESLIB,DISP=SHR
//IMS DD DSN=IMS.PSBLIB,DISP=SHR
// DD DSN=IMS.DBDLIB,DISP=SHR
//* IMSLOGR DD data set is required
//* IEFRDER DD data set is required
//DFSVSAMP DD *
OPTIONS, LTWA=YES
2048,7
1024,7
//SYSIN DD DUMMY
```

Example: restarting a DL/I batch job with JCL

Operational procedures can restart a DL/I batch job step for an application program using IMS XRST and symbolic CHKP calls.

You cannot restart a BMP application program in a Db2 DL/I batch environment. The symbolic checkpoint records are not accessed, causing an IMS user abend U0102.

To restart a batch job that terminated abnormally or prematurely, find the checkpoint ID for the job on the z/OS system log or from the SYSOUT listing of the failing job. Before you restart the job step, place the checkpoint ID in the CKPTID=value option of the DLIBATCH procedure, submit the job. If the default connection name is used (that is, you did not specify the connection name option in the DDITV02 input data set), the job name of the restart job must be the same as the failing job. Refer to the following skeleton example, in which the last checkpoint ID value was IVP80002:

```
//* G.IEFRDER data set required
//* G.IMSLOGR data set required
//G.DDOTV02 DD DSN=&TEMP2, DISP=(NEW, PASS, DELETE),
// SPACE=(TRK, (1,1), RLSE), UNIT=SYSDA,
// DCB=(RECFM=VB, BLKSIZE=4096, LRECL=4092)
//G.DDITV02 DD
  DB2X,SYS1,DSNMIN10,,A,-,BATCH001,,IVP8CP22
//*** ALWAYS ATTEMPT TO PRINT OUT THE DDOTVO2 DATA SET
//*****************************
//STEP8
             EXEC PGM=DFSERA10, COND=EVEN
//STEPLIB DD
//SYSPRINT DD
                    DSN=IMS.RESLIB, DISP=SHR
                    SYSOUT=A
                    DSNAME=&TEMP2,DISP=(OLD,DELETE)
//SYSUT1
             חח
             DD
//SYSIN
CONTROL CNTL K=000, H=8000
OPTION
          PRINT
//
```

Finding the DL/I batch checkpoint ID

When an application program issues an IMS CHKP call, IMS sends the checkpoint ID to the z/OS console and the SYSOUT listing in message DFS0540I.

About this task

IMS also records the checkpoint ID in the type X'41' IMS log record. Symbolic CHKP calls also create one or more type X'18' records on the IMS log. XRST uses the type X'18' log records to reposition DL/I databases and return information to the application program.

During the commit process the application program checkpoint ID is passed to Db2. If a failure occurs during the commit process, creating an indoubt work unit, Db2 remembers the checkpoint ID. You can use the following techniques to find the last checkpoint ID:

- Look at the SYSOUT listing for the job step to find message DFS0540I, which contains the checkpoint IDs that are issued. Use the last listed checkpoint ID.
- Look at the z/OS console log to find message DFS0540I that contains the checkpoint ID that is issued for this batch program. Use the last listed checkpoint ID.
- Submit the IMS Batch Backout utility to back out the DL/I databases to the last (default) checkpoint ID.
 When the batch backout finishes, message DFS395I provides the last valid IMS checkpoint ID. Use this checkpoint ID on restart.
- When restarting Db2, issue the command -DISPLAY THREAD(*) TYPE(INDOUBT) to obtain a possible indoubt unit of work (connection name and checkpoint ID). If you restarted the application program from this checkpoint ID, the program could work because the checkpoint is recorded on the IMS log; however, the program could fail with an IMS user abend U102 because IMS did not finish logging the information before the failure. In that case, restart the application program from the previous checkpoint ID.

Db2 performs one of two actions automatically when restarted, if the failure occurs outside the indoubt period: it either backs out the work unit to the prior checkpoint, or it commits the data without any assistance. If the operator then issues the following command, no work unit information is displayed:

```
-DISPLAY THREAD(*) TYPE(INDOUBT)
```

Running stored procedures from the Db2 command line processor

As an alternative to calling a stored procedure from an application program, you can use the Db2 command line processor to invoke stored procedures.

Procedure

To run a stored procedure from the Db2 command line processor:

- 1. Invoke the Db2 command line processor and connect to the appropriate Db2 subsystem. For more information about how to perform these tasks, see The Db2 command line processor (Db2 Commands).
- 2. Specify the CALL statement in the form that is acceptable for the Db2 command line processor.

Related tasks

Calling a stored procedure from your application

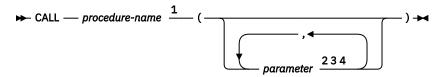

To run a stored procedure, you can either call it from a client program or invoke it from the Db2 command line processor.

Implementing Db2 stored procedures (Db2 Administration Guide)

Db2 command line processor CALL statement

Use the Db2 command line processor CALL statement to invoke stored procedures from the Db2 command line processor.

Use the following syntax for the Db2 command line processor CALL statement.

Notes:

- ¹ If you specify an unqualified stored procedure name, Db2 searches the schema list in the CURRENT PATH special register. Db2 searches this list for a stored procedure with the specified number of input and output parameters.
- ² Specify a question mark (?) as a placeholder for each output parameter.
- ³ For non-numeric, BLOB, or CLOB input parameters, enclose each value in single quotation marks ('). The exception is if the data is a BLOB or CLOB value that is to be read from a file. In that case, use the notation file://fully qualified file name.
- ⁴ Specify the input and output parameters in the order that they are specified in the signature for the stored procedure.

Examples

Example1

Assume that the TEST.DEPT_MEDIAN stored procedure was created with the following statement:

```
CREATE PROCEDURE TEST.DEPT_MEDIAN
(IN DEPTNUMBER SMALLINT, OUT MEDIANSALARY INT)
```

To invoke the stored procedure from the Db2 command line processor, you can specify the following CALL statement:

```
CALL TEST.DEPT_MEDIAN(51, ?)
```

Assume that the stored procedure returns a value of 25,000. The following information is displayed by the Db2 command line processor:

Example 2

Suppose that stored procedure TEST.BLOBSP is defined with one input parameter of type BLOB and one output parameter. You can invoke this stored procedure from the Db2 command line processor with the following statement:

```
CALL TEST.BLOBSP(file:///tmp/photo.bmp,?)
```

The Db2 command line processor reads the contents from /tmp/photo.bmp as the input parameter. Alternatively, you can invoke this stored procedure by specifying the input parameter in the CALL statement itself, as in the following example:

```
CALL TEST.BLOBSP('abcdef',?)
```

Example of running a batch Db2 application in TS0

Most application programs that are written for the batch environment run under the TSO Terminal Monitor Program (TMP) in background mode.

The following figure shows the JCL statements that you need in order to start such a job. The list that follows explains each statement.

- The JOB option identifies this as a job card. The USER option specifies the Db2 authorization ID of the user.
- The EXEC statement calls the TSO Terminal Monitor Program (TMP).
- The STEPLIB statement specifies the library in which the DSN Command Processor load modules and DSNHDECP or a user-specified application defaults module reside. It can also reference the libraries in which user applications, exit routines, and the customized DSNHDECP module reside. The customized DSNHDECP module is created during installation.
- Subsequent DD statements define additional files that are needed by your program.
- The DSN command connects the application to a particular Db2 subsystem.
- The RUN subcommand specifies the name of the application program to run.
- The PLAN keyword specifies plan name.
- The LIB keyword specifies the library that the application should access.
- The PARMS keyword passes parameters to the run time processor and the application program.
- END ends the DSN command processor.

Usage notes

- Keep DSN job steps short.
- **Recommendation:** Do not use DSN to call the EXEC command processor to run CLISTs that contain ISPEXEC statements; results are unpredictable.
- If your program abends or gives you a non-zero return code, DSN terminates.

• You can use a group attachment or subgroup attachment name instead of a specific *ssid* to connect to a member of a data sharing group.

Executing the terminal monitor program (TSO/E Customization)
DSN command (TSO) (Db2 Commands)

Example of calling applications in a command procedure

As an alternative to foreground or batch calls to an application, you can run a TSO or batch application by using a command procedure (CLIST).

The following CLIST calls a Db2 application program named MYPROG. *ssid* represents the Db2 subsystem name, or group attachment or subgroup attachment name.

IMS: To run a message-driven program

First, ensure that you can respond to the program's interactive requests for data and that you can recognize the expected results. Then, enter the transaction code that is associated with the program. Users of the transaction code must be authorized to run the program.

To run a non-message-driven program

CICSTo run a program

First, ensure that the corresponding entries in the SNT and RACF control areas allow run authorization for your application. The system administrator is responsible for these functions.

Submit the job control statements that are needed to run the program.

Also, be sure to define to CICS the transaction code that is assigned to your program and the program itself.

Make a new copy of the program

Issue the NEWCOPY command if CICS has not been reinitialized since the program was last bound and compiled.

Chapter 11. Testing and debugging an application program on Db2 for z/OS

Depending on the situation, testing your application program might involve setting up a test environment, testing SQL statements, debugging your programs, and reading output from the precompiler.

Related tasks

Modeling a production environment on a test subsystem (Db2 Performance)

Modeling your production system statistics in a test subsystem (Db2 Performance)

Designing a test data structure

When you test an application that accesses Db2 data, you should have Db2 data available for testing. To do this, you can create test tables and views.

About this task

- **Test views of existing tables:** If your application does not change a set of Db2 data and the data exists in one or more production-level tables, you might consider using a view of existing tables.
- **Test tables:** To create a test table, you need a database and table space. Talk with your DBA to make sure that a database and table spaces are available for your use.

If the data that you want to change already exists in a table, consider using the LIKE clause of CREATE TABLE. If you want others besides yourself to have ownership of a table for test purposes, you can specify a secondary ID as the owner of the table. You can do this with the SET CURRENT SQLID statement.

If your location has a separate Db2 system for testing, you can create the test tables and views on the test system. This information assumes that you do all testing on a separate system, and that the person who created the test tables and views has an authorization ID of TEST. The table names are TEST.EMP, TEST.PROJ and TEST.DEPT.

SET CURRENT SQLID statement (Db2 SQL)

Analyzing application data needs

To design tests of an application, you need to determine the type of data that the application uses and how the application accesses that data.

About this task

This information assumes that you do all testing on a separate system, and that the person who created the test tables and views has an authorization ID of TEST. The table names are TEST.EMP, TEST.PROJ and TEST.DEPT.

To design test tables and views, first analyze the data needs of your application.

Procedure

To analyze the data needs of your application:

1. List the data that your application accesses and describe how it accesses each data item. For example, suppose that you are testing an application that accesses the DSN8C10.EMP, DSN8C10.DEPT, and DSN8C10.PROJ tables. You might record the information about the data as shown in Table 153 on page 968.

Table 153. Description of the application data

Table or view name	Insert rows?	Delete rows?	Column name	Data type	Update access?
DSN8C10.EMP	No	No	EMPNO	CHAR(6)	No
			LASTNAME	VARCHAR(15)	No
			WORKDEPT	CHAR(3)	Yes
			PHONENO	CHAR(4)	Yes
			JOB	DECIMAL(3)	Yes
DSN8C10.DEPT	No	No	DEPTNO	CHAR(3)	No
			MGRNO	CHAR (6)	No
DSN8C10.PROJ	Yes	Yes	PROJNO	CHAR(6)	No
			DEPTNO	CHAR(3)	Yes
			RESPEMP	CHAR(6)	Yes
			PRSTAFF	DECIMAL(5,2)	Yes
			PRSTDATE	DECIMAL(6)	Yes
			PRENDATE	DECIMAL(6)	Yes

2. Determine the test tables and views that you need to test your application.

Create a test table on your list when either of the following conditions exists:

- The application modifies data in the table.
- You need to create a view that is based on a test table because your application modifies data in the view.

To continue the example, create these test tables:

• TEST.EMP, with the following format:

EMPNO	LASTNAME	WORKDEPT	PHONENO	JOB
:	:	:	:	:

• TEST.PROJ, with the same columns and format as DSN8C10.PROJ, because the application inserts rows into the DSN8C10.PROJ table.

To support the example, create a test view of the DSN8C10.DEPT table.

• TEST.DEPT view, with the following format:

DEPTNO	MGRNO
:	:

Because the application does not change any data in the DSN8C10.DEPT table, you can base the view on the table itself (rather than on a test table). However, a safer approach is to have a complete set of test tables and to test the program thoroughly using only test data.

Authorization for test tables and applications

Before you can create a table, you need to be authorized to create tables and to use the table space in which the table is to reside. You must also have authority to bind and run programs that you want to test.

Your DBA can grant you the necessary authorization to create and access tables and to bind and run programs.

If you intend to use existing tables and views (either directly or as the basis for a view), you need privileges to access those tables and views. Your DBA can grant those privileges.

To create a view, you must have authorization for each table and view on which you base the view. You then have the same privileges over the view that you have over the tables and views on which you based the view. Before trying the examples, have your DBA grant you the privileges to create new tables and views and to access existing tables. Obtain the names of tables and views that you are authorized to access (as well as the privileges you have for each table) from your DBA.

Example SQL statements to create a comprehensive test structure

You need to create a storage group, database, table space, and table to use as a test structure for your SQL application.

The following SQL statements show how to create a complete test structure to contain a small table named SPUFINUM. The test structure consists of:

- · A storage group named SPUFISG
- · A database named SPUFIDB
- A table space named SPUFITS in database SPUFIDB and using storage group SPUFISG
- · A table named SPUFINUM within the table space SPUFITS

```
CREATE STOGROUP SPUFISG
   VOLUMES (user-volume-number)
   VCAT DSNCAT;
CREATE DATABASE SPUFIDB;
CREATE TABLESPACE SPUFITS
   IN SPUFIDB
   USING STOGROUP SPUFISG ;
CREATE TABLE SPUFINUM
   ( XVAL CHAR(12) NOT NULL,
     ISFLOAT FLOAT,
     DEC30 DECIMAL(3,0),
     DEC31 DECIMAL(3,1),
     DEC32 DECIMAL(3,2),
     DEC33 DECIMAL(3,3),
     DEC10 DECIMAL(1,0),
     DEC11 DECIMAL(1,1)
     DEC150 DECIMAL(15,0),
     DEC151 DECIMAL(15,1)
     DEC1515 DECIMAL(15,15) )
   IN SPUFIDB. SPUFITS ;
```

Populating the test tables with data

To populate test tables, use SQL INSERT statements or the LOAD utility.

About this task

You can put test data into a table in several ways:

- INSERT ... VALUES (an SQL statement) puts one row into a table each time the statement executes.
- INSERT ... SELECT (an SQL statement) obtains data from an existing table (based on a SELECT clause) and puts it into the table that is identified in the INSERT statement.
- MERGE (an SQL statement) puts new data into a table and updates existing data.
- The LOAD utility obtains data from a sequential file (a non-Db2 file), formats it for a table, and puts it into a table.
- The Db2 sample UNLOAD program (DSNTIAUL) can unload data from a table or view and build control statements for the LOAD utility.
- The UNLOAD utility can unload data from a table and build control statements for the LOAD utility.
- Redirected recovery, the RECOVER utility with the FROM option, can recover data from a production table to a test table with no impact to the availability of the production data and applications. The production data can be recovered to the test object to a point in time or to the current state with transactional consistency. SQL or the UNLOAD utility can then be used on the data in the test table.

Methods for testing SQL statements

You can test your SQL statements by using SQL Processing Using File Input (SPUFI) or the Db2 command line processor.

Test with SPUFI:You can use SPUFI (an interface between ISPF and Db2) to test SQL statements in a TSO/ISPF environment. With SPUFI panels, you can put SQL statements into a data set that Db2 subsequently executes. The SPUFI Main panel has several functions that enable you to:

- Name an input data set to hold the SQL statements that are passed to Db2 for execution
- Name an output data set to contain the results of executing the SQL statements
- · Specify SPUFI processing options

Test with the Db2 command line processor: You can use the Db2 command line processor to test SQL statements from UNIX System Services on z/OS.

SQL statements that are executed under SPUFI or the Db2 command line processor operate on actual tables (in this case, the tables that you created for testing). Consequently, before you access Db2 data:

- Make sure that all tables and views that your SQL statements refer to exist.
- If the tables or views do not exist, create them (or have your database administrator create them). You can use SPUFI or the command line processor to issue the CREATE statements that are used to create the tables and views that you need for testing.

Related tasks

Executing SQL by using SPUFI

You can execute SQL statements dynamically in a TSO session by using the SPUFI (SQL processor using file input) facility.

Executing SQL by using SPUFI

You can execute SQL statements dynamically in a TSO session by using the SPUFI (SQL processor using file input) facility.

Before you begin

Before you use SPUFI, allocate an input data set to store the SQL statements that you want to execute, if such a data set does not already exist.

Before you begin this task, you can specify whether TSO message IDs are displayed by using the TSO PROFILE command. To view message IDs, type TSO PROFILE MSGID on the ISPF command line. To suppress message IDs, type TSO PROFILE NOMSGID.

These instructions assume that ISPF is available to you.

About this task

Important: Ensure that the TSO terminal CCSID matches the Db2 CCSID. If these CCSIDs do not match, data corruption can occur. If SPUFI issues the warning message DSNE345I, terminate your SPUFI session and notify the system administrator.

SPUFI can execute SQL statements that retrieve Unicode UTF-16 graphic data. However, SPUFI might not be able to display some characters, if those characters have no mapping in the target SBCS EBCDIC CCSID.

Procedure

To execute SOL by using SPUFI:

- 1. Open SPUFI and specify the initial options. To open SPUFI and specify initial options:
 - a) Select SPUFI from the DB2I Primary Option Menu as shown in <u>The DB2I primary option menu</u> (Introduction to Db2 for z/OS).
 - The SPUFI panel is displayed.
 - b) Specify the input data set name and output data set name.

 An example of a SPUFI panel in which an input data set and output data set have been specified is shown in the following figure.

```
DSNESP01
                                              SPUFI
                                                                              SSID: DSN
Enter the input data set name: (Can be sequential or partitioned)

1 DATA SET NAME.... ===> EXAMPLES(XMP1)
                                          (Enter if not cataloged)
  2 VOLUME SERIAL.... ===>
  3 DATA SET PASSWORD. ===>
                                          (Enter if password protected)
Enter the output data set name:
    4 DATA SET NAME.... ===> RESULT
                                          (Must be a sequential data set)
Specify processing options:
    5 CHANGE DEFAULTS... ===> Y
                                          (Y/N - Display SPUFI defaults panel?)
                                          (Y/N - Enter SQL statements?)
(Y/N - Execute SQL statements?)
  6 EDIT INPUT..... ===> Y
  7 EXECUTE..... ===> Y
  8 AUTOCOMMIT..... ===> Y
                                          (Y/N - Commit after successful run?)
  9 BROWSE OUTPUT.... ===> Y
                                          (Y/N - Browse output data set?)
For remote SQL processing:
10 CONNECT LOCATION ===>
 PRESS: ENTER to process
                                     END to exit
                                                          HELP for more information
```

Figure 67. The SPUFI panel filled in

- c) Specify new values in any of the other fields on the SPUFI panel. For more information about these fields, see "The SPUFI panel" on page 975.
- 2. Optional: Change the SPUFI defaults, as described in "Changing SPUFI defaults" on page 976.
- 3. Enter SQL statements in SPUFI.

If the input data set that you specified on the SPUFI panel already contains all of the SQL statements that you want to execute, you can bypass this editing step by specifying NO for the EDIT INPUT field on the SPUFI panel. To enter SQL statements by using SPUFI:

- a) If the EDIT panel is not already open, on the SPUFI panel, specify Y in the EDIT INPUT field and press ENTER. If the input data set that you specified is empty, an empty EDIT panel opens. Otherwise, if the input data set contained SQL statements, those SQL statements are displayed in an EDIT panel.
- b) On the EDIT panel, use the ISPF EDIT program to enter or edit any SQL statements that you want to execute. Move the cursor to the first blank input line, and enter the first part of an SQL statement. If the input data set that you specified on the SPUFI panel already contains all of the SQL statements that you want to execute, you can bypass this editing step by specifying NO for the EDIT INPUT field on the SPUFI panel.

You can enter the rest of the SQL statement on subsequent lines, as shown in the following figure:

Figure 68. The edit panel: After entering an SQL statement

Consider the following rules and recommendations when editing this input data set:

- Indent your lines and enter your statements on several lines to make your statements easier to read. Entering your statements on multiple lines does not change how your statements are processed.
- Do not put more than one SQL statement on a single line. If you do, the first statement executes, but Db2 ignores the other SQL statements on the same line. You can put more than one SQL statement in the input data set. Db2 executes the statements in the order in which you placed them in the data set.

• If the length of an SQL statement is greater than 71 bytes for an input data set with record length 79, or 72 bytes for an input data set with record length 80, you need to continue the SQL statement on additional lines of the SPUFI input data set. SPUFI concatenates the text on multiple lines without adding extra spaces at the end of any line. Therefore, if an SQL statement contains two values with a space between them, and the first value ends at the last allowed input position (71 or 72), you need to add an extra space on the next line before the second value.

For example, suppose that the record length of your SPUFI input data set is 80, so the maximum length of an input line is 72. Also suppose that the SQL statement that you wish to enter is 81 bytes long. Bytes 69 through 81 contain FROM MYTABLE;. If you split the SQL statement after FROM, the first line of the statement ends in column 72, so you need to include a space in column 1 of the next line, before MYTABLE;. Otherwise, when SPUFI concatenates the two lines, the result is FROMMYTABLE;. When SPUFI runs the SQL statement, the SQL statement fails with SQLCODE -104.

- End each SQL statement with the statement terminator that you specified on the CURRENT SPUFI DEFAULTS panel.
- Save the data set every 10 minutes or so by entering the SAVE command.
- c) Press the END PF key.

The data set is saved, and the SPUFI panel is displayed.

4. Process SQL statements with SPUFI.

You can use SPUFI to submit the SQL statements in a data set to Db2. To process SQL statements by using SPUFI:

- a) On the SPUFI panel, specify YES in the EXECUTE field.
- b) If you did not just finish using the EDIT panel to edit the input data set as described in "Entering SQL statements in SPUFI," specify NO In the EDIT INPUT field.
- c) Press Enter.

SPUFI passes the input data set to Db2 for processing. Db2 executes the SQL statement in the input data set and sends the output to the output data set.

The output data set opens.

Your SQL statement might take a long time to execute, depending on how large a table Db2 must search, or on how many rows Db2 must process. In this case, you can interrupt the processing by pressing the PA1 key. Then respond to the message that asks you if you really want to stop processing. This action cancels the executing SQL statement. Depending on how much of the input data set Db2 was able to process before you interrupted its processing, Db2 might not have opened the output data set yet, or the output data set might contain all or part of the results data that are produced so far.

Results

SQL statements that exceed resource limit thresholds

Your system administrator might use the Db2 resource limit facility (governor) to set time limits for processing SQL statements in SPUFI. Those limits can be error limits or warning limits.

If you execute an SQL statement through SPUFI that runs longer than this error time limit, SPUFI terminates processing of that SQL statement and all statements that follow in the SPUFI input data set. SPUFI displays a panel that lets you commit or roll back the previously uncommitted changes that you have made. That panel is shown in the following figure.

```
DSNESP04 SQL STATEMENT RESOURCE LIMIT EXCEEDED SSID: DSN

The following SQL statement has encountered an SQLCODE of -905 or -495:

Statement text

Your SQL statement has exceeded the resource utilization threshold set by your site administrator.

You must ROLLBACK or COMMIT all the changes made since the last COMMIT. SPUFI processing for the current input file will terminate immediately after the COMMIT or ROLLBACK is executed.

1 NEXT ACTION ===> (Enter COMMIT or ROLLBACK)

PRESS: ENTER to process HELP for more information
```

Figure 69. The resource limit facility error panel

If you execute an SQL statement through SPUFI that runs longer than the warning time limit for predictive governing, SPUFI displays the SQL STATEMENT RESOURCE LIMIT EXCEEDED panel. On this panel, you can tell Db2 to continue executing that statement, or stop processing that statement and continue to the next statement in the SPUFI input data set. That panel is shown in the following figure.

```
DSNESP05 SQL STATEMENT RESOURCE LIMIT EXCEEDED SSID: DSN

===>

The following SQL statement has encountered an SQLCODE of 495:

Statement text

You can now either CONTINUE executing this statement or BYPASS the execution of this statement. SPUFI processing for the current input file will continue after the CONTINUE or BYPASS processing is completed.

1 NEXT ACTION ===> (Enter CONTINUE or BYPASS)

PRESS: ENTER to process HELP for more information
```

Related information

Lesson 1.1: Querying data interactively (Introduction to Db2 for z/OS)

Content of a SPUFI input data set

A SPUFI input data set can contain SQL statements, comments, and SPUFI control statements.

You can put comments about SQL statements either on separate lines or on the same line. In either case, use two hyphens (--) to begin a comment. Specify any text other than #SET TERMINATOR or #SET TOLWARN after the comment marker. Db2 ignores everything else to the right of the two hyphens.

The SPUFI panel

The SPUFI panel is the first panel that you need to fill out to run the SPUFI application.

After you complete any fields on the SPUFI panel and press Enter, those settings are saved. When the SPUFI panel displays again, the data entry fields on the panel contain the values that you previously entered. You can specify data set names and processing options each time the SPUFI panel is displayed, as needed. Values that you do not change remain in effect.

The following descriptions explain the fields that are available on the SPUFI panel.

1,2,3 INPUT DATA SET NAME

Identify the input data set in fields 1 through 3. This data set contains one or more SQL statements that you want to execute. Allocate this data set before you use SPUFI, if one does not already exist. Consider the following rules:

- The name of the data set must conform to standard TSO naming conventions.
- The data set can be empty before you begin the session. You can then add the SQL statements by editing the data set from SPUFI.
- The data set can be either sequential or partitioned, but it must have the following DCB characteristics:
 - A record format (RECFM) of either F or FB.
 - A logical record length (LRECL) of either 79 or 80. Use 80 for any data set that the EXPORT command of QMF did not create.
- Data in the data set can begin in column 1. It can extend to column 71 if the logical record length is 79, and to column 72 if the logical record length is 80. SPUFI assumes that the last 8 bytes of each record are for sequence numbers.

If you use this panel a second time, the name of the data set you previously used displays in the field DATA SET NAME. To create a new member of an existing partitioned data set, change only the member name.

4 OUTPUT DATA SET NAME

Enter the name of a data set to receive the output of the SQL statement. You do not need to allocate the data set before you do this.

If the data set exists, the new output replaces its content. If the data set does not exist, Db2 allocates a data set on the device type specified on the CURRENT SPUFI DEFAULTS panel and then catalogs the new data set. The device must be a direct-access storage device, and you must be authorized to allocate space on that device.

Attributes required for the output data set are:

- · Organization: sequential
- · Record format: F, FB, FBA, V, VB, or VBA
- Record length: 80 to 32768 bytes, not less than the input data set

"Executing SQL by using SPUFI" on page 971 shows the simplest choice, entering **RESULT**. SPUFI allocates a data set named *userid*.RESULT and sends all output to that data set. If a data set named *userid*.RESULT already exists, SPUFI sends Db2 output to it, replacing all existing data.

5 CHANGE DEFAULTS

Enables you to change control values and characteristics of the output data set and format of your SPUFI session. If you specify **Y**(YES) you can look at the SPUFI defaults panel. See <u>"Changing SPUFI defaults" on page 976</u> for more information about the values you can specify and how they affect SPUFI processing and output characteristics. You do not need to change the SPUFI defaults for this example.

6 EDIT INPUT

To edit the input data set, leave Y(YES) on line 6. You can use the ISPF editor to create a new member of the input data set and enter SQL statements in it. (To process a data set that already contains a set

of SQL statements you want to execute immediately, enter **N** (NO). Specifying N bypasses the step 3 described in "Executing SQL by using SPUFI" on page 971.)

7 EXECUTE

To execute SQL statements contained in the input data set, leave Y(YES) on line 7.

SPUFI handles the SQL statements that can be dynamically prepared.

8 AUTOCOMMIT

To make changes to the Db2 data permanent, leave **Y**(YES) on line 8. Specifying **Y** makes SPUFI issue COMMIT if all statements execute successfully. If all statements do not execute successfully, SPUFI issues a ROLLBACK statement, which deletes changes already made to the file (back to the last commit point).

If you specify **N**, Db2 displays the SPUFI COMMIT OR ROLLBACK panel after it executes the SQL in your input data set. That panel prompts you to COMMIT, ROLLBACK, or DEFER any updates made by the SQL. If you enter DEFER, you neither commit nor roll back your changes.

9 BROWSE OUTPUT

To look at the results of your query, leave **Y**(YES) on line 9. SPUFI saves the results in the output data set. You can look at them at any time, until you delete or write over the data set.

10 CONNECT LOCATION

Specify the name of the database server, if applicable, to which you want to submit SQL statements. SPUFI then issues a type 2 CONNECT statement to this server.

SPUFI is a locally bound package. SQL statements in the input data set can process only if the CONNECT statement is successful. If the connect request fails, the output data set contains the resulting SQL return codes and error messages.

COMMIT statement (Db2 SQL)

ROLLBACK statement (Db2 SQL)

Changing SPUFI defaults

Before you execute SQL statements in SPUFI, you can change the default execution behavior, such as the SQL terminator and the isolation level.

About this task

SPUFI provides default values the first time that you use SPUFI for all options except the Db2 subsystem name. Any changes that you make to these values remain in effect until you change the values again.

Procedure

To change the SPUFI defaults:

- 1. On the SPUFI panel, specify YES in the CHANGE DEFAULTS field.
- 2. Press Enter.

The CURRENT SPUFI DEFAULTS panel opens. The following figure shows the initial default values.

```
DSNESP02
                           CURRENT SPUFI DEFAULTS
                                                                     SSID: DSN
Enter the following to control your SPUFI session:
1 SQL TERMINATOR .. ===> ;
2 ISOLATION LEVEL ===> RR
                                     (SQL Statement Terminator)
                                     (RR=Repeatable Read, CS=Cursor Stability)
                                      UR=Uncommitted Read)
 3 MAX SELECT LINES ===> 250
                                     (Maximum lines to be returned from a SELECT)
4 ALLOW SQL WARNINGS===> NO
5 CHANGE PLAN NAMES ===> NO
                                     (Continue fetching after SQL warning
                                     (Change the plan names used by SPUFI)
  SQL FORMAT ..... ===> SQL
                                     (SQL, SQLCOMNT, or SQLPL)
Output data set characteristics:
   SPACE UNIT ..... ===> TRK
                                     (TRK or CYL)
    PRIMARY SPACE ... ===> 5
                                     (Primary space allocation 1-999)
    SECONDARY SPACE . ===> 6
                                     (Secondary space allocation 0-999)
10 RECORD LENGTH ... ===> 4092
                                     (LRECL= logical record length)
    BLOCKSIZE ..... ===> 4096
                                     (Size of one block)
12 RECORD FORMAT.... ===> VB
                                     (RECFM= F, FB, FBA, V, VB, or VB)
13 DEVICE TYPE..... ===> SYSDA (Must be a DASD unit name)
Output format characteristics:
14 MAX NUMERIC FIELD ===> 33
                                     (Maximum width for numeric field)
15 MAX CHAR FIELD .. ===> 80 (Maximum width for character 16 COLUMN HEADING .. ===> NAMES (NAMES, LABELS, ANY, or BOTH)
                                     (Maximum width for character field)
                              END to exit
                                               HELP for more information
PRESS: ENTER to process
```

Figure 71. The SPUFI defaults panel

- 3. Specify any new values in the fields of this panel. All fields must contain a value.
- 4. Press Enter.

SPUFI saves your changes and one of the following panels or data sets open:

- The CURRENT SPUFI DEFAULTS PANEL 2 panel. This panel opens if you specified YES in the CHANGE PLAN NAMES field.
- EDIT panel. This panel opens if you specified YES in the EDIT INPUT field on the SPUFI panel.
- Output data set. This data set opens if you specified NO in the EDIT INPUT field on the SPUFI panel.
- SPUFI panel. This panel opens if you specified NO for all of the processing options on the SPUFI panel.

If you press the END key on the CURRENT SPUFI DEFAULTS panel, the SPUFI panel is displayed, and you lose all the changes that you made on the CURRENT SPUFI DEFAULTS panel.

5. If the CURRENT SPUFI DEFAULTS - PANEL 2 panel opens, specify values for the fields on that panel and press Enter. All fields must contain a value.

Important: If you specify an invalid or incorrect plan name, SPUFI might experience operational errors or your data might be contaminated.

SPUFI saves your changes and one of the following panels or data sets open:

- EDIT panel. This panel opens if you specified YES in the EDIT INPUT field on the SPUFI panel.
- Output data set. This data set opens if you specified NO in the EDIT INPUT field on the SPUFI panel.
- SPUFI panel. This panel opens if you specified NO for all of the processing options on the SPUFI panel.

Results

Next, continue with one of the following tasks:

- If you want to add SQL statements to the input data set or edit the SQL statements in the input data set, enter SQL statements in SPUFI.
- Otherwise if the input data set already contains the SQL statements that you want to execute, process SQL statements with SPUFI.

Related reference

CURRENT SPUFI DEFAULTS panel

Use the CURRENT SPUFI DEFAULTS panel to specify SPUFI default values.

CURRENT SPUFI DEFAULTS - PANEL 2 panel

Use the CURRENT SPUFI DEFAULTS - PANEL 2 panel to specify default plan name information.

CURRENT SPUFI DEFAULTS panel

Use the CURRENT SPUFI DEFAULTS panel to specify SPUFI default values.

The following descriptions explain the information on the CURRENT SPUFI DEFAULTS panel.

1 SOL TERMINATOR

Specify the character that you use to end each SQL statement. You can specify any character *except* the characters listed in the following table. A semicolon (;) is the default SQL terminator.

Table 154. Invalid special characters for the SQL terminator

Name	Character	Hexadecimal representation
blank		X'40'
comma	,	X'5E'
double quote	П	X'7F'
left parenthesis	(X'4D'
right parenthesis)	X'5D'
single quote	ı	X'7D'
underscore	_	X'6D'

Use a character other than a semicolon if you plan to execute a statement that contains embedded semicolons. For example, suppose you choose the character # as the statement terminator. Then a CREATE TRIGGER statement with embedded semicolons looks like the following statement:

```
CREATE TRIGGER NEW_HIRE
AFTER INSERT ON EMP
FOR EACH ROW MODE DB2SQL
BEGIN ATOMIC
UPDATE COMPANY_STATS SET NBEMP = NBEMP + 1;
END#
```

A CREATE PROCEDURE statement with embedded semicolons looks like the following statement:

```
CREATE PROCEDURE PROC1 (IN PARM1 INT, OUT SCODE INT)

LANGUAGE SQL

BEGIN

DECLARE SQLCODE INT;

DECLARE EXIT HANDLER FOR SQLEXCEPTION

SET SCODE = SQLCODE;

UPDATE TBL1 SET COL1 = PARM1;

END #
```

Be careful to choose a character for the SQL terminator that is not used within the statement.

You can also set or change the SQL terminator within a SPUFI input data set by using the --#SET TERMINATOR statement.

2 ISOLATION LEVEL

Specify the isolation level for your SQL statements.

3 MAX SELECT LINES

The maximum number of rows that a SELECT statement can return. To limit the number of rows retrieved, enter an integer greater than 0.

4 ALLOW SOL WARNINGS

Enter YES or NO to indicate whether SPUFI will continue to process an SQL statement after receiving SQL warnings:

YES

If a warning occurs when SPUFI executes an OPEN or FETCH for a SELECT statement, SPUFI continues to process the SELECT statement.

NO

If a warning occurs when SPUFI executes an OPEN or FETCH for a SELECT statement, SPUFI stops processing the SELECT statement. If SQLCODE +802 occurs when SPUFI executes a FETCH for a SELECT statement, SPUFI continues to process the SELECT statement.

You can also specify how SPUFI pre-processes the SQL input by using the --#SET TOLWARN statement.

5 CHANGE PLAN NAMES

If you enter YES in this field, you can change plan names on a subsequent SPUFI defaults panel, DSNESP07. Enter YES in this field only if you are certain that you want to change the plan names that are used by SPUFI. Consult with your Db2 system administrator if you are uncertain whether you want to change the plan names. Using an invalid or incorrect plan name might cause SPUFI to experience operational errors or it might cause data contamination.

6 SQL FORMAT

Specify how SPUFI pre-processes the SQL input before passing it to Db2. Select one of the following options:

SQL

This is the preferred mode for SQL statements other than SQL procedural language. When you use this option, which is the default, SPUFI collapses each line of an SQL statement into a single line before passing the statement to Db2. SPUFI also discards all SQL comments.

SQLCOMNT

This mode is suitable for all SQL, but it is intended primarily for SQL procedural language processing. When this option is in effect, behavior is similar to SQL mode, except that SPUFI does not discard SQL comments. Instead, it automatically terminates each SQL comment with a line feed character (hex 25), unless the comment is already terminated by one or more line formatting characters. Use this option to process SQL procedural language with minimal modification by SPUFI.

SQLPL

This mode is suitable for all SQL, but it is intended primarily for SQL procedural language processing. When this option is in effect, SPUFI retains SQL comments and terminates each line of an SQL statement with a line feed character (hex 25) before passing the statement to Db2. Lines that end with a split token are not terminated with a line feed character. Use this mode to obtain improved diagnostics and debugging of SQL procedural language.

You can also specify how SPUFI pre-processes the SQL input by using the --#SET SQLFORMAT statement.

7 SPACE UNIT

Specify how space for the SPUFI output data set is to be allocated.

TRK

Track

CYL

Cylinder

8 PRIMARY SPACE

Specify how many tracks or cylinders of primary space are to be allocated.

9 SECONDARY SPACE

Specify how many tracks or cylinders of secondary space are to be allocated.

10 RECORD LENGTH

The record length must be at least 80 bytes. The maximum record length depends on the device type you use. The default value allows a 32756-byte record.

Each record can hold a single line of output. If a line is longer than a record, the output is truncated, and SPUFI discards fields that extend beyond the record length.

11 BLOCKSIZE

Follow the normal rules for selecting the block size. For record format F, the block size is equal to the record length. For FB and FBA, choose a block size that is an even multiple of LRECL. For VB and VBA only, the block size must be 4 bytes larger than the block size for FB or FBA.

12 RECORD FORMAT

Specify F, FB, FBA, V, VB, or VBA. FBA and VBA formats insert a printer control character after the number of lines specified in the LINES/PAGE OF LISTING field on the DB2I Defaults panel. The record format default is VB (variable-length blocked).

13 DEVICE TYPE

Specify a standard z/OS name for direct-access storage device types. The default is SYSDA. SYSDA specifies that z/OS is to select an appropriate direct access storage device.

14 MAX NUMERIC FIELD

The maximum width of a numeric value column in your output. Choose a value greater than 0. The default is 33.

15 MAX CHAR FIELD

The maximum width of a character value column in your output. DATETIME and GRAPHIC data strings are externally represented as characters, and SPUFI includes their defaults with the default values for character fields. Choose a value greater than 0. The IBM-supplied default is 250.

16 COLUMN HEADING

You can specify NAMES, LABELS, ANY, or BOTH for column headings.

- · NAMES uses column names only.
- LABELS (default) uses column labels. Leave the title blank if no label exists.
- ANY uses existing column labels or column names.
- BOTH creates two title lines, one with names and one with labels.

Column names are the column identifiers that you can use in SQL statements. If an SQL statement has an AS clause for a column, SPUFI displays the contents of the AS clause in the heading, rather than the column name. You define column labels with LABEL statements.

Related concepts

Output from SPUFI

SPUFI formats and displays the output data set using the ISPF Browse program.

Related tasks

Changing SPUFI defaults

Before you execute SQL statements in SPUFI, you can change the default execution behavior, such as the SQL terminator and the isolation level.

Executing SQL by using SPUFI

You can execute SQL statements dynamically in a TSO session by using the SPUFI (SQL processor using file input) facility.

CURRENT SPUFI DEFAULTS - PANEL 2 panel

Use the CURRENT SPUFI DEFAULTS - PANEL 2 panel to specify default plan name information.

This panel opens if you specify YES in the CHANGE PLAN NAMES field of the CURRENT SPUFI DEFAULTS panel.

Figure 72 on page 981 shows the initial default values.

```
DSNESP07 CURRENT SPUFI DEFAULTS - PANEL 2 SSID: DSN

===>
Enter the following to control your SPUFI session:

1 CS ISOLATION PLAN ===> DSNESPCS (Name of plan for CS isolation level)

2 RR ISOLATION PLAN ===> DSNESPRR (Name of plan for RR isolation level)

3 UR ISOLATION PLAN ===> DSNESPUR (Name of plan for UR isolation level)

Indicate warning message status:

4 BLANK CCSID WARNING ===> YES (Show warning if terminal CCSID is blank)

PRESS: ENTER to process END to exit HELP for more information
```

Figure 72. CURRENT SPUFI DEFAULTS - PANEL 2

The following descriptions explain the information on the CURRENT SPUFI DEFAULTS - PANEL 2 panel.

1 CS ISOLATION PLAN

Specify the name of the plan that SPUFI uses when you specify an isolation level of cursor stability (CS). By default, this name is DSNESPCS.

2 RR ISOLATION PLAN

Specify the name of the plan that SPUFI uses when you specify an isolation level of repeatable read (RR). By default, this name is DSNESPRR.

3 UR ISOLATION PLAN

Specify the name of the plan that SPUFI uses when you specify an isolation level of uncommitted read (UR). By default, this name is DSNESPUR.

4 BLANK CCSID ALERT

Indicate whether to receive message DSNE345I when the terminal CCSID setting is blank. A blank terminal CCSID setting occurs when the terminal code page and character set cannot be queried or if they are not supported by ISPF.

Recommendation: To avoid possible data contamination use the default setting of YES, unless you are specifically directed by your Db2 system administrator to use NO.

Setting the SQL terminator character in a SPUFI input data set

In the SPUFI input data set, you can override the SQL terminator character that is specified on the CURRENT SPUFI DEFAULTS panel. The default SQL terminator is a semicolon (;).

About this task

Overriding the default SQL termination character is useful if you need to use a different SQL terminator character for one particular SQL statement.

To set the SQL terminator character in a SPUFI input data set, specify the text --#SET TERMINATOR character before that SQL statement to which you want this character to apply. This text specifies that SPUFI is to interpret character as a statement terminator. You can specify any single-byte character except the characters that are listed in Table 155 on page 982. Choose a character for the SQL terminator that is not used within the statement. The terminator that you specify overrides a terminator that you specified in option 1 of the CURRENT SPUFI DEFAULTS panel or in a previous --#SET TERMINATOR statement.

Table 155. Invalid special characters for the SQL terminator

Name	Character	Hexadecimal representation
blank		X'40'
comma	,	X'5E'
double quote	п	X'7F'
left parenthesis	(X'4D'
right parenthesis)	X'5D'
single quote	1	X'7D'
underscore	_	X'6D'

Use a character other than a semicolon if you plan to execute a statement that contains embedded semicolons. For example, suppose that you choose the character # as the statement terminator. In this case, a CREATE TRIGGER statement with embedded semicolons looks like this:

```
CREATE TRIGGER NEW_HIRE
AFTER INSERT ON EMP
FOR EACH ROW MODE DB2SQL
BEGIN ATOMIC
UPDATE COMPANY_STATS SET NBEMP = NBEMP + 1;
END#
```

Controlling toleration of warnings in SPUFI

When you use SPUFI, you can specify the action that SPUFI is to take when a warning occurs.

About this task

To control the toleration of warnings, specify one of the following TOLWARN control statements:

--#SET TOLWARN NO

If a warning occurs when SPUFI executes an OPEN or FETCH for SELECT statement, SPUFI stops processing the SELECT statement. If SQLCODE +802 occurs when SPUFI executes a FETCH for a SELECT statement, SPUFI continues to process the SELECT statement.

--#SET TOLWARN YES

If a warning occurs when SPUFI executes an OPEN or FETCH for SELECT statement, SPUFI continues to process the SELECT statement.

--#SET TOLWARN QUIET

The same as YES, except that SPUFI suppresses all SQL warning messages from OPEN or FETCH if the SQLCODE is 0 or greater.

Example

The following example activates and then deactivates toleration of SQL warnings:

```
SELECT * FROM MY.T1;
--#SET TOLWARN YES
SELECT * FROM YOUR.T1;
--#SET TOLWARN NO
```

Output from SPUFI

SPUFI formats and displays the output data set using the ISPF Browse program.

An output data set contains the following items for each SQL statement that Db2 executes:

- The executed SQL statement, copied from the input data set
- The results of executing the SQL statement.
- The SQLCODE, and if the execution is unsuccessful, the formatted SQLCA.

At the end of the data set are summary statistics that describe the processing of the input data set as a whole.

For SELECT statements that are executed with SPUFI, the message "SQLCODE IS 100" indicates an error-free result. If the message SQLCODE IS 100 is the only result, Db2 is unable to find any rows that satisfy the condition that is specified in the statement.

For all other types of SQL statements that are executed with SPUFI, the message "SQLCODE IS 0" indicates an error-free result.

Example SPUFI output

I

For example, the sample program returns the following output.

```
BROWSE-- userid.RESULT
                                                COLUMNS 001 072
 COMMAND INPUT ===>
                                                               SCROLL ===> PAGE

Figure 73. Result data set from the sample problem

Formatting rules for SELECT statement results in SPUFI

The results of SELECT statements follow these rules:

- If numeric or character data of a column cannot be displayed completely:
 - Character values and binary values that are too wide truncate on the right.
 - Numeric values that are too wide display as asterisks (*).
 - For columns other than LOB and XML columns, if truncation occurs, the output data set contains a
 warning message. Because LOB and XML columns are generally longer than the value you choose
 for field MAX CHAR FIELD on panel CURRENT SPUFI DEFAULTS, SPUFI displays no warning message
 when it truncates LOB or XML column output.

You can change the amount of data that is displayed for numeric and character columns by changing values on the CURRENT SPUFI DEFAULTS panel, as described in <u>"Changing SPUFI defaults" on page</u> 976.

- A null value is displayed as a series of hyphens (-).
- A ROWID, BLOB, BINARY, or VARBINARY column value is displayed in hexadecimal.
- A CLOB column value is displayed in the same way as a VARCHAR column value.
- A DBCLOB column value is displayed in the same way as a VARGRAPHIC column value.
- An XML column is displayed in the same way as a LOB column.
- A heading identifies each selected column, and is repeated at the top of each output page. The contents
 of the heading depend on the value that you specified in the COLUMN HEADING field of the CURRENT
 SPUFI DEFAULTS panel.

Content of the messages from SPUFI

Messages in the SPUFI output contain the following information:

- The SQLCODE, and if the execution is unsuccessful, the formatted SQLCA. If multiple SQL conditions
 occur, SPUFI returns the error SQLCODE first, followed by any previous SQLCODE conditions that
 occurred as the input SQL statement was executed. If the final SQLCODE is an error, most prior
 SQLCODE warnings can be ignored.
- What character positions of the input data set that SPUFI scanned to find SQL statements. This information helps you check the assumptions that SPUFI made about the location of line numbers (if any) in your input data set.
- · Some overall statistics:
 - Number of SQL statements that are processed
 - Number of input records that are read (from the input data set)
 - Number of output records that are written (to the output data set).

Other messages that you could receive from the processing of SQL statements include:

- The number of rows that Db2 processed, that either:
 - Your select operation retrieved
 - Your update operation modified
 - Your insert operation added to a table
 - Your delete operation deleted from a table
- Which columns display truncated data because the data was too wide

Testing an external user-defined function

Some commonly used debugging tools, such as TSO TEST, are not available in the environment where user-defined functions run. You need to use alternative testing strategies.

Testing a user-defined function by using z/OS Debugger

You can use z/OS Debugger to test Db2 for z/OS routines, including user-defined functions, that are written in any of the supported languages. z/OS Debugger works with Language Environment.

About this task

You can use z/OS Debugger either interactively or in batch mode. To test your user-defined function using z/OS Debugger, you must have z/OS Debugger installed on the z/OS system where the user-defined function runs.

Procedure

To debug your routine with z/OS Debugger, use one of the following approaches:

• Use z/OS Debugger interactively by completing the following steps.

- a) Compile the routine with the TEST option. The TEST option places information in the program that z/OS Debugger uses during a debugging session.
- b) Invoke z/OS Debugger.

One way to do that is to specify the Language Environment run time option TEST. The TEST option controls when and how z/OS Debugger is invoked. The most convenient place to specify run time options is in the RUN OPTIONS clause of the CREATE FUNCTION or ALTER FUNCTION statement for the user-defined function.

For example, you can code the TEST option using the following parameters:

```
TEST(ALL,*,PROMPT,TCPIP&ABC.EXAMPLE.COM%8001:*:)
```

For more information, see Syntax of the TEST runtime option and Example: TEST runtime options. For more information about interactive debugging from various interfaces, see the following topics:

- Remote debugging with an Eclipse IDE
- Debugging your programs in full-screen mode
- Use z/OS Debugger in batch mode by completing the following steps. z/OS Debugger must be installed on the z/OS system where the user-defined function runs.
 - a) Compile the user-defined function with the TEST option if you plan to use the Language Environment run time option TEST to invoke z/OS Debugger. The TEST option places information in the program that z/OS Debugger uses during a debugging session.
 - b) Allocate a log data set to receive the output from z/OS Debugger. Put a DD statement for the log data set in the start-up procedure for the stored procedures address space.
 - c) Enter commands in a data set that you want z/OS Debugger to execute. Put a DD statement for that data set in the start-up procedure for the stored procedures address space. To define the commands data set to z/OS Debugger, specify the commands data set name or DD name in the TEST run time option.

For example, to specify that z/OS Debugger uses the commands that are in the data set that is associated with the DD name TESTDD, include the following parameter in the TEST option:

```
TEST(ALL,TESTDD,PROMPT,*)
```

The first command in the commands data set should be:

```
SET LOG ON FILE ddname;
```

This command directs output from your debugging session to the log data set that you defined in the previous step. For example, if you defined a log data set with DD name INSPLOG in the stored procedures address space start-up procedure, the first command should be the following command:

```
SET LOG ON FILE INSPLOG;
```

- d) Invoke z/OS Debugger by using one of the following methods:
 - Specify the run time option TEST. The most convenient place to do that is in the RUN OPTIONS
 parameter of the CREATE or ALTER statement for the stored procedure.
 - Put CEETEST calls in the stored procedure source code. If you use this approach for an existing stored procedure, you must recompile, re-link, and bind it, and issue the STOP PROCEDURE and START PROCEDURE commands to reload the stored procedure.

You can combine the run time option TEST with CEETEST calls. For example, you might want to use TEST to name the commands data set but use CEETEST calls to control when z/OS Debugger takes control.

For more information, see Starting z/OS Debugger in batch mode.

CREATE FUNCTION statement (overview) (Db2 SQL)

Testing a user-defined function by routing the debugging messages to SYSPRINT

You can include simple print statements in your user-defined function code that you route to SYSPRINT. Then use System Display and Search Facility (SDSF) to examine the SYSPRINT contents while the WLM-established stored procedure address space is running.

About this task

You can serialize I/O by running the WLM-established stored procedure address space with NUMTCB=1.

Testing a user-defined function by using driver applications

You can write a small driver application that calls a user-defined function as a subprogram and passes the parameter list for the user-defined function. You can then test and debug the user-defined function as a normal Db2 application under TSO.

About this task

You can then use TSO TEST and other commonly used debugging tools.

Testing a user-defined function by using SQL INSERT statements

You can use SQL to insert debugging information into a Db2 table. This allows other machines in the network (such as workstations) to easily access the data in the table by using DRDA access.

About this task

Db2 discards the debugging information if the application executes the ROLLBACK statement. To prevent the loss of the debugging data, code the calling application so that it retrieves the diagnostic data before executing the ROLLBACK statement.

Debugging stored procedures

When debugging stored procedures, you might need to use different techniques than you would use for regular application programs. For example, some commonly used debugging tools, such as TSO TEST, are not available in the environment where stored procedures run.

Procedure

To debug a stored procedure, perform one or more of the following actions:

- Take one or more of the following general actions, which are appropriate in many situations with stored procedures:
 - Ensure that all stored procedures are written to handle any SQL errors.
 - Debug stored procedures as stand-alone programs on a workstation.
 - If you have debugging tools on a workstation, consider doing most of your development and testing on a workstation before installing a stored procedure on z/OS. This technique results in very little debugging activity on z/OS.
 - Record stored procedure debugging messages to a disk file or JES spool file.
 - Store debugging information in a table. This technique is especially useful for remote stored procedures.
 - Use the DISPLAY command to view information about particular stored procedures, including statistics and thread information.

- In the stored procedure that you are debugging, issue DISPLAY commands. You can view the DISPLAY results in the SDSF output. The DISPLAY results can help you find information about the started task that is associated with the address space for the WLM application environment.
- If necessary, use the STOP PROCEDURE command to stop calls to one or more problematic stored procedures. You can restart them later.
- If your stored procedures address space has the CEEDUMP data set allocated, look at the diagnostic information in the CEEDUMP output.
- For COBOL, C, and C++ stored procedures, use the Debug Tool for z/OS.
- For COBOL stored procedures, compile the stored procedure with the option TEST(SYM) if you want a formatted local variable dump to be included in the CEEDUMP output.
- For native SQL procedures, external SQL procedures, and Java stored procedures, use the Unified Debugger.
- For external stored procedures, consider taking one or both of the following actions:
 - Use a driver application.
 - Create or alter the stored procedure definition to include the PARAMETER STYLE SQL option. This option enables the stored procedure to share any error information with the calling application. Ensure that your procedure follows linkage conventions for stored procedures.
- If you changed a stored procedure or a startup JCL procedure for a WLM application environment, determine whether you need to refresh the WLM environment. You must refresh the WLM environment before certain stored procedure changes take effect.

Related tasks

Handling SQL conditions in an SQL procedure

In an SQL procedure, you can specify how the program should handle certain SQL errors and SQL warnings.

Related information

Db2 for z/OS Stored Procedures: Through the CALL and Beyond (IBM Redbooks)

Debugging stored procedures by using the Unified Debugger

You can use the Unified Debugger to remotely debug native SQL procedures, external SQL procedures, and Java stored procedures that execute on Db2 for z/OS servers. The Unified Debugger also supports debugging nested stored procedure calls.

About this task

With the Unified Debugger, you can observe the execution of the procedure code, set breakpoints for lines, and view or modify variable values.

Procedure

To debug stored procedures by using the Unified Debugger:

1. Set up the Unified Debugger by performing the following steps:

- a) Ensure that job DSNTIJRT successfully created the stored procedures that provide server support for the Unified Debugger. This job is run during the installation and migration process. The stored procedures that this job creates must run in WLM environments.
 - **Recommendation:** Initially, define and use the Db2 core WLM environment DSNWLM_GENERAL to run the SYSPROC.DBG_RUNSESSIONMANAGER stored procedure and core WLM environment DSNWLM_DEBUGGER to run the other stored procedures for Unified Debugger.
- b) Define the debug mode characteristics for the stored procedure that you want to debug by completing one of the following actions:
 - For native SQL procedures, define the procedures with the ALLOW DEBUG MODE option and the WLM ENVIRONMENT FOR DEBUG MODE option. If the procedure already exists, you can use the ALTER PROCEDURE statement to specify these options.
 - For an external SQL procedure, use DSNTPSMP to build the SQL procedure with the BUILD_DEBUG option.
 - If you deploy the procedure with Db2 Developer Extension, specify Enable debugging in the deployment options.
 - For Java stored procedures, define the procedures with the ALLOW DEBUG MODE option, select an appropriate WLM environment for Java debugging, and compile the Java code with the -G option.
- c) Grant the DEBUGSESSION privilege to the user who runs the debug client.
- 2. Include breakpoints in your routines or executable files.
- 3. Follow the instructions for debugging stored procedures in the documentation for Db2 Developer Extension. For more information, see Debugging native and external SQL stored procedures.

Db2 for z/OS Stored Procedures: Through the CALL and Beyond (IBM Redbooks)

Debugging stored procedures with z/OS Debugger

You can use z/OS Debugger to test z/OS routines, including stored procedures, that are written in any of the compiled languages that it supports. You can test these stored procedures either interactively or in batch mode.

Procedure

To debug your routine with z/OS Debugger, use one of the following approaches:

Use z/OS Debugger interactively by completing the following steps.

- a) Compile the routine with the TEST option. The TEST option places information in the program that z/OS Debugger uses during a debugging session.
- b) Invoke z/OS Debugger.

One way to do that is to specify the Language Environment run time option TEST. The TEST option controls when and how z/OS Debugger is invoked. The most convenient place to specify run time options is in the RUN OPTIONS parameter of the CREATE PROCUDURE or ALTER PROCEDURE statement for the stored procedure. For more information, see Preparing a Db2 stored procedures program.

For example, you can code the TEST option using the following parameters:

```
TEST(ALL,*,PROMPT,TCPIP&ABC.EXAMPLE.COM%8001:*:)
```

For more information, see Syntax of the TEST runtime option and Example: TEST runtime options. For more information about interactive debugging from various interfaces, see the following topics:

- Remote debugging with an Eclipse IDE
- Debugging your programs in full-screen mode
- Use z/OS Debugger in batch mode by completing the following steps. z/OS Debugger must be installed on the z/OS system where the stored procedure runs.
 - a) Compile the stored procedure with the TEST option if you plan to use the Language Environment run time option TEST to invoke z/OS Debugger. The TEST option places information in the program that z/OS Debugger uses during a debugging session.
 - b) Allocate a log data set to receive the output from z/OS Debugger. Put a DD statement for the log data set in the start-up procedure for the stored procedures address space.
 - c) Enter commands in a data set that you want z/OS Debugger to execute. Put a DD statement for that data set in the start-up procedure for the stored procedures address space. To define the commands data set to z/OS Debugger, specify the commands data set name or DD name in the TEST run time option.

For example, to specify that z/OS Debugger uses the commands that are in the data set that is associated with the DD name TESTDD, include the following parameter in the TEST option:

```
TEST(ALL,TESTDD,PROMPT,*)
```

The first command in the commands data set should be:

```
SET LOG ON FILE ddname;
```

This command directs output from your debugging session to the log data set that you defined in the previous step. For example, if you defined a log data set with DD name INSPLOG in the stored procedures address space start-up procedure, the first command should be the following command:

```
SET LOG ON FILE INSPLOG;
```

- d) Invoke z/OS Debugger by using one of the following methods:
 - Specify the run time option TEST. The most convenient place to do that is in the RUN OPTIONS
 parameter of the CREATE or ALTER statement for the stored procedure.
 - Put CEETEST calls in the stored procedure source code. If you use this approach for an existing stored procedure, you must recompile, re-link, and bind it, and issue the STOP PROCEDURE and START PROCEDURE commands to reload the stored procedure.

You can combine the run time option TEST with CEETEST calls. For example, you might want to use TEST to name the commands data set but use CEETEST calls to control when z/OS Debugger takes control.

For more information, see Starting z/OS Debugger in batch mode.

Recording stored procedure debugging messages in a file

You can debug external stored procedures and external SQL procedures by recording debugging messages in a disk file or in a JES spool file. You cannot use this debugging technique for native SQL procedures or Java stored procedures.

Procedure

To record stored procedure debugging messages in a file:

1. Specify the Language Environment (LE) MSGFILE run time option for the stored procedure. This option identifies where LE is to write the debugging messages. To specify this option, include the RUN OPTIONS clause in either the CREATE PROCEDURE statement or an ALTER PROCEDURE statement.

Specify the following MSGFILE parameters:

- Use the first MSGFILE parameter to specify the JCL DD statement that identifies the data set for the debugging messages. You can direct debugging messages to a disk file or JES spool file. To prevent multiple procedures from sharing a data set, ensure that you specify a unique DD statement.
- Use the ENQ option to serialize I/O to the message file. This action is necessary, because multiple TCBs can be active in the stored procedure address space. Alternatively, if you debug your applications infrequently or on a Db2 test system, you can serialize I/O by temporarily running the stored procedures address space with NUMTCB=1 in the stored procedures address space start-up procedure.
- 2. For each instance of MSGFILE that you specify, add a DD statement to the JCL procedure that is used to start the stored procedures address space.

Using Language Environment MSGFILE (z/OS Language Environment Programming Guide)

Driver applications for debugging procedures

You can write a small driver application that calls the stored procedure as a subprogram and passes the parameter list that the stored procedure supports. You can then test and debug the stored procedure as a normal Db2 application under TSO.

Using this method, you can use TSO TEST and other commonly used debugging tools.

Restriction: You cannot use this technique for SQL procedures

Db2 tables that contain debugging information

You can use SQL statements to insert debugging information into a Db2 table. Inserting this information into a table enables other machines in the network (such as a workstation) to easily access the data in the table by using DRDA access.

Db2 discards the debugging information if the application executes the ROLLBACK statement. To prevent the loss of the debugging data, code the calling application so that it retrieves the diagnostic data before executing the ROLLBACK statement.

Debugging an application program

Many sites have guidelines regarding what to do if a program abnormally terminates.

About this task

For information about the compiler or assembler test facilities, see the publications for the compiler or CODE/370. The compiler publications include information about the appropriate debugger for the language you are using.

You can also use ISPF Dialog Test to debug your program. You can run all or portions of your application, examine the results, make changes, and rerun it.

Dialog test (option 7) (z/OS ISPF User's Guide Vol II)

Locating the problem in an application

If your program does not run correctly, you need to isolate the problem. You should check several items.

About this task

Those items are:

- Output from the precompiler, which consists of errors and warnings. Ensure that you have resolved all errors and warnings.
- Output from the compiler or assembler. Ensure that you have resolved all error messages.
- Output from the linkage editor.
 - Have you resolved all external references?
 - Have you included all necessary modules in the correct order?
 - Did you include the correct language interface module? The correct language interface module is:
 - DSNELI or DSNULI for TSO
 - DFSLI000 for IMS
 - DSNCLI or DSNULI for CICS
 - DSNALI or DSNULI for the call attachment facility
 - DSNRLI or DSNULI for the Resource Recovery Services attachment facility
 - Did you specify the correct entry point to your program?
- · Output from the bind process.
 - Have you resolved all error messages?
 - Did you specify a plan name? If not, the bind process assumes that you want to process the DBRM for diagnostic purposes, but that you do not want to produce an application plan.
 - Have you specified all the packages that are associated with the programs that make up the application and their partitioned data set (PDS) names in a single application plan?
- Your JCL.

IMS

- If you are using IMS, have you included the DL/I option statement in the correct format?
- Have you included the region size parameter in the EXEC statement? Does it specify a region size that is large enough for the required storage for the Db2 interface, the TSO, IMS, or CICS system, and your program?
- Have you included the names of all data sets (Db2 and non-Db2) that the program requires?
- Your program.

You can also use dumps to help localize problems in your program. For example, one of the more common error situations occurs when your program is running and you receive a message that it abended. In this situation, your test procedure might be to capture a TSO dump. To do so, you must allocate a SYSUDUMP or SYSABEND dump data set before calling Db2. When you press the ENTER key (after the error message and READY message), the system requests a dump. You then need to use the FREE command to deallocate the dump data set.

Error and warning messages from the precompiler

In some circumstances, the statements that the Db2 precompiler generates might produce compiler or assembly error messages. You need to know why the messages occur when you compile Db2-produced source statements.

SYSTERM output from the precompiler

The SYSTERM output provides a brief summary of the results from the precompiler, all error messages that the precompiler generated, and the statement that is in error, when possible.

The Db2 precompiler provides SYSTERM output when you allocate the DD name SYSTERM. If you use the program preparation panels to prepare and run your program, DB2I allocates SYSTERM according to the TERM option that you specify.

You can use the line number that is provided in each error message in the SYSTERM output to locate the failing source statement.

Figure 74 on page 992 shows the format of SYSTERM output.

```
DB2 SQL PRECOMPILER MESSAGES

THERE WERE 0 MESSAGES SUPPRESSED BY THE FLAG OPTION.⁵
111664 BYTES OF STORAGE WERE USED BY THE PRECOMPILER.6
RETURN CODE IS 87
```

Figure 74. Db2 precompiler SYSTERM output

Notes:

- 1. Error message.
- 2. Source SQL statement.
- 3. Summary statements of source statistics.
- 4. Summary statement of the number of errors that were detected.
- 5. Summary statement that indicates the number of errors that were detected but not printed. This situation might occur if you specify a FLAG option other than I.
- 6. Storage requirement statement that indicates how many bytes of working storage that the Db2 precompiler actually used to process your source statements. That value helps you determine the storage allocation requirements for your program.
- 7. Return code: 0 = success, 4 = warning, 8 = error, 12 = severe error, and 16 = unrecoverable error.

SYSPRINT output from the precompiler

SYSPRINT output from the Db2 precompiler shows the results of the precompile operation. This output can also include a list of the options that were used, a source code listing, and a host variable cross-reference listing.

When you use the program preparation panels to prepare and run your program, Db2 allocates SYSPRINT according to TERM option that you specify (on line 12 of the PROGRAM PREPARATION: COMPILE, PRELINK, LINK, AND RUN panel). As an alternative, when you use the DSNH command procedure (CLIST), you can specify PRINT(TERM) to obtain SYSPRINT output at your terminal, or you can specify PRINT(qualifier) to place the SYSPRINT output into a data set named authorizationID.qualifier.PCLIST. Assuming that you do not specify PRINT as LEAVE, NONE, or TERM, Db2 issues a message when the precompiler finishes, telling you where to find your precompiler listings. This helps you locate your diagnostics quickly and easily.

The SYSPRINT output can provide information about your precompiled source module if you specify the options SOURCE and XREF when you start the Db2 precompiler.

The format of SYSPRINT output is as follows:

- A list of the Db2 precompiler options that are in effect during the precompilation (if you did not specify NOOPTIONS).
- A list of your source statements (only if you specified the SOURCE option). An example is shown in Figure 75 on page 994.
- A list of the symbolic names used in SQL statements (this listing appears only if you specify the XREF option). An example is show in Figure 76 on page 994.
- A summary of the errors that are detected by the Db2 precompiler and a list of the error messages that are generated by the precompiler. An example is shown in

The following code shows an example list of Db2 precompiler options as it is displayed in the SYSPRINT output.

```
DB2 SQL PRECOMPILER VERSION 11 REL. 1.0
OPTIONS SPECIFIED: HOST(PLI), SOURCE, XREF, STDSQL(NO), TWOPASS

```

Notes:

- 1. This section lists the options that are specified at precompilation time. This list does not appear if one of the precompiler option is NOOPTIONS.
- 2. This section lists the options that are in effect, including defaults, forced values, and options that you specified. The Db2 precompiler overrides or ignores any options that you specify that are inappropriate for the host language.

The following figure shows an example list of source statements as it is displayed in the SYSPRINT output.

```

Figure 75. Db2 precompiler SYSPRINT output: Source statements section

Notes:

- The left column of sequence numbers, which the Db2 precompiler generates, is for use with the symbol cross-reference listing, the precompiler error messages, and the BIND error messages.
- The right column shows sequence numbers that come from the sequence numbers that are supplied with your source statements.

The following figure shows an example list of symbolic names as it is displayed in the SYSPRINT output.

DB2 SQL PRECOMPILER	SYMBOL CROSS-F	REFERENCE LISTING	PAGE 29
DATA NAMES	DEFN	REFERENCE	
"ACTNO"	***	FIELD 1328	
"PREQACT"	***	FIELD	
"PREQPROJ"	***	1328 FIELD 1328	
"PROJNO"	****	FIELD 1331 1338	
•••			
PROJ_DATA	495	CHARACTER(35) 1329	
PROJ_NO	496	CHARACTER(3) 1331 1338	
"TPREREQ"	****	TABLE 1330 1337	

Figure 76. Db2 precompiler SYSPRINT output: Symbol cross-reference section

Notes:

DATA NAMES

Identifies the symbolic names that are used in source statements. Names enclosed in double quotation marks (") or apostrophes (') are names of SQL entities such as tables, columns, and authorization IDs. Other names are host variables.

DEFN

Is the number of the line that the precompiler generates to define the name. **** means that the object was not defined, or the precompiler did not recognize the declarations.

REFERENCE

Contains two kinds of information: the symbolic name, which the source program defines, and which lines refer to the symbolic name. If the symbolic name refers to a valid host variable, the list also identifies the data type or the word STRUCTURE.

The following code shows an example summary report of errors as it is displayed in the SYSPRINT output.

```
DB2 SQL PRECOMPILER STATISTICS

SOURCE STATISTICS

SOURCE LINES READ: 1523¹
NUMBER OF SYMBOLS: 128²
SYMBOL TABLE BYTES EXCLUDING ATTRIBUTES: 6432³

THERE WERE 1 MESSAGES FOR THIS PROGRAM.⁴
THERE WERE 0 MESSAGES SUPPRESSED.⁵
65536 BYTES OF STORAGE WERE USED BY THE PRECOMPILER.6
RETURN CODE IS 8.7
DSNH104I E LINE 590 COL 64 ILLEGAL SYMBOL: 'X'; VALID SYMBOLS ARE:,FROM8
```

Notes:

- 1. Summary statement that indicates the number of source lines.
- 2. Summary statement that indicates the number of symbolic names in the symbol table (SQL names and host names).
- 3. Storage requirement statement that indicates the number of bytes for the symbol table.
- 4. Summary statement that indicates the number of messages that are printed.
- 5. Summary statement that indicates the number of errors that are detected but not printed. You might get this statement if you specify the option FLAG.
- 6. Storage requirement statement that indicates the number of bytes of working storage that are actually used by the Db2 precompiler to process your source statements.
- 7. Return code 0 = success, 4 = warning, 8 = error, 12 = severe error, and 16 = unrecoverable error.
- 8. Error messages (this example detects only one error).

Techniques for debugging programs in TSO

Documenting the errors that are identified during testing of a TSO application helps you investigate and correct problems in the program.

The following information can be useful:

- The application plan name of the program
- The input data that is being processed
- The failing SQL statement and its function
- The contents of the SQLCA (SQL communication area) and, if your program accepts dynamic SQL statements, the SQLDA (SQL descriptor area)
- · The date and time of day
- The abend code and any error messages

When your program encounters an error that does not result in an abend, it can pass all the required error information to a standard error routine. Online programs might also send an error message to the terminal.

The TSO TEST command

The TSO TEST command is especially useful for debugging assembler programs.

The following example is a command procedure (CLIST) that runs a Db2 application named MYPROG under TSO TEST, and sets an address stop at the entry to the program. The Db2 subsystem name in this example is DB4.

```
PROC 0
TEST 'prefix.SDSNLOAD(DSN)' CP
DSN SYSTEM(DB4)
AT MYPROG.MYPROG.+0 DEFER
GO
RUN PROGRAM(MYPROG) LIBRARY('L186331.RUNLIB.LOAD(MYPROG)')
```

TEST command (TSO/E Command Reference)

Techniques for debugging programs in IMS

Documenting the errors that are identified during testing of an IMS application helps you investigate and correct problems in the program.

The following information can be useful:

- · The application plan name for the program
- · The input message that is being processed
- The name of the originating logical terminal
- · The failing statement and its function
- The contents of the SQLCA (SQL communication area) and, if your program accepts dynamic SQL statements, the SQLDA (SQL descriptor area)
- The date and time of day
- The PSB name for the program
- The transaction code that the program was processing
- The call function (that is, the name of a DL/I function)
- The contents of the PCB that the program call refers to
- If a DL/I database call was running, the SSAs, if any, that the call used
- The abend completion code, abend reason code, and any dump error messages

When your program encounters an error, it can pass all the required error information to a standard error routine. Online programs can also send an error message to the originating logical terminal.

An interactive program also can send a message to the master terminal operator (MTO) operator giving information about the termination of the program. To do that, the program places the logical terminal name of the master terminal in an express PCB and issues one or more ISRT calls.

Some organizations run a BMP at the end of the day to list all the errors that occurred during the day. If your organization does this, you can send a message by using an express PCB that has its destination set for that BMP.

Batch Terminal Simulator: The Batch Terminal Simulator (BTS) enables you to test IMS application programs. BTS traces application program DL/I calls and SQL statements, and it simulates data communication functions. It can make a TSO terminal appear as an IMS terminal to the terminal operator, which enables the user to interact with the application as though it were an online application. The user can use any application program that is under the user's control to access any database (whether DL/I or Db2) that is under the user's control. Access to Db2 databases requires BTS to operate in batch BMP or TSO BMP mode.

Techniques for debugging programs in CICS

Documenting the errors that are identified during testing of a CICS application helps you investigate and correct problems in the program.

The following information can be useful:

- The application plan name of the program
- · The input data that is being processed
- The ID of the originating logical terminal
- The failing SQL statement and its function
- The contents of the SQLCA (SQL communication area) and, if your program accepts dynamic SQL statements, the SQLDA (SQL descriptor area)
- The date and time of day
- · Data that is peculiar to CICS that you should record
- · Abend code and dump error messages
- · Transaction dump, if produced

Using CICS facilities, you can have a printed error record; you can also print the SQLCA and SQLDA contents.

Debugging aids for CICS

CICS provides the following aids to the testing, monitoring, and debugging of application programs:

- Execution (Command Level) Diagnostic Facility (EDF). EDF shows CICS commands for all releases of CICS.
- **Abend recovery.** You can use the HANDLE ABEND command to deal with abend conditions. You can use the ABEND command to cause a task to abend.
- Trace facility. A trace table can contain entries showing the execution of various CICS commands, SQL statements, and entries that are generated by application programs; you can have these entries written to main storage and, optionally, to an auxiliary storage device.
- **Dump facility.** You can specify areas of main storage to dump onto a sequential data set, either tape or disk, for subsequent offline formatting and printing with a CICS utility program.
- **Journals.** For statistical or monitoring purposes, facilities can create entries in special data sets called journals. The system log is a journal.
- **Recovery.** When an abend occurs, CICS restores certain resources to their original state so that the operator can easily resubmit a transaction for restart. You can use the SYNCPOINT command to subdivide a program so that you only need to resubmit the uncompleted part of a transaction.

CICS execution diagnostic facility

The CICS execution diagnostic facility (EDF) traces SQL statements in an interactive debugging mode, enabling application programmers to test and debug programs online without changing the program or the program preparation procedure.

EDF intercepts the running application program at various points and displays helpful information about the statement type, input and output variables, and any error conditions after the statement executes. It also displays any screens that the application program sends, so that you can converse with the application program during testing just as a user would on a production system.

EDF displays essential information before and after an SQL statement runs, while the task is in EDF mode. This can be a significant aid in debugging CICS transaction programs that contains SQL statements. The SQL information that EDF displays is helpful for debugging programs and for error analysis after an SQL error or warning. Using this facility reduces the amount of work that you need to do to write special error handlers.

EDF before execution

The following figure shows an example of an EDF screen before it executes an SQL statement. The names of the key information fields on this panel are in **boldface**.

Figure 77. EDF screen before a Db2 SQL statement

The Db2 SQL information in this screen is as follows:

EXEC SQL statement type

This is the type of SQL statement to execute. The SQL statement can be any valid SQL statement.

• DBRM=dbrm name

The name of the database request module (DBRM) that is currently processing. The DBRM, created by the Db2 precompiler, contains information about an SQL statement.

• STMT=statement number

This is the Db2 precompiler-generated statement number. The source and error message listings from the precompiler use this statement number, and you can use the statement number to determine which statement is processing. This number is a source line counter that includes host language statements. A statement number that is greater than 32 167 displays as 0.

SECT=section number

The section number of the plan that the SQL statement uses.

SQL statements that contain input host variables

The IVAR (input host variables) section and its attendant fields appear only when the executing statement contains input host variables.

The host variables section includes the variables from predicates, the values used for inserting or updating, and the text of dynamic SQL statements that are being prepared. The address of the input variable is AT X'nnnnnnnn'.

Additional host variable information:

TYPE=data type

Specifies the data type for this host variable. The basic data types include character string, graphic string, binary integer, floating-point, decimal, date, time, and timestamp.

• LEN=length

Specifies the length of the host variable.

IND=indicator variable status number

Specifies the indicator variable that is associated with this particular host variable. A value of zero indicates that no indicator variable exists. If the value for the selected column is null, Db2 puts a negative value in the indicator variable for this host variable.

DATA=host variable data

Specifies the data, displayed in hexadecimal format, that is associated with this host variable. If the data exceeds what can display on a single line, three periods (...) appear at the far right to indicate that more data is present.

EDF after execution

The following figure shows an example of the first EDF screen that is displayed after the executing an SQL statement. The names of the key information fields on this panel are in **boldface**.

```

Figure 78. EDF screen after a Db2 SQL statement

The Db2 SQL information in this screen is as follows:

• P.AUTH=primary authorization ID

The primary Db2 authorization ID.

• S.AUTH=secondary authorization ID

The secondary authorization ID. If the RACF list of group options is not active, Db2 uses the connected group name that the CICS attachment facility supplies as the secondary authorization ID. If the RACF list of group options is active, Db2 ignores the connected group name that the CICS attachment facility supplies, but the value is displayed in the Db2 list of secondary authorization IDs.

• PLAN=plan name

The name of the plan that is currently running. The PLAN represents the control structure that is produced during the bind process and that is used by Db2 to process SQL statements that are encountered while the application is running.

SQL Communication Area (SQLCA)

Information in the SQLCA. The SQLCA contains information about errors, if any occur. Db2 uses the SQLCA to give an application program information about the executing SQL statements.

Plus signs (+) on the left of the screen indicate that you can see additional EDF output by using PF keys to scroll the screen forward or back.

The OVAR (output host variables) section and its attendant fields are displayed only when the executing statement returns output host variables.

The following figure contains the rest of the EDF output for this example.

```
PROGRAM: TESTC05

Figure 79. EDF screen after a Db2 SQL statement, continued

The attachment facility automatically displays SQL information while in the EDF mode. (You can start EDF as outlined in the appropriate CICS application programmer's reference manual.) If this information is not displayed, contact the person that is responsible for installing and migrating Db2.

Related concepts

Data types of columns

When you create a Db2 table, you define each column to have a specific data type. The data type of a column determines what you can and cannot do with the column.

Indicator variables, arrays, and structures

An indicator variable is associated with a particular host variable. Each indicator variable contains a small integer value that indicates some information about the associated host variable. Indicator arrays and structures serve the same purpose for host-variable arrays and structures.

Related information

CICS debugging aids (CICS Transaction Server for z/OS)

Finding a violated referential or check constraint

When you receive an SQL error because of a constraint violation, look at the SQLCA for specific information.

About this task

Question: When a referential or check constraint has been violated, how do I determine which one it is?

Answer: When you receive an SQL error because of a constraint violation, print out the SQLCA. You can use the DSNTIAR routine to format the SQLCA for you. Check the SQL error message insertion text (SQLERRM) for the name of the constraint. For information about possible violations, see SQLCODEs -530 through -548.

Related concepts

Error (-) SQL codes (Db2 Codes)

Related tasks

Displaying SQLCA fields by calling DSNTIAR

If you use the SQLCA to check whether an SQL statement executed successfully, your program needs to read the data in the appropriate SQLCA fields. One easy way to read these fields is to use the assembler subroutine DSNTIAR.

Chapter 12. Sample data and applications supplied with Db2 for z/OS

You can use sample applications that are included with Db2 for z/OS to learn about how to program applications that take advantage Db2 capabilities. Db2 also provides models for your own situations.

To prepare and run the supplied sample applications, use the JCL in *prefix*.SDSNSAMP as a model:

Related reference

Db2 sample tables (Introduction to Db2 for z/OS)

Db2 sample tables

Much of the Db2 information refers to or relies on the Db2 sample tables. As a group, the tables include information that describes employees, departments, projects, and activities, and they make up a sample application that exemplifies many of the features of Db2.

GUPI

The sample storage group, databases, table spaces, tables, and views are created when you run the installation sample jobs DSNTEJ1 and DSNTEJ7. Db2 sample objects that include LOBs are created in job DSNTEJ7. All other sample objects are created in job DSNTEJ1. The CREATE INDEX statements for the sample tables are not shown here; they, too, are created by the DSNTEJ1 and DSNTEJ7 sample jobs.

Authorization on all sample objects is given to PUBLIC in order to make the sample programs easier to run. You can review the contents of any table by executing an SQL statement, for example SELECT * FROM DSN8C10.PROJ. For convenience in interpreting the examples, the department and employee tables are listed in full.

Related concepts

Phase 1: Creating and loading sample tables (Db2 Installation and Migration)

Activity table (DSN8C10.ACT)

The activity table describes the activities that can be performed during a project.

GUPI

The activity table resides in database DSN8D12A and is created with the following statement:

```
CREATE TABLE DSN8C10.ACT

(ACTNO SMALLINT NOT NULL,
ACTKWD CHAR(6) NOT NULL,
ACTDESC VARCHAR(20) NOT NULL,
PRIMARY KEY (ACTNO)

IN DSN8D12A.DSN8S12P
CCSID EBCDIC;
```

GUPI

Content of the activity table

The following table shows the content of the columns in the activity table.

Table 156. Columns of the activity table			
Column	Column name	Description	
1	ACTNO	Activity ID (the primary key)	

Table 156. Columns of	the activity	v table	(continued)
-----------------------	--------------	---------	-------------

Column	Column name	Description
2	ACTKWD	Activity keyword (up to six characters)
3	ACTDESC	Activity description

The activity table has the following indexes.

Table 157. Indexes of the activity table

Name	On column	Type of index
DSN8C10.XACT1	ACTNO	Primary, ascending
DSN8C10.XACT2	ACTKWD	Unique, ascending

Relationship to other tables

The activity table is a parent table of the project activity table, through a foreign key on column ACTNO.

Department table (DSN8C10.DEPT)

The department table describes each department in the enterprise and identifies its manager and the department to which it reports.

GUPI

The department table resides in table space DSN8D12A.DSN8S12D and is created with the following statement:

```
CREATE TABLE DSN8C10.DEPT

(DEPTNO CHAR(3) NOT NULL,
DEPTNAME VARCHAR(36) NOT NULL,
MGRNO CHAR(6) ,
ADMRDEPT CHAR(3) NOT NULL,
LOCATION CHAR(16) ,
PRIMARY KEY (DEPTNO) )
IN DSN8D12A.DSN8S12D
CCSID EBCDIC;
```

Because the department table is self-referencing, and also is part of a cycle of dependencies, its foreign keys must be added later with the following statements:

```
ALTER TABLE DSN8C10.DEPT
FOREIGN KEY RDD (ADMRDEPT) REFERENCES DSN8C10.DEPT
ON DELETE CASCADE;

ALTER TABLE DSN8C10.DEPT
FOREIGN KEY RDE (MGRNO) REFERENCES DSN8C10.EMP
ON DELETE SET NULL;
```

GUPI

Content of the department table

The following table shows the content of the columns in the department table.

Table 158. Columns of the department table

Column	Column name	Description
1	DEPTNO	Department ID, the primary key.

Table 158. Columns of the department table (continued)

Column	Column name	Description
2	DEPTNAME	A name that describes the general activities of the department.
3	MGRNO	Employee number (EMPNO) of the department manager.
4	ADMRDEPT	ID of the department to which this department reports; the department at the highest level reports to itself.
5	LOCATION	The remote location name.

The following table shows the indexes of the department table.

Table 159. Indexes of the department table

Name	On column	Type of index
DSN8C10.XDEPT1	DEPTNO	Primary, ascending
DSN8C10.XDEPT2	MGRNO	Ascending
DSN8C10.XDEPT3	ADMRDEPT	Ascending

The following table shows the content of the department table.

Table 160. DSN8C10.DEPT: department table

DEPTNO	DEPTNAME	MGRNO	ADMRDEPT	LOCATION
A00	SPIFFY COMPUTER SERVICE DIV.	000010	A00	
B01	PLANNING	000020	A00	
C01	INFORMATION CENTER	000030	A00	
D01	DEVELOPMENT CENTER		A00	
E01	SUPPORT SERVICES	000050	A00	
D11	MANUFACTURING SYSTEMS	000060	D01	
D21	ADMINISTRATION SYSTEMS	000070	D01	
E11	OPERATIONS	000090	E01	
E21	SOFTWARE SUPPORT	000100	E01	
F22	BRANCH OFFICE F2		E01	
G22	BRANCH OFFICE G2		E01	
H22	BRANCH OFFICE H2		E01	
I22	BRANCH OFFICE I2		E01	
J22	BRANCH OFFICE J2		E01	

The LOCATION column contains null values until sample job DSNTEJ6 updates this column with the location name.

Relationship to other tables

The department table is self-referencing: the value of the administering department must be a valid department ID.

The department table is a parent table of the following:

- The employee table, through a foreign key on column WORKDEPT
- The project table, through a foreign key on column DEPTNO

The department table is a dependent of the employee table, through its foreign key on column MGRNO.

Employee table (DSN8C10.EMP)

The sample employee table identifies all employees by an employee number and lists basic personnel information.

GUPI The employee table resides in the partitioned table space DSN8D12A.DSN8S12E. Because this table has a foreign key that references DEPT, that table and the index on its primary key must be created first. Then EMP is created with the following statement:

```
CREATE TABLE DSN8C10.EMP
                                                    NOT NULL,
      (EMPNO
                 CHAR(6)
       FIRSTNME VARCHAR(12)
                                                    NOT NULL,
                                                    NOT NULL,
       MIDINIT
                 CHAR(1)
       LASTNAME VARCHAR(15)
                                                    NOT NULL,
       WORKDEPT
                CHAR(3)
       PHONENO
                 CHAR(4)
                                  CONSTRAINT NUMBER CHECK
                 (PHONENO >= '0000' AND
                  PHONENO <= '9999')
       HIREDATE DATE
                 CHAR(8)
       J0B
       EDLEVEL
                 SMALLINT
       SEX
                 CHAR(1)
       BIRTHDATE DATE
                 DECIMAL(9,2)
DECIMAL(9,2)
       SALARY
       BONUS
       COMM
                 DECIMAL(9,2)
       PRIMARY KEY (EMPNO)
       FOREIGN KEY RED (WORKDEPT) REFERENCES DSN8C10.DEPT
                 ON DELETE SET NULL
 EDITPROC DSN8EAE1
 IN DSN8D12A.DSN8S12E
 CCSID EBCDIC;
```

GUPI

Content of the employee table

The following table shows the type of content of each of the columns in the employee table. The table has a check constraint, NUMBER, which checks that the four-digit phone number is in the numeric range 0000 to 9999.

Table 161. Columns of the employee table			
Column	Column name	Description	
1	EMPNO	Employee number (the primary key)	
2	FIRSTNME	First name of employee	
3	MIDINIT	Middle initial of employee	
4	LASTNAME	Last name of employee	
5	WORKDEPT	ID of department in which the employee works	
6	PHONENO	Employee telephone number	
7	HIREDATE	Date of hire	
8	JOB	Job held by the employee	
9	EDLEVEL	Number of years of formal education	
10	SEX	Sex of the employee (M or F)	

Table 161. Columns of the employee table (continued)

Column	Column name	Description
11	BIRTHDATE	Date of birth
12	SALARY	Yearly salary in dollars
13	BONUS	Yearly bonus in dollars
14	COMM	Yearly commission in dollars

The following table shows the indexes of the employee table.

Table 162. Indexes of the employee table

Name	On column	Type of index
DSN8C10.XEMP1	EMPNO	Primary, partitioned, ascending
DSN8C10.XEMP2	WORKDEPT	Ascending

The following table shows the first half (left side) of the content of the employee table. (<u>Table 164 on page 1008</u> shows the remaining content (right side) of the employee table.)

Table 163. Left half of DSN8C10.EMP: employee table. Note that a blank in the MIDINIT column is an actual value of " " rather than null.

EMPNO	FIRSTNME	MIDINIT	LASTNAME	WORKDEPT	PHONENO	HIREDATE
000010	CHRISTINE	I	HAAS	A00	3978	1965-01-01

Relationship to other tables

FIELDREP

(200340)

The employee table is a parent table of:

• The department table, through a foreign key on column MGRNO

Μ

1926-05-17

The project table, through a foreign key on column RESPEMP

16

23840.00

500.00

1907.00

The employee table is a dependent of the department table, through its foreign key on column WORKDEPT.

Employee photo and resume table (DSN8C10.EMP_PHOTO_RESUME)

The sample employee photo and resume table complements the employee table.

Each row of the photo and resume table contains a photo of the employee, in two formats, and the employee's resume. The photo and resume table resides in table space DSN8D12L.DSN8S12B. The following statement creates the table:

```
CREATE TABLE DSN8C10.EMP_PHOTO_RESUME

(EMPNO CHAR(06) NOT NULL,

EMP_ROWID ROWID NOT NULL GENERATED ALWAYS,

PSEG_PHOTO BLOB(500K),

BMP_PHOTO BLOB(100K),

RESUME CLOB(5K),

PRIMARY KEY (EMPNO))

IN DSN8D12L.DSN8S12B

CCSID EBCDIC;
```

Db2 requires an auxiliary table for each LOB column in a table. The following statements define the auxiliary tables for the three LOB columns in DSN8C10.EMP_PHOTO_RESUME:

```
CREATE AUX TABLE DSN8C10.AUX_BMP_PHOTO
IN DSN8D12L.DSN8S12M
STORES DSN8C10.EMP_PHOTO_RESUME
COLUMN BMP_PHOTO;

CREATE AUX TABLE DSN8C10.AUX_PSEG_PHOTO
IN DSN8D12L.DSN8S12L
STORES DSN8C10.EMP_PHOTO_RESUME
COLUMN PSEG_PHOTO;

CREATE AUX TABLE DSN8C10.AUX_EMP_RESUME
IN DSN8D12L.DSN8S12N
STORES DSN8C10.EMP_PHOTO_RESUME
COLUMN RESUME;
```

GUPI

Content of the employee photo and resume table

The following table shows the content of the columns in the employee photo and resume table.

Table 165. Columns o	f the employee p	hoto and	! resume table
----------------------	------------------	----------	----------------

Column	Column name	Description
1	EMPNO	Employee ID (the primary key).
2	EMP_ROWID	Row ID to uniquely identify each row of the table. Db2 supplies the values of this column.
3	PSEG_PHOTO	Employee photo, in PSEG format.
4	ВМР_РНОТО	Employee photo, in BMP format.
5	RESUME	Employee resume.

The following table shows the indexes for the employee photo and resume table.

Table 166. Indexes of the employee photo and resume table

Name	On column	Type of index
DSN8C10.XEMP_PHOTO_RESUME	EMPNO	Primary, ascending

The following table shows the indexes for the auxiliary tables that support the employee photo and resume table.

Table 167. Indexes of the auxiliary tables for the employee photo and resume table

Name	On table	Type of index
DSN8C10.XAUX_BMP_PHOTO	DSN8C10.AUX_BMP_PHOTO	Unique
DSN8C10.XAUX_PSEG_PHOTO	DSN8C10.AUX_PSEG_PHOTO	Unique
DSN8C10.XAUX_EMP_RESUME	DSN8C10.AUX_EMP_RESUME	Unique

Relationship to other tables

The employee photo and resume table is a parent table of the project table, through a foreign key on column RESPEMP.

Project table (DSN8C10.PROJ)

The sample project table describes each project that the business is currently undertaking. Data that is contained in each row of the table includes the project number, name, person responsible, and schedule dates.

The project table resides in database DSN8D12A. Because this table has foreign keys that reference DEPT and EMP, those tables and the indexes on their primary keys must be created first. Then PROJ is created with the following statement:

GUPI

```
CREATE TABLE DSN8C10.PROJ
                (PROJNO CHAR(6) PRIMARY KEY NOT NULL,
PROJNAME VARCHAR(24) NOT NULL WITH DEFAULT
                    'PROJECT NAME UNDÉFINED'
                 DEPTNO
                                           NOT NULL REFERENCES
                          CHAR(3)
                   DSN8C10.DEPT ON DELETE RESTRICT
                  RESPEMP CHAR(6)
                                           NOT NULL REFERENCES
                   DSN8C10.EMP ON DELETE RESTRICT,
                 PRSTAFF DECIMAL(5, 2)
                 PRSTDATE DATE
                 PRENDATE DATE
                 MAJPROJ CHAR(6))
         IN DSN8D12A.DSN8S12P
         CCSID EBCDIC;
```

Because the project table is self-referencing, the foreign key for that constraint must be added later with the following statement:

```
ALTER TABLE DSN8C10.PROJ
FOREIGN KEY RPP (MAJPROJ) REFERENCES DSN8C10.PROJ
ON DELETE CASCADE;
```

GUPI

Content of the project table

The following table shows the content of the columns of the project table.

Table 168. Columns of the project table

Column	Column name	Description	
1	PROJNO	Project ID (the primary key)	
2	PROJNAME	Project name	
3	DEPTNO	ID of department responsible for the project	

T 1- 1/0	0-1	£ 41	:	(1)
тарге 168.	Columns o	if the pro	nect table	(continued)

Column	Column name	Description
4	RESPEMP	ID of employee responsible for the project
5	PRSTAFF	Estimated mean number of persons that are needed between PRSTDATE and PRENDATE to complete the whole project, including any subprojects
6	PRSTDATE	Estimated project start date
7	PRENDATE	Estimated project end date
8	MAJPROJ	ID of any project of which this project is a part

The following table shows the indexes for the project table:

Table 169. Indexes of the project table

Name	On column	Type of index
DSN8C10.XPROJ1	PROJNO	Primary, ascending
DSN8C10.XPROJ2	RESPEMP	Ascending

Relationship to other tables

The table is self-referencing: a non-null value of MAJPROJ must be a valid project number. The table is a parent table of the project activity table, through a foreign key on column PROJNO. It is a dependent of the following tables:

- The department table, through its foreign key on DEPTNO
- The employee table, through its foreign key on RESPEMP

Project activity table (DSN8C10.PROJACT)

The sample project activity table lists the activities that are performed for each project.

The project activity table resides in database DSN8D12A. Because this table has foreign keys that reference PROJ and ACT, those tables and the indexes on their primary keys must be created first. Then PROJACT is created with the following statement:

GUPI

```
CREATE TABLE DSN8C10.PROJACT
      (PROJNO
                CHAR(6)
                                                 NOT NULL,
       ACTNO
                 SMALLINT
                                                 NOT NULL,
       ACSTAFF
                DECIMAL(5,2)
                                                 NOT NULL,
       ACSTDATE DATE
       ACENDATE
                DATE
       PRIMARY KEY (PROJNO, ACTNO, ACSTDATE),
      FOREIGN KEY RPAP (PROJNO) REFERENCES DSN8C10.PROJ
                                       ON DELETE RESTRICT,
      FOREIGN KEY RPAA (ACTNO) REFERENCES DSN8C10.ACT
                                       ON DELETE RESTRICT)
 IN DSN8D12A.DSN8S12P
  CCSID EBCDIC;
```

GUPI

Content of the project activity table

The following table shows the content of the columns of the project activity table.

Table 170.	Columns	of the	project	activity	/table
Tuble Inc.	Cottanting		PIOICOL	CLOLLVILL)	Laste

Column	Column name	Description
1	PROJNO	Project ID
2	ACTNO	Activity ID
3	ACSTAFF	Estimated mean number of employees that are needed to staff the activity
4	ACSTDATE	Estimated activity start date
5	ACENDATE	Estimated activity completion date

The following table shows the index of the project activity table:

Table 171. Index of the project activity table

Name	On columns	Type of index
DSN8C10.XPROJAC1	PROJNO, ACTNO, ACSTDATE	primary, ascending

Relationship to other tables

The project activity table is a parent table of the employee to project activity table, through a foreign key on columns PROJNO, ACTNO, and EMSTDATE. It is a dependent of the following tables:

- The activity table, through its foreign key on column ACTNO
- The project table, through its foreign key on column PROJNO

Related reference

Employee-to-project activity table (DSN8C10.EMPPROJACT)

The sample employee-to-project activity table identifies the employee who performs an activity for a project, tells the proportion of the employee's time that is required, and gives a schedule for the activity.

GUPI

The employee-to-project activity table resides in database DSN8D12A. Because this table has foreign keys that reference EMP and PROJACT, those tables and the indexes on their primary keys must be created first. Then EMPPROJACT is created with the following statement:

```
CREATE TABLE DSN8C10.EMPPROJACT
      (EMPNO
                 CHAR(6)
                                                  NOT NULL,
                                                  NOT NULL,
       PROJNO
                 CHAR(6)
                                                  NOT NULL,
       ACTNO
                 SMALL THT
       EMPTIME
                 DECIMAL(5,2)
       EMSTDATE
                 DATE
       EMENDATE DATE
       FOREIGN KEY REPAPA (PROJNO, ACTNO, EMSTDATE)
                 REFERENCES DSN8C10.PROJACT
                                        ON DELETE RESTRICT,
      FOREIGN KEY REPAE (EMPNO) REFERENCES DSN8C10.EMP
                                        ON DELETE RESTRICT)
 IN DSN8D12A.DSN8S12P
 CCSID EBCDIC;
```

GUPI

Content of the employee-to-project activity table

<u>Project table (DSN8C10.PROJ) (Introduction to Db2 for z/OS)</u> Unicode sample table (DSN8C10.DEMO_UNICODE) (Introduction to Db2 for z/OS)

Views on the sample tables

Db2 creates a number of views on the sample tables for use in the sample applications.

The following table indicates the tables on which each view is defined and the sample applications that use the view. All view names have the qualifier DSN8C10.

Table 175. Views on sample	tables	
View name	On tables or views	Used in application
VDEPT	DEPT	Organization Project
VHDEPT	DEPT	Distributed organization
VEMP	ЕМР	Distributed organization Organization Project
VPROJ	PROJ	Project
VACT	ACT	Project
VPROJACT	PROJACT	Project
VEMPPROJACT	EMPPROJACT	Project
VDEPMG1	DEPT EMP	Organization
VEMPDPT1	DEPT EMP	Organization
VASTRDE1	DEPT	
VASTRDE2	VDEPMG1 EMP	Organization
VPROJRE1	PROJ EMP	Project
VPSTRDE1	VPROJRE1 VPROJRE2	Project
VPSTRDE2	VPROJRE1	Project
VFORPLA	VPROJRE1 EMPPROJACT	Project
VSTAFAC1	PROJACT ACT	Project

Table 175. Views on sample tables (continued)

View name	On tables or views	Used in application
VSTAFAC2	EMPPROJACT ACT EMP	Project
VPHONE	EMP DEPT	Phone
VEMPLP	EMP	Phone

GUPI

The following SQL statement creates the view named VDEPT.

The following SQL statement creates the view named VHDEPT.

The following SQL statement creates the view named VEMP.

```
CREATE VIEW DSN8C10.VEMP

AS SELECT ALL EMPNO ,
 FIRSTNME,
 MIDINIT ,
 LASTNAME,
 WORKDEPT

FROM DSN8C10.EMP;
```

The following SQL statement creates the view named VPROJ.

```
CREATE VIEW DSN8C10.VPROJ

AS SELECT ALL

PROJNO, PROJNAME, DEPTNO, RESPEMP, PRSTAFF,

PRSTDATE, PRENDATE, MAJPROJ

FROM DSN8C10.PROJ;
```

The following SQL statement creates the view named VACT.

The following SQL statement creates the view named VPROJACT.

```
CREATE VIEW DSN8C10.VPROJACT

AS SELECT ALL

PROJNO,ACTNO, ACSTAFF, ACSTDATE, ACENDATE
FROM DSN8C10.PROJACT;
```

The following SQL statement creates the view named VEMPPROJACT.

```
CREATE VIEW DSN8C10.VEMPPROJACT
AS SELECT ALL
EMPNO, PROJNO, ACTNO, EMPTIME, EMSTDATE, EMENDATE
FROM DSN8C10.EMPPROJACT;
```

The following SQL statement creates the view named VDEPMG1.

```
CREATE VIEW DSN8C10.VDEPMG1
(DEPTNO, DEPTNAME, MGRNO, FIRSTNME, MIDINIT,
LASTNAME, ADMRDEPT)
AS SELECT ALL
DEPTNO, DEPTNAME, EMPNO, FIRSTNME, MIDINIT,
LASTNAME, ADMRDEPT
FROM DSN8C10.DEPT LEFT OUTER JOIN DSN8C10.EMP
ON MGRNO = EMPNO;
```

The following SQL statement creates the view named VEMPDPT1.

```
CREATE VIEW DSN8C10.VEMPDPT1
(DEPTNO, DEPTNAME, EMPNO, FRSTINIT, MIDINIT,
LASTNAME, WORKDEPT)
AS SELECT ALL
DEPTNO, DEPTNAME, EMPNO, SUBSTR(FIRSTNME, 1, 1), MIDINIT,
LASTNAME, WORKDEPT
FROM DSN8C10.DEPT RIGHT OUTER JOIN DSN8C10.EMP
ON WORKDEPT = DEPTNO;
```

The following SQL statement creates the view named VASTRDE1.

```
CREATE VIEW DSN8C10.VASTRDE1
(DEPT1NO, DEPT1NAM, EMP1NO, EMP1FN, EMP1MI, EMP1LN, TYPE2,
DEPT2NO, DEPT2NAM, EMP2NO, EMP2FN, EMP2MI, EMP2LN)
AS SELECT ALL
D1.DEPTNO, D1.DEPTNAME, D1.MGRNO, D1.FIRSTNME, D1.MIDINIT,
D1.LASTNAME, '1',
D2.DEPTNO, D2.DEPTNAME, D2.MGRNO, D2.FIRSTNME, D2.MIDINIT,
D2.LASTNAME
FROM DSN8C10.VDEPMG1 D1, DSN8C10.VDEPMG1 D2
WHERE D1.DEPTNO = D2.ADMRDEPT;
```

The following SQL statement creates the view named VASTRDE2.

```
CREATE VIEW DSN8C10.VASTRDE2

(DEPT1NO, DEPT1NAM, EMP1NO, EMP1FN, EMP1MI, EMP1LN, TYPE2,

DEPT2NO, DEPT2NAM, EMP2NO, EMP2FN, EMP2MI, EMP2LN)

AS SELECT ALL

D1.DEPTNO, D1.DEPTNAME, D1.MGRNO, D1.FIRSTNME, D1.MIDINIT,

D1.LASTNAME, '2',

D1.DEPTNO, D1.DEPTNAME, E2.EMPNO, E2.FIRSTNME, E2.MIDINIT,

E2.LASTNAME

FROM DSN8C10.VDEPMG1 D1, DSN8C10.EMP E2

WHERE D1.DEPTNO = E2.WORKDEPT;
```

The following figure shows the SQL statement that creates the view named VPROJRE1.

```
CREATE VIEW DSN8C10.VPROJRE1
(PROJNO,PROJNAME,PROJDEP,RESPEMP,FIRSTNME,MIDINIT,
LASTNAME,MAJPROJ)
AS SELECT ALL
PROJNO,PROJNAME,DEPTNO,EMPNO,FIRSTNME,MIDINIT,
LASTNAME,MAJPROJ
FROM DSN8C10.PROJ, DSN8C10.EMP
WHERE RESPEMP = EMPNO;
```

Figure 81. VPROJRE1

The following SQL statement creates the view named VPSTRDE1.

```
CREATE VIEW DSN8C10.VPSTRDE1
(PROJ1NO,PROJ1NAME,RESP1NO,RESP1FN,RESP1MI,RESP1LN,
PROJ2NO,PROJ2NAME,RESP2NO,RESP2FN,RESP2MI,RESP2LN)
```

```
AS SELECT ALL
P1.PROJNO,P1.PROJNAME,P1.RESPEMP,P1.FIRSTNME,P1.MIDINIT,

PA.ACSTAFF, PA.ACSTDATE,
PA.ACENDATE, '1'
FROM DSN8C10.PROJACT PA, DSN8C10.ACT AC
WHERE PA.ACTNO = AC.ACTNO;
```

The following SQL statement creates the view named VSTAFAC2.

```
CREATE VIEW DSN8C10.VSTAFAC2

(PROJNO, ACTNO, ACTDESC, EMPNO, FIRSTNME, MIDINIT, LASTNAME, EMPTIME, STDATE, ENDATE, TYPE)

AS SELECT ALL

EP.PROJNO, EP.ACTNO, AC.ACTDESC, EP.EMPNO,EM.FIRSTNME, EM.MIDINIT, EM.LASTNAME, EP.EMPTIME, EP.EMSTDATE, EP.EMENDATE, '2'

FROM DSN8C10.EMPPROJACT EP, DSN8C10.ACT AC, DSN8C10.EMP EM WHERE EP.ACTNO = AC.ACTNO AND EP.EMPNO = EM.EMPNO;
```

The following SQL statement creates the view named VPHONE.

```
CREATE VIEW DSN8C10.VPHONE
               (LASTNAME
               FIRSTNAME
               MIDDLEINITIAL,
               PHONENUMBER,
               EMPLOYEENUMBER,
               DEPTNUMBER,
               DEPTNAME)
                       LÁSTNAME,
   AS SELECT ALL
                       FIRSTNME,
                       MIDINIT
                       VALUE(PHONENO, '
                       EMPNO,
                       DEPTNO
                       DEPTNAME
```

```
FROM DSN8C10.EMP, DSN8C10.DEPT
WHERE WORKDEPT = DEPTNO;
```

The following SQL statement creates the view named VEMPLP.

```
CREATE VIEW DSN8C10.VEMPLP

(EMPLOYEENUMBER,
PHONENUMBER)

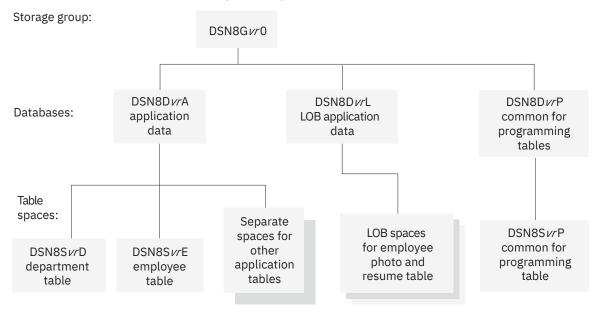

AS SELECT ALL EMPNO,
PHONENO
FROM DSN8C10.EMP;
```

GUPI

Storage of sample application tables

Normally, related data is stored in the same database.

The following figure shows how the sample tables are related to databases and storage groups. Two databases are used to illustrate the possibility.

vr is a 2-digit version identifier.

Figure 82. Relationship among sample databases and table spaces

In addition to the storage group and databases that are shown in the preceding figure, the storage group DSN8G12U and database DSN8D12U are created when you run DSNTEJ2A.

Storage group for sample application data

Sample application data is stored in storage group DSN8G120. The default storage group, SYSDEFLT, which is created when Db2 is installed, is not used to store sample application data.

GUPI

The storage group that is used to store sample application data is defined by the following statement:

```
CREATE STOGROUP DSN8G120
VOLUMES (DSNV01)
VCAT DSNC111;
```

GUPI

Databases for sample application data

Sample application data is stored in several different databases. The default database that is created when Db2 is installed is not used to store the sample application data.

DSN8D12P is the database that is used for tables that are related to programs. The other databases are used for tables that are related to applications. The databases are defined by the following statements:

```
CREATE DATABASE DSN8D12A
 STOGROUP DSN8G120
 BUFFERPOOL BP0
  CCSID EBCDIC;
CREATE DATABASE DSN8D12P
 STOGROUP DSN8G120
  BUFFERPOOL BP0
 CCSID EBCDIC;
CREATE DATABASE DSN8D12L
 STOGROUP DSN8G120
  BUFFERPOOL BPO
  CCSID EBCDIC;
CREATE DATABASE DSN8D12E
 STOGROUP DSN8G120
  BUFFERPOOL BPO
 CCSID UNICODE;
CREATE DATABASE DSN8D12U
 STOGROUP DSN8G12U
 CCSID EBCDIC;
```

GUPI

Table spaces for sample application data

The table spaces that are not explicitly defined are created implicitly in the DSN8D12A database, using the default space attributes.

GUPI

The following SQL statements explicitly define a series of table spaces.

```
CREATE TABLESPACE DSN8S12D
  IN DSN8D12A
  USING STOGROUP DSN8G120
        PRIQTY 20
SECQTY 20
        ERASE NO
  LOCKSIZE PAGE LOCKMAX SYSTEM
  BUFFERPOOL BP0
  CLOSE NO
  CCSID EBCDIC;
CREATE TABLESPACE DSN8S12E
  IN DSN8D12A
  USING STOGROUP DSN8G120
        PRIQTY 20
SECQTY 20
        ERASE NO
  NUMPARTS 4
    (PART 1 USING STOGROUP DSN8G120
                   PRIQTY 12
SECQTY 12,

CCSID UNICODE;
```

GUPI

SYSDUMMYx tables

Db2 for z/OS provides a set of SYSDUMMYx catalog tables.

GUPI

The last character of the table name identifies the associated encoding scheme as follows:

- SYSIBM.SYSDUMMY1 uses the EBCDIC encoding scheme.
- SYSIBM.SYSDUMMYE uses the EBCDIC encoding scheme.
- SYSIBM.SYSDUMMYA uses the ASCII encoding scheme.
- SYSIBM.SYSDUMMYU uses the UNICODE encoding scheme.

Although the SYSDUMMYx tables are implemented as catalog tables, they are similar to sample tables, and are used in some examples in the Db2 for z/OS documentation.

You can use any of the SYSDUMMYx tables when you need to write a query, but no data from a table is referenced. In any query, you must specify a table reference in the FROM clause, but if the query does not reference any data from the table, it does not matter which table is referenced in the FROM clause. Each of the SYSDUMMYx tables contains one row, so a SYSDUMMYx table can be referenced in a SELECT INTO statement without the need for a predicate to limit the result to a single row of data.

For example, when you want to retrieve the value of a special register or global variable, you can use a query that references a SYSDUMMYx table.

```
SELECT CURRENT PATH -- Retrieve the value of a special register
INTO :myvar
FROM SYSIBM.SYSDUMMY1;
SELECT TEMPORAL_LOGICAL_TRANSACTION_TIME -- Retrieve the value of a special register
INTO :myvar
FROM SYSIBM.SYSDUMMY1;
```

Sometimes when Db2 for z/OS processes an SQL statement, the statement is rewritten, and a reference to a SYSDUMMYx table is added. For example, some of the internal rewrites that result in adding a reference to a SYSDUMMYx table are for processing the search condition of a trigger, or the SQL PL control statements IF, REPEAT, RETURN, or WHILE. In these situations, the privilege set must include the SELECT privilege on the SYSDUMMYx table that is referenced.

GUPI

Related concepts

Objects with different CCSIDs in the same SQL statement (Db2 Internationalization Guide)

Related tasks

Avoiding character conversion for LOB locators

In certain situations, Db2 materializes the entire LOB value and converts it to the encoding scheme of a particular SQL statement. This extra processing can degrade performance and should be avoided.

Db2 productivity-aid sample programs

Db2 provides four sample programs that many users find helpful as productivity aids. These programs are shipped as source code, so you can modify them to meet your needs.

DSNTIAUL

DSNTIAUL is a sample program for unloading data, as an alternative to the UNLOAD utility. DSNTIAUL is written in the assembler language. DSNTIAUL can unload some or all rows from up to 100 Db2 tables. With DSNTIAUL, you can unload data of any Db2 built-in data type or distinct type. DSNTIAUL unloads the rows in a form that is compatible with the LOAD utility and generates utility control statements for LOAD. You can also used DSNTIAUL to execute any SQL non-SELECT statement that can be executed dynamically.

DSNTIAD

The DSNTIAD sample program can issue any SQL statement that can be executed dynamically, except for SELECT statements. DSNTIAD is written in assembler language.

DSNTEP2

DSNTEP2 is a sample dynamic SQL program that can issue any SQL statement that can be executed dynamically. DSNTEP2 is written in PL/I language and available in two versions: a source version that you can modify to meet your needs or an object code version that you can use without the need for a PL/I compiler.

DSNTEP4

The DSNTEP4 sample program is identical to DSNTEP2, except that it uses multi-row fetch for increased performance. DSNTEP4 is written in PL/I language and available in two versions: a source version that you can modify to meet your needs or an object code version that you can use without the need for a PL/I compiler.

Because these four programs also accept the static SQL statements CONNECT, SET CONNECTION, and RELEASE, you can use the programs to access Db2 tables at remote locations.

Preparing the productivity-aid sample programs

DSNTIAUL and DSNTIAD are shipped only as source code, so you must precompile, assemble, link, and bind them before you can use them. If you want to use the source code version of DSNTEP2 or DSNTEP4, you must precompile, compile, link, and bind it. You need to bind the object code version of DSNTEP2 or DSNTEP4 before you can use them. Usually a system administrator prepares the programs as part of the installation process.

Important: Always bind the package for the DSNTIAUL sample program with the REOPT(ALWAYS) bind option, and do not specify the CONCENTRATESTMT(YES) bind option for this package.

The following table indicates the installation jobs that prepare each sample program. All installation jobs are in data set DSN1210.SDSNSAMP.

Table 176. Jobs that prepare DSNTIAUL, DSNTIAD, DSNTEP2, and DSNTEP4	
Program name	Program preparation job
DSNTIAUL	DSNTEJ2A
DSNTIAD	DSNTIJTM
DSNTEP2 (source)	DSNTEJ1P
DSNTEP2 (object)	DSNTEJ1L
DSNTEP4 (source)	DSNTEJ1P
DSNTEP4 (object)	DSNTEJ1L

Application compatibility for the productivity-aid sample programs

If you are ready for the productivity-aid sample programs to start using new application capabilities in later Db2 12 function levels, you must rebind the packages for these programs with the corresponding APPLCOMPAT option.

The Db2 12 jobs for preparing the productivity-aid sample programs bind the packages with APPLCOMPAT(V12R1) by default, which is equivalent to APPLCOMPAT(V12R1M500).

For more information, see Controlling the Db2 application compatibility level (Db2 for z/OS What's New?) and Function levels and related levels in Db2 12 (Db2 for z/OS What's New?).

Running the productivity-aid sample programs

To run the sample programs, use the RUN (DSN) command. For more information, see <u>RUN subcommand</u> (DSN) (Db2 Commands) and the following topics.

Retrieval of UTF-16 Unicode data by DSNTEP2, DSNTEP4, and DSNTIAUL

You can use DSNTEP2, DSNTEP4, and DSNTIAUL to retrieve Unicode UTF-16 graphic data. However, these programs might not be able to display some characters, if those characters have no mapping in the target SBCS EBCDIC CCSID.

RUN subcommand (DSN) (Db2 Commands) Db2 for z/OS Exchange

DSNTIAUL sample program

You can use the DSNTIAUL program to unload data from Db2 tables into sequential data sets. The data is copied to the data sets and is not deleted from the table.

DSNTIAUL is a sample program for unloading data, as an alternative to the UNLOAD utility. DSNTIAUL is written in the assembler language. DSNTIAUL can unload some or all rows from up to 100 Db2 tables. With DSNTIAUL, you can unload data of any Db2 built-in data type or distinct type. DSNTIAUL unloads the rows in a form that is compatible with the LOAD utility and generates utility control statements for LOAD. You can also used DSNTIAUL to execute any SQL non-SELECT statement that can be executed dynamically.

When multi-row fetch is used, parallelism might be disabled in the last parallel group in the top-level query block for a query. For very simple queries, parallelism might be disabled for the entire query when multi-row fetch is used. To obtain full parallelism when running DSNTIAUL, switch DSNTIAUL to single-row fetch mode by specifying 1 for the *number-of-rows-per-fetch* parameter.

DSNTIAUL uses SQL to access Db2. Operations on a row-level or column-level access control enforced table are subject to the rules specified for the access control. If the table is row-level access control enforced, DSNTIAUL receives and returns only the rows of the table that satisfy the row permissions for the user. If the table is column-level access control enforced, DSNTIAUL receives and returns the values in the column values as modified by the column masks for the user.

Important: To avoid substitution characters in unloaded data, do not use DSNTIAUL to unload an EBCDIC table that contains a Unicode column.

Preparing the DSNTIAUL sample program

Before you can use the DSNTIAUL sample program, you must precompile, assemble, link, and bind it first. Also, when you are ready for DSNTIAUL to start using to use new capabilities in later Db2 12 function levels, you must rebind the packages at the corresponding APPLCOMPAT level.

Important: Always bind the package for the DSNTIAUL sample program with the REOPT(ALWAYS) bind option, and do not specify the CONCENTRATESTMT(YES) bind option for this package.

For more information, see "Db2 productivity-aid sample programs" on page 1024.

Running the DSNTIAUL sample program

To run the DSNTIAUL sample program, use the RUN (DSN) command and specify the following load module and plan name.

Load module name	DSNTIAUL
Plan name	DSNTIBC1

For more information about the RUN command, see RUN subcommand (DSN) (Db2 Commands).

DSNTIAUL parameters

PKGSET(collection)

Specifies that DSNTIAUL implicitly executes a SET CURRENT PACKAGESET statement to assign a value to the CURRENT PACKAGESET special register before processing the dynamic SQL statements in SYSIN.

collection

The value to assign to the CURRENT PACKAGESET special register. You can specify up to 40 characters.

SOL

Specify SQL to indicate that your input data set contains one or more complete SQL statements, each of which ends with a semicolon. You can include any SQL statement that can be executed dynamically in your input data set. In addition, you can include the static SQL statements CONNECT, SET CONNECTION, or RELEASE. Static SQL statements must be uppercase.

DSNTIAUL uses the SELECT statements to determine which tables to unload and dynamically executes all other statements except CONNECT, SET CONNECTION, and RELEASE. DSNTIAUL executes CONNECT, SET CONNECTION, and RELEASE statically to connect to remote locations.

number-of-rows-per-fetch

Specify a number from 1 to 32767 to specify the number of rows that DSNTIAUL retrieves for each SQL FETCH operation. If you do not specify this number, DSNTIAUL retrieves 100 rows for each FETCH. This parameter can be specified with the SQL parameter.

If the LOBFILE parameter is also specified, and the result set of a FETCH operation can contain NULL LOB values, *number-of-rows-per-fetch* must be 1.

TOLWARN

Specify NO (the default) or YES to indicate whether DSNTIAUL continues to retrieve rows after receiving an SQL warning:

(NO)

If a warning occurs when DSNTIAUL executes an OPEN or FETCH to retrieve rows, DSNTIAUL stops retrieving rows. If the SQLWARN1, SQLWARN2, SQLWARN6, or SQLWARN7 flag is set when DSNTIAUL executes a FETCH to retrieve rows, DSNTIAUL continues to retrieve rows.

(YES)

If a warning occurs when DSNTIAUL executes an OPEN or FETCH to retrieve rows, DSNTIAUL continues to retrieve rows.

(QUIET)

The same as YES except that the program suppresses all SQL warning messages from OPEN or FETCH statements if the SQLCODE is 0 or greater.

LOBFILE(prefix)

Specify LOBFILE to indicate that you want DSNTIAUL to dynamically allocate data sets, each to receive the full content of a LOB cell. (A LOB cell is the intersection of a row and a LOB column.) If you do not specify the LOBFILE option, you can unload up to only 32 KB of data from a LOB column.

prefix

Specify a high-level qualifier for these dynamically allocated data sets. You can specify up to 17 characters. The qualifier must conform with the rules for TSO data set names.

DSNTIAUL uses a naming convention for these dynamically allocated data sets of prefix.Qiiiiii.Cjjjjjj.Rkkkkkk, where these qualifiers have the following values:

prefix

The high-level qualifier that you specify in the LOBFILE option.

Qiiiiiiii

The sequence number (starting from 0) of a query that returns one or more LOB columns

Ciiiiiii

The sequence number (starting from 0) of a column in a query that returns one or more LOB columns

R*kkkkkk*

The sequence number (starting from 0) of a row of a result set that has one or more LOB columns.

The generated LOAD statement contains LOB file reference variables that can be used to load data from these dynamically allocated data sets.

If you do not specify the SQL parameter, your input data set must contain one or more single-line statements (without a semicolon) that use the following syntax:

```
table or view name [WHERE conditions] [ORDER BY columns]
```

Each input statement must be a valid SQL SELECT statement with the clause SELECT * FROM omitted and with no ending semicolon. DSNTIAUL generates a SELECT statement for each input statement by appending your input line to SELECT * FROM, then uses the result to determine which tables to unload. For this input format, the text for each table specification can be a maximum of 72 bytes and must not span multiple lines.

You can use the input statements to specify SELECT statements that join two or more tables or select specific columns from a table. If you specify columns, you need to modify the LOAD statement that DSNTIAUL generates.

DSNTIAUL data sets

Data set

Description

SYSIN

Input data set.

If you specify the SQL parameter, you can enter bracketed comments in DSNTIAUL input that includes dynamic SQL statements. Bracketed comments are not supported if the input includes the static SQL statements CONNECT, SET CONNECTION, or RELEASE. Bracketed comments begin with /* and end with */.

The record length for the input data set must be at least 72 bytes. DSNTIAUL reads only the first 72 bytes of each record.

SYSPRINT

Output data set. DSNTIAUL writes informational and error messages in this data set.

The record length for the SYSPRINT data set is 121 bytes.

SYSPUNCH

Output data set. DSNTIAUL writes the LOAD utility control statements in this data set.

SYSRECnn

Output data sets. The value *nn* ranges from 00 to 99. You can have a maximum of 100 output data sets for a single execution of DSNTIAUL. Each data set contains the data that is unloaded when DSNTIAUL processes a SELECT statement from the input data set. Therefore, the number of output

data sets must match the number of SELECT statements (if you specify parameter SQL) or table specifications in your input data set.

Define all data sets as sequential data sets. You can specify the record length and block size of the SYSPUNCH and SYSREC*nn* data sets. The maximum record length for the SYSPUNCH and SYSREC*nn* data sets is 32760 bytes.

DSNTIAUL return codes

Table 177. DSNTIAUL return codes		
Return code	Meaning	
0	Successful completion.	
4	An SQL statement received a warning code.	
	 If TOLWARN(YES) is specified, and the warning occurred on a FETCH or OPEN during the processing of a SELECT statement, Db2 performs the unload operation. 	
	 Otherwise if the SQL statement was a SELECT statement, Db2 did not perform the associated unload operation. 	
	If Db2 returns a +394, which indicates that it is using optimization hints, or a +395, which indicates one or more invalid optimization hints, Db2 performs the unload operation.	
8	An SQL statement received an error code. If the SQL statement was a SELECT statement, Db2 did not perform the associated unload operation or did not complete it.	
12	DSNTIAUL could not open a data set, an SQL statement returned a severe error code (-144, -302, -804, -805, -818, -902, -906, -911, -913, -922, -923, -924, or -927), or an error occurred in the SQL message formatting routine.	

Examples

Example: using DSNTIAUL to unload a subset of rows in a table

Suppose that you want to unload the rows for department D01 from the project table. Because you can fit the table specification on one line, and you do not want to execute any non-SELECT statements, you do not need the SQL parameter. Your invocation looks like the one that is shown in the following figure:

```
//UNLOAD EXEC PGM=IKJEFT01, DYNAMNBR=20
//SYSTSPRT DD SYSOUT=*
//SYSTSIN DD *
DSN SYSTEM(DSN)
RUN PROGRAM(DSNTIAUL) PLAN(DSNTIBC1) -
LIB('DSN1210.RUNLIB.LOAD')
//SYSPRINT DD SYSOUT=*
//SYSUDUMP DD SYSOUT=*
//SYSUDUMP DD SN=DSN8UNLD.SYSREC00,
// UNIT=SYSDA, SPACE=(32760, (1000,500)), DISP=(,CATLG),
// VOL=SER=SCR03
//SYSPUNCH DD DSN=DSN8UNLD.SYSPUNCH,
// UNIT=SYSDA, SPACE=(800, (15,15)), DISP=(,CATLG),
// VOL=SER=SCR03, RECFM=FB, LRECL=120, BLKSIZE=1200
//SYSIN DD *
DSN8C10.PROJ WHERE DEPTNO='D01'
```

Example: using DSNTIAUL to unload rows in more than one table

Suppose that you also want to use DSNTIAUL to perform the following actions:

- Unload all rows from the project table
- Unload only rows from the employee table for employees in departments with department numbers that begin with D, and order the unloaded rows by employee number

- Lock both tables in share mode before you unload them
- Retrieve 250 rows per fetch

For these activities, you must specify the SQL parameter and the *number-of-rows-per-fetch* parameter when you run DSNTIAUL. Your DSNTIAUL invocation is shown in the following figure:

```
//UNLOAD EXEC PGM=IKJEFT01, DYNAMNBR=20
//SYSTSPRT DD SYSOUT=*
//SYSTSIN DD
 DSN SYSTEM(DSN)
 RUN PROGRAM(DSNTIAUL) PLAN(DSNTIBC1) PARMS('SQL,250') -
       LIB('DSN1210.RUNLIB.LOAD')
//SYSPRINT DD SYSOUT=*
//SYSUDUMP DD SYSOUT=*
//SYSREC00 DD DSN=DSN8UNLD.SYSREC00
              UNIT=SYSDA, SPACE=(32760, (1000, 500)), DISP=(,CATLG),
              VOL=SER=SCR03
//SYSREC01 DD DSN=DSN8UNLD.SYSREC01
              UNIT=SYSDA, SPACE=(32760, (1000, 500)), DISP=(,CATLG),
              VOL=SER=SCR03
//SYSPUNCH DD DSN=DSN8UNLD.SYSPUNCH,
// UNIT=SYSDA,SPACE=(800,(15,15)),DISP=(,CATLG),
              VOL=SER=SCR03, RECFM=FB, LRECL=120, BLKSIZE=1200
//SYSIN
          DD *
LOCK TABLE DSN8C10.EMP IN SHARE MODE
LOCK TABLE DSN8C10.PROJ IN SHARE MODE;
SELECT * FROM DSN8C10.PROJ;
SELECT * FROM DSN8C10.EMP
  WHERE WORKDEPT LIKE 'D%'
  ORDER BY EMPNO;
```

Example: using DSNTIAUL to obtain LOAD utility control statements

If you want to obtain the LOAD utility control statements for loading rows into a table, but you do not want to unload the rows, you can set the data set names for the SYSREC*nn* data sets to DUMMY. For example, to obtain the utility control statements for loading rows into the department table, you invoke DSNTIAUL as shown in the following figure:

```
//UNLOAD EXEC PGM=IKJEFT01, DYNAMNBR=20
//SYSTSPRT DD SYSOUT=*
//SYSTSIN DD *
DSN SYSTEM(DSN)
RUN PROGRAM(DSNTIAUL) PLAN(DSNTIBC1) -
        LIB('DSN1210.RUNLIB.LOAD')
//SYSPRINT DD SYSOUT=*
//SYSUDUMP DD SYSOUT=*
//SYSREC00 DD DUMMY
//SYSPUNCH DD DSN=DSN8UNLD.SYSPUNCH,
// UNIT=SYSDA,SPACE=(800,(15,15)),DISP=(,CATLG),
// VOL=SER=SCR03,RECFM=FB,LRECL=120,BLKSIZE=1200
//SYSIN DD *
DSN8C10.DEPT
```

Example: using DSNTIAUL to unload LOB data

This example uses the sample LOB table with the following structure:

```
CREATE TABLE DSN8C10.EMP_PHOTO_RESUME
( EMPNO CHAR(06) NOT NULL,
EMP_ROWID ROWID NOT NULL GENERATED ALWAYS,
PSEG_PHOTO BLOB(500K),
BMP_PHOTO BLOB(100K),
RESUME CLOB(5K),
PRIMARY KEY (EMPNO))
IN DSN8D12L.DSN8S12B
CCSID EBCDIC;
```

The following call to DSNTIAUL unloads the sample LOB table. The parameters for DSNTIAUL indicate the following options:

The SQL parameter specifies that the input data set (SYSIN) contains SQL.

- The *number-of-rows-per-fetch* parameter value of 1 specifies that DSNTIAUL is to retrieve one row for each FETCH operation. A value of 1 is necessary if the LOB columns that you unload might contain NULL values.
- The LOBFILE parameter value of LOBFILE(DSN8UNLD) specifies that DSNTIAUL places the LOB data in data sets with a high-level qualifier of DSN8UNLD.

```
//UNLOAD EXEC FOR—
//SYSTSPRT DD SYSOUT=*
//SYSTSIN DD *
            EXEC PGM=IKJEFT01, DYNAMNBR=20
  DSN SYSTEM(DSN)
  RUN PROGRAM(DSNTIAUL) PLAN(DSNTIB91) -
  PARMS('SQL,1,LOBFILE(DSN8UNLD)') -
  LIB('DSN1210.RUNLIB.LOAD')
//SYSPRINT DD SYSOUT=*
//SYSUDUMP
             DD SYSOUT=*
//SYSREC00 DD DSN=DSN8UNLD.SYSREC00,
// UNIT=SYSDA,SPACE=(800,(15,15)),DISP=(,CATLG),
                VOL=SER=SCR03, RECFM=FB
//SYSPUNCH DD DSN=DSN8UNLD.SYSPUNCH,
                UNIT=SYSDA, SPACE=(800, (15,15)), DISP=(,CATLG),
                VOL=SER=SCR03, RECFM=FB
//SYSIN
             DD *
  SELECT * FROM DSN8C10.EMP_PHOTO_RESUME;
```

Given that the sample LOB table has 4 rows of data, DSNTIAUL produces the following output:

- Data for columns EMPNO and EMP_ROWID are placed in the data set that is allocated according to the SYSRECOO DD statement. The data set name is DSN8UNLD.SYSRECOO
- A generated LOAD statement is placed in the data set that is allocated according to the SYSPUNCH DD statement. The data set name is DSN8UNLD.SYSPUNCH
- The following data sets are dynamically created to store LOB data:
 - DSN8UNLD.Q0000000.C0000002.R0000000
 - DSN8UNLD.Q0000000.C0000002.R0000001
 - DSN8UNLD.Q0000000.C0000002.R0000002
 - DSN8UNLD.Q0000000.C0000002.R0000003
 - DSN8UNLD.Q0000000.C0000003.R0000000
 - DSN8UNLD.Q0000000.C0000003.R0000001
 - DSN8UNLD.Q0000000.C0000003.R0000002
 - DSN8UNLD.Q0000000.C0000003.R0000003
 - DSN8UNLD.Q0000000.C0000004.R0000000
 - DSN8UNLD.Q0000000.C0000004.R0000001
 - DSN8UNLD.Q0000000.C0000004.R0000002
 - DSN8UNLD.Q0000000.C0000004.R0000003

For example, DSN8UNLD.Q0000000.C0000004.R0000001 means that the data set contains data that is unloaded from the second row (R0000001) and the fifth column (C0000004) of the result set for the first query (Q0000000).

DSNTIAD sample program

You can use the DSNTIAD program to execute dynamic SQL statements other than SELECT statements.

The DSNTIAD sample program can issue any SQL statement that can be executed dynamically, except for SELECT statements. DSNTIAD is written in assembler language.

Preparing the DSNTIAD sample program

Before you can use the DSNTIAD sample program, you must precompile, assemble, link, and bind it first. Also, when you are ready for DSNTIAD to start using to use new capabilities in later Db2 12 function levels, you must rebind the packages at the corresponding APPLCOMPAT level.

For more information, see "Db2 productivity-aid sample programs" on page 1024

Running the DSNTIAD sample program

To run the DSNTIAD sample program, use the RUN (DSN) command and specify the following load module and plan name.

Load module name	DSNTIAD
Plan name	DSNTIAC1

For more information about the RUN command, see RUN subcommand (DSN) (Db2 Commands).

DSNTIAD parameters

PKGSET(collection)

Specifies that DSNTIAD implicitly executes a SET CURRENT PACKAGESET statement to assign a value to the CURRENT PACKAGESET special register before processing the dynamic SQL statements in SYSIN.

collection

The value to assign to the CURRENT PACKAGESET special register. You can specify up to 40 characters.

RC0

If you specify this parameter, DSNTIAD ends with return code 0, even if the program encounters SQL errors. If you do not specify RCO, DSNTIAD ends with a return code that reflects the severity of the errors that occur. Without RCO, DSNTIAD terminates if more than 10 SQL errors occur during a single execution.

SQLTERM(*termchar*)

Specify this parameter to indicate the character that you use to end each SQL statement. You can use any special character **except** one of those listed in the following table. SQLTERM(;) is the default.

Table 178.	Invalid speci	al characters	for the SOL	terminator

Name	Character	Hexadecimal representation	
blank		X'40'	
comma	,	X'6B'	
double quotation mark	11	X'7F'	
left parenthesis	(X'4D'	
right parenthesis)	X'5D'	
single quotation mark	ı	X'7D'	
underscore	_	X'6D'	

Use a character other than a semicolon if you plan to execute a statement that contains embedded semicolons.

For example, suppose that you specify the parameter SQLTERM(#) to indicate that the character # is the statement terminator. Then a CREATE TRIGGER statement with embedded semicolons looks like this:

```
CREATE TRIGGER NEW_HIRE
AFTER INSERT ON EMP
FOR EACH ROW MODE DB2SQL
BEGIN ATOMIC
UPDATE COMPANY_STATS SET NBEMP = NBEMP + 1;
END#
```

A CREATE PROCEDURE statement with embedded semicolons looks like the following statement:

```
CREATE PROCEDURE PROC1 (IN PARM1 INT, OUT SCODE INT)

LANGUAGE SQL

BEGIN

DECLARE SQLCODE INT;

DECLARE EXIT HANDLER FOR SQLEXCEPTION

SET SCODE = SQLCODE;

UPDATE TBL1 SET COL1 = PARM1;

END #
```

Be careful to choose a character for the statement terminator that is not used within the statement.

DSNTIAD data sets

Data set

Description

SYSIN

Input data set. In this data set, you can enter any number of non-SELECT SQL statements. Each SQL statement must be terminated with the SQL termination character. If you specify the SQLTERM(termchar) parameter, termchar is the SQL termination character. Otherwise, the SQL termination character is a semicolon. A statement can span multiple lines, but DSNTIAD reads only the first 72 bytes of each line.

Comments in DSNTIAD input are not supported.

SYSPRINT

Output data set. DSNTIAD writes informational and error messages in this data set. DSNTIAD sets the record length of this data set to 121 bytes and the block size to 1210 bytes.

Define all data sets as sequential data sets.

DSNTIAD return codes

Table 179. DSNTIAD return codes				
Return code	Meaning			
0	Successful completion, or the user-specified parameter RCO.			
4	An SQL statement received a warning code.			
8	An SQL statement received an error code.			
12	DSNTIAD could not open a data set, the length of an SQL statement was more than 2 MB, an SQL statement returned a severe error code (-8nn or -9nn), or an error occurred in the SQL message formatting routine.			

Example: invoking the DSNTIAD program

Suppose that you want to execute 20 UPDATE statements, and you do not want DSNTIAD to terminate if more than 10 errors occur. Your invocation looks like the one that is shown in the following figure:

```
//RUNTIAD EXEC PGM=IKJEFT01,DYNAMNBR=20
//SYSTSPRT DD SYSOUT=*
//SYSTSIN DD *
   DSN SYSTEM(DSN)
RUN PROGRAM(DSNTIAD) PLAN(DSNTIAC1) PARMS('RC0') -
        LIB('DSN1210.RUNLIB.LOAD')
//SYSPRINT DD SYSOUT=*
//SYSUDUMP DD SYSOUT=*
//SYSIN DD *
UPDATE DSN8C10.PROJ SET DEPTNO='J01' WHERE DEPTNO='A01';
UPDATE DSN8C10.PROJ SET DEPTNO='J02' WHERE DEPTNO='A02';
:
UPDATE DSN8C10.PROJ SET DEPTNO='J20' WHERE DEPTNO='A20';
```

DSNTEP2 and **DSNTEP4** sample programs

You can use the DSNTEP2 or DSNTEP4 programs to execute SQL statements dynamically.

DSNTEP2 is a sample dynamic SQL program that can issue any SQL statement that can be executed dynamically. DSNTEP2 is written in PL/I language and available in two versions: a source version that you can modify to meet your needs or an object code version that you can use without the need for a PL/I compiler.

The DSNTEP4 sample program is identical to DSNTEP2, except that it uses multi-row fetch for increased performance. DSNTEP4 is written in PL/I language and available in two versions: a source version that you can modify to meet your needs or an object code version that you can use without the need for a PL/I compiler.

When multi-row fetch is used, parallelism might be disabled for the last parallel group in the top-level query block, or entirely disabled for very simple queries. To obtain full parallelism, use DSNTEP2 or specify the control option SET MULT_FETCH 1 for DSNTEP4.

DSNTEP2 and DSNTEP4 write their results to the data set that is defined by the SYSPRINT DD statement. SYSPRINT data must have a logical record length that matches the PAGEWIDTH value in the DSNTEP2 or DSNTEP4 source program. If you use the original version of the program that is shipped with Db2, the logical record length is 133 bytes. If the SYSPRINT data do not have the same logical record length as the PAGEWIDTH value, the program issues return code 12 with abend U4038 and reason code 1. This abend occurs due to the PL/I file exception error IBM0201S ONCODE=81. The following error message is issued:

The UNDEFINEDFILE condition was raised because of conflicting DECLARE and OPEN attributes (FILE= SYSPRINT).

If you use applications or other automation to process output from DSNTEP2 or DSNTEP4, be aware that minor changes in the format can occur as a result of service or enhancements. Such changes might require you to adjust your processes that use the output of these programs.

Important: When you allocate a new data set with the SYSPRINT DD statement, either specify a DCB with RECFM=FBA and LRECL=nnn, where nnn matches the PAGEWIDTH value in the source program, or do not specify the DCB parameter.

Preparing the DSNTEP2 and DSNTEP4 sample programs

Before you can use the DSNTEP2 and DSNTEP4 sample programs, you must prepare them. If you use the source-code versions of DSNTEP2 or DSNTEP4, you must precompile, compile, link, and bind them first. If you use the object-code versions of DSNTEP2 or DSNTEP4 you must bind them first.

Also, when you are ready for DSNTEP2 or DSNTEP4 to start using to use new capabilities in later Db2 12 function levels, you must rebind the packages at the corresponding APPLCOMPAT level.

For more information, see "Preparing the productivity-aid sample programs" in <u>"Db2 productivity-aid sample programs"</u> on page 1024.

Running the DSNTEP2 and DSNTEP4 sample programs

To run the DSNTEP2 and DSNTEP4 sample programs, use the RUN (DSN) command and specify the following load module and plan name.

DSNTEP2 load module and plan

Load module	DSNTEP2
Plan	DSNTEPC1

DSNTEP4 load module and plan

Load module	DSNTEP4
Plan	DSNTP412

For more information about the RUN command, see RUN subcommand (DSN) (Db2 Commands).

DSNTEP2 and **DSNTEP4** parameters

PKGSET(collection)

Specifies that DSNTEP2 or DSNTEP4 implicitly executes a SET CURRENT PACKAGESET statement to assign a value to the CURRENT PACKAGESET special register before processing the dynamic SQL statements in SYSIN.

collection

The value to assign to the CURRENT PACKAGESET special register. You can specify up to 40 characters.

For an example, see "Example: Running dynamic SQL statements at different application compatibility levels in the same SYSIN" on page 1039.

ALIGN(MID) or ALIGN(LHS)

Specifies the alignment.

ALIGN(MID)

Specifies that DSNTEP2 or DSNTEP4 output should be centered. ALIGN(MID) is the default.

ALIGN(LHS)

Specifies that the DSNTEP2 or DSNTEP4 output should be left-justified.

NOMIXED or MIXED

Specifies whether DSNTEP2 or DSNTEP4 contains any DBCS characters.

NOMIXED

Specifies that the DSNTEP2 or DSNTEP4 input contains no DBCS characters. <u>NOMIXED</u> is the default.

MIXED

Specifies that the DSNTEP2 or DSNTEP4 input contains some DBCS characters.

PREPWARN

Specifies that DSNTEP2 or DSNTEP4 is to display details about any SQL warnings that are encountered at PREPARE time.

Regardless of whether you specify PREPWARN, when an SQL warning is encountered at PREPARE time, the program displays the message SQLWARNING ON PREPARE and sets the return code to 4. When you specify PREPWARN, the program also displays the details about any SQL warnings.

SQLFORMAT

Specifies how DSNTEP2 or DSNTEP4 pre-processes SQL statements before passing them to Db2. Select one of the following options:

SOL

This is the preferred mode for SQL statements other than SQL procedural language. When you use this option, which is the default, DSNTEP2 or DSNTEP4 collapses each line of an SQL statement into a single line before passing the statement to Db2. DSNTEP2 or DSNTEP4 also discards all SQL comments.

SQLCOMNT

This mode is suitable for all SQL, but it is intended primarily for SQL procedural language processing. When this option is in effect, behavior is similar to SQL mode, except that DSNTEP2 or DSNTEP4 does not discard SQL comments. Instead, it automatically terminates each SQL comment with a line feed character (hex 25), unless the comment is already terminated by one or more line formatting characters. Use this option to process SQL procedural language with minimal modification by DSNTEP2 or DSNTEP4.

SOLPL

This mode is suitable for all SQL, but it is intended primarily for SQL procedural language processing. When this option is in effect, DSNTEP2 or DSNTEP4 retains SQL comments and terminates each line of an SQL statement with a line feed character (hex 25) before passing the statement to Db2. Lines that end with a split token are not terminated with a line feed character. Use this mode to obtain improved diagnostics and debugging of SQL procedural language.

SQLTERM(*termchar*)

Specifies the character that you use to end each SQL statement. You can use any character except one of those that are listed in Table 178 on page 1031. <u>SQLTERM(;)</u> is the default.

Use a character other than a semicolon if you plan to execute a statement that contains embedded semicolons.

See "Example: changing the SQL terminator" on page 1039.

TOLWARN

Indicates whether DSNTEP2 or DSNTEP4 continues to process SQL SELECT statements after receiving an SQL warning. You can specify one of the following values:

NO

Indicates that the program stops processing the SELECT statement if a warning occurs when the program executes an OPEN or FETCH for a SELECT statement. NO is the default value for TOLWARN.

The following exceptions exist:

- If SQLCODE +445 or SQLCODE +595 occurs when DSNTEP2 or DSNTEP4 executes a FETCH for a SELECT statement, the program continues to process the SELECT statement.
- If SQLCODE +354 occurs when DSNTEP4 executes a FETCH for a SELECT statement, the program continues to process the SELECT statement.
- If SQLCODE +802 occurs when DSNTEP2 or DSNTEP4 executes a FETCH for a SELECT statement, the program continues to process the SELECT statement if the TOLARTHWRN control statement is set to YES.

YES

Indicates that the program continues to process the SELECT statement if a warning occurs when the program executes an OPEN or FETCH for a SELECT statement.

QUIET

The same as YES except that the program suppresses all SQL warning messages from OPEN or FETCH statements if the SQLCODE is 0 or greater.

Settings that you can change in the DSNTEP2 or DSNTEP4 source programs to modify output formatting

If the DSNTEP2 or DSNTEP4 output formatting does not meet your requirements, you can change some variables in the source code to modify the formatting.

For example, if you want to increase the maximum width of a page, the maximum size of a print line, and the maximum number of characters in the output of a character column, you can increase the values of the PAGEWIDTH, MAXPAGWD, and MAXCOLWD variable values.

For a complete description of the settings that you can change, see the information under PROGRAM SIZES in the DSNTEP2 and DSNTEP4 prologs.

DSNTEP2 and **DSNTEP4** data sets

The following data sets are used by DSNTEP2 and DSNTEP4:

SYSIN

Input data set. In this data set, you can enter any number of SQL statements, each terminated with a semicolon. A statement can span multiple lines, but DSNTEP2 or DSNTEP4 reads only the first 72 bytes of each line. You must explicitly commit any SQL statements except the last one.

You can enter comments in DSNTEP2 or DSNTEP4 input with an asterisk (*) in column 1 or two hyphens (--) anywhere on a line. Text that follows the asterisk is considered to be comment text. Text that follows two hyphens can be comment text or a control statement. Comments are not considered in dynamic statement caching. Comments and control statements cannot span lines.

You can enter control statements of the following form in the DSNTEP2 and DSNTEP4 input data set:

```
--#SET control-option value
```

You can specify the following control option statements. If you specify a value of NO for any of the options in this list, the program behaves as if you did not specify the parameter.

--#SET PKGSET value

Specifies that DSNTEP2 or DSNTEP4 implicitly executes a SET CURRENT PACKAGESET statement to assign a value to the CURRENT PACKAGESET special register before processing dynamic SQL statements after this control statement in SYSIN. *value* is the value to assign to CURRENT PACKAGESET special register. You can specify up to 40 characters.

For an example, see <u>"Example: Running dynamic SQL statements at different application compatibility levels in the same SYSIN" on page 1039.</u>

--#SET TERMINATOR value

The SQL statement terminator. *value* is any single-byte character other than one of those that are listed in "DSNTIAD sample program" on page 1030. The default is the value of the SQLTERM parameter.

See "Example: changing the SQL terminator within a series of SQL statements" on page 1040.

--#SET ROWS_FETCH value

The number of rows that are to be fetched from the result table. *value* is a numeric literal between -1 and the number of rows in the result table. -1 means that all rows are to be fetched. The default is -1.

--#SET ROWS_OUT value

The number of fetched rows that are to be sent to the output data set. *value* is a numeric literal between -1 and the number of fetched rows. -1 means that all fetched rows are to be sent to the output data set. The default is -1.

--#SET MULT FETCH value

This option is valid only for DSNTEP4. Use MULT_FETCH to specify the number of rows that are to be fetched at one time from the result table. The default fetch amount for DSNTEP4 is 100 rows, but you can specify from 1 to 32676 rows.

--#SET TOLWARN value

Indicates whether DSNTEP2 or DSNTEP4 continues to process SQL SELECT statements after receiving an SQL warning. You can specify one of the following values:

NO

Indicates that the program stops processing the SELECT statement if a warning occurs when the program executes an OPEN or FETCH for a SELECT statement. NO is the default value for TOLWARN.

The following exceptions exist:

- If SQLCODE +445 or SQLCODE +595 occurs when DSNTEP2 or DSNTEP4 executes a FETCH for a SELECT statement, the program continues to process the SELECT statement.
- If SQLCODE +354 occurs when DSNTEP4 executes a FETCH for a SELECT statement, the program continues to process the SELECT statement.
- If SQLCODE +802 occurs when DSNTEP2 or DSNTEP4 executes a FETCH for a SELECT statement, the program continues to process the SELECT statement if the TOLARTHWRN control statement is set to YES.

YES

Indicates that the program continues to process the SELECT statement if a warning occurs when the program executes an OPEN or FETCH for a SELECT statement.

QUIET

The same as YES except that the program suppresses all SQL warning messages from OPEN or FETCH statements if the SQLCODE is 0 or greater.

--#SET TOLARTHWRN value

Indicates whether DSNTEP2 and DSNTEP4 continue to process an SQL SELECT statement after an arithmetic SQL warning (SQLCODE +802) is returned. *value* is either NO (the default) or YES.

--#SET PREPWARN value

Specifies that DSNTEP2 or DSNTEP4 is to display details about any SQL warnings that are encountered at PREPARE time.

Regardless of whether you specify PREPWARN, when an SQL warning is encountered at PREPARE time, the program displays the message SQLWARNING ON PREPARE and sets the return code to 4. When you specify PREPWARN, the program also displays the details about any SQL warnings.

--#SET SQLFORMAT value

Specifies how DSNTEP2 or DSNTEP4 pre-processes SQL statements before passing them to Db2. Select one of the following options:

SQL

This is the preferred mode for SQL statements other than SQL procedural language. When you use this option, which is the default, DSNTEP2 or DSNTEP4 collapses each line of an SQL statement into a single line before passing the statement to Db2. DSNTEP2 or DSNTEP4 also discards all SQL comments.

SOLCOMNT

This mode is suitable for all SQL, but it is intended primarily for SQL procedural language processing. When this option is in effect, behavior is similar to SQL mode, except that DSNTEP2 or DSNTEP4 does not discard SQL comments. Instead, it automatically terminates each SQL comment with a line feed character (hex 25), unless the comment is already terminated by one or more line formatting characters. Use this option to process SQL procedural language with minimal modification by DSNTEP2 or DSNTEP4.

SQLPL

This mode is suitable for all SQL, but it is intended primarily for SQL procedural language processing. When this option is in effect, DSNTEP2 or DSNTEP4 retains SQL comments and terminates each line of an SQL statement with a line feed character (hex 25) before passing the statement to Db2. Lines that end with a split token are not terminated with a line feed character. Use this mode to obtain improved diagnostics and debugging of SQL procedural language.

--#SET MAXERRORS value

value specifies that number of errors that DSNTEP2 and DSNTEP4 handle before processing stops. The default is 10. Use a value of -1 to indicate that a program is to tolerate an unlimited number of errors.

SYSPRINT

Output data set. DSNTEP2 and DSNTEP4 write informational and error messages in this data set. DSNTEP2 and DSNTEP4 write output records of no more than 133 bytes.

Define all data sets as sequential data sets.

DSNTEP2 and **DSNTEP4** return codes

Table 180. DSN1	Table 180. DSNTEP2 and DSNTEP4 return codes				
Return code	Meaning				
0	Successful completion.				
4	An SQL statement received a warning code.				
8	An SQL statement received an error code.				
12	The length of an SQL statement was more than 2097152 bytes, an SQL statement returned a severe error code (-8nn or -9nn), or an error occurred in the SQL message formatting routine.				

Examples

Example: invoking DSNTEP2

Suppose that you want to use DSNTEP2 to execute SQL SELECT statements that might contain DBCS characters. You also want left-aligned output. Your invocation looks like the following example.

Example: invoking DSNTEP4

Suppose that you want to use DSNTEP4 to execute SQL SELECT statements that might contain DBCS characters, and you want center-aligned output. You also want DSNTEP4 to fetch 250 rows at a time. Your invocation looks like the one in the following figure:

```
//RUNTEP2 EXEC PGM=IKJEFT01,DYNAMNBR=20
//SYSTSPRT DD SYSOUT=*
//SYSTSIN DD *
DSN SYSTEM(DSN)
RUN PROGRAM(DSNTEP4) PLAN(DSNTEPC1) PARMS('/ALIGN(MID) MIXED') -
LIB('DSN1210.RUNLIB.LOAD')
//SYSPRINT DD SYSOUT=*
//SYSUDUMP DD SYSOUT=*
//SYSUDUMP DD SYSOUT=*
//SYSIN DD *
--#SET MULT_FETCH 250
SELECT * FROM DSN8C10.EMP;
```

Example: Changing the application compatibility level of dynamic SQL statements

Suppose that Db2 is at function level V12R1M508 or higher, but you want to use DSTNEP2 to run dynamic SQL statements at a lower application compatibility level. You can use the following example commands bind packages for DSNTEP2 with two different APPLCOMPAT options:

```
BIND PACKAGE (M503TEP2) MEMBER(DSN@EP2L) APPLCOMPAT(V12R1M503) +
CURRENTDATA(NO) ACT(REP) ISO(CS) ENCODING(EBCDIC)
BIND PACKAGE (M508TEP2) MEMBER(DSN@EP2L) APPLCOMPAT(V12R1M508) +
CURRENTDATA(NO) ACT(REP) ISO(CS) ENCODING(EBCDIC)
BIND PLAN(DSNTEP2) PKLIST(M508TEP2.,M503TEP2.) +
ACTION(REPLACE) RETAIN +
CURRENTDATA(NO) ISO(CS) ENCODING(EBCDIC) SQLRULES(DB2)
```

In this example, V12R1M508 is the default application compatibility level for DSNTEP2 because the package named M508TEP2 is bound with APPLCOMPAT(V12R1M508) and is listed first in the BIND PLAN step. However, you can also use DSNTEP2 to issue dynamic SQL statements at application compatibility level V12R1M503. To do so in this example, specify the following parameters when you run DSNTEP2.

```
RUN PROGRAM(DSNTEP2) PARMS('/PKGSET(M503TEP2)')
```

DSNTEP2 implicitly issues the following statement before it runs the dynamic SQL statements, and it runs dynamic SQL statements at application compatibility level V12R1M503:

```
SET CURRENT PACKAGESET = 'M503TEP2'
```

Example: Running dynamic SQL statements at different application compatibility levels in the same SYSIN

Assume that you issued the same BIND commands from the previous example, and suppose that you want to create a new multi-table segmented table space, which can only be created at application compatibility V12R1M503 or lower. As in the previous example, the default application compatibility level is V12R1M508, but you can use the following example --#SET PKGSET control statement to run some statements at a lower application compatibility in the same SYSIN.

```
--#SET PKGSET M503TEP2
CREATE TABLESPACE SEGTS1...
CREATE TABLE TB1 IN SEGTS1...
CREATE TABLE TB2 IN SEGTS1...
--#SET PKGSET M508TEP2

ALTER TABLESPACE SEGTS1 MOVE TABLE TB1 TO TABLESPACE PBGTS1...
ALTER TABLESPACE SEGTS1 MOVE TABLE TB2 TO TABLESPACE PBGTS2...
```

In this example, the first three statements succeed because the -# SET PKGSET control statement tells DSNTEP2 to run them at application compatibility level V12R1M503. Another -# SET PKGSET control statement changes the application compatibility level to V12R1M508 because ALTER TABLESPACE statements must run at this level or higher to specify the MOVE TABLE clause.

Example: changing the SQL terminator

Suppose that you specify the parameter SQLTERM(#) to indicate that the character # is the statement terminator. Then a CREATE TRIGGER statement with embedded semicolons looks like this:

```
CREATE TRIGGER NEW_HIRE

AFTER INSERT ON EMP

FOR EACH ROW MODE DB2SQL

BEGIN ATOMIC

UPDATE COMPANY_STATS SET NBEMP = NBEMP + 1;

END#
```

A CREATE PROCEDURE statement with embedded semicolons looks like the following statement:

```
CREATE PROCEDURE PROC1 (IN PARM1 INT, OUT SCODE INT)
LANGUAGE SQL
BEGIN
```

```
DECLARE SQLCODE INT;
DECLARE EXIT HANDLER FOR SQLEXCEPTION
SET SCODE = SQLCODE;
UPDATE TBL1 SET COL1 = PARM1;
END #
```

Be careful to choose a character for the statement terminator that is not used within the statement.

Example: changing the SQL terminator within a series of SQL statements

Suppose that you have an existing set of SQL statements to which you want to add a CREATE TRIGGER statement that has embedded semicolons. You can use the --#SET TERMINATOR control statement. You can use the default SQLTERM value, which is a semicolon, for all of the existing SQL statements.

Before you execute the CREATE TRIGGER statement, include the --#SET TERMINATOR # control statement to change the SQL terminator to the character #:

```
SELECT * FROM DEPT;
SELECT * FROM ACT;
SELECT * FROM EMPPROJACT;
SELECT * FROM PROJ;
SELECT * FROM PROJACT;
--#SET TERMINATOR #
CREATE TRIGGER NEW_HIRE
AFTER INSERT ON EMP
FOR EACH ROW MODE DB2SQL
BEGIN ATOMIC
UPDATE COMPANY_STATS SET NBEMP = NBEMP + 1;
END#
```

See the following discussion of the SYSIN data set for more information about the --#SET control statement.

Sample applications supplied with Db2 for z/OS

Db2 provides sample applications to help you with Db2 programming techniques and coding practices within each of the four environments: batch, TSO, IMS, and CICS. The sample applications contain various applications that might apply to managing a company.

This topic describes the Db2 sample applications and the environments under which each application runs. It also provides information on how to use the applications, and how to print the application listings.

You can examine the source code for the sample application programs in the online sample library included with the Db2 product. The name of this sample library is DSN1210.SDSNSAMP.

Using the sample applications

You can use the applications interactively by accessing data in the sample tables on screen displays (panels). You can also access the sample tables in batch when using the phone applications. All sample objects have PUBLIC authorization, which makes the samples easier to run.

Types of sample applications

Db2 provides a number of sample applications that manage sample company information. These applications also demonstrate how to use stored procedures, user-defined functions, and LOBs.

Organization application:

The organization application manages the following company information:

- Department administrative structure
- Individual departments
- · Individual employees.

Management of information about department administrative structures involves how departments relate to other departments. You can view or change the organizational structure of an individual department, and the information about individual employees in any department. The organization application runs interactively in the ISPF/TSO, IMS, and CICS environments and is available in PL/I and COBOL.

Project application:

The project application manages information about a company's project activities, including the following:

- Project structures
- Project activity listings
- · Individual project processing
- · Individual project activity estimate processing
- · Individual project staffing processing.

Each department works on projects that contain sets of related activities. Information available about these activities includes staffing assignments, completion-time estimates for the project as a whole, and individual activities within a project. The project application runs interactively in IMS and CICS and is available in PL/I only.

Phone application:

The phone application lets you view or update individual employee phone numbers. There are different versions of the application for ISPF/TSO, CICS, IMS, and batch:

- ISPF/TSO applications use COBOL and PL/I.
- CICS and IMS applications use PL/I.
- Batch applications use C, C++, COBOL, FORTRAN, and PL/I.

Stored procedure applications:

There are three sets of stored procedure applications:

IFI applications

These applications let you pass Db2 commands from a client program to a stored procedure, which runs the commands at a Db2 server using the instrumentation facility interface (IFI). There are two sets of client programs and stored procedures. One set has a PL/I client and stored procedure; the other set has a C client and stored procedure.

ODBA application

This application demonstrates how you can use the IMS ODBA interface to access IMS databases from stored procedures. The stored procedure accesses the IMS sample DL/I database. The client program and the stored procedure are written in COBOL.

Utilities stored procedure application

This application demonstrates how to call the utilities stored procedure.

SQL procedure applications

Sample applications are available for both external SQL procedures and native SQL procedures:

• The applications for external SQL procedures demonstrate how to write, prepare, and invoke such procedures. One set of applications demonstrates how to prepare SQL procedures using JCL. The other set of applications shows how to prepare SQL procedures using the SQL procedure processor. The client programs are written in C.

• The sample job for a native SQL procedure shows how to prepare a native SQL procedure, how to manage versions of native SQL procedures, and optionally, how to deploy a native SQL procedure to a remote server. The sample also prepares and executes a sample caller in the C language

WLM refresh application

This application is a client program that calls the Db2-supplied stored procedure WLM_REFRESH to refresh a WLM environment. This program is written in C.

System parameter reporting application

This application is a client program that calls the Db2–supplied stored procedure ADMIN_INFO_SYSPARM to display the current settings of system parameters. This program is written in C.

All stored procedure applications run in the TSO batch environment.

User-defined function applications:

The user-defined function applications consist of a client program that invokes the sample user-defined functions and a set of user-defined functions that perform the following functions:

- Convert the current date to a user-specified format
- · Convert a date from one format to another
- · Convert the current time to a user-specified format
- · Convert a date from one format to another
- · Return the day of the week for a user-specified date
- · Return the month for a user-specified date
- Format a floating point number as a currency value
- Return the table name for a table, view, or alias
- Return the qualifier for a table, view or alias
- Return the location for a table, view or alias
- Return a table of weather information

All programs are written in C or C++ and run in the TSO batch environment.

LOB application:

The LOB application demonstrates how to perform the following tasks:

- · Define Db2 objects to hold LOB data
- Populate Db2 tables with LOB data using the LOAD utility, or using INSERT and UPDATE statements when the data is too large for use with the LOAD utility
- Manipulate the LOB data using LOB locators

The programs that create and populate the LOB objects use DSNTIAD and run in the TSO batch environment. The program that manipulates the LOB data is written in C and runs under ISPF/TSO.

Application languages and environments for the sample applications

The sample applications demonstrate how to run Db2 applications in the TSO, IMS, or CICS environments.

The following table shows the environments under which each application runs, and the languages the applications use for each environment.

Programs	ISPF/TSO	IMS	CICS	Batch	SPUFI
Dynamic SQL programs				Assembler PL/I	
Exit routines	Assembler	Assembler	Assembler	Assembler	Assembler
Organization	COBOL	COBOL PL/I	COBOL PL/I		
Phone	COBOL PL/I Assembler ¹	PL/I	PL/I	COBOL FORTRAN PL/I C C++	
Project		PL/I	PL/I		
SQLCA formatting routines		Assembler	Assembler	Assembler	Assembler
Stored procedures		COBOL		PL/I C SQL	
User-defined functions				C C++	
LOBs	С				

Notes:

Sample applications in TSO

A set of Db2 sample applications run in the TSO environment.

Table 182. Sample Db2 applications for TSO

Application	Program name	Preparation JCL member name	Attachment facility	Description
Phone	DSN8BC3	DSNTEJ2C	DSNELI	This COBOL batch program lists employee telephone numbers and updates them if requested.
Phone	DSN8BD3	DSNTEJ2D	DSNELI	This C batch program lists employee telephone numbers and updates them if requested.
Phone	DSN8BE3	DSNTEJ2E	DSNELI	This C++ batch program lists employee telephone numbers and updates them if requested.

^{1.} Assembler subroutine DSN8CA.

Application	Program name	Preparation JCL member name	Attachment facility	Description
Phone	DSN8BP3	DSNTEJ2P	DSNELI	This PL/I batch program lists employee telephone numbers and updates them if requested.
Phone	DSN8BF3	DSNTEJ2F	DSNELI	This FORTRAN program lists employee telephone numbers and updates them if requested.
Organization	DSN8HC3	DSNTEJ3C or DSNTEJ6	DSNALI	This COBOL ISPF program displays and updates information about a local department. It can also display and update information about an employee at a local or remote location.
Phone	DSN8SC3	DSNTEJ3C	DSNALI	This COBOL ISPF program lists employee telephone numbers and updates them if requested.
Phone	DSN8SP3	DSNTEJ3P	DSNALI	This PL/I ISPF program lists employee telephone numbers and updates them if requested.
UNLOAD	DSNTIAUL	DSNTEJ2A	DSNELI	This assembler language program unloads the data from a table or view and to produce LOAD utility control statements for the data.
Dynamic SQL	DSNTIAD	DSNTIJTM	DSNELI	This assembler language program dynamically executes non-SELECT statements read in from SYSIN; that is, it uses dynamic SQL to execute non-SELECT SQL statements.
Dynamic SQL	DSNTEP2	DSNTEJ1P or DSNTEJ1L	DSNELI	This PL/I program dynamically executes SQL statements read in from SYSIN. Unlike DSNTIAD, this application can also execute SELECT statements.
Stored procedures ¹	DSN8EP1	DSNTEJ6P	DSNELI	The jobs DSNTEJ6P and DSNTEJ6S prepare a PL/I version of the application. This
Stored procedure ¹	DSN8EP2	DSNTEJ6S	DSNRLI	sample executes Db2 commands using the instrumentation facility interface (IFI).
Stored procedures ¹	<u>DSN8EPU</u>	DSNTEJ6U	DSNELI	The sample that is prepared by job DSNTEJ6U invokes the utilities stored procedure.
Stored procedures ¹	DSN8ED1	DSNTEJ6D	DSNELI	The jobs DSNTEJ6D and DSNTEJ6T prepare a C version of the application. The C stored
Stored procedures ¹	DSN8ED2	DSNTEJ6T	DSNRLI	 procedure uses result sets to return command to the client. This sample executes Db2 commands using the instrumentation facility interface (IFI).

Data sets that the precompiler uses

When you invoke the precompiler you need to provide data sets that contain input for the precompiler, such as the host programming statements and SQL statements. You also need to provide data sets where the precompiler can store its output, such as the modified source code and diagnostics messages.

     STATUS = VERSION 6
     Function =
/*
/*
/*
        Pass DB2 commands received from standard input to
        stored procedure DSN8ED2 for execution. Receive the
        command results from DSN8ED2 as result set. Unload the
        result set and print the contents to standard output.
        Dependencies = None
        Restrictions =

    DB2 commands must be preceded by a hyphen and
followed by a semicolon. Lines with an asterisk

              in the first column or two hyphens as the first
              nonblank characters are interpreted as comment
                      Two hyphens placed after the command text in
              in a line indicate that the rest of the line is
              comments only.
           2. A command may be no more than 4096 bytes.
        Input =
           1. A single input parameter that indicates the location
              of the stored procedure. The contents must be a
              valid DB2 location name of at most 16 characters.
           2. Lines of length INPUTL from standard input.
              Only the first INPUSED bytes are used. Lines are
              considered to be either command text or comments.
              Command text begins with a hyphen and ends with a
              semicolon. Comments begin with an asterisk in column one or two hyphens as the first two nonblank
              characters. Command text may span lines, but comment
              text may not.
        Output =
              Lines of length OUTLEN to standard output.
              Each line contains one of the following:
              a. Command text.
              b. Results returned by the DB2 for MVS/ESA command
,

/*************
     Fxit-error =
         Return code = 4 - Warnings occurred.
              The DB2 for MVS/ESA Instrumentation Facility Interface (IFI) invocation of the DB2 command resulted in a
              return code 4. The accompanying reason code indicates
              the specific problem.
        Return code = 8 - Errors occurred.
- The DB2 for MVS/ESA Instrumentation Facility Interface
               (IFI) invocation of the DB2 command resulted in a
              return code 8. The accompanying reason code indicates
              the specific problem.
         Return code = 12 - Severe errors occurred.
              Input parameter 1 did not contain the name of the
              DB2 server where the stored procedure resides.
              The input dataset (SYSIN) did not contain any data.
              Command input did not begin with a hyphen.
              Command input was not ended with a semicolon.
              An input statement contained more than STMTMAX
              bytes.
              Connection to the stored procedure location failed.
              The SQL CALL statement to the stored procedure failed. The DB2 for MVS/ESA Instrumentation Facility Interface
               (IFI) invocation of the DB2 command resulted in a
              return code 12. The accompanying reason code indicates
              the specific problem.
              The call to the stored procedure, DSN8ED2, succeeded
              but DSN8ED2 experienced SQL problems.
                                                           The formatted
              SQL error message appears in SYSPRINT.
The call to the stored procedure, DSN8ED2, succeeded but no result set was returned. SYSPRINT messages
              should provide more information.
              A result set was returned by DSN8ED2 but one of the \star/ following occurred (see SYSPRINT messages for details):\star/
                The locator variable could not be associated with
                 the result set.
              - The result set cursor could not be allocated
                No data could be fetched from the result set cursor.

      DSN8ED1:
        Extract the name of the DB2 server where stored procedure
        DSN8ED2 resides from input parameter number 1.
      - Call build_DB2_command to create a logical DB2 command record*/
from one or more records from SYSIN. */
      - If a command was created successfully, do the following until*/
        all input has been processed or severe errors occur.

    Call connect_to_sp_server to connect to the DB2 server specified in the first input parameter.
    Call send_DB2_command_to_sp to invoke stored procedure

             DSN8ED2 to process the command.
             Call output_results_from_sp to unload the result set from DSN8ED2 to SYSPRINT.
- Call build_DB2_command to create the next logical DB2
             command record from SYSIN records.
      End DSN8ED1
      build_DB2_command:
      - Read a record from SYSIN
      - Do the following until either a full command is built, end
        of file is reached, or an error occurs:
        - if the first byte of the record is '*' or the first two nonblank bytes of the record are '--' then the whole
        record is a comment. Disregard it.
- if '--' is encountered after nonblanks are found then the
          rest of the record is a comment and can be disregarded.

    else if a semicolon is found inside a delimited string
call copy_byte_to_cmd_buf to add it to the command string.

           - a delimited string is one that starts but has not yet
        terminated with a single quote or a double quote - else if a semicolon is found outside a delimited string
          then the command is complete.
        - else if a nonblank is found then call copy_byte_to_cmd_buf
          to add it to the command string.
        - else if a blank is found inside a delimited string then
          call copy_byte_to_cmd_buf to add it to the command string.
        - else if a blank is found outside a delimited string and the preceding byte was nonblank then call copy_byte_to_
          cmd_buf to add it to the command string.
          else if a blank is found outside a delimited string and
          the preceding byte was blank then disregard the blank.

"Sample applications in TSO" on page 1043

A set of Db2 sample applications run in the TSO environment.

DSN8ES1

Accepts a department number from the caller and returns parameters containing the total earnings (salaries and bonuses) for employees in that department, as well as the number of employees who got a bonus.

                                                                        * 00160000
                                                                        * 00220000
 Function: Demonstrates how to use WLM_REFRESH, the sample stored
            procedure for refreshing a WLM environment
                                                                        * 00230000
                                                                        * 00240000
                                                                        * 00250000
    Dependencies: Requires IBM C/C++ for OS/390 V1R3 or higher
                                                                        * 00260000
                                                                        * 00270000
   Restrictions:
                                                                          00280000
                                                                          00290000
* Module type: C program
                                                                        * 00300000
 Processor: IBM C/C++ for OS/390 V1R3 or higher Module size: See linkedit output
                                                                        * 00310000
                                                                        * 00320000
  Attributes: Re-entrant and re-usable
                                                                        * 00330000
                                                                        * 00340000
                                                                        * 00350000
 Entry Point: DSN8ED6
      Purpose: See Function
Linkage: Standard OS/390 linkage
                                                                        * 00360000
                                                                        * 00370000
                                                                        * 00380000
                                                                        * 00390000
  Parameters: DSN8ED6 uses the C "main" argument convention of
                                                                        * 00400000
               argv (argument vector) and argc (argument count).
                                                                        * 00410000
                                                                        * 00420000
               - ARGV[0] = (input) pointer to a char[9], null-
terminated string having the name of
                                                                        * 00430000
                                                                        * 00440000
                                                                        * 00450000
                             this program (DSN8ED6)
                                                                        * 00460000
                - ARGV[1] = (input) pointer to a char[32] null-
                             terminated string having the name of
                                                                        * 00470000
                             the WLM environment to be refreshed.
                                                                        * 00480000
               - ARGV[2] = (input) pointer to a char[4], null-
terminated string having the DB2 sub-
                                                                        * 00490000
                                                                        * 00500000
                             system id associated with the WLM
                                                                        * 00510000
                             environment to be refreshed
                                                                        * 00520000
                - ARGV[3] = (input) pointer to a char[8], null-

"Sample applications in TSO" on page 1043

A set of Db2 sample applications run in the TSO environment.

DSN8ED7

Calls Db2-provided stored procedure ADMIN_INFO_SYSPARM, which returns the current settings of the Db2 subsystem parameters.

```
/*********************************
* Module name = DSN8ED7 (DB2 sample program)
* DESCRIPTIVE NAME = Caller for SYSPROC.ADMIN_INFO_SYSPARM
                    (IFCID 106 formatter stored procedure)
     Licensed Materials - Property of IBM
     5635-DB2
     (C) COPYRIGHT 1982, 2006 IBM Corp. All Rights Reserved.
     STATUS = Version 11
* Function: Calls DB2-provided stored procedure ADMIN_INFO_SYSPARM,
           which returns the current settings of the DB2 subsystem
           parameters. These settings are then written in
           report format to standard output.
   Dependencies: Requires IBM C/C++ for z/OS
   Restrictions:
* Module type: C program
   Processor: IBM C/C++ for z/OS
* Module size: See linkedit output
 Attributes: Re-entrant and re-usable
 Entry Point: DSN8ED7
*
     Purpose: See Function
     Linkage: Standard z/OS linkage
  Parameters: none
* Normal Exit: Return Code: 0000
              - Message: report of DB2 subsystem parameter settings *
  Error Exit: Return Code: 0012
               - Message: <formatted SQL text from DSNTIAR>
```

```

*
             - Control blocks
  Pseudocode:
   DSN8ED7:
   - Call ADMIN_INFO_SYSPARM
- if unsuccessful, call sql_error to issue a diagnostic mes-
       sage, then end with code 0012.
   - Associate a locator variable with the result set
   - Allocate the result set cursor
   - Fetch first row from the result set
- Print headings
   - Output the content of the result set's current row and fetch
     the next row, until are rows have been fetched
   - Check for successful processing of result set
   End DSN8ED7
   sql_error:
    call DSNTIAR to format the unexpected SQLCODE.
   End sql_error
*

"Sample applications in TSO" on page 1043

A set of Db2 sample applications run in the TSO environment.

DSN8ED9

Demonstrates how to use an application program to call DSN8ES3, a sample native SQL procedure.

```
Restrictions:
* Module type: C program
* Processor: DB2 Precompiler
               IBM C/C++ for z/OS
* Module size: See linkedit output
  Attributes: Reentrant and reusable
  Entry point: DSN8ED9
      Purpose: See Function
      Linkage: Standard MVS program invocation, three parameters.
   Parameters: DSN8ED9 uses the C "main" argument convention of
               argv (argument vector) and argc (argument count).

    ARGV[0]: (input) pointer to a char[9],

                          null-terminated string having the name of
                          this program (DSN8ED9)

    ARGV[1]: (input) pointer to a char[129],

                          null-terminated string having the schema
               of a stored procedure
- ARGV[2]: (input) pointer to a char[129],
                          null-terminated string having the name of
                          a stored procedure
               ARGV[3]: (input) pointer to a char[17],
                          null-terminated string having the name of
the server where DSN8ES3 is to be run.
This is an optional parameter; the local
                          server is used if no argument is provided. *
      Inputs: None
      Outputs: Standard output (SYSPRINT)
  Normal Exit: Return Code: 0
               - Message: CREATE PROCEDURE statement for specified
                          stored procedure
  Normal with Warnings Exit: Return Code: 0004
               - Message: DSN8ES3 ran successfully but returned
                          no output
   Error Exit: Return Code: 0012
               - Message: DSN8ES3 has completed with return code <n> *
               - Message: The length of the argument specified for
                          the <parameter-name> does not fall within the required bounds of <minimum-length>
                          and <maximum-length>
               - Message: DSN8ED9 was invoked with <parameter-count> *
                          parameters. At least 2 parameters are
                          required
               - Message: <formatted SQL text from DSNTIAR>
  External References:

        message: 'Object is not an external stored procedure'
                                                                                00460000
    - Open a cursor on the SYSPARMS table
                                                                                00470000
                                                                                00480000
    - Fetch the first row
--
    - If a row is found, insert the CREATE PROCEDURE clause in the
                                                                                00490000
                                                                                00500000
      result set
    - For each row in the SYSPARMS cursor, build a parameter clause:
                                                                                00510000
      - Start with the parameter type (IN, OUT, or INOUT)
                                                                                00520000
      - Append the parameter name
                                                                                00530000
--
      - Append the parameter data type
                                                                                00540000
      - For string data types, add the CCSID clause
- Insert the entry in the result set table
                                                                                00550000
                                                                                00560000
    - Build the remaining clauses and insert each in the result set
- Build and insert the RESULTS SETS clause
                                                                                00570000
                                                                                00580000
--
      - Build and insert the EXTERNAL NAME clause
                                                                                00590000
      - Build and insert the LANGUAGE clause
                                                                                00600000
      - Build and insert the SQL data access type clause
                                                                                00610000
      - Build and insert the PARAMETER STYLE clause
                                                                                00620000
      - Build and insert the DETERMINISTIC clause

                                                                          * 01600000
 - Parse day, month, and year (sequence unknown) components from * 01610000
 the input date by breaking on delimiters (blank, /, ., and -). * 01620000 - Use the input format to determine sequence of date components. * 01630000
 - if format invalid, issue SQLSTATE 38602 and a diag. message * 01640000 - Call checkDay to validate the day component * 01650000
    - if not valid day, issue SQLSTATE 38602 and a diag. message
                                                                          * 01660000
 - Call checkMonth to validate the month component and convert it * 01670000 (if required) from a calendar month name or roman numeral to * 01680000
   a month number (1-12). * 01690000 - if not valid month, issue SQLSTATE 38602 and a diag. message * 01700000
   Call checkYear to validate the year component.
                                                                           * 01710000
     if not valid year, issue SQLSTATE 38602 and a diag. message
                                                                          * 01720000
 End deconDate
                                                                           * 01730000
                                                                           * 01740000
 reconDate
                                                                           * 01750000
  Use the output format to edit and sequence the date components * 01760000
   - call addOprefix to prepend leading 0's to the day and/or
                                                                          * 01770000
     month component(s), as appropriate
                                                                           * 01780000
                                                                          * 01790000
   - or call removeOprefix to drop leading 0's from the day and/
     or month component(s), as appropriate
                                                                           * 01800000
   - call nameMonth to convert the month number (1-12) to calen-
                                                                           * 01810000
     dar name, if appropriate
                                                                           * 01820000
   - call romanMonth to convert the month number (1-12) to roman
                                                                          * 01830000
     numeral, if appropriate
                                                                           * 01840000
   - call addCentury to convert a non-century year to century
                                                                           * 01850000
    date, if appropriate
                                                                           * 01860000
                                                                          * 01870000
   - call removeCentury to convert a century year to non-century
                                                                           * 01880000
     if appropriate
     - convert the month to a calendar name or roman numeral, if
                                                                          * 01890000
                                                                           * 01900000
       appropriate
                                                                          * 01910000
      - convert the year to a non-century format, if appropriate
   - if output format is invalid, issue SQLSTATE 38603 and a
                                                                           * 01920000
     diagnostic message
                                                                           * 01930000
 - Call buildDate to create the output date from the edited, re-
                                                                           * 01940000
   sequenced date components
                                                                           * 01950000
 End reconDate

   in the standard form, 1-12.
 End unnameMonth
                                                                           * 02120000
                                                                           * 02130000
 romanMonth
                                                                            02140000
 - convert a month in the standard form, 1-12, to the correspond- \star 02150000
   ing roman numeral, I-XII.
                                                                           * 02160000
 End romanMonth
                                                                           * 02170000
                                                                           * 02180000
 unromanMonth
                                                                           * 02190000
   convert a roman numeral (I-XII) to the corresponding month no. * 02200000
   in the standard form, 1-12.
                                                                           * 02210000
 End unromanMonth
                                                                           * 02220000
                                                                           * 02230000
```

```
checkYear
                                                                    * 02240000
    - Verify that the year component of the input date is one of the * 02250000
     following, in accordance with the input format:
- A valid century year (0000-9999)
                                                                    * 02260000
                                                                     * 02270000
      - A valid non-century year (00-99)
                                                                     * 02280000
    - If not valid, set error flag and return null value for year
                                                                     * 02290000
    End checkYear
                                                                     * 02300000
                                                                     * 02310000
    checkMonth
                                                                     * 02320000
    - Verify the month component of the input date in accordance
                                                                     * 02330000
      with the input format:
                                                                     * 02340000
      - if the month is a calendar name, call unnameMonth to convert * 02350000
      it to a month number (1-12).

- if the month is a roman numeral, call unromanMonth to con-
                                                                     * 02360000
                                                                     * 02370000
       vert it to a month number (1-12).
                                                                     * 02380000
     If not valid, set error flag and return null value for month
                                                                     * 02390000
    End checkMonth
                                                                     * 02400000
                                                                     * 02410000
    checkDay
                                                                     * 02420000
    - Verify that the day component of the input date is one or two
                                                                    * 02430000
                                                                     * 02440000
     numeric characters
    - If not valid, set error flag and return null value for day
                                                                     * 02450000
    End checkDay
                                                                     * 02460000
                                                                     * 02470000
    add0prefix
                                                                     * 02480000
     prepend a day or month with a leading 0 if it is less than 10
                                                                    * 02490000
    End addOprefix
                                                                     * 02500000
                                                                     * 02510000
    removeOprefix
