- If you specify **DFBETA** or **SDBETA** on the **SAVE** subcommand, the number of new variables saved is the total number of variables in the equation.

**FITS.** Save all influence statistics. **FITS** saves **DFFIT**, **SDFIT**, **DFBETA**, **SDBETA**, and **COVRATIO**. You cannot specify new variable names when using this keyword. Default names are generated.

#### Example

```
/SAVE=PRED(PREDVAL) RESID(RESIDUAL) COOK(CDISTANC)
```

- This subcommand adds three variables to the end of the active dataset: *PREDVAL*, containing the unstandardized predicted value for each case; *RESIDUAL*, containing the unstandardized residual; and *CDISTANC*, containing Cook’s distance.

#### Example

```
/SAVE=PRED RESID
```

- This subcommand adds two variables named *PRE\_1* and *RES\_1* to the end of the active dataset.

### Example

```
REGRESSION DEPENDENT=Y  
/METHOD=ENTER X1 X2  
/SAVE DFBETA(DFBVAR).
```

- The SAVE subcommand creates and saves three new variables with the names *DFBVAR0*, *DFBVAR1*, and *DFBVAR2*.

### Example

```
REGRESSION VARIABLES=SAVINGS INCOME POP15 POP75 GROWTH  
/DEPENDENT=SAVINGS  
/METHOD=ENTER INCOME POP15 POP75  
/SAVE=PRED(PREDV) SDBETA(BETA) ICIN.
```

- The SAVE subcommand adds seven variables to the end of the file: *PREDV*, containing the unstandardized predicted value for the case; *BETA0*, the standardized *DFBETA* for the intercept; *BETA1*, *BETA2*, and *BETA3*, the standardized *DFBETA*'s for the three independent variables in the model; *LICI\_1*, the lower bound for the prediction interval for an individual case; and *UICI\_1*, the upper bound for the prediction interval for an individual case.

---

## TEMPLATE Subcommand

TEMPLATE uses an existing file as a template and applies it to any charts generated by the current REGRESSION command. The template overrides the default settings that are used to create any charts. Templates are created in the Chart Editor by saving an existing chart as a template.

### Example

```
REGRESSION VARIABLES=pop15,pop75,income,growth,savings  
/DEPENDENT=savings  
/METHOD=ENTER pop15,pop75,income  
/METHOD=ENTER growth  
/RESIDUALS HISTOGRAM(ZRESID)  
/TEMPLATE='/templates/mytemplate.sgt'.
```

---

## Chapter 221. RELIABILITY

RELIABILITY is available in Statistics Base Edition.

```
RELIABILITY VARIABLES={varlist}
                    {ALL }

[/SCALE(scalename)=varlist ]

[/MODEL={ALPHA      }
        {SPLIT[(n)  }
        {GUTTMAN   }
        {PARALLEL  }
        {STRICTPARALLEL}

[/STATISTICS={DESCRIPTIVE} [SCALE] [{ANOVA      } ] [ALL] ]
             {COVARIANCES} [TUKEY]  {ANOVA FRIEDMAN}
             {CORRELATIONS} [HOTELLING] {ANOVA COCHRAN }

[/SUMMARY={MEANS} [VARIANCE] [COV] [CORR] [TOTAL] [ALL] ]

[/ICC={MODEL(ONEWAY)
      {MODEL({MIXED**})} [TYPE({CONSISTENCY**})]}
      {RANDOM } {ABSOLUTE }
      [CIN={95**}] [TESTVAL={0**}]
      {n } {p }

[/METHOD=COVARIANCE]

[/MISSING={EXCLUDE**}
          {INCLUDE }

[/MATRIX = [IN({*
            {savfile'|'dataset'}
            )]] [OUT({*
            {savfile'|'dataset'}
            )]] [NOPRINT]]
```

\*\*Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Release History

#### Release 17.0

- Increased limits on numbers of variables allowed on the VARIABLES and SCALE lists.

### Example

```
RELIABILITY VARIABLES=SCORE1 TO SCORE10
  /SCALE (OVERALL) = ALL
  /MODEL = ALPHA
  /SUMMARY = MEANS TOTAL.
```

---

## Overview

RELIABILITY estimates reliability statistics for the components of multiple-item additive scales. It uses any one of five models for reliability analysis and offers a variety of statistical displays. RELIABILITY can also be used to perform a repeated measures analysis of variance, a two-way factorial analysis of variance with one observation per cell, Tukey’s test for additivity, Hotelling’s *T*-square test for equality of means in repeated measures designs, and Friedman’s two-way analysis of variance on ranks. For more complex repeated measures designs, use the GLM procedure (available in the Advanced Models option).

### Options

**Model Type.** You can specify any one of five models on the MODEL subcommand.

**Statistical Display.** Statistics available on the STATISTICS subcommand include descriptive statistics, correlation and covariance matrices, a repeated measures analysis of variance table, Hotelling's *T*-square, Tukey's test for additivity, Friedman's chi-square for the analysis of ranked data, and Cochran's *Q*.

**Computational Method.** You can force RELIABILITY to use the covariance method, even when you are not requesting any output that requires it, by using the METHOD subcommand.

**Matrix Input and Output.** You can read data in the form of correlation matrices and you can write correlation-type matrix materials to a data file using the MATRIX subcommand.

### Basic Specification

The basic specification is VARIABLES and a variable list. By default, RELIABILITY displays the number of cases, number of items, and Cronbach's alpha. Whenever possible, it uses an algorithm that does not require the calculation of the covariance matrix.

### Subcommand Order

- VARIABLES must be specified first.
- The remaining subcommands can be named in any order.

### Operations

- STATISTICS and SUMMARY are cumulative. If you enter them more than once, all requested statistics are produced for each scale.
- If you request output that is not available for your model or for your data, RELIABILITY ignores the request.
- RELIABILITY uses an economical algorithm whenever possible but calculates a covariance matrix when necessary (see "METHOD Subcommand" on page 1651).

### Limitations

- Maximum 1 VARIABLES subcommand.
- Maximum 1 SCALE subcommand.
- Maximum 10,000 variables on the VARIABLES subcommand.
- Maximum 10,000 variables on the SCALE subcommand.

---

## VARIABLES Subcommand

VARIABLES specifies the variables to be used in the analysis. Only numeric variables can be used.

- VARIABLES is required and must be specified first.
- You can use keyword ALL to refer to all user-defined variables in the active dataset.

---

## SCALE Subcommand

SCALE defines a scale for analysis, providing a label for the scale and specifying its component variables. If SCALE is omitted, all variables named on VARIABLES are used, and the label for the scale is ALL.

- The label is specified in parentheses after SCALE. It can have a maximum of 255 bytes before being truncated.
- RELIABILITY does not add any new variables to the active dataset. The label is used only to identify the output. If the analysis is satisfactory, use COMPUTE to create a new variable containing the sum of the component items.
- Variables named on SCALE must have been named on the VARIABLES subcommand. Use the keyword ALL to refer to all variables named on the VARIABLES subcommand.

## Example

```
RELIABILITY VARIABLES = ITEM1 TO ITEM20  
/SCALE (A) = ITEM1 TO ITEM10.
```

```
RELIABILITY VARIABLES = ITEM1 TO ITEM20  
/SCALE (B) = ITEM1 TO ITEM20.
```

- Analyses for scales A and B both use only cases that have complete data for items 1 through 20.

---

## MODEL Subcommand

MODEL specifies the type of reliability analysis for the scale named on the SCALE subcommand.

**ALPHA.** *Cronbach's  $\alpha$ .* Standardized item  $\alpha$  is displayed. This is the default.

**SPLIT [(n)].** *Split-half coefficients.* You can specify a number in parentheses to indicate how many items should be in the second half. For example, MODEL SPLIT (6) uses the last six variables for the second half and all others for the first. By default, each half has an equal number of items, with the odd item, if any, going to the first half.

**GUTTMAN.** *Guttman's lower bounds for true reliability.*

**PARALLEL.** *Maximum-likelihood reliability estimate under parallel assumptions.* This model assumes that items have the same variance but not necessarily the same mean.

**STRICTPARALLEL.** *Maximum-likelihood reliability estimate under strictly parallel assumptions.* This model assumes that items have the same means, the same true score variances over a set of objects being measured, and the same error variance over replications.

---

## STATISTICS Subcommand

STATISTICS displays optional statistics. There are no default statistics.

- STATISTICS is cumulative. If you enter it more than once, all requested statistics are produced for each scale.

**DESCRIPTIVES.** *Item means and standard deviations.*

**COVARIANCES.** *Inter-item variance-covariance matrix.*

**CORRELATIONS.** *Inter-item correlation matrix.*

**SCALE.** *Scale means and scale variances.*

**TUKEY.** *Tukey's test for additivity.* This helps determine whether a transformation of the items is needed to reduce nonadditivity. The test displays an estimate of the power to which the items should be raised in order to be additive.

**HOTELLING.** *Hotelling's T-square.* This is a test for equality of means among the items.

**ANOVA.** *Repeated measures analysis of variance table.*

**FRIEDMAN.** *Friedman's chi-square and Kendall's coefficient of concordance.* These apply to ranked data. You must request ANOVA in addition to FRIEDMAN; Friedman's chi-square appears in place of the usual  $F$  test. If the ANOVA keyword is not specified, the FRIEDMAN keyword is silently ignored.

**COCHRAN.** *Cochran's Q.* This applies when all items are dichotomies. You must request ANOVA in addition to COCHRAN; the *Q* statistic appears in place of the usual *F* test. If the ANOVA keyword is not specified, the COCHRAN keyword is silently ignored.

**ALL.** *All applicable statistics.*

---

## ICC Subcommand

ICC displays intraclass correlation coefficients for single measure and average measure. Single measure applies to single measurements—for example, the rating of judges, individual item scores, or the body weights of individuals. Average measure, however, applies to average measurements, for example, the average rating of *k* judges, or the average score for a *k*-item test.

**MODEL.** *Model.* You can specify the model for the computation of ICC. There are three keywords for this option. ONEWAY is the one-way random effects model (people effects are random). RANDOM is the two-way random effect model (people effects and the item effects are random). MIXED is the two-way mixed (people effects are random and the item effects are fixed). MIXED is the default. Only one model can be specified.

**TYPE.** *Type of definition.* When the model is RANDOM or MIXED, one of the two TYPE keywords may be given. CONSISTENCY is the consistency definition and ABSOLUTE is the absolute agreement definition. For the consistency coefficient, the between measures variance is excluded from the denominator variance, and for absolute agreement, it is not.

**CIN.** *The value of the percent for confidence interval and significance level of the hypothesis testing.*

**TESTVAL.** *The value with which an estimate of ICC is compared.* The value should be between 0 and 1.

---

## SUMMARY Subcommand

SUMMARY displays summary statistics for each individual item in the scale.

- SUMMARY is cumulative. If you enter it more than once, all requested statistics are produced for the scale.
- You can specify one or more of the following:

**MEANS.** *Statistics on item means.* The average, minimum, maximum, range, ratio of maximum to minimum, and variance of the item means.

**VARIANCE.** *Statistics on item variances.* This displays the same statistics as for MEANS.

**COVARIANCES.** *Statistics on item covariances.* This displays the same statistics as for MEANS.

**CORRELATIONS.** *Statistics on item correlations.* This displays the same statistics as for MEANS.

**TOTAL.** *Statistics comparing each individual item to the scale composed of the other items.* The output includes the scale mean, variance, and Cronbach's  $\alpha$  without the item, and the correlation between the item and the scale without it.

**ALL.** *All applicable summary statistics.*

---

## METHOD Subcommand

By default, RELIABILITY uses a computational method that does not require the calculation of a covariance matrix wherever possible. METHOD forces RELIABILITY to calculate the covariance matrix. Only a single specification applies to METHOD:

**COVARIANCE.** *Calculate and use the covariance matrix, even if it is not needed.*

If METHOD is not specified, RELIABILITY computes the covariance matrix for all variables on each VARIABLES subcommand only if any of the following is true:

- You specify a model other than ALPHA or SPLIT.
- You request COV, CORR, FRIEDMAN, or HOTELLING on the STATISTICS subcommand.
- You request anything other than TOTAL on the SUMMARY subcommand.
- You write the matrix to a matrix data file, using the MATRIX subcommand.

---

## MISSING Subcommand

MISSING controls the deletion of cases with user-missing data.

- RELIABILITY deletes cases from analysis if they have a missing value for any variable named on the VARIABLES subcommand. By default, both system-missing and user-missing values are excluded.

**EXCLUDE.** *Exclude user-missing and system-missing values.* This is the default.

**INCLUDE.** *Treat user-missing values as valid.* Only system-missing values are excluded.

---

## MATRIX Subcommand

MATRIX reads and writes IBM SPSS Statistics matrix data files.

- Either IN or OUT and the matrix file in parentheses are required. When both IN and OUT are used on the same RELIABILITY procedure, they can be specified on separate MATRIX subcommands or on the same subcommand.
- If both IN and OUT are used on the same RELIABILITY command and there are grouping variables in the matrix input file, these variables are treated as if they were split variables. Values of the grouping variables in the input matrix are passed on to the output matrix (see “Split Files” on page 1652).

**OUT ('savfile'|'dataset').** *Write a matrix data file or dataset.* Specify either a filename, a previously declared dataset name, or an asterisk, enclosed in parentheses. Filenames should be enclosed in quotes and are stored in the working directory unless a path is included as part of the file specification. If you specify an asterisk (\*), the matrix data file replaces the active dataset. If you specify an asterisk or a dataset name, the file is not stored on disk unless you use SAVE or XSAVE.

**IN ('savfile'|'dataset').** *Read a matrix data file or dataset.* Specify either a filename, dataset name created during the current session, or an asterisk enclosed in parentheses. An asterisk reads the matrix data from the active dataset. Filenames should be enclosed in quotes and are read from the working directory unless a path is included as part of the file specification.

## Matrix Output

- RELIABILITY writes correlation-type matrices that include the number of cases, means, and standard deviations with the matrix materials. These matrix materials can be used as input to RELIABILITY or other procedures.
- Any documents contained in the active dataset are not transferred to the matrix file.
- RELIABILITY displays the scale analysis when it writes matrix materials. To suppress the display of scale analysis, specify keyword NOPRINT on MATRIX.

## Matrix Input

- RELIABILITY can read a matrix data file created by a previous RELIABILITY command or by another procedure. The matrix input file must have records of type N, MEAN, STDDEV, and CORR for each split-file group. For more information, see the Universals section.
- Variable names, variable and value labels, and print and write formats are read from the dictionary of the matrix data file.
- MATRIX=IN cannot be used unless an active dataset has already been defined. To read an existing matrix data file at the beginning of a session, use GET to retrieve the matrix file and then specify IN(\*) on MATRIX.

## Format of the Matrix Data File

- The matrix data file includes two special variables: *ROWTYPE\_* and *VARNAME\_*. Variable *ROWTYPE\_* is a short string variable having values N, MEAN, STDDEV, and CORR. Variable *VARNAME\_* is a short string variable whose values are the names of the variables used to form the correlation matrix.
- When *ROWTYPE\_* is CORR, *VARNAME\_* gives the variable associated with that row of the correlation matrix.
- The remaining variables in the matrix file are the variables used to form the correlation matrix.

## Split Files

- When split-file processing is in effect, the first variables in the matrix data file will be the split variables, followed by *ROWTYPE\_*, *VARNAME\_*, and the dependent variable(s).
- If grouping variables are in the matrix input file, their values are between *ROWTYPE\_* and *VARNAME\_*. The grouping variables are treated like split-file variables.
- A full set of matrix materials is written for each split-file group defined by the split variables.
- A split variable cannot have the same variable name as any other variable written to the matrix data file.
- If split-file processing is in effect when a matrix is written, the same split file must be in effect when that matrix is read by any procedure.

## Missing Values

Missing-value treatment affects the values written to a matrix data file. When reading a matrix data file, be sure to specify a missing-value treatment on RELIABILITY that is compatible with the treatment that was in effect when the matrix materials were generated.

## Example: Matrix Output to External File

```
DATA LIST / TIME1 TO TIME5 1-10.  
BEGIN DATA  
0 0 0 0 0  
0 0 1 1 0  
0 0 1 1 1  
0 1 1 1 1  
0 0 0 0 1  
0 1 0 1 1  
0 0 1 1 1  
1 0 0 1 1  
1 1 1 1 1  
1 1 1 1 1  
END DATA.  
RELIABILITY VARIABLES=TIME1 TO TIME5  
/MATRIX=OUT('/data/re1mtx.sav').  
LIST.
```

- RELIABILITY reads data from the active dataset and writes one set of matrix materials to file *re1mtx.sav*.
- The active dataset is still the file defined by DATA LIST. Subsequent commands are executed in this file.

## Example: Matrix Output to Active Dataset

```
DATA LIST / TIME1 TO TIME5 1-10.
BEGIN DATA
  0 0 0 0 0
  0 0 1 1 0
  0 0 1 1 1
  0 1 1 1 1
  0 0 0 0 1
  0 1 0 1 1
  0 0 1 1 1
  1 0 0 1 1
  1 1 1 1 1
  1 1 1 1 1
END DATA.
RELIABILITY VARIABLES=TIME1 TO TIME5
/MATRIX=OUT(*) NOPRINT.
LIST.
```

- RELIABILITY writes the same matrix as in the previous example. However, the matrix data file replaces the active dataset. The LIST command is executed in the matrix file, not in the file defined by DATA LIST.
- Because NOPRINT is specified on MATRIX, scale analyses are not displayed.

## Example: Matrix Output to Active Dataset

```
GET FILE='/data/re1mtx.sav'.
RELIABILITY VARIABLES=ALL
/MATRIX=IN(*).
```

- This example assumes that you are starting a new session and want to read an existing matrix data file. GET retrieves the matrix data file *re1mtx.sav*.
- MATRIX=IN specifies an asterisk because the matrix data file is the active dataset. If MATRIX=IN('/data/re1mtx.sav') is specified, an error message is issued.
- If the GET command is omitted, an error message is issued.

## Example: Matrix Input from External File

```
GET FILE='/data/personnel.sav'.
FREQUENCIES VARIABLE=AGE.

RELIABILITY VARIABLES=ALL
/MATRIX=IN('/data/re1mtx.sav').
```

- This example performs a frequencies analysis on file *personnel.sav* and then uses a different file containing matrix data for RELIABILITY. The file is an existing matrix data file. In order for this to work, the analysis variables named in *re1mtx.sav* must also exist in *personnel.sav*.
- *re1mtx.sav* must have records of type N, MEAN, STDDEV, and CORR for each split-file group.
- *re1mtx.sav* does not replace *personnel.sav* as the active dataset.

## Example: Matrix Input from Working File

```
GET FILE='/data/personnel.sav'.
CORRELATIONS VARIABLES=V1 TO V5
/MATRIX=OUT(*).
RELIABILITY VARIABLES=V1 TO V5
/MATRIX=IN(*).
```

- RELIABILITY uses matrix input from procedure CORRELATIONS. An asterisk is used to specify the active dataset for both the matrix output from CORRELATIONS and the matrix input for RELIABILITY.

---

## Chapter 222. RENAME VARIABLES

```
RENAME VARIABLES {(varname=newname) [(varname ...)]}  
                {(varnames=newnames) }
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Example

```
RENAME VARIABLES (JOB CAT=TITLE).
```

---

## Overview

RENAME VARIABLES changes the names of variables in the active dataset while preserving their original order, values, variable labels, value labels, missing values, and print and write formats.

### Basic Specification

- The basic specification is an old variable name, an equals sign, and the new variable name. The equals sign is required.

### Syntax Rules

- Multiple sets of variable specifications are allowed. Each set can be enclosed in parentheses.
- You can specify a list of old variable names followed by an equals sign and a list of new variable names. The same number of variables must be specified on both lists. A single set of parentheses enclosing the entire specification is required for this method.
- Keyword TO can be used on the left side of the equals sign to refer to variables in the active dataset, and on the right side of the equals sign to generate new variable names.
- Old variable names do not need to be specified according to their order in the active dataset.
- Name changes take place in one operation. Therefore, variable names can be exchanged between two variables.
- Multiple RENAME VARIABLES commands are allowed.
- RENAME VARIABLES cannot follow either a TEMPORARY or a MODEL PROGRAM command.

---

## Examples

### Renaming Multiple Variables

```
RENAME VARIABLES (MOHIRED=MOSTART) (YRHIRED=YRSTART).
```

- MOHIRED is renamed to MOSTART and YRHIRED to YRSTART. The parentheses are optional.

```
RENAME VARIABLES (MOHIRED YRHIRED=MOSTART YRSTART).
```

- The same name changes are specified as in the previous example. The parentheses are required, since variable lists are used.

### Exchanging Variable Names

```
RENAME VARIABLES (A=B) (B=A).
```

- Variable names are exchanged between two variables: A is renamed to B, and B is renamed to A.

---

## Mixed Case Variable Names

You can use the `RENAME VARIABLES` command to change the case of any characters in a variable name.

### Example

```
RENAME VARIABLES (newvariable = NewVariable).
```

- For the existing variable name specification, case is ignored. Any combination of upper and lower case will work.
- For the new variable name, case will be preserved as entered for display purposes.

---

## Chapter 223. REPEATING DATA

REPEATING DATA [FILE=file]

```
[/ENCODING='encoding specification']  
/STARTS=beg col[-end col] /OCCURS={value }  
                                {varname}  
[/LENGTH={value } ] [/CONTINUED[=beg col[-end col]]]  
  {varname}  
[/ID={col loc}=varname] [/{TABLE }]  
  {format }              {NOTABLE}  
/DATA=variable specifications
```

### Release History

#### Release 16.0

- ENCODING subcommand added for Unicode support.

### Example

```
INPUT PROGRAM.  
DATA LIST / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.  
REPEATING DATA STARTS=12 /OCCURS=NUMVEH  
  /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.  
END INPUT PROGRAM.
```

---

## Overview

REPEATING DATA reads input cases whose records contain repeating groups of data. For each repeating group, REPEATING DATA builds one output case in the active dataset. All of the repeating groups in the data must contain the same type of information, although the number of groups for each input case may vary. Information common to the repeating groups for each input case can be recorded once for that case and then spread to each resulting output case. In this respect, a file with a repeating data structure is like a hierarchical file with both levels of information recorded on a single record rather than on separate record types. For information on reading hierarchical files, see FILE TYPE–END FILE TYPE.

REPEATING DATA must be used within an INPUT PROGRAM structure or within a FILE TYPE structure with mixed or nested data. In an INPUT PROGRAM structure, REPEATING DATA must be preceded by a DATA LIST command. In a FILE TYPE structure, DATA LIST is needed only if there are variables to be spread to each resulting output case.

### Options

**Length of Repeating Groups.** If the length of the repeating groups varies across input cases, you can specify a variable that indicates the length on the LENGTH subcommand. You can also use LENGTH if you do not want to read all the data in each repeating group.

**Continuation Records.** You can use the CONTINUED subcommand to indicate that the repeating groups for each input case are contained on more than one record. You can check the value of an identification variable across records for the same input case using the ID subcommand.

**Summary Tables.** You can suppress the display of the table that summarizes the names, locations, and formats of the variables specified on the DATA subcommand using the NOTABLE subcommand.

### Basic Specification

The basic specification requires three subcommands: STARTS, OCCURS, and DATA.

- STARTS specifies the beginning column of the repeating data segments. When there are continuation records, STARTS can specify the ending column of the last repeating group on the first record of each input case.
- OCCURS specifies the number of repeating groups on each input case. OCCURS can specify a number if the number of repeating groups is the same for all input cases. Otherwise, OCCURS should specify the name of a variable whose value for each input case indicates the number of repeating groups for that case.
- DATA specifies names, location within the repeating segment, and format for each variable to be read from the repeated groups.

#### Subcommand Order

- DATA must be the last subcommand specified on REPEATING DATA.
- The remaining subcommands can be named in any order.

#### Syntax Rules

- REPEATING DATA can be specified only within an INPUT PROGRAM structure, or within a FILE TYPE structure with mixed or nested data. DATA LIST, REPEATING DATA, and any transformation commands used to build the output cases must be placed within the INPUT PROGRAM or FILE TYPE structure. Transformations that apply to the output cases should be specified after the END INPUT PROGRAM or END FILE TYPE command.
- LENGTH must be used if the last variable specified on the DATA subcommand is not read from the last position of each repeating group or if the length of the repeating groups varies across input cases.
- CONTINUED must be used if repeating groups for each input case are continued on successive records.
- The DATA LIST command used with REPEATING DATA must define all fixed-format data for the records.
- Repeating groups are usually recorded at the end of the fixed-format records, but fixed-format data may follow the repeating data in data structures such as IBM SMF and RMF records. Use the following sequence in such cases.

```
DATA LIST .../* Read the fixed-format data before repeating data
REREAD COLUMNS= .../* Skip repeating data
DATA LIST .../* Read the fixed-format data after repeating data
REPEATING DATA ... /*Read repeating data
```

---

## Operations

- Fixed-location data specified on the DATA LIST are spread to each output case.
- If LENGTH is not specified, the program uses the default length for repeating data groups, which is determined from specifications on the DATA subcommand. For more information on the default length, see the LENGTH subcommand.

## Cases Generated

- The number of output cases generated is the number specified on the OCCURS subcommand. Physical record length or whether fields are non-blank does not affect the number of cases generated.
- If the number specified for OCCURS is nonpositive or missing, no cases are generated.

## Records Read

- If CONTINUED is not specified, all repeating groups are read from the first record of each input case.
- If CONTINUED is specified, the first continuation record is read when the first record for the input case is exhausted, that is, when the next repeating group would extend past the end of the record. The ending column for the first record is defined on STARTS. If the ending column is not specified on STARTS, the logical record length is used.

- Subsequent continuation records are read when the current continuation record is exhausted. Exhaustion of the current continuation record is detected when the next repeating group would extend past the end of the record. The ending column for continuation records is defined on CONTINUED. If the ending column is not specified on CONTINUED, the logical record length is used.
- For inline data, the record length is always 80. For data stored in a file, the record length is generally whatever was specified on the FILE HANDLE command or the default of 1024. Shorter records are extended with blanks when they are read. For IBM implementations, the physical record length is available and is used.

## Reading Past End of Record

If one or more fields extend past the end of the actual record, or if CONTINUED is specified and the ending column specified on either STARTS or CONTINUED is beyond the end of the actual record, the program takes the following action:

- For string data with format A, the data record is considered to be extended logically with blanks. If the entire field lies past the end of the record, the resulting value will be all blanks.
- For numeric data, a warning is issued and the resulting value is system-missing.

---

## Examples

### Basic Example

\* Build a file with each case representing one vehicle and spread information about the household to each case.

```
INPUT PROGRAM.
DATA LIST / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
REPEATING DATA STARTS=12 /OCCURS=NUMVEH
  /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.
END INPUT PROGRAM.
```

```
BEGIN DATA
1001 02 02 FORD T8PONTIAC C6
1002 04 01 CHEVY C4
1003 02 03 CADILAC C8FORD T6VW C4
END DATA.
LIST.
```

- Data are extracted from a file representing household records. Each input case is recorded on a single record; there are no continuation records.
- The total number of persons living in the house and number of vehicles owned by the household is recorded on each record. The first field of numbers (columns 1–4) for each record is an identification number unique to each record. The next two fields of numbers are number of persons in household and number of vehicles. The remainder of the record contains repeating groups of information about each vehicle: the make of vehicle, model, and number of cylinders.
- INPUT PROGRAM indicates the beginning of the input program and END INPUT PROGRAM indicates the end of the input program.
- DATA LIST reads the variables from the household portion of the record. All fixed-format variables are defined on DATA LIST.
- REPEATING DATA reads the information from the repeating groups and builds the output cases. Repeating groups start in column 12. The number of repeating groups for each input case is given by the value of variable NUMVEH. Three variables are defined for each repeating group: MAKE, MODEL, and NUMCYL.
- The first input record contains two repeating groups, producing two output cases in the active dataset. One output case is built from the second input record which contains information on one vehicle, and three output cases are built from the third record. The values of the fixed-format variables defined on DATA LIST are spread to every new case built in the active dataset. Six cases result, as shown below.

SEQNUM	NUMPERS	NUMVEH	MAKE	MODEL	NUMCYL
1	2	2	FORD	T	8
1	2	2	PONTIAC	C	6
2	4	1	CHEVY	C	4
3	2	3	CADILAC	C	8
3	2	3	FORD	T	6
3	2	3	VW	C	4

NUMBER OF CASES READ = 6      NUMBER OF CASES LISTED = 6

## Using REPEATING DATA With Mixed File Types

\* Use REPEATING DATA with FILE TYPE MIXED: read only type 3 records.

```
FILE TYPE MIXED RECORD=#SEQNUM 2-4.
RECORD TYPE 003.
REPEATING DATA STARTS=12 /OCCURS=3
  /DATA=MAKE 1-8(A) MODEL 9(A) NUMCYL 10.
END FILE.
END FILE TYPE.
```

```
BEGIN DATA
1001 02 02 FORD T8PONTIAC C6
1002 04 01 CHEVY C4
1003 02 03 CADILAC C8FORD T6VW C4
END DATA.
LIST.
```

- The task in this example is to read only the repeating data for records with value 003 for variable *#SEQNUM*.
- REPEATING DATA is used within a FILE TYPE structure, which specifies a mixed file type. The record identification variable *#SEQNUM* is located in columns 2–4.
- RECORD TYPE specifies that only records with value 003 for *#SEQNUM* are copied into the active dataset. All other records are skipped.
- REPEATING DATA indicates that the repeating groups start in column 12. The OCCURS subcommand indicates there are three repeating groups on each input case, and the DATA subcommand specifies names, locations, and formats for the variables in the repeating groups.
- The DATA LIST command is not required in this example, since none of the information on the input case is being spread to the output cases. However, if there were multiple input cases with value 003 for *#SEQNUM* and they did not all have three repeating groups, DATA LIST would be required to define a variable whose value for each input case indicated the number of repeating groups for that case. This variable would then be specified on the OCCURS subcommand.

## Using Transformations With REPEATING DATA

```
INPUT PROGRAM.
DATA LIST / PARENTID 1 DATE 3-6 NCHILD 8.
REPEATING DATA STARTS=9 /OCCURS=NCHILD
  /DATA=BIRTHDAY 2-5 VACDATE 7-10.
END INPUT PROGRAM.

COMPUTE AGE=DATE - BIRTHDAY.
COMPUTE VACAGE=VACDATE - BIRTHDAY.

DO IF PARENTID NE LAG(PARENTID,1) OR $CASENUM EQ 1.
COMPUTE CHILD=1.
ELSE.
COMPUTE CHILD=LAG(CHILD,1)+1.
END IF.
FORMAT AGE VACAGE CHILD (F2).
```

```
BEGIN DATA
1 1987 2 1981 1983 1982 1984
2 1988 1 1979 1984
3 1988 3 1978 1981 1981 1986 1983 1986
4 1988 1 1984 1987
END DATA.
LIST.
```

- Data are from a file that contains information on parents within a school district. Each input case is recorded on a single record; there are no continuation records.

- Each record identifies the parents by a number and indicates how many children they have. The repeating groups give the year of birth and year of vaccination for each child.
- REPEATING DATA indicates that the repeating groups begin in column 9. The value of *NCHILD* indicates how many repeating groups there are for each record.
- The first two COMPUTE commands compute the age for each child and age at vaccination. These transformation commands are specified outside the input program.
- Because the repeating groups do not have descriptive values, the DO IF structure computes variable *CHILD* to distinguish between the first-born child, second-born child, and so forth. The value for *CHILD* will be 1 for the first-born, 2 for the second-born, and so forth. The LIST output is shown below.

```
PARENTID DATE NCHILD BIRTHDAY VACDATE AGE VACAGE CHILD
```

```
 1  1987   2   1981   1983   6   2   1
 1  1987   2   1982   1984   5   2   2
 2  1988   1   1979   1984   9   5   1
 3  1988   3   1978   1981  10   3   1
 3  1988   3   1981   1986   7   5   2
 3  1988   3   1983   1986   5   3   3
 4  1988   1   1984   1987   4   3   1
```

```
NUMBER OF CASES READ =      7  NUMBER OF CASES LISTED =      7
```

---

## STARTS Subcommand

STARTS indicates the beginning location of the repeating data segment on the first record of each input case. STARTS is required and can specify either a number or a variable name.

- If the repeating groups on the first record of each input case begin in the same column, STARTS specifies a column number.
- If the repeating groups on the first record of each input case do not begin in the same column, STARTS specifies the name of a variable whose value for each input case indicates the beginning location of the repeating groups on the first record. The variable can be defined on DATA LIST or created by transformation commands that precede REPEATING DATA.
- When repeating groups are continued on multiple records for each input case, STARTS must also specify an ending location if there is room on the logical record length for more repeating groups than are contained on the first record of each input case. The ending column applies only to the first record of each input case. See the CONTINUED subcommand for an example.
- The ending column can be specified as a number or a variable name. Specifications for the beginning column and the ending column are separated by a hyphen. The values of the variable used to define the ending column must be valid values and must be larger than the starting value.
- If the variable specified for the ending column is undefined or missing for an input case, the program displays a warning message and builds no output cases from that input case. If the variable specified for the ending column on STARTS has a value that is less than the value specified for the starting column, the program issues a warning and builds output cases only from the continuation records of that input case; it does not build cases from the first record of the case.
- If the ending location is required but not supplied, the program generates output cases with system-missing values for the variables specified on the DATA subcommand and may misread all data after the first or second record in the data file (see the CONTINUED subcommand).

### Repeating Groups in the Same Location

```
INPUT PROGRAM.
DATA LIST FILE=VEHICLE / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
REPEATING DATA STARTS=12 /OCCURS=NUMVEH
 /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.
END INPUT PROGRAM.
```

- STARTS specifies column number 12. The repeating groups must therefore start in column 12 of the first record of each input case.

## Repeating Groups in Varying Locations

```
INPUT PROGRAM.
DATA LIST FILE=VEHICLE / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
+ DO IF (SEQNUM LE 100).
+ COMPUTE FIRST=12.
+ ELSE.
+ COMPUTE FIRST=15.
+ END IF.
REPEATING DATA STARTS=FIRST /OCCURS=NUMVEH
  /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.
END INPUT PROGRAM.
```

- This example assumes that each input case is recorded on a single record and that there are no continuation records. Repeating groups begin in column 12 for all records with sequence numbers 1 through 100 and in column 15 for all records with sequence numbers greater than 100.
- The sequence number for each record is defined as variable *SEQNUM* on the *DATA LIST* command. The *DO IF*–*END IF* structure creates the variable *FIRST* with value 12 for records with sequence numbers through 100 and value 15 for records with sequence numbers greater than 100.
- Variable *FIRST* is specified on the *STARTS* subcommand.

---

## OCCURS Subcommand

*OCCURS* specifies the number of repeating groups for each input case. *OCCURS* is required and specifies a number if the number of groups is the same for all input cases or a variable if the number of groups varies across input cases. The variable must be defined on a *DATA LIST* command or created with transformation commands.

### Specifying the Number of Repeating Groups Using a Data Field

```
INPUT PROGRAM.
DATA LIST / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
REPEATING DATA STARTS=12 /OCCURS=NUMVEH
  /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.
END INPUT PROGRAM.
```

```
BEGIN DATA
1001 02 02 FORD T8PONTIAC C6
1002 04 01 CHEVY C4
1003 02 03 CADILAC C8FORD T6VW C4
END DATA.
LIST.
```

- Data for each input case are recorded on a single record; there are no continuation records.
- The value for variable *NUMVEH* in columns 9 and 10 indicates the number of repeating groups on each record. One output case is built in the active dataset for each occurrence of a repeating group.
- In the data, *NUMVEH* has the value 2 for the first case, 1 for the second, and 3 for the third. Thus, six cases are built from these records. If the value of *NUMVEH* is 0, no cases are built from that record.

### Specifying a Fixed Number of Repeating Groups

\* Read only the first repeating group from each record.

```
INPUT PROGRAM.
DATA LIST FILE=VEHICLE / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
REPEATING DATA STARTS=12 /OCCURS=1
  /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.
END INPUT PROGRAM.
LIST.
```

- Since *OCCURS* specifies that there is only one repeating group for each input case, only one output case is built from each input case regardless of the actual number of repeating groups.

---

## DATA Subcommand

*DATA* specifies a name, location within each repeating segment, and format for each variable to be read from the repeating groups. *DATA* is required and must be the last subcommand on *REPEATING DATA*.

- The specifications for *DATA* are the same as for the *DATA LIST* command.

- The specified location of the variables on DATA is their location within each repeating group—not their location within the record.
- Any input format available on the DATA LIST command can be specified on the DATA subcommand. Both FORTRAN-like and the column-style specifications can be used.

### Example

```
INPUT PROGRAM.
DATA LIST FILE=VEHICLE / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
REPEATING DATA STARTS=12 /OCCURS=NUMVEH
  /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.
END INPUT PROGRAM.
LIST.
```

- Variable *MAKE* is a string variable read from positions 1 through 8 of each repeating group; *MODEL* is a single-character string variable read from position 9; and *NUMCYL* is a one-digit numeric variable read from position 10.
- The DATA LIST command defines variables *SEQNUM*, *NUMPERS*, and *NUMVEH*. These variables are spread to each output case built from the repeating groups.

---

## FILE Subcommand

REPEATING DATA always reads the file specified on its associated DATA LIST or FILE TYPE command. The FILE subcommand on REPEATING DATA explicitly specifies the name of the file.

- FILE must specify the same file as its associated DATA LIST or FILE TYPE command.

### Example

```
INPUT PROGRAM.
DATA LIST FILE=VEHICLE / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
REPEATING DATA FILE=VEHICLE /STARTS=12 /OCCURS=NUMVEH
  /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.
END INPUT PROGRAM.
LIST.
```

- FILE on REPEATING DATA specifically identifies the *VEHICLE* file, which is also specified on the DATA LIST command.

---

## ENCODING Subcommand

ENCODING specifies the encoding format of the file. The keyword is followed by an equals sign and a quoted encoding specification.

- In Unicode mode, the default is UTF8. For more information, see SET command, UNICODE subcommand.
- In code page mode, the default is the current locale setting. For more information, see SET command, LOCALE subcommand.
- The quoted encoding value can be: *Locale* (the current locale setting), UTF8, UTF16, UTF16BE (big endian), UTF16LE (little endian), a numeric Windows code page value (for example, '1252'), or an IANA code page value (for example, 'iso8859-1' or cp1252).
- In Unicode mode, the defined width of string variables is tripled for code page and UTF-16 text data files. Use ALTER TYPE to automatically adjust the defined width of string variables.

---

## LENGTH Subcommand

LENGTH specifies the length of each repeating data group. The default length is the number of columns between the beginning column of the repeating data groups and the ending position of the last variable specified on DATA. (For the first record of each input case, STARTS specifies the beginning column of the repeating groups. For continuation records, repeating groups are read from column 1 by default or from the column specified on CONTINUED.)

- The specification on LENGTH can be a number or the name of a variable.

- LENGTH must be used if the last variable specified on the DATA subcommand is not read from the last position of each repeating group, or if the length of the repeating groups varies across input cases.
- If the length of the repeating groups varies across input cases, the specification must be a variable whose value for each input case is the length of the repeating groups for that case. The variable can be defined on DATA LIST or created with transformation commands.
- If the value of the variable specified on LENGTH is undefined or missing for an input case, the program displays a warning message and builds only one output case for that input case.

### Example

\* Read only the variable MAKE for each vehicle.

\* The data contain two values that are not specified on the DATA subcommand. The first is in position 9 of the repeating groups, and the second is in position 10.

```
INPUT PROGRAM.
DATA LIST FILE=VEHICLE / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
REPEATING DATA STARTS=12 /OCCURS=NUMVEH /LENGTH=10
  /DATA=MAKE 1-8 (A).
END INPUT PROGRAM.
```

- LENGTH indicates that each repeating group is 10 columns long. LENGTH is required because MAKE is not read from the last position of each repeating group. As illustrated in previous examples, each repeating group also includes variable MODEL (position 9) and NUMCYL (position 10).
- DATA specifies that MAKE is in positions 1 through 8 of each repeating group. Positions 9 and 10 of each repeating group are skipped.

---

## CONTINUED Subcommand

CONTINUED indicates that the repeating groups are contained on more than one record for each input case.

- Each repeating group must be fully recorded on a single record: a repeating group cannot be split across records.
- The repeating groups must begin in the same column on all continuation records.
- If CONTINUED is specified without beginning and ending columns, the program assumes that the repeating groups begin in column 1 of continuation records and searches for repeating groups by scanning to the end of the record or to the value specified by OCCURS. See the topic "Operations" on page 1658 for more information.
- If the repeating groups on continuation records do not begin in column 1, CONTINUED must specify the column in which the repeating groups begin.
- If there is room on the logical record length for more repeating groups than are contained on the first record of each input case, the STARTS subcommand must indicate an ending column for the records. The ending column on STARTS applies only to the first record of each input case.
- If there is room on the logical record length for more repeating groups than are contained on the continuation records of each input case, the CONTINUED subcommand must indicate an ending column. The ending column on CONTINUED applies to all continuation records.

### Basic Example

\* This example assumes the logical record length is 80.

```
INPUT PROGRAM.
DATA LIST / ORDERID 1-5 NITEMS 7-8.
REPEATING DATA STARTS=10 /OCCURS=NITEMS /CONTINUED=7
  /DATA=ITEM 1-9 (A) QUANTITY 11-13 PRICE (DOLLAR7.2,1X).
END INPUT PROGRAM.
```

```
BEGIN DATA
10020 07 01-923-89 001 25.99 02-899-56 100 101.99 03-574-54 064 61.29
10020 04-780-32 025 13.95 05-756-90 005 56.75 06-323-47 003 23.74
10020 07-350-95 014 11.46
20030 04 01-781-43 010 10.97 02-236-54 075 105.95 03-655-83 054 22.99
20030 04-569-38 015 75.00
END DATA.
LIST.
```

- Data are extracted from a mail-order file. Each input case represents one complete order. The data show two complete orders recorded on a total of five records.
- The order number is recorded in columns 1 through 5 of each record. The first three records contain information for order 10020; the next two records contain information for order 20030. The second field of numbers on the first record of each order indicates the total number of items ordered. The repeating groups begin in column 10 on the first record and in column 7 on continuation records. Each repeating data group represents one item ordered and contains three variables—the item inventory number, the quantity ordered, and the price.
- DATA LIST defines variables *ORDERID* and *NITEMS* on the first record of each input case.
- STARTS on REPEATING DATA indicates that the repeating groups on the first record of each input case begin in column 10.
- OCCURS indicates that the total number of repeating groups for each input case is the value of *NITEMS*.
- CONTINUED must be used because the repeating groups are continued on more than one record for each input case. CONTINUED specifies a beginning column because the repeating groups begin in column 7 rather than in column 1 on the continuation records.
- DATA defines variables *ITEM*, *QUANTITY*, and *PRICE* for each repeating data group. *ITEM* is in positions 1–9, *QUANTITY* is in positions 11–13, and *PRICE* is in positions 14–20 and is followed by one blank column. The length of the repeating groups is therefore 21 columns. The LIST output is shown below.

ORDERID	NITEMS	ITEM	QUANTITY	PRICE
10020	7	01-923-89	1	\$25.99
10020	7	02-899-56	100	\$101.99
10020	7	03-574-54	64	\$61.29
10020	7	04-780-32	25	\$13.95
10020	7	05-756-90	5	\$56.75
10020	7	06-323-47	3	\$23.74
10020	7	07-350-95	14	\$11.46
20030	4	01-781-43	10	\$10.97
20030	4	02-236-54	75	\$105.95
20030	4	03-655-83	54	\$22.99
20030	4	04-569-38	15	\$75.00

NUMBER OF CASES READ = 11      NUMBER OF CASES LISTED = 11

### Specifying an Ending Column on the STARTS Subcommand

\* This example assumes the logical record length is 80.

```

INPUT PROGRAM.
DATA LIST / ORDERID 1-5 NITEMS 7-8.
REPEATING DATA STARTS=10-55 /OCCURS=NITEMS /CONTINUED=7
  /DATA=ITEM 1-9 (A) QUANTITY 11-13 PRICE (DOLLAR7.2,1X).
END INPUT PROGRAM.

BEGIN DATA
10020 07 01-923-89 001 25.99 02-899-56 100 101.99
10020 03-574-54 064 61.29 04-780-32 025 13.95 05-756-90 005 56.75
10020 06-323-47 003 23.74 07-350-95 014 11.46
20030 04 01-781-43 010 10.97 02-236-54 075 105.95
20030 03-655-83 054 22.99 04-569-38 015 75.00
END DATA.
LIST.

```

- Data are the same as in the previous example; however, records are entered differently. The first record for each input case contains only two repeating groups.
- DATA LIST defines variables *ORDERID* and *NITEMS* in columns 1–8 on the first record of each input case. Column 9 is blank. DATA defines variables *ITEM*, *QUANTITY*, and *PRICE* in positions 1–20 of each repeating group, followed by a blank. Thus, each repeating group is 21 columns wide. The length of the first record of each input case is therefore 51 columns: 21 columns for each of two repeating groups, plus the eight columns defined on DATA LIST, plus column 9, which is blank. The operating system's logical record length is 80, which allows room for one more repeating group on the first

record of each input case. STARTS must therefore specify an ending column that does not provide enough columns for another repeating group; otherwise, the program creates an output case with missing values for the variables specified on DATA.

- STARTS specifies that the program is to scan only columns 10–55 of the first record of each input case looking for repeating data groups. It will scan continuation records beginning in column 7 until the value specified on the OCCURS subcommand is reached.

### Specifying an Ending Column on the CONTINUED Subcommand

\* This example assumes the logical record length is 80.

```
INPUT PROGRAM.  
DATA LIST / ORDERID 1-5 NITEMS 7-8.  
REPEATING DATA STARTS=10-55 /OCCURS=NITEMS /CONTINUED=7-55  
/DATA=ITEM 1-9 (A) QUANTITY 11-13 PRICE (DOLLAR7.2,1X).  
END INPUT PROGRAM.
```

```
BEGIN DATA  
10020 07 01-923-89 001 25.99 02-899-56 100 101.99  
10020 03-574-54 064 61.29 04-780-32 025 13.95  
10020 05-756-90 005 56.75 06-323-47 003 23.74  
10020 07-350-95 014 11.46  
20030 04 01-781-43 010 10.97 89-236-54 075 105.95  
20030 03-655-83 054 22.99 04-569-38 015 75.00  
END DATA.  
LIST.
```

- The data are the same as in the previous two examples, but records are entered differently. The first record and the continuation records for each input case store only two repeating groups each.
- The operating system's logical record length is 80, which allows room for more repeating groups on all records.
- STARTS specifies that the program is to scan only columns 10-55 of the first record of each input case looking for repeating data groups.
- CONTINUED specifies that the program is to scan only columns 7–55 of all continuation records.

---

## ID Subcommand

ID compares the value of an identification variable across records of the same input case. ID can be used only when CONTINUED is specified. The identification variable must be defined on a DATA LIST command and must be recorded on all records in the file.

- The ID subcommand has two specifications: the location of the variable on the continuation records and the name of the variable (as specified on the DATA LIST command). The specifications must be separated from each other by an equals sign.
- The format specified on the ID subcommand must be the same as the format specified for the variable on DATA LIST. However, the location can be different on the continuation records.
- If the values of the identification variable are not the same on all records for a single input case, the program displays an error message and stops reading data.

### Example

```
INPUT PROGRAM.  
DATA LIST / ORDERID 1-5 NITEMS 7-8.  
REPEATING DATA STARTS=10-50 /OCCURS=NITEMS  
/CONTINUED=7 /ID=1-5=ORDERID  
/DATA=ITEM 1-9 (A) QUANTITY 11-13 PRICE 15-20 (2).  
END INPUT PROGRAM.
```

```
BEGIN DATA  
10020 04 45-923-89 001 25.9923-899-56 100 101.99  
10020 63-780-32 025 13.9554-756-90 005 56.75  
20030 03 45-781-43 010 10.9789-236-54 075 105.95  
20030 32-569-38 015 75.00  
END DATA.  
LIST.
```

- The order number in the data is recorded in columns 1–5 of each record.

- *ORDERID* is defined on the DATA LIST command as a five-column integer variable. The first specification on the ID subcommand must therefore specify a five-column integer variable. The location of the variable can be different on continuation records.

---

## TABLE and NOTABLE Subcommands

TABLE displays a table summarizing all variables defined on the DATA subcommand. The summary table lists the names, locations, and formats of the variables and is identical in format to the summary table displayed by the DATA LIST command. NOTABLE suppresses the table. TABLE is the default.

### Example

```
INPUT PROGRAM.  
DATA LIST FILE=VEHICLE / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.  
REPEATING DATA STARTS=12 /OCCURS=NUMVEH /NOTABLE  
/DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.  
END INPUT PROGRAM.
```

- NOTABLE suppresses the display of the summary table.

---

## Chapter 224. REPORT

REPORT is available in the Statistics Base Edition.

```
REPORT [/FORMAT={MANUAL } ] [{NOLIST } ] [ALIGN({LEFT })] [TSPACE({1})]
      {AUTOMATIC} {LIST[(n)]} {CENTER} {n}
      {RIGHT }
      [CHDSpace({1})] [FTSPACE({1})] [SUMSPACE({1})] [COLSPACE({4})]
      {n} {n} {n} {n}
      [BRKSPACE({ 1 })][LENGTH({1,length})] [MARGINS({1,width})]
      { n } {t,b } {1,r }
      {-1†} {*,* } {*,* }
      [CHALIGN({TOP })] [UNDERScore({OFF})] [PAGE1({1})] [MISSING {'.'}]
      {BOTTOM†} {ON†} {n} {'s'}
      [ONEBREAKCOLUMN {OFF**}] [INDENT {2**}] [CHWRAP {OFF**}] [PREVIEW {OFF**}]
      {ON } {n } {ON } {ON }
[/OUTFILE=file]
[/STRING=stringname (varname[(width)] [(BLANK)] ['literal'])]
/VARIABLES=varname ({VALUE}) [+ varname({VALUE})] ['col head'] [option list]
      {LABEL} {LABEL}
      {DUMMY} {DUMMY}
```

where option list can contain any of the following:

```
(width) (OFFSET({0 }) ) (LEFT )
        {n } {CENTER†}
        {CENTER†} {RIGHT }
```

```
[/MISSING={VAR } ]
      {NONE }
      {LIST[([varlist])[{1}]]}
```

```
[/TITLE=[{LEFT } ] 'line1' 'line2'...] [/FOOTNOTE=[{LEFT } ] 'line1' 'line2'...]
      {CENTER } {CENTER }
      {RIGHT } {RIGHT }

```

```
[/BREAK=varlist ['col head'] [option list]]
```

where option list can contain any of the following:

```
(width) ({VALUE } ) ({NOTOTAL} ) ({SKIP({1} )})
      {LABEL†} {TOTAL } {n}
      {PAGE[(RESET)]}
(OFFSET({0 }) ) (UNDERScore[(varlist)]) ({LEFT }) ({NONAME})
      {n } {CENTER†} {CENTER†} {NAME }
      {CENTER†} {RIGHT }
```

```
[/SUMMARY=function...['summary title'][(break col #)] [SKIP({0})]
      {n}
or [/SUMMARY=PREVIOUS[({1})]]
      {n}
```

where function is

```
aggregate [(varname[({PLAIN })][(d)] [varname...])]
      {format††}
or composite(argument)[(report col[({PLAIN })][(d)])]
      {format††}
```

\*\*Default if the keyword is omitted.

†Default if FORMAT=AUTOMATIC.

††Any printable output format is valid. See FORMATS.

Aggregate functions: VALIDN, VARIANCE, PLT(n), SUM, KURTOSIS, PIN(min, max), MIN, SKEWNESS, FREQUENCY(min, max), MAX, MEDIAN(min, max), PERCENT(min, max), MEAN, MODE(min, max), STDDEV, PGT(n).

Composite functions: DIVIDE(arg<sub>1</sub> arg<sub>2</sub> [factor]), MULTIPLY(arg<sub>1</sub>...arg<sub>n</sub>), PCT(arg<sub>1</sub> arg<sub>2</sub>), SUBTRACT(arg<sub>1</sub> arg<sub>2</sub>), ADD(arg<sub>1</sub>...arg<sub>n</sub>), GREAT(arg<sub>1</sub>...arg<sub>n</sub>), LEAST(arg<sub>1</sub>...arg<sub>n</sub>), AVERAGE(arg<sub>1</sub>...arg<sub>n</sub>) .

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Example

```
REPORT FORMAT=LIST
/VARIABLES=PRODUCT (LABEL) ' ' 'Retail' 'Products'
        SALES 'Annual' 'Sales' '1981'
/BREAK=DEPT 'Department' (LABEL)
/SUMMARY=VALIDN (PRODUCT) MEAN (SALES).
```

---

## Overview

REPORT produces case listings and summary statistics and gives you considerable control over the appearance of the output. REPORT calculates all the univariate statistics available in DESCRIPTIVES and the statistics and subpopulation means available in MEANS. In addition, REPORT calculates statistics not directly available in any other procedure, such as computations involving aggregated statistics.

REPORT provides complete report format defaults but also lets you customize a variety of table elements, including column widths, titles, footnotes, and spacing. Because REPORT is so flexible and the output has so many components, it is often efficient to preview report output using a small number of cases until you find the format that best suits your needs.

### Basic specification

The basic specification depends on whether you want a listing report or a summary report. A listing report without subgroup classification requires FORMAT and VARIABLES. A listing report with subgroup classification requires FORMAT, VARIABLES, and BREAK. A summary report requires VARIABLES, BREAK, and SUMMARY.

**Listing reports.** FORMAT=LIST and VARIABLES with a variable list are required. Case listings are displayed for each variable named on VARIABLES. There are no break groups or summary statistics unless BREAK or SUMMARY is specified.

**Summary reports.** VARIABLES, BREAK, and SUMMARY are required. The report is organized according to the values of the variable named on BREAK. The variable named on BREAK must be named on a preceding SORT CASES command. Specified statistics are computed for the variables specified on VARIABLES for each subgroup defined by the break variables.

### Subcommand order

The following order must be observed among subcommands when they are used:

- FORMAT must precede all other subcommands.
- VARIABLES must precede BREAK.
- OUTFILE must precede BREAK.
- Each SUMMARY subcommand must immediately follow its associated BREAK. Multiple SUMMARY subcommands associated with the same BREAK must be specified consecutively.
- TITLE and FOOTNOTE can appear anywhere after FORMAT except between BREAK and SUMMARY.
- MISSING must follow VARIABLES and precede the first BREAK.
- STRING must precede VARIABLES.

### Syntax rules

- Only one each of the FORMAT, STRING, VARIABLES, and MISSING subcommands is allowed.

- To obtain multiple break groups, use multiple BREAK subcommands.
- To obtain multiple summaries for a break level, specify multiple SUMMARY subcommands for the associated BREAK.
- Keywords on REPORT subcommands have default specifications that are in effect if the keyword is not specified. Specify keywords only when you wish to change a default.
- Keywords are enclosed in parentheses if the subcommand takes variable names as arguments.

### Operations

- REPORT processes cases sequentially. When the value of a break variable changes, REPORT displays a statistical summary for cases processed since the last set of summary statistics was displayed. Thus, the file must be sorted in order on the break variable or variables.
- The maximum width and page length of the report are determined by the SET command.
- If a column is not wide enough to display numeric values, REPORT first rounds decimal digits, then converts to scientific notation if possible, and then displays asterisks. String variables that are wider than the column are truncated.
- The format used to display values in case listings is controlled by the dictionary format of the variable. Each statistical function in REPORT has a default format.

### Limitations

- Maximum 500 variables per VARIABLES subcommand. You can specify more than 500 variables if you stack them. See the topic “VARIABLES subcommand” on page 1675 for more information.
- Maximum 10 dummy variables per VARIABLES subcommand.
- Maximum 20 MODE and MEDIAN requests per SUMMARY subcommand.
- Maximum 20 PGT, PLT, and PIN requests per SUMMARY subcommand.
- Maximum 50 strings per STRING subcommand.
- The length of titles and footnotes cannot exceed the report width.
- The length of string variables created on STRING cannot exceed the page width.
- There is no fixed limit on the number of BREAK and SUMMARY subcommands. However, the page width limits the number of variables that can be displayed and thereby limits the number of break variables.
- The maximum width of a report is 255 characters.
- The number of report variables that can be specified depends upon the width of the report, the width of the variable columns, and the number of BREAK subcommands.
- Maximum 50 variables for the FREQUENCY or PERCENT functions.
- Memory requirements significantly increase if FREQUENCY, PERCENT, MEDIAN, or MODE is requested for variables with a wide range of values. The amount of workspace required is  $20 + 8 * (\max - \min + 1)$  bytes per variable per function per break. If the same range is used for different statistics for the same variable, only one set of cells is collected. For example, FREQUENCY(1,100)(VARA) PERCENT(1,100)(VARA) requires only 820 bytes.
- If TOTAL is in effect, workspace requirements are almost doubled.
- Memory requirements also increase if value labels are displayed for variables with many value labels. The amount of workspace required is  $4 + 24 * n$  bytes per variable, where  $n$  is the number of value labels specified for the variable.

---

## Examples

```

SORT CASES BY DEPT.
REPORT FORMAT=LIST
/VARIABLES=PRODUCT (LABEL) ' ' 'Retail' 'Products'
        SALES 'Annual' 'Sales' '1981'
/BREAK=DEPT 'Department' (LABEL)
/SUMMARY=VALIDN (PRODUCT) MEAN (SALES) 'No.Sold,Mean Sales'.

```

- This report is a listing of products and sales by department. A summary of the total number of products sold and the average sales by department is also produced.
- Cases are first sorted by *DEPT* so that cases are grouped by department for the case listing and for the calculation of statistics.
- *FORMAT* requests a report that lists individual cases within each break group.
- *VARIABLES* specifies *PRODUCT* and *SALES* as the report variables. Keyword *LABEL* requests that the case listings for *PRODUCT* display value labels instead of values. Three-line column headings are provided for each report column. The first line of the column heading is blank for the variable *PRODUCT*.
- *BREAK* identifies *DEPT* as the break variable and provides a one-line column title for the break column. *LABEL* displays the value label instead of the value itself.
- *SUMMARY* calculates the valid number of cases for *PRODUCT* and the mean of *SALES* for each value of *DEPT*. A title is provided for the summary line to override the default title, *VALIDN*.

---

## Defaults

**Column heads.** *REPORT* uses variable labels as default column heads; if no variable labels have been specified, variable names are used. If *ONEBREAKCOLUMN* is *ON*, the default head for the first *BREAK* subcommand is used.

**Column widths.** Default column widths are determined by *REPORT*, using the maximum of the following for each column:

- The widest print format in the column, whether it is a variable print format or a summary print format.
- The width of any temporary variable defined with the *STRING* subcommand on *REPORT*.
- If a column heading is assigned, the length of the longest title line in the heading when *CHWRAP* is off, and the longest word in the title when *CHWRAP* is on. Underscores, which are removed on printing, can be used to create longer words in the title.
- When no column heading is specified, the length of the longest word in the variable label, or the length of the variable name.
- If you specify *LABEL* on *VARIABLES* or *BREAK*, the length of the variable's longest value label. If *FORMAT=MANUAL* is in effect, 20 is the maximum value used for this criterion.
- The minimum column width is 8 when *FORMAT=MANUAL*; it can be less when *FORMAT=AUTOMATIC*.

**Automatic fit.** When the above criteria for column width result in a report that is too wide for the report margins, *FORMAT=AUTOMATIC* shrinks the report. *AUTOMATIC* performs the following two steps sequentially, stopping as soon as the report fits within the margins:

1. *AUTOMATIC* reduces intercolumn spacing incrementally until it reaches a minimum intercolumn space of 1. It will never reduce it to 0.
2. *AUTOMATIC* shortens widths for strings specified on the *STRING* subcommand or for value label strings when the *LABEL* option is specified. It begins with the longest string if that string is at least 15 characters wide and shortens the column width as much as needed (up to 40% of its length), wrapping the string within the new width. If necessary, it repeats the step, using different defined strings. It will not shorten the column width of the same string twice.

*REPORT* does *not* implement the automatic fit unless *AUTOMATIC* is specified on the *FORMAT* subcommand.

***AUTOMATIC* versus *MANUAL* defaults.** Many default settings depend on whether you specify *AUTOMATIC* or *MANUAL* on *FORMAT*.

<sup>1</sup> No effect when *ONEBREAKCOLUMN* is on.

<sup>2</sup> *LEFT* when *ONEBREAKCOLUMN* is on.

<sup>3</sup> 0 when ONEBREAKCOLUMN is on.

## Options

**Format.** REPORT provides full format defaults and offers you optional control over page length, vertical spacing, margin and column widths, page titles, footnotes, and labels for statistics. The maximum width and length of the report are controlled by specifications on the SET command. The FORMAT subcommand on REPORT controls how the report is laid out on a page and whether case listings are displayed. The VARIABLES subcommand specifies the variables that are listed or summarized in the report (**report variables**) and controls the titles, width, and contents of report columns. The BREAK subcommand specifies the variables that define groups (**break variables**) and controls the titles, width, and contents of break columns. SUMMARY specifies statistics and controls the titles and spacing of summary lines. The TITLE and FOOTNOTE subcommands control the specification and placement of multiple-line titles and footnotes. STRING concatenates variables to create temporary variables that can be specified on VARIABLES or BREAK.

**Output file.** You can direct reports to a file separate from the file used for the rest of the output from your session using the OUTFILE subcommand.

**Statistical display.** The statistical display is controlled by the SUMMARY subcommand. Statistics can be calculated for each category of a break variable and for the group as a whole. Available statistics include mean, variance, standard deviation, skewness, kurtosis, sum, minimum, maximum, mode, median, and percentages. Composite functions perform arithmetic operations using two or more summary statistics calculated on single variables.

**Missing values.** You can override the default to include user-missing values in report statistics and listings with the MISSING subcommand. You can also use FORMAT to define a missing-value symbol to represent missing data.

---

## FORMAT subcommand

FORMAT controls the overall width and length of the report and vertical spacing. Keywords and their arguments can be specified in any order.

- MANUAL and AUTOMATIC are alternatives. The default is MANUAL.
- LIST and NOLIST are alternatives. The default is NOLIST.

**MANUAL.** *Default settings for manual format.* MANUAL displays values for break variables, right-justifies numeric values and their column headings, left-justifies value labels and string values and their column headings, top-aligns and does not underscore column headings, extends column widths to accommodate the variable's longest value label (but not the longest word in the variable label) up to a width of 20, and generates an error message when a report is too wide for its margins. MANUAL is the default.

**AUTOMATIC.** *Default settings for automatic format.* AUTOMATIC displays labels for break variables, centers all data, centers column headings but left-justifies column headings if value labels or string values exceed the width of the longest word in the heading, bottom-aligns and underscores column headings, extends column widths to accommodate the longest word in a variable label or the variable's longest value label, and shrinks a report that is too wide for its margins.

**LIST(n).** *Individual case listing.* The values of all variables named on VARIABLES are displayed for each case. The optional *n* inserts a blank line after each *n* cases. By default, no blank lines are inserted. Values for cases are listed using the default formats for the variables.

**NOLIST.** *No case listing.* This is the default.

**PAGE(n).** *Page number for the first page of the report.* The default is 1.

**LENGTH(t,b)** . *Top and bottom line numbers of the report.* You can specify any numbers to define the report page length. By default, the top of the report begins at line 1, and the bottom of the report is the last line of the system page. You can use an asterisk for *t* or *b* to indicate a default value. If the specified length does not allow even one complete line of information to be displayed, REPORT extends the length specification and displays a warning.

**MARGINS(l,r)** . *Columns for the left and right margins.* The right column cannot exceed 255. By default, the left margin is display column 1 and the right margin is the rightmost display column of the system page. You can use an asterisk for *l* or *r* to indicate a default value.

**ALIGN.** *Placement of the report relative to its margins.* LEFT, CENTER, or RIGHT can be specified in the parentheses following the keyword. LEFT left-justifies the report. CENTER centers the report between its margins. RIGHT right-justifies the report. The default is LEFT.

**COLSPACE(n)** . *Number of spaces between each column.* The default is 4 or the average number of spaces that will fit within report margins, whichever is less. When AUTOMATIC is in effect, REPORT overrides the specified column spacing if necessary to fit the report between its margins.

**CHALIGN.** *Alignment of column headings.* Either TOP or BOTTOM can be specified in the parentheses following the keyword. TOP aligns all column headings with the first, or top, line of multiple-line headings. BOTTOM aligns headings with the last, or bottom, line of multiple-line headings. When AUTOMATIC is in effect, the default is BOTTOM; when MANUAL is in effect, the default is TOP.

**UNDERSCORE** . *Underscores for column headings.* Either ON or OFF can be specified in the parentheses following the keyword. ON underscores the bottom line of each column heading for the full width of the column. OFF does not underscore column headings. The default is ON when AUTOMATIC is in effect and OFF when MANUAL is in effect.

**TSPACE(n).** *Number of blank lines between the report title and the column heads.* The default is 1.

**CHDSPACE(n)** . *Number of blank lines beneath the longest column head.* The default is 1.

**BRKSPACE(n)** . *Number of blank lines between the break head and the next line.* The next line is a case if LIST is in effect or the first summary line if NOLIST is in effect. BRKSPACE(-1) places the first summary statistic or the first case listing on the same line as the break value. When a summary line is placed on the same line as the break value, the summary title is suppressed. When AUTOMATIC is in effect, the default is -1; when MANUAL is in effect, it is 1.

**SUMSPACE(n)** . *Number of blank lines between the last summary line at the lower break level and the first summary line at the higher break level when they break simultaneously.* SUMSPACE also controls spacing between the last listed case and the first summary line if LIST is in effect. The default is 1.

**FTSPACE(n)** . *Minimum number of blank lines between the last listing on the page and the footnote.* The default is 1.

**MISSING 's'** . *Missing-value symbol.* The symbol can be only one character and represents both system- and user-missing values. The default is a period.

**ONEBREAKCOLUMN.** *Display subgroups defined on multiple BREAK subcommands in a single column.* You can specify OFF or ON in parentheses after the keyword. The default is OFF. When ONEBREAKCOLUMN is ON, it applies to all BREAK subcommands. See the topic "BREAK subcommand" on page 1678 for more information.

**INDENT(n).** *Indentation of break values and summary titles of each successive subgroup defined by one BREAK subcommand in a single break column.* INDENT is effective only when ONEBREAKCOLUMN is on. Multiple

variables specified on one BREAK subcommand are indented as a block. The default specification is 2. When ONEBREAKCOLUMN is OFF, specification on INDENT is ignored.

**CHWRAP.** *Automatically wrap user-specified column heads.* You can specify OFF or ON in parentheses after the keyword. The default is OFF. When CHWRAP is ON, user-specified heads for either break or variable columns are wrapped. If multiple lines are specified for a head, each line is wrapped, if necessary, independent of other lines. To prevent wrapping at blanks, use the underscore character (\_) to signify a hard blank in your head specification. The underscore serves as a hard blank only in user-specified heads and only when CHWRAP is ON. The underscore does not appear in the printed heading.

**PREVIEW.** *Display the first page of output only.* You can specify OFF or ON either in parentheses or with one blank space separating the specification from the keyword. The default is OFF. When PREVIEW is ON, the program stops processing after the first page for you to quickly check the format of your report.

---

## OUTFILE subcommand

OUTFILE directs the report to a file separate from the file used for the rest of the output from your session. This allows you to print the report without having to delete the extraneous material that would be present in the output.

- OUTFILE must follow FORMAT and must precede BREAK.
- You can append multiple reports to the same file by naming the same file on the OUTFILE subcommand for each REPORT command.

Note: The first time a particular file is named on the OUTFILE subcommand within a job or session, the file is created or, if it already exists, it is erased. It remains open until the job or session finishes. Later uses of the same file in REPORT append their output to it. Attempts to erase the file may fail.

### Example

```
REPORT FORMAT=AUTOMATIC LIST
/OUTFILE=PRSNLRPT
/VARIABLES=LNAME AGE TENURE JTENURE SALARY
/BREAK=DIVISION
/SUMMARY=MEAN.
```

```
REPORT FORMAT=AUTOMATIC
/OUTFILE=PRSNLRPT
/VARIABLES=LNAME AGE TENURE JTENURE SALARY
/BREAK=DIVISION
/SUMMARY=MEAN
/SUMMARY=MIN
/SUMMARY=MAX.
```

- Both a listing report and a summary report are written to file *PRSNLRPT*.

---

## VARIABLES subcommand

The required VARIABLES subcommand names the variables to be listed and summarized in the report. You can also use VARIABLES to control column titles, column widths, and the contents of report columns.

- The minimum specification on VARIABLES is a list of report variables. The number of variables that can be specified is limited by the system page width.
- Each report variable defines a report column. The value of the variable or an aggregate statistic calculated for the variable is displayed in that variable's report column.
- Variables are assigned to columns in the order in which they are named on VARIABLES.
- Variables named on BREAK can also be named on VARIABLES.
- When FORMAT=LIST, variables can be stacked in a single column by linking them with plus signs (+) on the VARIABLES subcommand. If no column heading is specified, REPORT uses the default heading from the first variable on the list. Only values from the first variable in the column are used to calculate summaries.

- Optional specifications apply only to the immediately preceding variable or list of variables implied by the T0 keyword. Options can be specified in any order.
- All optional specifications except column headings must be enclosed in parentheses; column headings must be enclosed in quotes.

## Column contents

The following options can be used to specify the contents of the report column for each variable:

**(VALUE)**. *Display the values of the variable.* This is the default.

**(LABEL)**. *Display value labels.* If value labels are not defined, values are displayed.

**(DUMMY)**. *Display blank spaces.* DUMMY defines a report column for a variable that does not exist in the active dataset. Dummy variables are used to control spacing or to reserve space for statistics computed for other variables. Do not name an existing variable as a dummy variable.

- VALUE and LABEL have no effect unless LIST has been specified on the FORMAT subcommand.
- When AUTOMATIC is in effect, value labels or string values are centered in the column based on the length of the longest string or label; numeric values are centered based on the width of the widest value or summary format. When MANUAL is in effect, value labels or string values are left-justified in the column and numeric values are right-justified. (See the OFFSET keyword.)

## Column heading

The following option can be used to specify a heading for the report column:

**'column heading'**. *Column heading for the preceding variable.* The heading must be enclosed in quotes. If no column heading is specified, the default is the variable label or, if no variable label has been specified, the variable name.

- To specify multiple-line headings, enclose each line in quotes, using the conventions for strings. The specifications for title lines should be separated by at least one blank.
- Default column headings wrap for as many lines as are required to display the entire label. If AUTOMATIC is in effect, user-specified column headings appear exactly as specified, even if the column width must be extended. If MANUAL is in effect, user-specified titles wrap to fit within the column width.

## Column heading alignment

The following options can be used to specify how column headings are aligned:

**(LEFT)**. *Left-aligned column heading.*

**(CENTER)**. *Centered column heading.*

**(RIGHT)**. *Right-aligned column heading.*

- If AUTOMATIC is in effect, column headings are centered within their columns by default. If value labels or string values exceed the width of the longest word in the heading, the heading is left-justified.
- If MANUAL is in effect, column headings are left-justified for value labels or string values and right-justified for numeric values by default.

## Column format

The following options can be used to specify column width and adjust the position of the column contents:

**(width)**. *Width for the report column.* If no width is specified for a variable, REPORT determines a default width using the criteria described under Defaults. If you specify a width that is not wide enough to

display numeric values, REPORT first rounds decimal digits, then converts to scientific notation if possible, and then displays asterisks. Value labels or string values that exceed the width are wrapped.

**(OFFSET).** *Position of the report column contents.* The specification is either *n* or CENTER specified in parentheses. OFFSET( *n* ) indicates the number of spaces to offset the contents from the left for value labels or string values, and from the right for numeric values. OFFSET(CENTER) centers contents within the center of the column. If AUTOMATIC is in effect, the default is CENTER. If MANUAL is in effect, the default is 0. Value labels and string values are left-justified and numeric values are right-justified.

#### Example

```
/VARIABLES=V1 TO V3(LABEL) (15)
  V4 V5 (LABEL)(OFFSET (2))(10)
  SEP1 (DUMMY) (2) ''
  V6 'Results using' "Lieben's Method" 'of Calculation'
```

- The width of the columns for variables *V1* through *V3* is 15 each. Value labels are displayed for these variables in the case listing.
- The column for variable *V4* uses the default width. Values are listed in the case listing.
- Value labels are displayed for variable *V5*. The column width is 10. Column contents are offset two spaces from the left.
- *SEP1* is a dummy variable. The column width is 2, and there is at least one space on each side of *SEP1*. Thus, there are at least four blanks between the columns for *V5* and *V6*. *SEP1* is given a null title to override the default column title *SEP1*.
- *V6* has a three-line title. Its column uses the default width, and values are listed in the case listing.

---

## STRING subcommand

STRING creates a temporary string variable by concatenating variables and user-specified strings. These variables exist only within the REPORT procedure.

- The minimum specification is a name for the string variable followed by a variable name or a user-specified string enclosed in parentheses.
- The name assigned to the string variable must be unique.
- Any combination of string variables, numeric variables, and user-specified strings can be used in the parentheses to define the string.
- Keyword T0 cannot be used within the parentheses to imply a variable list.
- More than one string variable can be defined on STRING.
- If a case has a missing value for a variable within the parentheses, the variable passes the missing value to the temporary variable without affecting other elements specified.
- A string variable defined in REPORT cannot exceed the system page width.
- String variables defined on STRING can be used on VARIABLES or BREAK.

The following options can be used to specify how components are to be concatenated:

**(width).** *Width of the preceding variable within the string.* The default is the dictionary width of the variable. The maximum width for numeric variables within the string definition is 16. The maximum width for a string variable is the system page width. If the width specified is less than that required by the value, numeric values are displayed as asterisks and string values are truncated. If the width exceeds the width of a value, numeric values are padded with zeros on the left and string values are padded with blanks on the right.

**(BLANK).** *Left-pad values of the preceding numeric variable with blanks.* The default is to left-pad values of numeric variables with zeros. If a numeric variable has a dollar or comma format, it is automatically left-padded with blanks.

**'literal'** . *User-specified string.* Any combination of characters can be specified within quotes.

### Example

```
/STRING=JOB1(AVAR NVAR)
      JOB2(AVAR(2) NVAR(3))
      JOB3(AVAR(2) NVAR(BLANK) (4))
```

- STRING defines three string variables to be used within the report.
- Assume that *AVAR* is a string variable read from a four-column field using keyword FIXED on DATA LIST and that *NVAR* is a computed numeric variable with the default format of eight columns with two implied decimal places.
- If a case has value KJ for *AVAR* and value 241 for *NVAR*, *JOB1* displays the value 'KJ 00241.00', *JOB2* the value 'KJ241', and *JOB3* the value 'KJ 241'. If *NVAR* has the system-missing value for a case, *JOB1* displays the value 'KJ'.

### Example

```
/STRING=SOCSEC(S1 '-' S2 '-' S3)
```

- STRING concatenates the three variables *S1*, *S2*, and *S3*, each of which contains a segment of the social security number.
- Hyphens are inserted between the segments when the values of *SOCSEC* are displayed.
- This example assumes that the variables *S1*, *S2*, and *S3* were read from three-column, two-column, and four-column fields respectively, using the keyword FIXED on DATA LIST. These variables would then have default format widths of 3, 2, and 4 columns and would not be left-padded with zeros.

---

## BREAK subcommand

BREAK specifies the variables that define the subgroups for the report, or it specifies summary totals for reports with no subgroups. BREAK also allows you to control the titles, width, and contents of break columns and to begin a new page for each level of the break variable.

- A break occurs when any one of the variables named on BREAK changes value. Cases must be sorted by the values of all BREAK variables on all BREAK subcommands.
- The BREAK subcommand must precede the SUMMARY subcommand that defines the summary line for the break.
- A break column is reserved for each BREAK subcommand if ONEBREAKCOLUMN is OFF (the default).
- To obtain multiple break levels, specify multiple break variables on a BREAK subcommand.
- If more than one variable is specified on a BREAK subcommand, a single break column is used. The value or value label for each variable is displayed on a separate line in the order in which the variables are specified on BREAK. The first variable specified changes most slowly. The default column width is the longest of the default widths for any of the break variables.
- To obtain summary totals without any break levels, use keyword TOTAL in parentheses on BREAK without listing any variables. TOTAL must be specified on the first BREAK subcommand.
- When MISSING=VAR is specified, user-missing values are displayed in case listings but are not included in summary statistics. When NONE is specified, user-missing values are ignored. System-missing values are displayed as missing in case and break listings.
- Optional specifications apply to all variables in the break column and to the break column as a whole. Options can be specified in any order following the last variable named.
- All optional specifications except column headings must be enclosed in parentheses; column headings must be enclosed in quotes.

## Column contents

The following can be used to specify the contents of the break column:

**(VALUE)**. *Display values of the break variables.*

**(LABEL)**. *Display value labels.* If no value labels have been defined, values are displayed.

- The value or label is displayed only once for each break change but it is repeated at the top of the page in a multiple-page break group.
- When AUTOMATIC is in effect, the default is LABEL; when MANUAL is in effect, the default is VALUE.
- When AUTOMATIC is in effect, the value or label is centered in the column. When MANUAL is in effect, value labels and string values are left-justified and numeric values are right-justified. Keywords OFFSET, ONEBREAKCOLUMN, and INDENT can also affect positioning.

## Column heading

The following option specifies headings used for the break column.

**'column heading'**. *Column heading for the break column.* The heading must be included in quotes. The default heading is the variable label of the break variable or, if no label has been defined, the variable name. If the break column is defined by more than one variable, the label or name of the first variable is used. If ONEBREAKCOLUMN is ON, the specified or implied column heading for the first BREAK subcommand is used.

- To specify multiple-line headings, enclose each line in a set of quotes, following the conventions for strings. Separate the specifications for heading lines with at least one blank.
- Default column headings wrap for as many lines as are required to display the entire label.
- User-specified column headings appear exactly as specified if CHWRAP is OFF (the default). If CHWRAP is ON, any user-defined line longer than the specified or default column width is automatically wrapped.

## Column heading alignment

The following options can be used to specify how column headings are aligned:

**(LEFT)**. *Left-aligned column heading.*

**(CENTER)**. *Centered column heading.*

**(RIGHT)**. *Right-aligned column heading.*

- When AUTOMATIC is in effect, column headings are centered within their columns by default. If value labels or string values exceed the width of the longest word in the heading, the heading is left-justified.
- When MANUAL is in effect, column headings are left-justified for value labels or string values and right-justified for numeric values.
- When ONEBREAKCOLUMN is ON, all column contents are left aligned. Specifications of CENTER and RIGHT on BREAK are ignored.

## Column format

The following options can be used to format break columns:

**(width)**. *Column width for the break column.* If no width is specified for a variable, REPORT determines a default width using the criteria described under Defaults. If ONEBREAKCOLUMN is ON, the column width specified or implied by the first BREAK subcommand is used. If you specify a width that is not wide enough to display numeric values, REPORT first rounds decimal digits, then converts them to scientific notation if possible, and then displays asterisks. Value labels or string values that exceed the width are wrapped.

**(OFFSET)**. *Position of the break column contents.* The specification is either *n* or CENTER specified in parentheses. OFFSET( *n* ) indicates the number of spaces to offset the contents from the left for value labels or string values, and from the right for numeric values. OFFSET(CENTER) centers contents within the column. If AUTOMATIC is in effect, the default is CENTER. If MANUAL is in effect, the default is 0: value labels

and string values are left-justified and numeric values are right-justified. If ONEBREAKCOLUMN is ON, the offset is applied along with the indentation specified on INDENT, always from the left. The specification of CENTER on OFFSET is ignored.

**(UNDERScore)**. Use underscores below case listings. Case listing columns produced by FORMAT LIST are underscored before summary statistics are displayed. You can optionally specify the names of one or more report variables after UNDERScore; only the specified columns are underscored.

**(TOTAL)**. Display the summary statistics requested on the next SUMMARY subcommand for all the cases in the report. TOTAL must be specified on the first BREAK subcommand and applies only to the next SUMMARY subcommand specified.

**(NOTOTAL)**. Display summary statistics only for each break. This is the default.

**(SKIP(n))**. Skip n lines after the last summary line for a break before beginning the next break. The default for n is 1.

**(PAGE)**. Begin each break on a new page. If RESET is specified on PAGE, the page counter resets to the PAGE1 setting on the FORMAT subcommand every time the break value changes for the specified variable. PAGE cannot be specified for listing reports with no break levels.

**(NAME)**. Display the name of the break variable next to each value or value label of the break variable. NAME requires enough space for the length of the variable name plus two additional characters (for a colon and a blank space) in addition to the space needed to display break values or value labels. NAME is ignored if the break column width is insufficient.

**(NONAME)**. Suppress the display of break variable names. This is the default.

### Example

```

SORT DIVISION BRANCH DEPT.
REPORT FORMAT=AUTOMATIC MARGINS (1,70) BRKSPACE(-1)

/VARIABLES=SPACE(DUMMY) ' ' (4)
           SALES 'Annual' 'Sales' '1981' (15) (OFFSET(2))
           EXPENSES 'Annual' 'Expenses' '1981' (15) (OFFSET(2))

/BREAK=DIVISION
           BRANCH (10) (TOTAL) (OFFSET(1))
/SUMMARY=MEAN

/BREAK=DEPT 'Department' (10)
/SUMMARY=MEAN.
```

- This example creates a report with three break variables. *BRANCH* breaks within values of *DIVISION*, and *DEPT* breaks within values of *BRANCH*.
- *FORMAT* sets margins to a maximum of 70 columns and requests that summary lines be displayed on the same line as break values. Because *LIST* is not specified on *FORMAT*, only summary statistics are displayed.
- *VARIABLES* defines three report columns, each occupied by a report variable: *SPACE*, *SALES*, and *EXPENSES*.
- The variable *SPACE* is a dummy variable that exists only within *REPORT*. It has a null heading and a width of 4. It is used as a space holder to separate the break columns from the report columns.
- *SALES* has a three-line heading and a width of 15. The values of *SALES* are offset two spaces from the right.
- *EXPENSES* is the third report variable and has the same width and offset specifications as *SALES*.
- The leftmost column in the report is reserved for the first two break variables, *DIVISION* and *BRANCH*. Value labels are displayed, since this is the default for *AUTOMATIC*. The break column has a width of 10 and the value labels are offset one space from the left. Value labels more than nine

characters long are wrapped. The default column heading is used. TOTAL requests a summary line at the end of the report showing the mean of all cases in the report.

- The first SUMMARY subcommand displays the mean of each report variable in its report column. This line is displayed each time the value of *DIVISION* or *BRANCH* changes.
- The third break variable, *DEPT*, occupies the second column from the left in the report. The break column has a width of 10 and has a one-line heading. Value labels are displayed in the break column, and those exceeding 10 characters are wrapped.
- The second SUMMARY subcommand displays the mean for each report variable when the value of *DEPT* changes.

## Using Dates as break variables

Under some circumstances, date values used as break variables may display as asterisks in the output because there is not enough space to display the date value. There are several options for dealing this situation:

- Decrease the offset value of the date variable on the BREAK subcommand. The default offset for dates is 4. Try using an offset of 2 or 0. For example: `DateVar (OFFSET(0))`.
- Include a width specification for the date variable on the BREAK subcommand. The value should be at greater than or equal to the defined width of the variable plus the offset value. For example, with a defined variable width of 10 and the default offset of 4, specify a width of 14, as in: `DateVar (14)`.
- Use the FORMATS command to increase the defined width of the date variable. For example, if the defined width is 10, increase it to 14, as in: `FORMATS DateVar (Date14)`. See the topic Chapter 106, “FORMATS,” on page 743 for more information.

---

## SUMMARY subcommand

SUMMARY calculates a wide range of aggregate and composite statistics.

- SUMMARY must be specified if LIST is not specified on FORMAT.
- The minimum specification is an aggregate or a composite function and its arguments. This must be the first specification on SUMMARY.
- Each SUMMARY subcommand following a BREAK subcommand specifies a new summary line.
- The default location of the summary title is the column of the break variable to which the summary applies. When more than one function is named on SUMMARY, the default summary title is that of the function named first. Both the title and its default column location can be altered. See the topic “Summary titles” on page 1684 for more information.
- The default format can be altered for any function. (See the topic “Summary print formats” on page 1685 for more information. )
- SUMMARY subcommands apply only to the preceding BREAK subcommand. If there is no SUMMARY subcommand after a BREAK subcommand, no statistics are displayed for that break level.
- To use the summary specifications from a previous BREAK subcommand for the current BREAK subcommand, specify keyword PREVIOUS on SUMMARY. See the topic “Other summary keywords” on page 1686 for more information.
- Summary statistics are displayed in report columns. With aggregate functions, you can compute summary statistics for all report variables or for a subset. See the topic “Aggregate functions” on page 1682 for more information. With composite functions, you can compute summaries for all or a subset of report variables and you have additional control over the placement of summary statistics in particular report columns. See the topic “Composite functions” on page 1683 for more information.
- Multiple summary statistics requested on one SUMMARY subcommand are all displayed on the same line. More than one function can be specified on SUMMARY as long as you do not attempt to place two results in the same report column (REPORT will not be executed if you do). To place results of more than one function in the same report column, use multiple SUMMARY subcommands.

- Any composite and aggregate functions except FREQUENCY and PERCENT can be specified on the same summary line.
- To insert blank lines between summaries when more than one summary line is requested for a break, use keyword SKIP followed by the number of lines to skip in parentheses. The default is 0. See the topic “Other summary keywords” on page 1686 for more information.

## Aggregate functions

Use the aggregate functions to request descriptive statistics for report variables.

- If no variable names are specified as arguments to an aggregate function, the statistic is calculated for all variables named on VARIABLES (all report variables).
- To request an aggregate function for a subset of report variables, specify the variables in parentheses after the function keyword.
- All variables specified for an aggregate function must have been named on VARIABLES.
- Keyword T0 cannot be used to specify a list of variables for an aggregate function.
- The result of an aggregate function is always displayed in the report column reserved for the variable for which the function was calculated.
- To use several aggregate functions for the same report variable, specify multiple SUMMARY subcommands. The results are displayed on different summary lines.
- The aggregate functions FREQUENCY and PERCENT have special display formats and cannot be placed on the same summary line with other aggregate or composite functions. They can be specified only once per SUMMARY subcommand.
- Aggregate functions use only cases with valid values.

**VALIDN.** *Valid number of cases.* This is the only function available for string variables.

**SUM.** *Sum of values.*

**MIN.** *Minimum value.*

**MAX.** *Maximum value.*

**MEAN.** *Mean.*

**STDDEV.** *Standard deviation.* Aliases are SD and STDEV.

**VARIANCE.** *Variance.*

**KURTOSIS.** *Kurtosis.*

**SKEWNESS.** *Skewness.*

**MEDIAN(min,max)** . *Median value for values within the range.* MEDIAN sets up integer-valued bins for counting all values in the specified range. Noninteger values are truncated when the median is calculated.

**MODE(min,max)** . *Modal value for values within the range.* MODE sets up integer-valued bins for counting all values in the specified range. Noninteger values are truncated when the mode is calculated.

**PGT(n).** *Percentage of cases with values greater than n.* Alias PCGT.

**PLT(n).** *Percentage of cases with values less than n.* Alias PCLT.

**PIN(min,max)** . *Percentage of cases within the inclusive value range specified.* Alias PCIN.

**FREQUENCY(min,max)** . *Frequency counts for values within the inclusive range.* FREQUENCY sets up integer-valued bins for counting all values in the specified range. Noninteger values are truncated when the frequency is computed. FREQUENCY cannot be mixed with other aggregate statistics on a summary line.

**PERCENT(min,max)** . *Percentages for values within the inclusive range.* PERCENT sets up integer-valued bins for counting all values in the specified range. Noninteger values are truncated when the percentages are computed. PERCENT cannot be mixed with other aggregate statistics on a summary line.

### Example

```
SORT CASES BY BVAR AVAR.  
REPORT FORMAT=AUTOMATIC LIST /VARIABLES=XVAR YVAR ZVAR
```

```
/BREAK=BVAR  
/SUMMARY=SUM  
/SUMMARY=MEAN (XVAR YVAR ZVAR)  
/SUMMARY=VALIDN(XVAR)
```

```
/BREAK=AVAR  
/SUMMARY=PREVIOUS.
```

- **FORMAT** requests a case listing, and **VARIABLES** establishes a report column for variables *XVAR*, *YVAR*, and *ZVAR*. The report columns have default widths and titles.
- Both break variables, *BVAR* and *AVAR*, have default widths and headings.
- Every time the value of *BVAR* changes, three summary lines are displayed. The first line contains the sums for variables *XVAR*, *YVAR*, and *ZVAR*. The second line contains the means of all three variables. The third line displays the number of valid cases for *XVAR* in the report column for *XVAR*.
- Every time the value of *AVAR* changes within each value of *BVAR*, the three summary lines requested for *BVAR* are displayed. These summary lines are based on cases with the current values of *BVAR* and *AVAR*.

### Example

```
SORT CASES BY DEPT.  
REPORT FORMAT=AUTOMATIC  
/VARIABLES=WAGE BONUS TENURE  
/BREAK=DEPT (23)  
/SUMMARY=SUM(WAGE BONUS) MEAN(TENURE) 'Sum Income: Mean Tenure'.
```

- **SUMMARY** defines a summary line consisting of the sums of *WAGE* and *BONUS* and the mean of *TENURE*. The result of each aggregate function is displayed in the report column of the variable for which the function is calculated.
- A title is assigned to the summary line. A width of 23 is defined for the break column to accommodate the title for the summary line.

## Composite functions

Use composite functions to obtain statistics based on aggregated statistics, to place a summary statistic in a column other than that of the report variable for which it was calculated, or to manipulate variables not named on **VARIABLES**.

- Composite functions can be computed for the following aggregate functions: **VALIDN**, **SUM**, **MIN**, **MAX**, **MEAN**, **STDEV**, **VARIANCE**, **KURTOSIS**, **SKEWNESS**, **PGT**, **PLT**, and **PIN**. Constants can also be arguments to composite functions.
- When used within composite functions, aggregate functions can have only one variable as an argument.
- A composite function and its arguments cannot be separated by other **SUMMARY** specifications.
- The result of a composite function can be placed in any report column, including columns of dummy or string variables, by specifying a target column. To specify a target column, enclose the variable name of the column in parentheses after the composite function and its arguments. By default, the results of a composite function are placed in the report column of the first variable specified on the composite function that is also specified on **VARIABLES**.

- The format for the result of a composite function can be specified in parentheses after the name of the column location, within the parentheses that enclose the column-location specification.

**DIVIDE**(arg arg. *Divide the first argument by the second and then multiply the result by the factor if it is specified.*

**MULTIPLY**(arg. *Multiply the arguments.*

**PCT**(arg. *The percentage of the first argument over the second.*

**SUBTRACT**(arg. *Subtract the second argument from the first.*

**ADD**(arg. *Add the arguments.*

**GREAT**(arg. *The maximum of the arguments.*

**LEAST**(arg. *The minimum of the arguments.*

**AVERAGE**(arg. *The average of the arguments.*

### Example

```

SORT CASES BY DEPT.
REPORT FORMAT=AUTOMATIC BRKSPACE(-1)
/VARIABLES=WAGE BONUS SPACE1 (DUMMY) '' BNFT1 BNFT2 SPACE2 (DUMMY)''
/BREAK=DEPT

/SUMMARY=MEAN(WAGE BONUS BNFT1 BNFT2)
ADD(VALIDN(WAGE)) (SPACE2)

/SUMMARY=ADD(SUM(WAGE) SUM(BONUS))
ADD(SUM(BNFT1) SUM(BNFT2)) 'Totals' SKIP(1)

/SUMMARY=DIVIDE(MEAN(WAGE) MEAN(BONUS)) (SPACE1 (COMMA)(2))
DIVIDE(MEAN(BNFT1) MEAN(BNFT2)) (SPACE2 (COMMA)(2)) 'Ratios'
SKIP(1).

```

- **VARIABLES** defines six report columns. The columns for *WAGE*, *BONUS*, *BNFT1*, and *BNFT2* contain aggregate statistics based on those variables. The variables *SPACE1* and *SPACE2* are dummy variables that are created for use as space holders; each is given a blank heading to suppress the default column heading.
- The first **SUMMARY** computes the means of the variables *WAGE*, *BONUS*, *BNFT1*, and *BNFT2*. Because **BRKSPACE=-1**, this summary line will be placed on the same line as the break value and will have no summary title. The means are displayed in the report column for each variable. **SUMMARY** also computes the valid number of cases for *WAGE* and places the result in the *SPACE2* column.
- The second **SUMMARY** adds the sum of *WAGE* to the sum of *BONUS*. Since no location is specified, the result is displayed in the *WAGE* column. In addition, the sum of *BNFT1* is added to the sum of *BNFT2* and the result is placed in the *BNFT1* column. The title for the summary line is *Totals*. One line is skipped before the summary line requested by this **SUMMARY** subcommand is displayed.
- The third summary line divides the mean of *WAGE* by the mean of *BONUS* and places the result in *SPACE1*. The ratio of the mean of *BNFT1* to the mean of *BNFT2* is displayed in the *SPACE2* column. The results are displayed with commas and two decimal places. The title for the summary line is *Ratios*. One line is skipped before the summary line requested by this **SUMMARY** subcommand is displayed.

## Summary titles

- You can specify a summary title enclosed in quotes, following the conventions for strings.
- The summary title must be specified after the first function and its arguments. It cannot separate any function from its arguments.
- A summary title can be only one line long.

- A summary title wider than the break column extends into the next break column to the right. If the title is wider than all of the available break columns, it is truncated.
- Only one summary title can be specified per summary line. If more than one is specified, the last is used.
- The summary title is left- or right-justified depending upon whether the break title is left- or right-justified.
- The default location for the summary title is the column of the BREAK variable to which the summary applies. With multiple breaks, you can override the default placement of the title by specifying, in parentheses following the title, the number of the break column in which you want the summary title to be displayed.
- In a report with no break levels, REPORT displays the summary title above the summary line at the left margin.

*Table 74. Default title for summary lines*

<b>Function</b>	<b>Title</b>
VALIDN	N
VARIANCE	Variance
SUM	Sum
MEAN	Mean
STDDEV	StdDev
MIN	Minimum
MAX	Maximum
SKEWNESS	Skewness
KURTOSIS	Kurtosis
PGT(n)	>n
PLT(n)	<n
PIN(min,max)	In $n_1$ to $n_2$
FREQUENCY(min,max)	Total
PERCENT(min,max)	Total
MEDIAN(min,max)	Median
MODE(min,max)	Mode

## Summary print formats

All functions have default formats that are used to display results. You can override these defaults by specifying a format keyword and/or the number of decimal places.

- Any printable formats or the PLAIN keyword can be specified. Format specifications must be enclosed in parentheses.
- For aggregate functions, the format and/or number of decimal places is specified after the variable name, within the parentheses that enclose the variable name. The variable must be explicitly named as an argument.
- For composite functions, the format and/or number of decimal places is specified after the variable name of the column location, within the parentheses that enclose the variable name. The column location must be explicitly specified.
- If the report column is wide enough, SUM, MEAN, STDDEV, MIN, MAX, MEDIAN, MODE, and VARIANCE use DOLLAR or COMMA format if a DOLLAR or COMMA format has been declared for the variable on either the FORMATS or PRINT FORMATS command.
- If the column is not wide enough to display the decimal digits for a given function, REPORT displays fewer decimal places. If the column is not wide enough to display the integer portion of the number, REPORT uses scientific notation if possible, or, if not, displays asterisks.
- An exact value of 0 is displayed with one 0 to the left of the decimal point and as many 0 digits to the right as specified by the format. A number less than 1 in absolute value is displayed without a 0 to the left of the decimal point, except with DOLLAR and COMMA formats.

**(PLAIN).** Uses the setting on *SET DECIMAL* for the thousands separator and decimal delimiter. PLAIN overrides dictionary formats. This is the default for all functions except SUM, MEAN, STDDEV, MIN, MAX, MEDIAN, MODE, and VARIANCE. For these functions, the default is the dictionary format of the variable for which the function is computed.

**(d).** Number of decimal places.

#### Example

```
/SUMMARY=MEAN(INCOME (DOLLAR) (2))
ADD(SUM(INCOME)SUM(WEALTH)) (WEALTH(DOLLAR(2)))
```

- SUMMARY displays the mean of *INCOME* with dollar format and two decimal places. The result is displayed in the *INCOME* column.
- The sums of *INCOME* and *WEALTH* are added, and the result is displayed in the *WEALTH* column with dollar format and two decimal places.

Table 75. Default print formats for functions

Function	Format type	Width	Decimal places
VALIDN	F	5	0
SUM	Dictionary	Dictionary + 2	Dictionary
MEAN	Dictionary	Dictionary	Dictionary
STDDEV	Dictionary	Dictionary	Dictionary
VARIANCE	Dictionary	Dictionary	Dictionary
MIN	Dictionary	Dictionary	Dictionary
MAX	Dictionary	Dictionary	Dictionary
SKEWNESS	F	5	2
KURTOSIS	F	5	2
PGT	PCT	6	1
PLT	PCT	6	1
PIN	PCT	6	1
MEDIAN	Dictionary	Dictionary	Dictionary
MODE	Dictionary	Dictionary	Dictionary
PERCENT	F	6	1
FREQUENCY	F	5	0
DIVIDE	F	Dictionary	0
PCT	PCT	6	2
SUBTRACT	F	Dictionary	0
ADD	F	Dictionary	0
GREAT	F	Dictionary	0
LEAST	F	Dictionary	0
AVERAGE	F	Dictionary	0
MULTIPLY	F	Dictionary	0

Where DATE formats are specified, functions with the dictionary format type display the DATE formats, using the column width as the display width.

## Other summary keywords

The following additional keywords can be specified on SUMMARY. These keywords are not enclosed in parentheses.

**SKIP(n).** Blank lines before the summary line. The default is 0. If SKIP is specified for the first SUMMARY subcommand for a BREAK, it skips the specified lines after skipping the number of lines specified for BRKSPACE on FORMAT. Similarly, with case listings SKIP skips *n* lines after the blank line at the end of the listing.

**PREVIOUS(n)** . Use the *SUMMARY* subcommands specified for the *n*th *BREAK*. If *n* is not specified, *PREVIOUS* refers to the set of *SUMMARY* subcommands for the previous *BREAK*. If an integer is specified, the *SUMMARY* subcommands from the *n*th *BREAK* are used. If *PREVIOUS* is specified, no other specification can be used on that *SUMMARY* subcommand.

---

## TITLE and FOOTNOTE subcommands

*TITLE* and *FOOTNOTE* provide titles and footnotes for the report.

- *TITLE* and *FOOTNOTE* are optional and can be placed anywhere after *FORMAT* except between the *BREAK* and *SUMMARY* subcommands.
- The specification on *TITLE* or *FOOTNOTE* is the title or footnote in quotes. To specify a multiple-line title or footnote, enclose each line in quotes and separate the specifications for each line by at least one blank.
- The default *REPORT* title is the title specified on the *TITLE* command. If there is no *TITLE* command specified in your session, the default *REPORT* title is the first line of the header.
- Titles begin on the first line of the report page. Footnotes end on the last line of the report page.
- Titles and footnotes are repeated on each page of a multiple-page report.
- The positional keywords *LEFT*, *CENTER*, and *RIGHT* can each be specified once. The default is *CENTER*.
- If the total width needed for the combined titles or footnotes for a line exceeds the page width, *REPORT* generates an error message.

**LEFT.** *Left-justify titles or footnotes within the report page margins.*

**RIGHT.** *Right-justify titles or footnotes within the report page margins.*

**CENTER.** *Center titles and footnotes within the report page width.*

The following can be specified as part of the title or footnote.

**)PAGE.** *Display the page number right-justified in a five-character field.*

**)DATE.** *Display the current date in the form dd/mmm/yy, right-justified in a nine-character field.*

**)var.** *Display this variable's value label at this position.* If you specify a variable that has no value label, the value is displayed, formatted according to its print format. You cannot specify a scratch or system variable or a variable created with the *STRING* subcommand. If you want to use a variable named *DATE* or *PAGE* in the file, change the variable's name with the *RENAME VARIABLES* command before you use it on the *TITLE* or *FOOTNOTE* subcommands, to avoid confusion with the *)PAGE* and *)DATE* keywords.

- *)PAGE*, *)DATE*, and *)var* are specified within quotes and can be mixed with string segments within the quotes.
- A variable specified on *TITLE* or *FOOTNOTE* must be defined in the active dataset, but does not need to be included as a column on the report.
- One label or value from each variable specified on *TITLE* or *FOOTNOTE* is displayed on every page of the report. If a new page starts with a case listing, *REPORT* takes the value label from the first case listed. If a new page starts with a *BREAK* line, *REPORT* takes the value label from the first case of the new break group. If a new page starts with a summary line, *REPORT* takes the value label from the last case of the break group being summarized.

### Example

```
/TITLE=LEFT 'Personnel Report' 'Prepared on )DATE'  
RIGHT 'Page: )PAGE'
```

- *TITLE* specifies two lines for a left-justified title and one line for a right-justified title. These titles are displayed at the top of each page of the report.

- The second line of the left-justified title contains the date on which the report was processed.
- The right-justified title displays the page number following the string *Page:* on the same line as the first line of the left-justified title.

---

## MISSING subcommand

MISSING controls the treatment of cases with missing values.

- MISSING specifications apply to variables named on VARIABLES and SUMMARY and to strings created with the STRING subcommand.
- Missing-value specifications are ignored for variables named on BREAK when MISSING=VAR or NONE. There is one break category for system-missing values and one for each user-missing value.
- The character used to indicate missing values is controlled by the FORMAT subcommand.

**VAR.** *Missing values are treated separately for each variable.* Missing values are displayed in case listings but are not included in the calculation of summary statistics on a function-by-function basis. This is the default.

**NONE.** *User-missing values are treated as valid values.* This applies to all variables named on VARIABLES.

**LIST[[varlist][n]]** . *Cases with the specified number of missing values across the specified list of variables are not used.* The variable list and *n* are specified in parentheses. If *n* is not specified, the default is 1. If no variables are specified, all variables named on VARIABLES are assumed.

### Example

```
/MISSING= LIST (XVAR, YVAR, ZVAR 2)
```

- Any case with two or more missing values across the variables XVAR, YVAR, and ZVAR is omitted from the report.

---

## Chapter 225. REPOSITORY ATTRIBUTES

```
REPOSITORY ATTRIBUTES FILE='file specification'  
  [DESCRIPTION='description']  
  [KEYWORDS='keywords']  
  [AUTHOR='author']  
  [VERSIONLABEL='label']  
  [EXPIRATION=days]  
  [TOPICS='topics']  
  [/SECURITY ID='id' [PERMISSION= [READ**] [WRITE] [DELETE] [MODIFY] [OWNER] ] ]
```

\*\* Default if the keyword is omitted.

### Release History

#### Release 16.0

- Command introduced as PER ATTRIBUTES.

#### Release 17.0

- VERSIONLABEL keyword extended to support multiple labels.

#### Release 18.0

- PER ATTRIBUTES deprecated. Command name changed to REPOSITORY ATTRIBUTES.

### Example

```
REPOSITORY COPY  
  FILE='/myscripts/cust_value.py'  
  OUTFILE='SPSSCR://scripts/cust_value.py'.  
REPOSITORY ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'  
  DESCRIPTION='Customer Value Calculation'  
  KEYWORDS='customer;value'.
```

---

## Overview

The REPOSITORY ATTRIBUTES command allows you to set attributes--such as a version label and security settings--for an object in a IBM SPSS Collaboration and Deployment Services Repository.

- When copying to a IBM SPSS Collaboration and Deployment Services Repository with the REPOSITORY COPY command, use the REPOSITORY ATTRIBUTES command (following REPOSITORY COPY) to specify attributes of the object.

### Basic Specification

The basic specification is the FILE keyword, which specifies the IBM SPSS Collaboration and Deployment Services Repository object whose attributes are to be set. All other keywords and subcommands are optional.

### Syntax Rules

- The SECURITY subcommand can be specified multiple times.
- Each keyword can only be specified once.
- Keywords and subcommands can be used in any order.
- Keywords and subcommand names must be spelled in full.
- Equals signs (=) shown in the syntax chart are required.

### Operations

- Use of the REPOSITORY ATTRIBUTES command requires a connection to a IBM SPSS Collaboration and Deployment Services Repository. Connections are established with the REPOSITORY CONNECT command.
- REPOSITORY ATTRIBUTES overwrites any existing values of specified attributes.

---

## FILE Keyword

The FILE keyword is required and specifies the IBM SPSS Collaboration and Deployment Services Repository object whose attributes are to be set.

- The form of the file specification for an object in a IBM SPSS Collaboration and Deployment Services Repository is the scheme name SPSSCR , followed by a colon, either one or two slashes (forward or backward), and a file path, all enclosed in quotes. For example:  
'SPSSCR://scripts/myscript.py'
- Paths can be specified with forward slashes (/) or backslashes (\).
- You can define a file handle to a file or a directory in a IBM SPSS Collaboration and Deployment Services Repository and use that handle in file specifications for IBM SPSS Collaboration and Deployment Services Repository objects.
- You can use the CD command to set the working directory to a directory in the currently connected IBM SPSS Collaboration and Deployment Services Repository, allowing you to use relative paths in file specifications for IBM SPSS Collaboration and Deployment Services Repository objects.
- File specifications for IBM SPSS Collaboration and Deployment Services Repository objects must specify the filename exactly as provided when the file was stored. If the file was stored with an extension, then you must supply the extension. If the file was stored without an extension then do not include one.

For examples of file specifications, see the examples for the REPOSITORY COPY command .

---

## DESCRIPTION Keyword

The DESCRIPTION keyword specifies a description for an object in a IBM SPSS Collaboration and Deployment Services Repository and replaces any existing description for the object. Specify the value as a quoted string.

### Example

```
REPOSITORY ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'  
DESCRIPTION='Customer Value Calculation'.
```

---

## KEYWORDS Keyword

KEYWORDS specifies one or more keywords to associate with an object in a IBM SPSS Collaboration and Deployment Services Repository to aid in searching. Specify the value as a quoted string.

- Multiple keywords should be separated by semicolons.
- Blank spaces at the beginning and end of each keyword are ignored, but blank spaces within keywords are honored.
- The specified keywords replace any existing ones for the object.

### Example

```
REPOSITORY ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'  
KEYWORDS='customer;value'.
```

---

## AUTHOR Keyword

The AUTHOR keyword specifies the author of an object in a IBM SPSS Collaboration and Deployment Services Repository. By default, the author is set to the login name of the user who created the object. Specify the value as a quoted string.

### Example

```
REPOSITORY ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'  
  AUTHOR='GSWEET'.
```

---

## VERSIONLABEL Keyword

The VERSIONLABEL keyword specifies one or more version labels for an object in a IBM SPSS Collaboration and Deployment Services Repository--for example, "production" or "development". Two versions of an object cannot have any of the same labels. If you specify a label associated with another version, it will be removed from that version and associated with the one you're modifying. For a single label, specify the value as a quoted string. For multiple labels, specify the value as a blank-separated list of quoted strings--for example, 'label1' 'label2'.

- By default, the specified labels will be applied to the latest version of the object that is accessible to the current user. You can apply labels to a version other than the latest one by specifying the version in the file specification on the FILE keyword. See the topic Chapter 308, "File Specifications for IBM SPSS Collaboration and Deployment Services Repository Objects," on page 2217 for more information.

### Example

```
REPOSITORY ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'  
  VERSIONLABEL='development'.
```

---

## EXPIRATION Keyword

The EXPIRATION keyword specifies an expiration date for an object in a IBM SPSS Collaboration and Deployment Services Repository. This provides a mechanism to make sure dated information is not displayed after a certain date. Expired documents are not deleted but are automatically removed to a special category where they can be accessed only by the site administrator, who can delete, archive, or republish them.

- Specify the value as an integer representing the number of days from the current day (inclusive) to the last day (inclusive) that the document will be active.

### Example

```
REPOSITORY ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'  
  EXPIRATION = 366.
```

---

## TOPICS Keyword

The TOPICS keyword allows you to associate an object in a IBM SPSS Collaboration and Deployment Services Repository with one or more topics. Topics allow you to organize documents by subject matter and have a hierarchical structure.

- Topics are specified as a quoted path that includes each level of the hierarchy for that topic, with successive levels separated by a forward slash. A forward slash at the beginning of the path is optional.
- Use a semicolon as the delimiter when specifying multiple topics.
- Objects can only be associated with existing topics. REPOSITORY ATTRIBUTES cannot be used to create new topics.
- The specified topics replace any existing ones for the object.

### Example

```
REPOSITORY ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'  
  TOPICS = '/engineering/scripts;/marketing/analyses'.
```

---

## SECURITY Subcommand

The SECURITY subcommand allows you to specify security settings for an object in a IBM SPSS Collaboration and Deployment Services Repository. Specify the identifier of the user or group with the ID keyword, and specify the access level with the PERMISSION keyword. You can specify settings for multiple users or groups by including multiple instances of the SECURITY subcommand.

### ID Keyword

The ID keyword specifies the ID of the user or group for which access is being granted. Specify the value in quotes.

### PERMISSION Keyword

The PERMISSION keyword is optional and specifies the access level granted to the specified user or group. One or more of the following access levels can be specified: READ, WRITE, MODIFY (grants ability to modify permissions), DELETE, and OWNER.

- If PERMISSION is omitted, the access level is READ.
- READ access is always granted, whether or not it is specified on the PERMISSION keyword.
- If OWNER is specified, all other values are ignored (an owner has all permissions).

### Example

```
REPOSITORY ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'  
  /SECURITY ID='admin' PERMISSION=OWNER  
  /SECURITY ID='--everyone--' PERMISSION=READ WRITE.
```

---

## Chapter 226. REPOSITORY CONNECT

```
REPOSITORY CONNECT
  /SERVER HOST='host[:{8080**}]' [SSL={NO**}]
        {port }           {YES }
  /LOGIN  USER='userid'
        PASSWORD='password'
        [PROVIDER='security provider']
        [ENCRYPTEDPWD={YES**}]
        {NO }
```

\*\* Default if the keyword or value is omitted.

### Release History

#### Release 15.0

- Command introduced as PER CONNECT.

#### Release 17.0

- DOMAIN keyword deprecated on the LOGIN subcommand.
- PROVIDER keyword introduced on the LOGIN subcommand.

#### Release 18.0

- PER CONNECT deprecated. Command name changed to REPOSITORY CONNECT.

### Example

```
REPOSITORY CONNECT
  /SERVER HOST='PER1'
  /LOGIN  USER='MyUserID'
        PASSWORD='abc12345'
        ENCRYPTEDPWD=NO.
```

---

## Overview

The REPOSITORY CONNECT command establishes a connection to a IBM SPSS Collaboration and Deployment Services Repository and logs in the user. A connection enables you to store objects to, and retrieve objects from, a IBM SPSS Collaboration and Deployment Services Repository.

### Options

**Server.** You can specify a connection port and whether to connect to the specified server using Secure Socket Layer (SSL) technology, if it is enabled on the server.

**Login.** You can specify whether the password is provided as encrypted or unencrypted (plain text).

**Single Sign-On.** Single sign-on allows users to connect to a IBM SPSS Collaboration and Deployment Services Repository without explicitly providing a user ID and password. The necessary authentication is performed with the user's existing credentials on the current machine--obtained, for example, from Windows Active Directory. If your IBM SPSS Collaboration and Deployment Services Repository supports single sign-on (contact your local system administrator for details), you can omit the LOGIN subcommand.

### Basic Specification

The basic specification for REPOSITORY CONNECT is the host server, user name, and password. By default, server port 8080 is used, the connection is established without SSL, and the specified password is

assumed to be encrypted. To create an encrypted password, generate (paste) the REPOSITORY CONNECT command syntax from the IBM SPSS Collaboration and Deployment Services Repository Connect dialog box.

#### Syntax Rules

- Each subcommand can be specified only once.
- Subcommands can be used in any order.
- An error occurs if a keyword or attribute is specified more than once within a subcommand.
- Equals signs (=) and forward slashes (/) shown in the syntax chart are required.
- Subcommand names and keywords must be spelled in full.

#### Operations

- REPOSITORY CONNECT establishes a connection to an IBM SPSS Collaboration and Deployment Services Repository and logs in the specified user. Any existing connection terminates when the new one is established.
- You can specify whether a connection is established when the REPOSITORY CONNECT command is encountered or whether the connection is deferred until it is required. The behavior is determined by the REPDEFER subcommand of the SET command.
- The connection terminates if the IBM SPSS Statistics session ends.
- An error occurs if a connection cannot be established to the specified host server.
- An error occurs if the connection cannot be authenticated--for example, if the password is invalid for the specified user.

#### Example

```
REPOSITORY CONNECT
  /SERVER HOST='PER1:80'
  /LOGIN  USER='MyUserID'
          PASSWORD='abc12345'
          ENCRYPTEDPWD=NO.
```

- The SERVER subcommand specifies a connection to host 'PER1' on port 80.
- ENCRYPTEDPWD=NO indicates that the password is not encrypted.

---

## SERVER Subcommand

The SERVER subcommand specifies the host server and whether to establish a secure connection.

**HOST.** *Server that hosts the IBM SPSS Collaboration and Deployment Services Repository.* Specify the name of the server in quotes. The default port is 8080. To connect to another port, specify the port number after the host name; for example, 'PER1:80'. A colon must separate the host name and port.

**SSL.** *Use Secure Socket Layer technology.* Specifies whether to establish a secure connection to the host server. The default is NO. SSL is available only if supported on the host server.

---

## LOGIN Subcommand

The LOGIN subcommand specifies login information, including user name and password.

**USER.** *User name.* Specify the user name in quotes.

**PASSWORD.** *Password.* Specify the password in quotes.

**PROVIDER.** *Security provider.* You can optionally specify the security provider against which to validate the user/password combination. Contact your local administrator for details.

**ENCRYPTEDPWD.** *Password encryption.* By default, the specified password is treated as encrypted. To indicate that the password is entered as plain text, specify ENCRYPTEDPWD=NO.

---

## Chapter 227. REPOSITORY COPY

```
REPOSITORY COPY
  FILE='file specification'
  OUTFILE='file specification'.
```

### Release History

#### Release 16.0

- Command introduced as PER COPY.

#### Release 18.0

- PER COPY deprecated. Command name changed to REPOSITORY COPY.

### Example

```
REPOSITORY COPY
  FILE='/myscripts/demo.py'
  OUTFILE='SPSSCR://scripts/demo.py'.
```

---

## Overview

The REPOSITORY COPY command allows you to copy an arbitrary file from the local file system to a IBM SPSS Collaboration and Deployment Services Repository or to copy a file from a IBM SPSS Collaboration and Deployment Services Repository to the local file system.

- When copying to a IBM SPSS Collaboration and Deployment Services Repository, use the REPOSITORY ATTRIBUTES command--following REPOSITORY COPY--to specify properties such as a description, keywords, and security settings for the object.

### Basic Specification

The only specification is the FILE keyword, which specifies the source file, and the OUTFILE keyword, which specifies the target location. Each keyword can specify a location in the local file system or a location in the current IBM SPSS Collaboration and Deployment Services Repository.

### File Specifications for IBM SPSS Collaboration and Deployment Services Repository Objects

- The form of the file specification for an object in a IBM SPSS Collaboration and Deployment Services Repository is the scheme name SPSSCR , followed by a colon, either one or two slashes (forward or backward), and a file path, all enclosed in quotes. For example:  
'SPSSCR://scripts/myscript.py'
- Paths can be specified with forward slashes (/) or backslashes (\).
- You can define a file handle to a file or a directory in a IBM SPSS Collaboration and Deployment Services Repository and use that handle in file specifications for IBM SPSS Collaboration and Deployment Services Repository objects.
- You can use the CD command to set the working directory to a directory in the currently connected IBM SPSS Collaboration and Deployment Services Repository, allowing you to use relative paths in file specifications for IBM SPSS Collaboration and Deployment Services Repository objects.
- File extensions are not added to files stored to a IBM SPSS Collaboration and Deployment Services Repository. Files are stored to a IBM SPSS Collaboration and Deployment Services Repository with an automatically determined MIME type that describes the type of file. Including a file extension is not necessary but is recommended.

- When copying a file from a IBM SPSS Collaboration and Deployment Services Repository you must specify the filename exactly as provided when the file was stored. If the file was stored with an extension, then you must supply the extension. If the file was stored without an extension then do not include one.
- When copying from a IBM SPSS Collaboration and Deployment Services Repository, the latest version of the specified object that is accessible to the current user is retrieved. To specify a version by label, use `SPSSCR://<path>#L.<label>`. To specify a version by the version marker (consists of an integer version number followed by a time stamp that uniquely specifies a version), use `SPSSCR://<path>#M.<version marker>`. See the topic Chapter 308, “File Specifications for IBM SPSS Collaboration and Deployment Services Repository Objects,” on page 2217 for more information.

## Operations

- `REPOSITORY COPY` will fail if a IBM SPSS Collaboration and Deployment Services Repository location is specified (for either `FILE` or `OUTFILE`) and there is no connection to a IBM SPSS Collaboration and Deployment Services Repository. Connections are established with the `REPOSITORY CONNECT` command.
- Specifying an existing IBM SPSS Collaboration and Deployment Services Repository file on the `OUTFILE` keyword results in a new version of the file, as opposed to overwriting the latest version.
- The `PERMISSIONS`, `SAVE`, and `XSAVE` commands will generate errors if you attempt to set permissions for IBM SPSS Collaboration and Deployment Services Repository objects. Permissions for IBM SPSS Collaboration and Deployment Services Repository objects are set with the `REPOSITORY ATTRIBUTES` command or using administration tools included with IBM SPSS Collaboration and Deployment Services.
- The `ERASE FILE` command will generate an error if you attempt to delete a IBM SPSS Collaboration and Deployment Services Repository object.

---

## Examples

### Copying from the Local File System to a IBM SPSS Collaboration and Deployment Services Repository

```
REPOSITORY COPY
  FILE='/myscripts/cust_value.py'
  OUTFILE='SPSSCR://scripts/cust_value.py'.
REPOSITORY ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'
  KEYWORDS='customer;value'
  /SECURITY ID='rprime' PERMISSION=OWNER.
```

- The local file `/myscripts/cust_value.py` is copied to the location `/scripts/cust_value.py` in the current IBM SPSS Collaboration and Deployment Services Repository.
- The `REPOSITORY ATTRIBUTES` command specifies keywords and security settings for this IBM SPSS Collaboration and Deployment Services Repository object.

### Copying from a IBM SPSS Collaboration and Deployment Services Repository to the Local File System

```
REPOSITORY COPY
  FILE='SPSSCR://scripts/demo.py'
  OUTFILE='/myscripts/demo.py'.
```

- The IBM SPSS Collaboration and Deployment Services Repository object `/scripts/demo.py` is copied to the local file `/myscripts/demo.py`.

### Copying from a Labelled Version in a IBM SPSS Collaboration and Deployment Services Repository to the Local File System

```
REPOSITORY COPY
  FILE='SPSSCR://scripts/demo.py#L.production'
  OUTFILE='/myscripts/demo.py'.
```

- The version of the IBM SPSS Collaboration and Deployment Services Repository object `/scripts/demo.py` with the label `production` is copied to the local file `/myscripts/demo.py`.

### Using a File Handle to a IBM SPSS Collaboration and Deployment Services Repository Location

```
FILE HANDLE custval /NAME='SPSSCR://CustomerValue'.
REPOSITORY COPY
FILE='custval/cust_value.py'
OUTFILE='/myscripts/cust_value.py'.
```

- The handle *custval* is associated with the IBM SPSS Collaboration and Deployment Services Repository directory */CustomerValue*, and the REPOSITORY COPY command retrieves the latest version of the file *cust\_value.py* from this directory in the current IBM SPSS Collaboration and Deployment Services Repository.

#### Setting the Working Directory to a IBM SPSS Collaboration and Deployment Services Repository Location

```
CD 'SPSSCR://CustomerValue'.
REPOSITORY COPY
FILE='cust_value.py'
OUTFILE='/myscripts/cust_value.py'.
```

- The working directory is set to the IBM SPSS Collaboration and Deployment Services Repository directory */CustomerValue*, and the REPOSITORY COPY command retrieves the latest version of the file *cust\_value.py* from this directory in the current IBM SPSS Collaboration and Deployment Services Repository.

---

## Chapter 228. REREAD

```
REREAD [FILE=file]
      [COLUMN=expression]
```

### Example

```
INPUT PROGRAM.
DATA LIST /KIND 10-14 (A).

DO IF (KIND EQ 'FORD').
REREAD.
DATA LIST /PARTNO 1-2 PRICE 3-6 (DOLLAR,2) QUANTITY 7-9.
END CASE.

ELSE IF (KIND EQ 'CHEVY').
REREAD.
DATA LIST /PARTNO 1-2 PRICE 15-18 (DOLLAR,2) QUANTITY 19-21.
END CASE.
END IF.

END INPUT PROGRAM.

BEGIN DATA
111295100FORD
11      CHEVY 295015
END DATA.
```

---

## Overview

REREAD instructs the program to reread a record in the data. It is available only within an INPUT PROGRAM structure and is generally used to define data using information obtained from a previous reading of the record. REREAD is usually specified within a conditional structure, such as DO IF–END IF, and is followed by a DATA LIST command. When it receives control for a case, REREAD places the pointer back to the column specified for the current case and begins reading data as defined by the DATA LIST command that follows.

### Options

**Data Source.** You can use inline data or data from an external file specified on the FILE subcommand. Using external files allows you to open multiple files and merge data.

**Beginning Column.** You can specify a beginning column other than column 1 using the COLUMN subcommand.

### Basic Specification

The basic specification is the command keyword REREAD. The program rereads the current case according to the data definitions specified on the following DATA LIST.

### Subcommand Order

Subcommands can be specified in any order.

### Syntax Rules

- REREAD is available only within an INPUT PROGRAM structure.
- Multiple REREAD commands can be used within the input program. Each must be followed by an associated DATA LIST command.

### Operations

- REREAD causes the next DATA LIST command to reread the most recently processed record in the specified file.
- When it receives control for a case, REREAD places the pointer back to column 1 for the current case and begins reading data as defined by the DATA LIST that follows. If the COLUMN subcommand is specified, the pointer begins reading in the specified column and uses it as column 1 for data definition.
- REREAD can be used to read part of a record in FIXED format and the remainder in LIST format. Mixing FIXED and FREE formats yields unpredictable results.
- Multiple REREAD commands specified without an intervening DATA LIST do not have a cumulative effect. All but the last are ignored.

---

## Examples

### Using REREAD to Process Different Record Formats

```

INPUT PROGRAM.
DATA LIST /PARTNO 1-2 KIND 10-14 (A).

DO IF (KIND EQ 'FORD').
REREAD.
DATA LIST /PRICE 3-6 (DOLLAR,2) QUANTITY 7-9.
END CASE.

ELSE IF (KIND EQ 'CHEVY').
REREAD.
DATA LIST /PRICE 15-18 (DOLLAR,2) QUANTITY 19-21.
END CASE.
END IF.
END INPUT PROGRAM.

BEGIN DATA
111295100FORD      CHAPMAN AUTO SALES
121199005VW       MIDWEST VOLKSWAGEN SALES
11 395025FORD     BETTER USED CARS
11  CHEVY 195005  HUFFMAN SALES & SERVICE
11  VW 595020    MIDWEST VOLKSWAGEN SALES
11  CHEVY 295015  SAM'S AUTO REPAIR
11  CHEVY 210 20  LONGFELLOW CHEVROLET
9555032 VW        HYDE PARK IMPORTS
END DATA.
LIST.

```

- Data are extracted from an inventory of automobile parts. The automobile part number always appears in columns 1 and 2, and the automobile type always appears in columns 10 through 14. The location of other information such as price and quantity depends on both the part number and the type of automobile.
- The first DATA LIST extracts the part number and type of automobile.
- Depending on the information from the first DATA LIST, the records are reread using one of two DATA LIST commands, pulling the price and quantity from different places.
- The two END CASE commands limit the active dataset to only those cases with part 11 and automobile type Ford or Chevrolet. Without the END CASE commands, cases would be created for other part numbers and automobile types, with missing values for price, quantity, and buyer.

The output from the LIST command is as follows:

```

PARTNO KIND  PRICE QUANTITY
11  FORD  $12.95  100
11  FORD  $3.95   25
11  CHEVY $1.95   5
11  CHEVY $2.95  15
11  CHEVY $2.10  20

```

### Multiple REREAD Commands for the Same Record

```

INPUT PROGRAM.
DATA LIST  NOTABLE/ CDIMAGE 1-20(A).
REREAD    COLUMN = 6. /* A, C, and E are in column 6
REREAD    COLUMN = 11. /* B, D, and F are in column 11
DATA LIST  NOTABLE/ INFO 1(A).

```

```

END INPUT PROGRAM.
BEGIN DATA
1  A  B
2  C  D
3  E  F
END DATA.
LIST.

```

- Multiple REREAD commands are used without an intervening DATA LIST. Only the last one is used. Thus, the starting column comes from the last REREAD specified and the pointer is reset to column 11.

The output from the LIST command is as follows:

```

CDIMAGE          INFO
1  A  B          B
2  C  D          D
3  E  F          F

```

---

## FILE Subcommand

FILE specifies an external raw data file from which the next DATA LIST command reads data.

- The default file is the file specified on the immediately preceding DATA LIST command.
- If the file specified on FILE is not the default file, the same file must be specified on the next DATA LIST. Otherwise, the FILE subcommand is ignored and the DATA LIST command reads the next record from the file specified on it or, if no file is specified, from the file specified on the previous DATA LIST command.

### Example

```

INPUT PROGRAM.
DATA LIST FILE=UPDATE END=#EOF NOTABLE
  /#ID 1-3.          /*Get rep ID in new sales file.
DATA LIST FILE = SALESREP NOTABLE
  /ID 1-3 SALES 4-11(F,2)
  NEWSALE 12-19(F,2).    /*Get rep record from master file.

LOOP IF #EOF OR (#ID GT ID). /*If UPDATE ends or no new sales made.
+ COMPUTE NEWSALE = 0.      /*Set NEWSALE to 0
+ END CASE.                /*Build a case.
+ DATA LIST FILE = SALESREP NOTABLE
  /ID 1-3 SALES 4-11(F,2)
  NEWSALE 12-19(F,2).    /*Continue reading masterfile.
END LOOP

DO IF NOT #EOF.           /*If new sales made.
+ REREAD FILE=UPDATE COLUMN = 4. /*Read new sales from UPDATE.
+ DATA LIST FILE=UPDATE
  /NEWSALE 1-8(F,2).
+ COMPUTE SALES=SALES+NEWSALE. /*Update master file.
END IF.
END CASE.                /*Build a case.
END INPUT PROGRAM.

```

LIST.

- This example uses REREAD to merge two raw data files (*SALESREP* and *UPDATE*).
- Both files are sorted by sales representative ID number. The *UPDATE* file contains only records for sales representatives who have made new sales, with variables *ID* and *NEWSALE*. The master file *SALESREP* contains records for all sales representatives, with variables *SALES* (which contains year-to-date sales) and *NEWSALE* (which contains the update values each time the file is updated).
- If a sales representative has made no new sales, there is no matching ID in the *UPDATE* file. When *UPDATE* is exhausted or when the ID's in the two files do not match, the loop structure causes the program to build a case with *NEWSALE* equal to 0 and then continue reading the master file.
- When the ID's match (and the *UPDATE* file is not yet exhausted), the REREAD command is executed. The following DATA LIST rereads the record in *UPDATE* that matches the *ID* variable. *NEWSALE* is read from the *UPDATE* file starting from column 4 and *SALES* is updated. Note that the following DATA LIST specifies the same file.

- When the updated base is built, the program returns to the first DATA LIST command in the input program and reads the next ID from the *UPDATE* file. If the *UPDATE* file is exhausted (*#EOF=1*), the loop keeps reading records from the master file until it reaches the end of the file.
- The same task can be accomplished using MATCH FILES. With MATCH FILES, the raw data must be read and saved as IBM SPSS Statistics data files first.

---

## COLUMN Subcommand

COLUMN specifies a beginning column for the REREAD command to read data. The default is column 1. You can specify a numeric expression for the column.

### Specifying a Numeric Expression for the Column

```
INPUT PROGRAM.
DATA LIST /KIND 10-14 (A).
COMPUTE #COL=1.
IF (KIND EQ 'CHEVY') #COL=13.

DO IF (KIND EQ 'CHEVY' OR KIND EQ 'FORD').
REREAD COLUMN #COL.
DATA LIST /PRICE 3-6 (DOLLAR,2) QUANTITY 7-9.
END CASE.
END IF.
END INPUT PROGRAM.
BEGIN DATA
111295100FORD      CHAPMAN AUTO SALES
121199005VW       MIDWEST VOLKSWAGEN SALES
11 395025FORD     BETTER USED CARS
11   CHEVY 195005   HUFFMAN SALES & SERVICE
11   VW   595020    MIDWEST VOLKSWAGEN SALES
11   CHEVY 295015   SAM'S AUTO REPAIR
12   CHEVY 210 20   LONGFELLOW CHEVROLET
   9555032 VW      HYDE PARK IMPORTS
END DATA.
LIST.
```

- The task in this example is to read *PRICE* and *QUANTITY* for Chevrolets and Fords only. A scratch variable is created to indicate the starting column positions for *PRICE* and *QUANTITY*, and a single DATA LIST command is used to read data for both types of automobiles.
- Scratch variable *#COL* is set to 13 for Chevrolets and 1 for all other automobiles. For Fords, the data begin in column 1. Variable *PRICE* is read from columns 3–6 and *QUANTITY* is read from columns 7–9. When the record is a Chevrolet, the data begins in column 13. Variable *PRICE* is read from columns 15–18 (15 is 3, 16 is 4, and so forth), and *QUANTITY* is read from columns 19–21.

### Reading Both FIXED and LIST Input With REREAD

```
INPUT PROGRAM.
DATA LIST   NOTABLE FIXED/ A 1-14(A). /*Read the FIXED portion
REREAD     COLUMN = 15.
DATA LIST  LIST/ X Y Z.                /*Read the LIST portion
END INPUT PROGRAM.
```

\* The value 1 on the first record is in column 15.

```
BEGIN DATA
FIRST RECORD  1 2 3 -1 -2 -3
NUMBER 2      4 5
THE THIRD    6 7 8
#4
FIFTH AND LAST9 10 11
END DATA.
LIST.
```

- Columns 1–14 are read in FIXED format. REREAD then resets the pointer to column 15. Thus, beginning in column 15, values are read in LIST format.
- The second DATA LIST specifies only three variables. Thus, the values –1, –2, and –3 on the first record are not read.
- The program generates a warning for the missing value on record 2 and a second warning for the three missing values on record 4.

- On the fifth and last record there is no delimiter between value LAST and value 9. REREAD can still read the 9 in LIST format.

---

## Chapter 229. RESPONSE RATE

RESPONSE RATE is available in SPSS Statistics Premium Edition or the Direct Marketing option.

```
RESPONSE RATE
/VARIABLES
  NUMERATOR=varname
  DENOMINATOR=varname
  GROUP=varname
[/MINRATE {RATE=NONE**|value  }]
           {FORMULA=value1, value1}
[/MAXCOUNT {COUNT=ALL**|value}]
            {PERCENT=value  }
```

\*\*Default if subcommand omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Release history

Release 18.0

- Command introduced.

### Example

```
RESPONSE RATE
/VARIABLES
  NUMERATOR=Responses
  DENOMINATOR=Customers
  GROUP=Rank
/MINRATE RATE=5
/MAXCOUNT COUNT=6000.
```

---

## Overview

RESPONSE RATE calculates group response rates and cumulative group response rates, expressed as a percentage, where response rate is calculated as NUMERATOR divided by DENOMINATOR for each category of GROUP, and cumulative response rate is calculated as the cumulative sum of NUMERATOR divided by the cumulative sum of DENOMINATOR for the current and all preceding categories of GROUP.

- Output includes a table of response rates, sum of the DENOMINATOR variable, cumulative response rates, and cumulative sum of the DENOMINATOR variable in ascending order of the GROUP variable, and a line chart of response rates and cumulative sum of the DENOMINATOR variable.
- If MINRATE or MAXCOUNT are specified, the table is color-coded based on the specified cumulative value(s), and the line charts include reference lines at the specified value(s).

The RESPONSE RATE command is intended primarily for use as part of the Postal Code Response Rate dialog interface, and some of the results refer to a new, aggregated dataset that is created by the dialog interface. See the topic for more information. When you use the RESPONSE RATE command outside of the Postal Code Response Rate dialog interface, this new, aggregated dataset is not created. See the topic for more information.

### Basic specification

- The basic specification is the command name RESPONSE RATE and a VARIABLES subcommand.
- The MINRATE and MAXCOUNT subcommands are optional.

### Operations

- Cases with missing values for any variables specified on the VARIABLES subcommand are excluded from the analysis (listwise deletion).
- If the sum of DENOMINATOR is 0 or negative for a value of GROUP, that group is excluded from the analysis.

Subcommand order

Subcommands can be specified in any order.

Syntax rules

- The VARIABLES subcommand is required.
- The VARIABLES subcommand must include NUMERATOR, DENOMINATOR and GROUP variables.
- Equals signs (=) shown in the syntax chart and in examples are required.
- Command, subcommand, and keyword names must be spelled out fully. Abbreviation is not allowed.

---

## Examples

Minimum Specification

```
RESPONSE RATE
/VARIABLES
  NUMERATOR=Responses
  DENOMINATOR=Customers
  GROUP=PostalRank.
```

- Response rates are displayed for each group defined by *PostalRank*.
- Results are displayed in ascending order of the value of *PostalRank*.

MINRATE and MAXCOUNT

```
RESPONSE RATE
/VARIABLES
  NUMERATOR=Responses
  DENOMINATOR=Customers
  GROUP=PostalRank
/MINRATE=5
/MAXCOUNT=6000.
```

- Rows with a cumulative response rate above 5% and a cumulative customer count below 6,000 are displayed with a green background in the table; those with cumulative response rates below 5% or a cumulative count above 6,000 are displayed with a red background.
- The upper panel of the chart includes a reference line at the 5% response rate level, and the lower panel includes a reference line at a cumulative count of 6,000 customers.

---

## VARIABLES subcommand

The VARIABLES subcommand specifies the variables to use. This subcommand is required and includes three required keywords:

**NUMERATOR.** *The variable used as the numerator to calculate response rates.* The variable must be numeric.

**DENOMINATOR.** *The variable used as the denominator to calculate response rates.* The variable must be numeric.

**GROUP.** *The grouping variable.* Response rates are calculated for each category of the grouping variable. The variable can be string or numeric.

Each keyword must be followed by an equals sign (=) and a variable name.

Response rate is calculated as the NUMERATOR divided by DENOMINATOR for each category of GROUP. Cumulative response rate is calculated as the cumulative sum of NUMERATOR divided by the cumulative sum of DENOMINATOR, where cumulative sum is the sum for the current and all preceding (lower) values of GROUP. Response rates are expressed as percentages.

#### Example

```
RESPONSE RATE
/VARIABLES
  NUMERATOR=Responses
  DENOMINATOR=Customers
  GROUP=PostalRank.
```

---

## MINRATE subcommand

The optional MINRATE subcommand specifies a minimum cumulative response rate to use to color-code the output table and to use as a reference line on the response rate line chart. The following alternatives are available for specifying minimum response rate:

**RATE=NONE.** *No minimum response rate.* This is the default if the subcommand is omitted.

**RATE=value.** *Use the specified percentage value as the minimum cumulative response rate.* Specify a value greater than 0 and less than 100.

**FORMULA=value1,value2.** *Calculate minimum cumulative response rate based on the formula  $(value1/value2)*100$ .* Both values must be positive numbers. The result should be a value greater than 0 and less than 100. In direct marketing, for example, *value1* might be the cost of mailing a package, and *value2* might be net revenue per response. If the cost of mailing a package is \$0.75 and the net revenue per response is \$56, then the minimum response rate is:  $(0.75/56)*100=1.34\%$

Each keyword must be followed by an equals sign (=) and a variable name.

- If MINRATE is specified without MAXCOUNT, all rows with a cumulative response rate equal to or greater than the specified minimum are displayed with a green background, and all rows with a cumulative response rate less than the specified minimum are displayed with a red background.
- If MAXCOUNT is also specified, only rows with a cumulative response rate above the specified minimum *and* rows with a cumulative count below the specified maximum are displayed with a green background. For example, if the response rate is higher than the specified minimum, but the cumulative count is greater than the specified maximum, then the row will have a red background.

#### Example

```
RESPONSE RATE
/VARIABLES
  NUMERATOR=Responses
  DENOMINATOR=Customers
  GROUP=PostalRank
/MINRATE=5.
```

---

## MAXCOUNT subcommand

The optional MAXCOUNT subcommand specifies the maximum cumulative total of the DENOMINATOR variable to use to color-code the output table and to use as a reference line on the cumulative count line chart. For each category of the GROUP total, the cumulative total is the sum of the DENOMINATOR values for all preceding categories plus the current category. For example, if DENOMINATOR represents number of customers, then the cumulative total for any GROUP category is the total number of customers for all groups up to and including that group.

The following alternatives are available for specifying maximum count:

**COUNT=ALL.** *No maximum.* This is the default if the subcommand is omitted.

**COUNT=value.** Use the specified value as the maximum cumulative total. The value must be a positive integer.

**PERCENT=value.** Determine the maximum cumulative total based on the specified percentage of the overall total. The value must be greater than 0 and less than 100.

- If MAXCOUNT is specified without MINRATE, all rows with a cumulative total for the DENOMINATOR variable less than or equal to the specified maximum are displayed with a green background, and all subsequent rows are displayed with a red background.
- If MINRATE is also specified, rows are only displayed with a green background if the maximum cumulative total is not exceeded *and* the cumulative response rate is higher than the specified minimum. For example, if the response rate is less than the specified minimum, the row will be displayed with a red background regardless of the cumulative total.

### Example

```
RESPONSE RATE  
/VARIABLES  
  NUMERATOR=Responses  
  DENOMINATOR=Customers  
  GROUP=PostalRank  
/MAXCOUNT=6000.
```

---

## Chapter 230. RESTORE

RESTORE

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

---

### Overview

RESTORE restores SET and CD specifications that were stored by a previous PRESERVE command. RESTORE and PRESERVE are especially useful when using the macro facility. PRESERVE–RESTORE sequences can be nested up to five levels.

#### Basic Specification

The only specification is the command keyword. RESTORE has no additional specifications.

#### Limitations

RESTORE does not restore SET THREADS and SET MCACHE settings.

---

### Example

```
PRESERVE.  
SET CD '/mydata'.  
GET FILE 'mydatafile.sav'.  
SET TNUMBERS=BOTH.  
FREQUENCIES VARIABLES=DIVISION  
RESTORE.  
FREQUENCIES VARIABLES=DIVISION.
```

- PRESERVE stores all current SET specifications and the current working directory setting.
- SET CD changes the working directory.
- SET TNUMBERS=BOTH changes the TNUMBERS setting to display both values and value labels in pivot tables.
- The pivot table results from the first FREQUENCIES command will display both category values and labels.
- RESTORE reestablishes the SET specifications and the working directory that were in effect prior to when PRESERVE was specified.
- The pivot table results from the second FREQUENCIES command will use the TNUMBERS setting in effect prior to PRESERVE (the default is to display only labels).

---

## Chapter 231. RMV

```
RMV new variables={LINT (varlist)      }
                  {MEAN (varlist [{,2 }]) }
                  {      {,n }      }
                  {      {ALL}      }
                  {MEDIAN (varlist [{,2 }])}
                  {      {,n }      }
                  {      {ALL}      }
                  {SMEAN (varlist)      }
                  {TREND (varlist)      }

[/new variables=function (varlist [,span])]
```

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Example

```
RMV NEWVAR1=LINT(OLDVAR1).
```

---

## Overview

RMV produces new variables by copying existing variables and replacing any system- or user-missing values with estimates computed by one of several methods. You can also use RMV to replace the values of existing variables. The estimated values are computed from valid data in the existing variables.

### Basic Specification

The basic specification is one or more new variable names, an equals sign, a function, and an equal number of existing variables. RMV displays a list of the new variables, the number of missing values replaced, the case numbers of the first and last nonmissing cases, the number of valid cases, and the function used to produce the variables.

### Syntax Rules

- The existing variables (and span, if specified) must be enclosed in parentheses.
- The equals sign is required.
- You can specify more than one equation on RMV.
- Equations are separated by slashes.
- You can specify only one function per equation.
- You can create more than one new variable per equation by specifying more than one new variable name on the left and an equal number of existing variables on the right.

### Operations

- Each new variable is added to the active dataset.
- If the new variable named already exists, its values are replaced.
- If the new variable named does not already exist, it is created.
- If the same variable is named on both sides of the equation, the new variable will replace the existing variable. Valid values from the existing variable are copied into the new variable, and missing values are replaced with estimates.
- Variables are created in the order in which they are specified on the RMV command.
- If multiple variables are created on a single equation, the first new variable is based on the first existing variable, the second new variable is based on the second existing variable, and so forth.
- RMV automatically generates a variable label for each new variable describing the function and variable used to create it and the date and time of creation.

- The format of a new variable depends on the function specified and on the format of the existing variable.
- RMV honors the TSET MISSING setting that is currently in effect.
- RMV does not honor the USE command.

#### Limitations

- Maximum 1 function per equation.
- There is no limit on the number of variables created by an equation.
- There is no limit on the number of equations per RMV command.

---

## LINT Function

LINT replaces missing values using linear interpolation. The last valid value before the missing value and the first valid value after the missing value are used for the interpolation.

- The only specification on LINT is a variable or variable list in parentheses.
- LINT will not replace missing values at the endpoints of variables.

#### Example

```
RMV NEWVAR1=LINT(OLDVAR1).
```

- This example produces a new variable called *NEWVAR1*.
- *NEWVAR1* will have the same values as *OLDVAR1* but with missing values replaced by linear interpolation.

---

## MEAN Function

MEAN replaces missing values with the mean of valid surrounding values. The number of surrounding values used to compute the mean depends on the span.

- The specification on MEAN is a variable or variable list and a span, in parentheses.
- The span specification is optional and can be any positive integer or keyword ALL.
- A span of *n* uses *n* valid cases before and after the missing value.
- If span is not specified, it defaults to 2.
- Keyword ALL computes the mean of all valid values.
- MEAN will not replace missing values if there are not enough valid surrounding cases to satisfy the span specification.

#### Example

```
RMV B=MEAN(A,3).
```

- This example produces a new variable called *B*.
- *B* will have the same values as variable *A* but with missing values replaced by means of valid surrounding values.
- Each mean is based on six values—that is, the three nearest valid values on each side of the missing value.

---

## MEDIAN Function

MEDIAN replaces missing values with the median of valid surrounding values. The number of surrounding values used to compute the median depends on the span.

- The specification on MEDIAN is a variable or variable list and a span, in parentheses.
- The span specification is optional and can be any positive integer or keyword ALL.
- A span of *n* uses *n* valid cases before and after the missing value.

- If span is not specified, it defaults to 2.
- Keyword ALL computes the median of all valid values.
- MEDIAN will not replace missing values if there are not enough valid surrounding cases to satisfy the span specification.

#### Example

```
RMV B=MEDIAN(A,3).
```

- This example produces a new variable called *B*.
- *B* will have the same values as *A* but with missing values replaced by medians of valid surrounding values.
- Each median is based on six values—that is, the three nearest valid values on each side of the missing value.

---

## SMEAN Function

SMEAN replaces missing values in the new variable with the variable mean.

- The only specification on SMEAN is a variable or variable list in parentheses.
- The SMEAN function is equivalent to the MEAN function with a span specification of ALL.

#### Example

```
RMV VAR1 TO VAR4=SMEAN(VARA VARB VARC VARD).
```

- Four new variables (*VAR1*, *VAR2*, *VAR3*, and *VAR4*) are created.
- *VAR1* copies the values of *VARA*, *VAR2* copies *VARB*, *VAR3* copies *VARC*, and *VAR4* copies *VARD*. Any missing values in an existing variable are replaced with the mean of that variable.

---

## TREND Function

TREND replaces missing values in the new variable with the linear trend for that point. The existing variable is regressed on an index variable scaled 1 to *n*. Missing values are replaced with their predicted values.

- The only specification on TREND is a variable or variable list in parentheses.

#### Example

```
RMV YHAT=TREND(VARY).
```

- This example creates a new variable called *YHAT*.
- *YHAT* has the same values as *VARY* but with missing values replaced by predicted values.

---

## Chapter 232. ROC

ROC is available in Statistics Base Edition.

```
ROC varlist BY varname({varvalue })
                        {'varvalue'}

[/MISSING = {EXCLUDE**}]
                {INCLUDE }

[/CRITERIA = [CUTOFF({INCLUDE**})] [TESTPOS({LARGE**})] [CI({95** })]
                {EXCLUDE }                {SMALL }                {value}

                [DISTRIBUTION({FREE** })]]
                        {NEGEXPO}

[/PLOT = [CURVE**[(REFERENCE)]]] [NONE]]

[/PRINT = [SE] [(MODELQUALITY)] [COORDINATES]].
```

\*\* Default if subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Release History

Release 18.0

- MODELQUALITY keyword introduced.

### Example

```
ROC
  pred BY default (1).
```

---

## Overview

ROC produces a receiver operating characteristic (ROC) curve and an estimate of the area under the curve.

### Options

**Distributional Assumptions.** In the CRITERIA subcommand, the user can choose the nonparametric or parametric method to estimate the standard error of the area under the curve. Currently, the bi-negative exponential distribution is the only parametric option.

**Optional Output.** In addition to an estimate of the area under the ROC curve, the user may request its standard error, a confidence interval, and a  $p$  value under the null hypothesis that the area under the curve equals 0.5. A table of cutoff values and coordinates used to plot the ROC curve may also be displayed.

### Basic Specification

The basic specification is one variable as the test result variable and one variable as the actual state variable with one of its values. ROC uses the nonparametric (distribution-free) method to calculate the area under the ROC curve. The default and minimum output is a chart of the ROC curve and a table of the area under the curve.

### Syntax Rules

- Minimum syntax: You always need a test result variable and one actual state variable with one of its values in the ROC command line.
- The test result variable must be numeric, but the state variable can be any type with any format.
- Subcommands can be specified in any order.
- When a subcommand is duplicated, only the last one is honored given that all duplicates have no syntax errors. A syntax warning is issued.
- Within a subcommand, if two or more exclusive or contradictory keywords are given, the latter keywords override the earlier ones. A syntax warning is issued.
- If a keyword is duplicated within a subcommand, it is silently ignored.

#### Limitations

- Only the nonparametric method and one parametric method are available as the computational options for the standard error of the area under the curve at this moment. In the future, binormal and bilogistic distributions may be added to the parametric option.

---

## varlist BY varname(varvalue)

The `varlist` specifies one or more test result variables. They must be of numeric type.

The `varname` separated from the `varlist` by the word `BY` specifies the actual state variable. It can be of any type and any format. The user must also specify a `varvalue` in brackets after the second `varname` to define the “positive” group of the actual state variable. All other valid state values are assumed to indicate the negative group.

---

## MISSING Subcommand

Cases with system-missing values in the test result variable and the actual state variable are always excluded from the analysis. However, the `MISSING` subcommand allows the user to redefine the user-missing values to be valid.

**EXCLUDE.** *Exclude both user-missing and system-missing values.* Cases with a system-missing value or a user-missing value in either the test result variable or the actual state variable are excluded from the analysis. This is the active default.

**INCLUDE.** *User-missing values are treated as valid.* Cases with a system-missing value in either the test result variable or the actual state variable are excluded from the analysis.

---

## CRITERIA Subcommand

The `CRITERIA` subcommand allows the user to decide whether or not the cutoff value is included as the positive test result value, whether or not the larger or smaller value direction of the test result variable indicates the positive test result, the confidence level of the asymptotic confidence interval produced by `/PRINT = SE`, and the estimation method for the standard error of the area under the curve.

**CUTOFF(INCLUDE).** *Positive classification of test result values includes the cutoff values.* Note that the positive test result direction is controlled by the `TESTPOS` keyword. This is the active default.

**CUTOFF(EXCLUDE).** *Positive classification of test result values excludes the cutoff values.* This distinction leads to the different sets of cutoff values, but none of the output (chart or table) is affected at this moment because the user cannot choose the cutoff values for the classification.

**TESTPOS(LARGE).** *The user can specify which direction of the test result variable indicates increasing strength of conviction that the subject is test positive.* The larger the test result value is, the more positive the test result is. `LARGE` is the active default.

**TESTPOS(SMALL).** *The smaller the test result value is, the more positive the test result is.*

**CI(n).** *Confidence level in the (two-sided) asymptotic confidence interval of the area. The user can specify any confidence level in (0, 100) for the asymptotic confidence interval created by /PRINT = SE. The active default parameter value is 95.*

**DISTRIBUTION(FREE).** *The method of calculating the standard error of the area under the curve. When FREE, the standard error of the area under the curve is estimated nonparametrically—that is, without any distributional assumption.*

**DISTRIBUTION(NEGEXPO).** *The standard error is estimated assuming the bi-negative exponential distribution. This latter option is valid only when the number of positive actual state observations equals the number of negative actual state observations.*

---

## PRINT Subcommand

The PRINT subcommand controls the display of optional table and chart output. Note that the area under the curve is always displayed.

**SE (MODELQUALITY).** *Standard error of the area estimate. In addition to the standard error of the estimated area under the curve, the asymptotic 95% (or other user-specified confidence level) confidence interval as well as the asymptotic  $p$  value under the null hypothesis that the true area = 0.5 are calculated. The optional (MODELQUALITY) specification produces a simple bar chart that displays the value of the lower bound of the confidence interval of the area under the curve, expressed as a proportion, on a scale of 0 to 1. Note that the area under the curve statistic is asymptotically normally distributed.*

**COORDINATES.** *Coordinate points of the ROC curve along with the cutoff values. Pairs of sensitivity and 1 – specificity values are given with the cutoff values for each curve.*

---

## PLOT Subcommand

The PLOT subcommand controls the display of chart output.

**CURVE(REFERENCE).** *The ROC curve chart is displayed. The keyword CURVE is the active default. In addition, the user has an option to draw the diagonal reference line (sensitivity = 1 – specificity) by the bracketed parameter REFERENCE.*

**NONE.** *No charts are displayed.*

---

## Chapter 233. SAMPLE

```
SAMPLE {decimal value}
      {n FROM m      }
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. See the topic “Command Order” on page 40 for more information.

### Example

```
SAMPLE .25.
```

---

## Overview

SAMPLE permanently draws a random sample of cases for processing in all subsequent procedures. For a temporary sample, use a TEMPORARY command before SAMPLE.

### Basic Specification

The basic specification is either a decimal value between 0 and 1 or the sample size followed by keyword FROM and the size of the active dataset.

- To select an approximate percentage of cases, specify a decimal value between 0 and 1.
- To select an exact-size random sample, specify a positive integer that is less than the file size, and follow it with keyword FROM and the file size.

### Operations

- SAMPLE is a permanent transformation.
- Sampling is based on a pseudo-random-number generator that depends on a seed value that is established by the program. On some implementations of the program, this number defaults to a fixed integer, and a SAMPLE command that specifies *n* FROM *m* will generate the identical sample whenever a session is rerun. To generate a different sample each time, use the SET command to reset SEED to a different value for each session. See the SET command for more information.
- If sampling is done by using the *n* FROM *m* method, and the TEMPORARY command is specified, successive samples will not be the same because the seed value changes each time that a random-number series is needed within a session.
- A proportional sample (a sample that is based on a decimal value) usually does not produce the exact proportion that is specified.
- If the number that is specified for *m* following FROM is less than the actual file size, the sample is drawn only from the first *m* cases.
- If the number following FROM is greater than the actual file size, the program samples an equivalent proportion of cases from the active dataset.
- If SAMPLE follows SELECT IF, SAMPLE samples only cases that are selected by SELECT IF.
- If SAMPLE precedes SELECT IF, cases are selected from the sample.
- If more than one SAMPLE command is specified in a session, each command acts on the sample that was selected by the preceding SAMPLE command.
- If N OF CASES is used with SAMPLE, the program reads as many records as required to build the specified *n* cases. It makes no difference whether N OF CASES precedes or follows SAMPLE.

### Limitations

SAMPLE cannot be placed in a FILE TYPE-END FILE TYPE or INPUT PROGRAM-END INPUT PROGRAM structure. SAMPLE can be placed nearly anywhere following these commands in a transformation program. See the topic Chapter 304, "Commands and Program States," on page 2187 for more information. .

---

## Examples

### Sampling an Approximate Percentage of Cases

```
SAMPLE .25.
```

- This command samples approximately 25% of the cases in the active dataset.

### Sampling a Specific Number of Cases

```
SAMPLE 500 FROM 3420.
```

- The active dataset must have 3420 or more cases to obtain a random sample of exactly 500 cases.
- If the file contains fewer than 3420 cases, proportionally fewer cases are sampled.
- If the file contains more than 3420 cases, a random sample of 500 cases is drawn from the first 3420 cases.

### Sampling Subgroups

```
DO IF SEX EQ 'M'.  
SAMPLE 1846 FROM 8000.  
END IF.
```

- SAMPLE is placed inside a DO IF-END IF structure to sample subgroups differently. Assume that this survey is for 10,000 people in which 80% of the sample is male, while the known universe is 48% male. To obtain a sample that corresponds to the known universe and that maximizes the size of the sample, 1846 ( $48/52 \times 2000$ ) males and all females must be sampled. The DO IF structure restricts the sampling process to the males.

---

## Chapter 234. SAVE

```
SAVE OUTFILE='filespec'  
  
  [/VERSION={3**}]  
    {2 }  
  
  [/UNSELECTED=[{RETAIN}]  
    {DELETE }]  
  
  [/KEEP={ALL** }] [/DROP=varlist]  
    {varlist}  
  
  [/RENAME=(old varlist=new varlist)...]  
  
  [/MAP] [/{COMPRESSED**}]  
    {UNCOMPRESSED}  
    {ZCOMPRESSED }  
  
  [/NAMES]  
  
  [/PERMISSIONS={READONLY }]  
    {WRITEABLE }  
  
  [/PASSPROTECT PASSWORD={NONE** } [ENCRYPTEDPW={NO**}] ]  
    {'password'} {YES }
```

\*\*Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Release history

#### Release 21.0

- ZCOMPRESSED subcommand added.
- PASSPROTECT subcommand added.

### Example

```
SAVE OUTFILE='/data/empl.sav'.
```

---

## Overview

SAVE produces a data file in IBM SPSS Statistics format, which contains data plus a dictionary. The dictionary contains a name for each variable in the data file plus any assigned variable and value labels, missing-value flags, and variable print and write formats. The dictionary also contains document text that was created with the DOCUMENTS command.

XSAVE also creates IBM SPSS Statistics data files. The difference is that SAVE causes data to be read, while XSAVE is not executed until data are read for the next procedure.

See SAVE TRANSLATE for information about saving data files that can be used by other programs.

### Options

**Compatibility with Earlier Releases.** You can save a data file that can be read by releases prior to 7.5.

**Variable Subsets and Order.** You can use the DROP and KEEP subcommands to save a subset of variables and reorder the variables that are saved.

**Filtered Cases.** If filtering is in effect, you use the UNSELECTED subcommand to specify inclusion or exclusion of filtered cases. By default, all cases are included.

**Variable Names.** You can use the RENAME subcommand to rename variables as they are copied into the IBM SPSS Statistics data file.

**Variable Map.** To confirm the names and order of the variables that are saved in the data file, use the MAP subcommand. MAP displays the variables that are saved in the data file next to their corresponding names in the active dataset.

**Data Compression.** You can use the COMPRESSED or ZCOMPRESSED subcommand to write the data file in compressed form. You can use the UNCOMPRESSED subcommand to write the data file in an uncompressed form. See the topic “COMPRESSED, UNCOMPRESSED, and ZCOMPRESSED Subcommands” on page 1727 for more information.

**Encryption.** You can use the PASSPROTECT subcommand to save the file as encrypted, allowing you to protect confidential information stored in the file. See the topic “PASSPROTECT Subcommand” on page 1728 for more information.

### Basic Specification

The basic specification is the OUTFILE subcommand, which specifies a name for the data file to be saved.

### Subcommand Order

- Subcommands can be specified in any order.

### Syntax Rules

- OUTFILE is required and can be specified only once. If OUTFILE is specified more than once, only the last specified OUTFILE is in effect.
- KEEP, DROP, RENAME, and MAP can each be used as many times as needed.
- Only one of the subcommands COMPRESSED, UNCOMPRESSED, or ZCOMPRESSED can be specified per SAVE command.

### Operations

- SAVE is executed immediately and causes the data to be read.
- The new data file dictionary is arranged in the same order as the active dataset dictionary, unless variables are reordered with the KEEP subcommand. Documentary text from the active dataset dictionary is always saved unless it is dropped with the DROP DOCUMENTS command before SAVE.
- New variables that were created by transformations and procedures that occurred prior to the SAVE command are included in the new data file, and variables that were altered by transformations are saved in their modified form. Results of any temporary transformations that immediately precede the SAVE command are included in the file; scratch variables are not included.
- The active dataset is still available for transformations and procedures after SAVE is executed.
- SAVE processes the dictionary first and displays a message that indicates how many variables will be saved. After the data are written, SAVE indicates how many cases were saved. If the second message does not appear, the file was probably not completely written.

---

## Examples

### Renaming Variables for a Saved Version

```
GET FILE='hubempl.sav'.  
SAVE OUTFILE='data/emp188.sav' /RENAME=(AGE=AGE88) (JOB CAT=JOB CAT88).
```

- The GET command retrieves the IBM SPSS Statistics data file *hubempl.sav*.

- The RENAME subcommand renames variable *AGE* to *AGE88* and variable *JOB* to *JOB88*.
- SAVE causes the data to be read and saves a new data file with the filename *empl88.sav*. The original data file *hubempl.sav* is not changed.

### Performing Temporary Transformations Prior to Saving

```
GET FILE='/data/hubempl.sav'.
TEMPORARY.
RECODE DEPT85 TO DEPT88 (1,2=1) (3,4=2) (ELSE=9).
VALUE LABELS DEPT85 TO DEPT88 1 'MANAGEMENT' 2 'OPERATIONS' 9 'UNKNOWN'.
SAVE OUTFILE='/data/hubtemp.sav'.
CROSSTABS DEPT85 TO DEPT88 BY JOBCAT.
```

- The GET command retrieves the IBM SPSS Statistics data file *hubempl.sav*.
- The TEMPORARY command indicates that RECODE and VALUE LABELS are in effect only for the next command that reads the data (SAVE).
- The RECODE command recodes values for all variables between and including *DEPT85* and *DEPT88* on the active dataset.
- The VALUE LABELS command specifies new labels for the recoded values.
- The OUTFILE subcommand on SAVE specifies *hubtemp.sav* as the new data file. The *hubtemp.sav* file will include the recoded values for *DEPT85* to *DEPT88* and the new value labels.
- The CROSSTABS command crosstabulates *DEPT85* to *DEPT88* with *JOB*. Because the RECODE and VALUE LABELS commands were temporary, the CROSSTABS output does not reflect the recoding and new labels.
- If XSAVE were specified instead of SAVE, the data would be read only once. Both the saved data file and the CROSSTABS output would reflect the temporary recoding and labeling of the department variables.

---

## OUTFILE Subcommand

OUTFILE specifies the data file to be saved. OUTFILE is required and can be specified only once. If OUTFILE is specified more than once, only the last OUTFILE is in effect.

---

## VERSION Subcommand

VERSION allows you to save a data file that can be opened in releases prior to 7.5. If VERSION is not specified or is specified with no value, the default of 3 is used, which saves the file in a format that cannot be read by releases prior to 7.5. Specify 2 to save a file that is compatible with earlier releases.

## Variable Names

For data files with variable names that are longer than eight bytes in version 10.x or 11.x, unique, eight-byte versions of variable names are used (but the original variable names are preserved for use in release 12.0 or later). In releases prior to version 10.0, the original long variable names are lost if you save the data file.

---

## UNSELECTED Subcommand

UNSELECTED determines whether cases that were excluded on a previous FILTER or USE command are to be retained or deleted in the saved data file. The default is RETAIN. The UNSELECTED subcommand has no effect when the active dataset does not contain unselected cases.

**RETAIN.** *Retain the unselected cases.* All cases in the active dataset are saved. This setting is the default when UNSELECTED is specified by itself.

**DELETE.** *Delete the unselected cases.* Only cases that meet the FILTER or USE criteria are saved in the data file.

---

## DROP and KEEP Subcommands

DROP and KEEP are used to save a subset of variables. DROP specifies the variables that are not to be saved in the new data file; KEEP specifies the variables that are to be saved in the new data file; variables that are not named on KEEP are dropped.

- Variables can be specified in any order. The order of variables on KEEP determines the order of variables in the data file. The order on DROP does not affect the order of variables in the data file.
- Keyword ALL on KEEP refers to all remaining variables that were not previously specified on KEEP or DROP. ALL must be the last specification on KEEP.
- If a variable is specified twice on the same subcommand, only the first mention is recognized.
- Multiple DROP and KEEP subcommands are allowed. If a variable is specified that is not in the active dataset, or that has been dropped because of a previous DROP or KEEP subcommand, an error results, and the SAVE command is not executed.
- Keyword T0 can be used to specify a group of consecutive variables in the active file.

### Example

```
GET FILE='/data/personnel.sav'.
COMPUTE TENURE=(12-CMONTH +(12*(88-CYEAR)))/12.
COMPUTE JTENURE=(12-JMONTH +(12*(88-JYEAR)))/12.
VARIABLE LABELS      TENURE 'Tenure in Company'
                    JTENURE 'Tenure in Grade'.
SAVE OUTFILE='/data/personnel88.sav' /DROP=GRADE STORE
/KEEP=LNAME NAME TENURE JTENURE ALL.
```

- The variables *TENURE* and *JTENURE* are created by COMPUTE commands and are assigned variable labels by the VARIABLE LABELS command. *TENURE* and *JTENURE* are added to the end of the active dataset.
- DROP excludes variables *GRADE* and *STORE* from file *personnel88.sav*. KEEP specifies that *LNAME*, *NAME*, *TENURE*, and *JTENURE* are the first four variables in file *personnel88.sav*, followed by all remaining variables not specified on DROP. These remaining variables are saved in the same sequence as they appear in the original file.

---

## RENAME Subcommand

RENAME changes the names of variables as they are copied into the new data file.

- The specification on RENAME is a list of old variable names followed by an equals sign and a list of new variable names. The same number of variables must be specified on both lists. Keyword T0 can be used in the first list to refer to consecutive variables in the active dataset and can be used in the second list to generate new variable names. The entire specification must be enclosed in parentheses.
- Alternatively, you can specify each old variable name individually, followed by an equals sign and the new variable name. Multiple sets of variable specifications are allowed. The parentheses around each set of specifications are optional.
- RENAME does not affect the active dataset. However, if RENAME precedes DROP or KEEP, variables must be referred to by their new names on DROP or KEEP.
- Old variable names do not need to be specified according to their order in the active dataset.
- Name changes take place in one operation. Therefore, variable names can be exchanged between two variables.
- Multiple RENAME subcommands are allowed.

### Examples

```
SAVE OUTFILE='/data/empl88.sav'
/RENAME AGE=AGE88 JOBCAT=JOBCAT88.
```

- RENAME specifies two name changes for the file *empl88.sav*: The variable *AGE* is renamed to *AGE88*, and the variable *JOBCAT* is renamed to *JOBCAT88*.

```
SAVE OUTFILE='/data/empl88.sav'
/RENAME (AGE JOBCAT=AGE88 JOBCAT88).
```

- The name changes are identical to the changes in the previous example: *AGE* is renamed to *AGE88*, and *JOB**CAT* is renamed to *JOB**CAT**88*. The parentheses are required with this method.

---

## MAP Subcommand

MAP displays a list of the variables in the saved data file and their corresponding names in the active dataset.

- The only specification is keyword MAP.
- Multiple MAP subcommands are allowed. Each MAP subcommand maps the results of subcommands that precede it (but not results of subcommands that follow it).

### Example

```
GET FILE='/data/hubempl.sav'.
SAVE OUTFILE='/data/empl88.sav' /RENAME=(AGE=AGE88)(JOB
```

- MAP confirms the new names for *AGE* and *JOB**CAT* and the order of variables in the *empl88.sav* file (*LNAME*, *NAME*, and *JOB**CAT**88*, followed by all remaining variables from the active dataset).

---

## COMPRESSED, UNCOMPRESSED, and ZCOMPRESSED Subcommands

COMPRESSED and ZCOMPRESSED save the file in compressed form. UNCOMPRESSED saves the file in uncompressed form.

- The only specification is the keyword COMPRESSED, UNCOMPRESSED, or ZCOMPRESSED.
- In a file compressed with COMPRESSED, small integers (from -99 to 155) are stored in one byte instead of the eight bytes that are used in an uncompressed file.
- In a file compressed with ZCOMPRESSED, case data (regardless of type) are compressed block by block with a high compression ratio. Only IBM SPSS Statistics version 21 or later can open a file compressed with ZCOMPRESSED. Therefore, it is recommended that you use the *.zsave* file extension when saving files with ZCOMPRESSED. Older versions of IBM SPSS Statistics will ignore this extension.
- Compressed data files occupy less disk space than uncompressed data files. Files compressed with ZCOMPRESSED occupy the least disk space.
- Compressed files may take more or less time to open and save, depending on the file size and system configuration. Extra time is needed to de-compress and compress the files. However, because compressed files are smaller on disk, they reduce the time needed to read and write from disk. As the file size gets larger, this time savings surpasses the extra time needed to de-compress and compress the files. This is especially true for files compressed with ZCOMPRESSED, because these files are smallest on disk.
- The GET command, which reads IBM SPSS Statistics data files, does not need to specify whether the files that it reads are compressed or uncompressed.
- Only one of the subcommands COMPRESSED, UNCOMPRESSED, or ZCOMPRESSED can be specified per SAVE command. COMPRESSED is the default.

---

## NAMES Subcommand

For all variable names that are longer than eight bytes, NAMES displays the eight-byte equivalents that will be used if you read the data file into a version prior to release 12.0.

---

## PERMISSIONS Subcommand

The PERMISSIONS subcommand sets the operating system read/write permissions for the file.

**READONLY.** *File permissions are set to read-only for all users. The file cannot be saved by using the same file name with subsequent changes unless the read/write permissions are changed in the operating system or the subsequent SAVE command specifies PERMISSIONS=WRITEABLE.*

**WRITEABLE.** *File permissions are set to allow writing for the file owner. If file permissions were set to read-only for other users, the file remains read-only for them.*

Your ability to change the read/write permissions may be restricted by the operating system.

---

## PASSPROTECT Subcommand

The PASSPROTECT subcommand specifies the settings for saving a data file as an encrypted file. Once encrypted, the file can only be opened by providing the correct password.

**PASSWORD.** Specifies the password required to open this file. Passwords are limited to 10 characters and are case-sensitive. The specified value must be enclosed in quotation marks. The keyword NONE specifies that the file will not be encrypted and is the default.

*Warning:* Passwords cannot be recovered if they are lost. If the password is lost the file cannot be opened.

### ENCRYPTEDPW Keyword

The ENCRYPTEDPW keyword specifies whether the password is encrypted.

**NO.** The password is not encrypted. It is treated as plain text. This is the default.

**YES.** The password is encrypted. Passwords are always encrypted when pasting syntax from the Save Data As dialog. *Note:* ENCRYPTEDPW=YES should only be used when the password is known to be encrypted.

### Creating strong passwords

- Use eight or more characters.
- Include numbers, symbols and even punctuation in your password.
- Avoid sequences of numbers or characters, such as "123" and "abc", and avoid repetition, such as "111aaa".
- Do not create passwords that use personal information such as birthdays or nicknames.
- Periodically change the password.

*Note:* Encrypted data files and output documents cannot be opened in versions of IBM SPSS Statistics prior to version 21. Encrypted syntax files cannot be opened in versions prior to version 22.

---

## Chapter 235. SAVE CODEPAGE

```
SAVE CODEPAGE
  /OUTFILE='filespec'

  [/ENCODING={LOCALE** } ]
    { 'encoding' }

  [/UNSELECTED=[{RETAIN}]
    {DELETE}]

  [/KEEP={ALL** } ] [/DROP=varlist]
    {varlist}

  [/PASSPROTECT PASSWORD={'password'} [ENCRYPTEDPW={NO**}] ]
    {NONE** } {YES }
```

\*\*Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

Release history

Release 23.0

- Command introduced.

Example

```
SAVE CODEPAGE
  /OUTFILE='data/empl.sav'
  /ENCODING='de_DE.windows-1252'.
```

---

## Overview

In Unicode mode, SAVE CODEPAGE produces a data file in the specified locale character encoding.

### Options

**Encoding.** You can use the ENCODING subcommand to specify the character encoding.

**Variable Subsets and Order.** You can use the DROP and KEEP subcommands to save a subset of variables and reorder the variables that are saved.

**Filtered Cases.** If filtering is in effect, you can use the UNSELECTED subcommand to specify inclusion or exclusion of filtered cases. By default, all cases are included.

**Encryption.** You can use the PASSPROTECT subcommand to save the file as encrypted, allowing you to protect confidential information stored in the file.

### Basic specification

The basic specification is the OUTFILE subcommand, which specifies a name for the data file to be saved.

### Syntax rules

- OUTFILE is required. All other subcommands are optional.
- KEEP and DROP can each be used as many times as needed.
- ENCODING, UNSELECTED, and PASSPROTECT can each be used only once.

## Operations

- SAVE CODEPAGE is executed immediately and causes the data to be read.
- The new data file dictionary is arranged in the same order as the active dataset dictionary, unless variables are reordered with the KEEP subcommand.
- New variables that were created by transformations and procedures that occurred prior to the SAVE CODEPAGE command are included in the new data file, and variables that were altered by transformations are saved in their modified form. Results of any temporary transformations that immediately precede the SAVE CODEPAGE command are included in the file; scratch variables are not included.
- The active dataset is not changed by SAVE CODEPAGE. The file encoding specified on SAVE CODEPAGE does not affect the active dataset. SAVE CODEPAGE operates in a manner similar to commands that create data files in external formats, such as WRITE and SAVE TRANSLATE.

## Limitations

- SAVE CODEPAGE is only available in Unicode mode. An error occurs if you use this command in code page mode. For more information on Unicode and code page mode, see the SET command, UNICODE subcommand.

---

## OUTFILE Subcommand

OUTFILE specifies the data file to be saved. OUTFILE is required and can be specified only once. The file specification should be enclosed in quotation marks.

---

## ENCODING Subcommand

ENCODING specifies the code page character encoding format of the file. The keyword is followed by an equals sign and the keyword LOCALE or a quoted encoding specification.

### LOCALE

Saves the file in the current locale encoding. This is the default setting. For more information, see the SET command, LOCALE subcommand.

### 'encoding'

The quoted encoding value can be a numeric Windows code page value (for example, '1252'), or an IANA code page value (for example, 'iso8859-1' or cp1252).

### Example

```
SAVE CODEPAGE  
  /OUTFILE='/data/emp1.sav'  
  /ENCODING='cp1252'.
```

---

## UNSELECTED Subcommand

UNSELECTED determines whether cases that were excluded on a previous FILTER or USE command are to be retained or deleted in the saved data file. The default is RETAIN. The UNSELECTED subcommand has no effect when the active dataset does not contain unselected cases.

### RETAIN

*Retain the unselected cases.* All cases in the active dataset are saved. This setting is the default when UNSELECTED is specified by itself.

### DELETE

*Delete the unselected cases.* Only cases that meet the FILTER or USE criteria are saved in the data file.

---

## DROP and KEEP Subcommands

DROP and KEEP are used to save a subset of variables. DROP specifies the variables that are not to be saved in the new data file; KEEP specifies the variables that are to be saved in the new data file; variables that are not named on KEEP are dropped.

- Variables can be specified in any order. The order of variables on KEEP determines the order of variables in the data file. The order on DROP does not affect the order of variables in the data file.
- Keyword ALL on KEEP refers to all remaining variables that were not previously specified on KEEP or DROP. ALL must be the last specification on KEEP.
- If a variable is specified twice on the same subcommand, only the first mention is recognized.
- Multiple DROP and KEEP subcommands are allowed. If a variable is specified that is not in the active dataset, or that has been dropped because of a previous DROP or KEEP subcommand, an error results, and the SAVE CODEPAGE command is not executed.
- Keyword TO can be used to specify a group of consecutive variables in the active file.

---

## PASSPROTECT Subcommand

The PASSPROTECT subcommand specifies the settings for saving a data file as an encrypted file. Once encrypted, the file can only be opened by providing the correct password.

**PASSWORD.** Specifies the password required to open this file. Passwords are limited to 10 characters and are case-sensitive. The specified value must be enclosed in quotation marks. The keyword NONE specifies that the file will not be encrypted and is the default.

*Warning:* Passwords cannot be recovered if they are lost. If the password is lost the file cannot be opened.

### ENCRYPTEDPW Keyword

The ENCRYPTEDPW keyword specifies whether the password is encrypted.

**NO.** The password is not encrypted. It is treated as plain text. This is the default.

**YES.** The password is encrypted. Passwords are always encrypted when pasting syntax from the Save Data As dialog. *Note:* ENCRYPTEDPW=YES should only be used when the password is known to be encrypted.

### Creating strong passwords

- Use eight or more characters.
- Include numbers, symbols and even punctuation in your password.
- Avoid sequences of numbers or characters, such as "123" and "abc", and avoid repetition, such as "111aaa".
- Do not create passwords that use personal information such as birthdays or nicknames.
- Periodically change the password.

*Note:* Encrypted data files and output documents cannot be opened in versions of IBM SPSS Statistics prior to version 21. Encrypted syntax files cannot be opened in versions prior to version 22.

---

## Chapter 236. SAVE DATA COLLECTION

This command is available only on Windows operating systems.

SAVE DATA COLLECTION

/OUTFILE='filespec'

/METADATA='filespec'

[/UNSELECTED={**RETAIN\*\***}]  
{DELETE}

[/KEEP={**ALL\*\*** } ] [/DROP=varlist]  
{varlist}

[/MAP]

\*\*Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

Release history

Release 15.0

- Command introduced as SAVE DIMENSIONS.

Release 18.0

- SAVE DIMENSIONS deprecated. Command name changed to SAVE DATA COLLECTION.

Example

```
SAVE DATA COLLECTION
/OUTFILE='data/survey.sav'
/METADATA='data/survey.mdd'.
```

---

### Overview

SAVE DATA COLLECTION produces IBM SPSS Statistics data files and Data Collection metadata files that you can use to read the IBM SPSS Statistics data file into Data Collection applications.

**Note:** There may be instances where the data cannot be re-loaded to the Data Collection database in the correct format due to the complexity in the structure.

Options

**Variable subsets and order.** You can use the DROP and KEEP subcommands to save a subset of variables and reorder the variables that are saved.

**Filtered cases.** If filtering is in effect, you use the UNSELECTED subcommand to specify inclusion or exclusion of filtered cases. By default, all cases are included.

**Variable map.** To confirm the names and order of the variables that are saved in the IBM SPSS Statistics data file, use the MAP subcommand. MAP displays the variables that are saved in the IBM SPSS Statistics data file next to their corresponding names in the active dataset.

Basic specification

The basic specification is the `OUTFILE` subcommand that specifies a name for the IBM SPSS Statistics data file to be saved and the `METADATA` subcommand that specifies the name for the Data Collection metadata file.

Subcommand order

- Subcommands can be specified in any order.

Syntax rules

- `OUTFILE` and `METADATA` are required and can be specified only once.
- `KEEP`, `DROP`, `MAP`, and `UNSELECTED` are optional.

Operations

For new variables and datasets not created from Data Collection data sources, IBM SPSS Statistics variable attributes are mapped to Data Collection metadata attributes.

If the active dataset was created from a Data Collection data source:

- The new metadata file is created by merging the original metadata attributes with metadata attributes for any new variables, plus any changes to original variables that might affect their metadata attributes (for example, addition of, or changes to, value labels).
- For original variables read from the Data Collection data source, any metadata attributes not recognized by IBM SPSS Statistics are preserved in their original state. For example, IBM SPSS Statistics converts grid variables to regular IBM SPSS Statistics variables, but the metadata that defines these grid variables is preserved when you save the new metadata file.
- If any Data Collection variables were automatically renamed to conform to IBM SPSS Statistics variable naming rules, the metadata file maps the converted names back to the original Data Collection variable names.

The presence or absence of value labels can affect the metadata attributes of variables and consequently the way those variables are read by Data Collection applications. If value labels have been defined for any nonmissing values of a variable, they should be defined for all nonmissing values of that variable; otherwise, the unlabeled values will be dropped when the data file is read by Data Collection.

Limitations

This feature is only available with IBM SPSS Statistics installed on Microsoft Windows operating systems, and is only available in local analysis mode. This feature is not available in distributed analysis mode using IBM SPSS Statistics Server.

To write Data Collection metadata files, you must have the following items installed:

- .NET framework. To obtain the most recent version of the .NET framework, go to <http://www.microsoft.com/net>.
- Data Collection Survey Reporter Developer Kit.

---

## **OUTFILE subcommand**

`OUTFILE` specifies the IBM SPSS Statistics data file to be saved.

- `OUTFILE` is required and can be specified only once.
- File specifications should be enclosed in quotes.
- The standard extension for IBM SPSS Statistics data files is `.sav`. You should explicitly specify the extension; it will not be automatically appended to the file name.

---

## METADATA subcommand

METADATA specifies the Data Collection metadata file to be saved. See the Operations section of the Overview for more information.

- METADATA is required and can be specified only once.
- File specifications should be enclosed in quotes.
- The standard extension for a Data Collection metadata file is *.mdd*. You should explicitly specify the extension; it will not be automatically appended to the file name.

---

## UNSELECTED subcommand

UNSELECTED determines whether cases that were excluded on a previous FILTER or USE command are to be retained or deleted in the IBM SPSS Statistics data file. The default is RETAIN. The UNSELECTED subcommand has no effect when the active dataset does not contain unselected cases. Since the metadata file does not contain case data, this subcommand has no effect on the contents of the metadata file.

**RETAIN.** *Retain the unselected cases.* All cases in the active dataset are saved. This is the default.

**DELETE.** *Delete the unselected cases.* Only cases that meet the FILTER or USE criteria are saved in the IBM SPSS Statistics data file.

---

## DROP and KEEP subcommands

DROP and KEEP are used to save a subset of variables. DROP specifies the variables that are not to be saved in the new data file; KEEP specifies the variables that are to be saved in the new data file; variables that are not named on KEEP are dropped.

- Variables can be specified in any order. The order of variables on KEEP determines the order of variables in the data file. The order on DROP does not affect the order of variables in the data file.
- Keyword ALL on KEEP refers to all remaining variables that were not previously specified on KEEP or DROP. ALL must be the last specification on KEEP.
- If a variable is specified twice on the same subcommand, only the first mention is recognized.
- Multiple DROP and KEEP subcommands are allowed. If a variable is specified that is not in the active dataset or that has been dropped because of a previous DROP or KEEP subcommand, an error results, and the SAVE DATA COLLECTION command is not executed.
- Keyword T0 can be used to specify a group of consecutive variables in the active file.
- If the active dataset was created from a Data Collection data source, any original variables defined as grid or array elements in the Data Collection data source are retained in the metadata file, even if those variables are not included in the IBM SPSS Statistics data file. Thus, the original grid or array structure is preserved, but there will be no case data for any variables not included in the IBM SPSS Statistics data file.

### Example

```
SAVE DATA COLLECTION
  /OUTFILE='data/survey.sav'
  /METADATA='data/survey.mdd'
  /DROP gridVar7
  /KEEP gridVar1 to gridVar8.
```

Assuming that the order of the variables in the active dataset is *gridVar1, gridVar2, gridVar3,...gridVar8* and that all eight variables are grid variables in the original Data Collection data source, *gridVar7* will be dropped from *survey.sav*, but the original metadata for *gridVar7* will be preserved in *survey.mdd*.

---

## MAP subcommand

MAP displays a list of the variables in the IBM SPSS Statistics data file and their corresponding names in the active dataset.

- The only specification is keyword MAP.
- Multiple MAP subcommands are allowed. Each MAP subcommand maps the results of the DROP and KEEP subcommands that precede it (but not results of subcommands that follow it).

### Example

```
SAVE DATA COLLECTION
  /OUTFILE='/data/survey.sav'
  /METADATA='/data/survey.mdd'
  /DROP var7 /MAP
  /KEEP var1 to var8 /MAP.
```

---

## Chapter 237. SAVE MODEL

SAVE MODEL OUTFILE='filename'

```
[/KEEP={ALL**      }]
      {model names}
      {procedures }

[/DROP={model names}]
      {procedures }

[/TYPE={MODEL**}]
      {COMMAND}
```

\*\*Default if the subcommand is omitted.

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Example

```
SAVE MODEL OUTFILE='ACFMD.DAT'.
```

---

## Overview

SAVE MODEL saves the models that are created by certain procedures in a model file. The saved model file can be read later in the session or in another session with the READ MODEL command.

### Options

You can save a subset of models into the file using the DROP and KEEP subcommands. You can use the TYPE subcommand to control whether models are specified by model name or by the name of the procedure that generated them.

### Basic Specification

The basic specification is the OUTFILE subcommand followed by a filename.

- By default, SAVE MODEL saves all currently active models in the specified file. Each model that is saved in the file includes information such as the procedure that created it, the model name, the specified variable names, subcommands and specifications used, and parameter estimates. The names of the models are either the default *MOD\_n* names or the names that are assigned on the MODEL NAME command. In addition to the model specifications, the TSET settings that are currently in effect are saved.

### Subcommand Order

- Subcommands can be specified in any order.

### Syntax Rules

- If a subcommand is specified more than once, only the last subcommand is executed.

### Operations

- SAVE MODEL is executed immediately.
- Model files are designed to be written and read by specific procedures and should not be edited.
- The active models are not affected by the SAVE MODEL command.
- DATE specifications are not saved in the model file.
- Models are not saved in IBM SPSS Statistics data files.

- The following procedures can generate models that can be saved with the SAVE MODEL command: AREG, ARIMA, EXSMOOTH, SEASON, and SPECTRA in the Forecasting module; ACF, CASEPLOT, CCF, CURVEFIT, PACF, PPLLOT, and TSPLIT in the Core system; and WLS and 2SLS in the Regression module.

#### Limitations

- A maximum of one filename can be specified.
- The READ MODEL command can only read models created by a SAVE MODEL command on the same operating system/platform.

---

## OUTFILE Subcommand

OUTFILE names the file where models will be stored and is the only required subcommand.

- The only specification on OUTFILE is the name of the model file.
- The filename should be enclosed in quotes.
- Only one filename can be specified.
- You can store models in other directories by specifying a fully qualified filename.

---

## KEEP and DROP Subcommands

KEEP and DROP allow you to save a subset of models. By default, all currently active models are saved.

- KEEP specifies models to be saved in the model file.
- DROP specifies models that are not saved in the model file.
- Models can be specified by using individual model names or the names of the procedures that created them. To use procedure names, you must specify COMMAND on the TYPE subcommand.
- Model names are either the default *MOD\_n* names or the names that are assigned with MODEL NAME.
- If you specify a procedure name on KEEP, all models that are created by that procedure are saved; on DROP, any models created by that procedure are not included in the model file.
- Model names and procedure names cannot be mixed on a single SAVE MODEL command.
- If more than one KEEP or DROP subcommand is specified, only the last subcommand is executed.
- You can specify the keyword ALL on KEEP to save all models that are currently active. This setting is the default.

#### Example

```
SAVE MODEL OUTFILE='ACFCCF.DAT'
  /KEEP=ACF1 ACF2.
```

- In this example, only models *ACF1* and *ACF2* are saved in model file *ACFCCF.DAT*.

---

## TYPE Subcommand

TYPE indicates whether models are specified by model name or procedure name on DROP and KEEP.

- One keyword, MODEL or COMMAND, can be specified after TYPE.
- MODEL is the default and indicates that models are specified as model names.
- COMMAND indicates that the models are specified by procedure name.
- TYPE has no effect if KEEP or DROP is not specified.
- The TYPE specification applies only to the current SAVE MODEL command.

#### Example

```
SAVE MODEL OUTFILE='CURVE1.DAT'
  /KEEP=CURVEFIT
  /TYPE=COMMAND.
```

- This command saves all models that were created by the CURVEFIT procedure into the model file *CURVE1.DAT*.

---

## Chapter 238. SAVE TRANSLATE

SAVE TRANSLATE

```
[{/OUTFILE=file          }]  
{/CONNECT=ODBC connect string}  
  
[{/UNENCRYPTED}]

```

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

## Release History

### Release 14.0

- Value STATA added to list for TYPE subcommand.
- EDITION subcommand introduced for TYPE=STATA.
- SQL subcommand introduced.
- MISSING subcommand introduced.
- Field/column names specified on the RENAME subcommand can contain characters (for example, spaces, commas, slashes, plus signs) that are not allowed in IBM SPSS Statistics variable names.
- Continuation lines for connection strings on the CONNECT subcommand do not need to begin with a plus sign.

### Release 15.0

- ENCRYPTED subcommand introduced.
- Value CSV added to list for TYPE subcommand.
- TEXTOPTIONS subcommand introduced for TYPE=CSV and TYPE=TAB.

### Release 16.0

- VERSION=12 introduced for writing data in Excel 2007 XLSX format with TYPE=XLS.

### Release 17.0

- UNENCRYPTED subcommand introduced.

### Release 18.0

- VERSION=9 introduced for writing SAS 9+ files with TYPE=SAS.

### Release 19

- ENCODING subcommand introduced.

### Release 22.0

- BOM keyword added to ENCODING subcommand.

### Release 23.0

- Support for versions 9-13 of Stata added to VERSION subcommand.
- BULKLOADING subcommand added.

#### Release 24.0

- VALUE keyword added to FIELDNAMES subcommand.
- ODBCOPTIONS subcommand added.
- EXCELOPTIONS subcommand added.

#### Release 25.0

- Support for version 14 of Stata added to VERSION subcommand. Stata 14 supports Unicode data.

### Example

```
SAVE TRANSLATE OUTFILE='/data/sales.xlsx'  
/TYPE=XLS /VERSION=12.
```

---

## Overview

SAVE TRANSLATE translates the active dataset into a file that can be used by other software applications. Supported formats are 1-2-3, Symphony, Multiplan, Excel, dBASE II, dBASE III, dBASE IV, tab-delimited text files, comma-delimited text files, SAS, Stata, SPSS/PC+ data files, and ODBC database sources. For ODBC database sources, it can also manipulate database tables.

### Options

**Variable Subsets.** You can use the DROP and KEEP subcommands to specify variables to omit or retain in the resulting file.

**Variable Names.** You can use the RENAME subcommand to rename variables as they are copied to the external file format. For spreadsheets and text data files, use FIELDNAMES to include the variable names in the file.

**Variable Map.** To confirm the names and order of the variables that are saved in the resulting file, use the MAP subcommand. MAP displays the variables that are saved in the file next to their corresponding names in the active dataset.

**Value Labels.** For Excel spreadsheets and tab-delimited and comma-delimited text files, you can use the CELLS subcommand to export value labels rather than values in spreadsheet files. For SAS files, you can use the VALFILE subcommand to create a SAS syntax file containing your data's value labels. For Stata files, value labels for numeric variables are automatically saved as Stata value labels.

### Limitations

- A maximum of 2,048 cases can be saved to 1-2-3 Release 1A; a maximum of 8,192 cases can be saved to 1-2-3 Release 2.0 or Symphony files.
- A maximum of 16,384 cases can be saved to Excel 2.1. For Excel 95, Excel 97 and Excel 2007, if the number of cases exceeds the single sheet maximum, multiple sheets are created in the workbook.
- A maximum of 256 variables can be saved to Excel 2.1 Excel 95, and Excel 97; a maximum of 16,000 variables can be saved to Excel 2007.
- A maximum of 65,535 cases and 32 variables can be saved to dBASE II, a maximum of one billion cases (subject to disk space availability) and 128 variables can be saved to dBASE III, and a maximum of one billion cases (subject to disk space availability) and 255 variables can be saved to dBASE IV.
- A maximum of 2,047 variables can be saved to Stata 5–6 and Intercooled Stata 7–14. A maximum of 32,767 variables can be saved to Stata SE 7–14.
- A maximum of 32,767 variables can be saved to SAS 6-8.

---

## Operations

- The active dataset remains available after SAVE TRANSLATE is executed.
- If the active dataset contains more variables than the file can receive, SAVE TRANSLATE writes the maximum number of variables that the file can receive.

## Spreadsheets

Variables in the active dataset become columns, and cases become rows in the spreadsheet file.

- If you specify FIELDNAMES, variable names become the first row.
- To save value labels instead of data values, use the CELLS subcommand. See the topic “CELLS Subcommand” on page 1751 for more information.
- System-missing values are translated to #NULL! in Excel files.

IBM SPSS Statistics formats are translated as follows:

*Table 76. Format conversion for spreadsheets*

IBM SPSS Statistics	1-2-3/Symphony	Excel
Number	Fixed	0.00;#;##0.00;...
COMMA	Comma	0.00;#;##0.00;...
DOLLAR	Currency	\$.##0.);...
DATE	Date	d-mmm-yy
TIME	Time	hh:mm:ss
String	Label	General

## dBASE

Variables in the active dataset become fields, and cases become records in the database file.

- Characters that are allowed in variable names, but not in dBASE field names, are translated to colons in dBASE II and underscores in dBASE III and dBASE IV.
- Numeric variables containing the system-missing value are translated to \*\*\*\* in dBASE III and dBASE IV and 0 in dBASE II.
- The width and precision of translated numeric variables are taken from the print format—the total number of characters for the number is taken from the width of the print format, and the number of digits to the right of the decimal point is taken from the decimals in the print format. To adjust the width and precision, use the PRINT FORMATS command before using SAVE TRANSLATE. Values that cannot be converted to the given width and precision are converted to missing values.
- A maximum of 65,535 cases and 32 variables can be saved to dBASE II, a maximum of one billion cases (subject to disk space availability) and 128 variables can be saved to dBASE III, and a maximum of one billion cases (subject to disk space availability) and 255 variables can be saved to dBASE IV.

Variable formats are translated to dBASE formats as follows:

*Table 77. Format conversion for dBASE files*

IBM SPSS Statistics	dBASE
Number	Numeric
String	Character
Dollar	Numeric
Comma	Numeric

## Comma-Delimited (CSV) Text Files

Variables in the active dataset become columns, and cases become rows in the text file.

- If you specify FIELDNAMES, variable names are written in the first row.

- To save value labels instead of data values, use the CELLS subcommand. See the topic “CELLS Subcommand” on page 1751 for more information.
- Use the TEXTOPTIONS subcommand to override the default delimiter, qualifier, decimal indicator, or data value formatting. See the topic “TEXTOPTIONS Subcommand” on page 1751 for more information.
- System-missing values are translated to a blank space in text files.

## Tab-Delimited Text Files

Variables in the active dataset become columns, and cases become rows in the text file.

- If you specify FIELDNAMES, variable names are written to the first row.
- To save value labels instead of data values, use the CELLS subcommand. See the topic “CELLS Subcommand” on page 1751 for more information.
- Use the TEXTOPTIONS subcommand to override the default decimal indicator or data value formatting. See the topic “TEXTOPTIONS Subcommand” on page 1751 for more information.
- System-missing values are translated to a blank space in text files.

*Note:* Tab characters embedded in string values are preserved as tab characters in the tab-delimited file. No distinction is made between tab characters embedded in values and tab characters that separate values.

## SAS Files

Data can be saved in numerous SAS data file formats. A SAS transport file is a sequential file that is written in SAS transport format and can be read by SAS with the XPORT engine and PROC COPY or the DATA step.

- Certain characters that are allowed in IBM SPSS Statistics variable names are not valid in SAS, such as @, #, and \$. These illegal characters are replaced with an underscore when the data are exported.
- IBM SPSS Statistics variable names that contain multibyte characters (e.g., Japanese or Chinese characters) are converted to variable names of the general form *Vnnn*, where *nnn* is an integer value.
- IBM SPSS Statistics variable labels containing more than 40 characters are truncated when exported to a SAS v6 file.
- Where they exist, IBM SPSS Statistics variable labels are mapped to the SAS variable labels. If no variable label exists in the IBM SPSS Statistics data, the variable name is mapped to the SAS variable label.
- SAS allows only one value for missing, whereas IBM SPSS Statistics allows the definition of numerous missing values. As a result, all missing values in IBM SPSS Statistics are mapped to a single missing value in the SAS file.
- SAS data file names can be up to 32 characters in length. Blank spaces and non-alphanumeric characters other than the underscore (“\_”) are not allowed and names have to start with a letter or an underscore, numbers can follow.

The following table shows the variable type matching between the original data in IBM SPSS Statistics and the exported data in SAS.

*Table 78. Format conversion for SAS files*

IBM SPSS Statistics Variable Type	SAS Variable Type	SAS Data Format
Numeric	Numeric	12
Comma	Numeric	12
Dot	Numeric	12
Scientific Notation	Numeric	12
Date	Numeric	Date
Date (Time)	Numeric	Time
Date (Date-Time)	Numeric	DateTime
Dollar	Numeric	12

Table 78. Format conversion for SAS files (continued)

IBM SPSS Statistics Variable Type	SAS Variable Type	SAS Data Format
Custom Currency	Numeric	12
String	Character	\$8

## Stata Files

- Data can be written in Stata 5–14 format and in both Intercooled and SE format (version 7 or later).
- Data files that are saved in Stata 5 format can be read by Stata 4.
- The first 80 bytes of variable labels are saved as Stata variable labels.
- For Stata releases 4–8, the first 80 bytes of value labels for numeric variables are saved as Stata value labels. For Stata release 9 or later, the complete value labels for numeric variables are saved. Value labels are dropped for string variables, non-integer numeric values, and numeric values greater than an absolute value of 2,147,483,647.
- For versions 7 and later, the first 32 bytes of variable names in case-sensitive form are saved as Stata variable names. For earlier versions, the first eight bytes of variable names are saved as Stata variable names. Any characters other than letters, numbers, and underscores are converted to underscores.
- IBM SPSS Statistics variable names that contain multi-byte characters (for example, Japanese or Chinese characters) are converted to generic single-byte variable names. This only applies to Stata 4–13 data. IBM SPSS Statistics can save multi-byte variable names to Stata 14 data (because Stata 14 data is UTF-8 encoded).
- For versions 5–6 and Intercooled versions 7 and later, the first 80 bytes of string values are saved. For Stata SE 7–12, the first 244 bytes of string values are saved. For Stata SE 13 or later, complete string values are saved, regardless of length.
- For versions 5–6 and Intercooled versions 7 and later, only the first 2,047 variables are saved. For Stata SE 7 or later, only the first 32,767 variables are saved.
- Stata 14 supports Unicode data.

Table 79. How Stata variable type and format map to IBM SPSS Statistics type and format

IBM SPSS Statistics Variable Type	Stata Variable Type	Stata Data Format
Numeric	Numeric	g
Comma	Numeric	g
Dot	Numeric	g
Scientific Notation	Numeric	g
Date*, Datetime	Numeric	D_m_Y
Time, DTime	Numeric	g (number of seconds)
Wkday	Numeric	g (1–7)
Month	Numeric	g (1–12)
Dollar	Numeric	g
Custom Currency	Numeric	g
String	String	s

\*Date, Adate, Edate, SDate, Jdate, Qyr, Moyr, Wkyr

## SPSS/PC+ System Files

Variables are saved as they are defined. The resulting file is given the extension `.sys` if no extension is explicitly specified. The dictionary is saved so that labels, formats, missing value specifications, and other dictionary information are preserved. This format is available only on Windows operating systems.

## ODBC Database Sources

The following rules apply when writing to a database with TYPE=ODBC:

- If you specify a table name that does not exist in the database, a new table with that name is created.
- If any case cannot be stored in the database for any reason, an error is returned. Therefore, either all cases are stored or no cases are stored.
- At insert time, a check is performed to see whether the value that is being stored in a column is likely to cause an overflow. If so, the user is warned about the overflow and is informed that a *SYSMIS* is stored instead.
- If any variable names in the active dataset contain characters that are not allowed by the database, they are replaced by an underscore. If this process causes a duplicate variable name, a new variable name is generated.

By default, IBM SPSS Statistics variable formats are mapped to database field types based on the following general scheme. Actual database field types may vary, depending on the database.

*Table 80. Format conversion for databases*

IBM SPSS Statistics Variable Format	Database Field Type
Numeric	Float or Double
Comma	Float or Double
Dot	Float or Double
Scientific Notation	Float or Double
Date	Date or Datetime or Timestamp
Datetime	Datetime or Timestamp
Time, DTime	Float or Double (number of seconds)
Wkday	Integer (1–7)
Month	Integer (1–12)
Dollar	Float or Double
Custom Currency	Float or Double
String	Char or Varchar

- For database Datetime/Timestamp formats that don't allow fractional seconds, fraction seconds in IBM SPSS Statistics Datetime values are truncated.
- The default width of Char database data types for IBM SPSS Statistics string variables is the defined width of the string variable. If the defined width of the string exceeds the maximum width allowed by the database, the values are truncated to the maximum width, and a warning is issued.
- You can override the default settings by using the SQL subcommand to create or update tables. See the topic "SQL Subcommand" on page 1754 for more information.

---

## TYPE Subcommand

TYPE indicates the format of the resulting file.

- TYPE can be omitted for spreadsheet files if the file extension that is named on OUTFILE is the default for the type of file that you are saving.
- TYPE with the keyword DB2, DB3, or DB4 is required for translating to dBASE files.
- TYPE takes precedence over the file extension.

**ODBC.** *Database accessed via ODBC.*

**XLS.** *Excel.*

**CSV.** *Comma-delimited text data files.*

**TAB.** *Tab-delimited text data files.*

**SAS.** *SAS data files and SAS transport files.*

**STATA.** *Stata data files.*

**DB2.** *dBASE II.*

**DB3.** *dBASE III or dBASE III PLUS.*

**DB4.** *dBASE IV.*

**WK1.** *1-2-3 Release 2.0.*

**WKS.** *1-2-3 Release 1.4.*

**SYM.** *Symphony releases.*

**SLK.** *Multiplan (symbolic format).*

**PC.** *SPSS/PC+ system files.* This format is available only on Windows operating systems.

#### Example

```
SAVE TRANSLATE OUTFILE='PROJECT.XLS' /TYPE=XLS (/VERSION=8).
```

- SAVE TRANSLATE translates the active dataset into the Excel workbook file named *PROJECT.XLS*.

---

## VERSION Subcommand

VERSION specifies the file version for multiversion applications. For example, this subcommand is necessary to differentiate between different versions of Excel.

- VERSION is required for all applications listed below, except Excel.
- If VERSION is not specified with TYPE=XLS, the Excel file is saved in version 2.1 format.

*Table 81. Version numbers and applications*

<b>Version</b>	<b>Application</b>
1	Symphony Release 1.0
2	Excel 2.1, Symphony Release 2.0, dBASE II
3	dBASE III or dBASE III PLUS
4	dBASE IV
5	Excel 95 Workbook, Stata 4–5
6	SAS v6, Stata 6
7	SAS v7–8, Stata 7
8	Excel 97–2003 Workbook, Stata 8
9	SAS 9, Stata 9
10	Stata 10
11	Stata 11
12	Excel 2007 Workbook, Stata 12
13	Stata 13
14	Stata 14
X	SAS transport file

#### Example

```
SAVE TRANSLATE OUTFILE='STAFF.XLS' /TYPE=XLS /VERSION=8.
```

- SAVE TRANSLATE creates an Excel workbook file in the version 97 format.

## ENCODING Subcommand

The ENCODING subcommand specifies the character encoding for SAS, Stata, tab-delimited text, and CSV data files.

- The ENCODING subcommand is only valid with TYPE=SAS, TYPE=STATA, TYPE=TAB, and TYPE=CSV.
- The subcommand name is preceded by a slash and followed by an optional equals sign and a quoted value.
- For SAS and Stata files, the quoted value can be LOCALE or SYSTEM or one of the values in the Encodings column in Character Encoding table. For SAS 9 files, the value can also be UTF8.
- For tab-delimited text files and CSV files, the quoted value can be LOCALE, UTF8, UTF16, UTF16BE, UTF16LE, a numeric Windows code page value (for example, '1252'), or an IANA code page value (for example, 'iso8859-1' or cp1252)
- For SAS 9, tab-delimited text, and CSV files, the default is UTF8 in Unicode mode and LOCALE in code page mode. For Stata and earlier releases of SAS, the default is always LOCALE.
- The ENCODING setting also applies to the value labels file specified on the optional VALFILE subcommand for TYPE=SAS.

### Example

```
SAVE TRANSLATE
  /OUTFILE='/data/sasdata.sas7bdat'
  /VALFILE='/data/sas1labels.sas'
  /TYPE=SAS /VERSION=7 /PLATFORM=WINDOWS
  /ENCODING='Windows-1252'.
```

### BOM Keyword

By default, files encoded in any of the UTF formats include a byte order mark (BOM). Some applications cannot interpret the byte order mark. You can use the BOM keyword to suppress the byte order mark.

#### BOM=YES

Include the byte order mark in UTF files. This option is the default.

#### BOM=NO

No not include the byte order mark in UTF files.

### Character encoding values for SAS and Stata

Table 82. Character Encoding.

Character Set	Encoding
IBM SPSS Statistics Locale	Locale
Operating System Locale	System
Western	ISO-8859-1
Western	ISO-8859-15
Western	IBM850
Western	Windows-1252
Celtic	ISO-8859-14
Greek	ISO-8859-7
Greek	Windows-1253
Nordic	ISO-8859-10
Baltic	Windows-1257

Table 82. Character Encoding (continued).

Character Set	Encoding
Central European	IBM852
Central European	ISO-8859-2
Cyrillic	IBM855
Cyrillic	ISO-8859-5
Cyrillic	Windows-1251
Cyrillic/Russian	CP-866
Chinese Simplified	GBK
Chinese Simplified	ISO-2022-CN
Chinese Traditional	Big5
Chinese Traditional	EUC-TW
Japanese	EUC-JP
Japanese	ISO-2022-JP
Japanese	Shift-JIS
Korean	EUC-KR
Thai	Windows-874
Turkish	IBM857
Turkish	ISO-8859-9
Arabic	Windows-1256
Arabic	IBM864
Hebrew	ISO-8859-8
Hebrew	Windows-1255
Hebrew	IBM862

---

## OUTFILE Subcommand

OUTFILE assigns a name to the file to be saved. The only specification is the name of the file. On some operating systems, file specifications should be enclosed in quotes.

### Example

```
SAVE TRANSLATE OUTFILE='STAFF.DBF'/TYPE=DB3.
```

- SAVE TRANSLATE creates a dBASE III file called *STAFF.DBF*. The TYPE subcommand is required to specify the type of dBASE file to save.

---

## FIELDNAMES Subcommand

FIELDNAMES writes variable names to the first row in spreadsheets and tab-delimited and comma-delimited text files.

- By default, variable names are not included in the file.
- For Excel files, version 8 or later, you can also select to write either variable names or variable labels.

### VALUE=NAME

Writes variable names. This setting is the default setting if FIELDNAMES is used without a VALUE keyword.

## VALUE=LABELS

Writes variable labels. If a variable does not have a defined variable label, the variable name is used.

### Example

```
SAVE TRANSLATE OUTFILE='/data/csvfile.csv' /TYPE=CSV /FIELDNAMES.
```

---

## CELLS Subcommand

For TYPE=XLS (/VERSION=8), TYPE=TAB, and TYPE=CSV, the CELLS subcommand specifies whether data values or value labels are saved.

**CELLS=VALUES.** *Saves data values.* This is the default.

**CELLS=LABELS.** *Saves value labels instead of values.* For values with no corresponding value label, the value is saved.

### Example

```
SAVE TRANSLATE OUTFILE='/data/sales.xls'  
/TYPE=XLS /VERSION=8  
/CELLS=LABELS.
```

---

## TEXTOPTIONS Subcommand

For TYPE=CSV, the TEXTOPTIONS subcommand controls the delimiter and qualifier. For TYPE=CSV and TYPE=TAB, it controls the decimal indicator and the data value formatting. For all other types, this subcommand is ignored.

**DELIMITER="char".** *Specifies the delimiter (separator) between values.* The value must be a single character (single byte), enclosed in quotes (single or double quotes). The default is either a comma or semicolon, based on the decimal indicator. If the decimal indicator is a period, then the default separator is a comma. If the decimal indicator is a comma, then the default separator is a semicolon. The value cannot be the same as the QUALIFIER or DECIMAL value. This setting only applies for TYPE=CSV. For other types, it is ignored.

**QUALIFIER="char".** *Specifies the qualifier to use to enclose values that contain the delimiter character.* The default is a double quote. The value must be a single character (single byte), enclosed in quotes (single or double quotes). Values that contain the qualifier character will also be enclosed by the qualifier and qualifiers within the value will be doubled. The value cannot be the same as the DELIMITER or DECIMAL value. This setting only applies for TYPE=CSV. For other types, it is ignored.

**DECIMAL=DOT|COMMA.** *Specifies the value to use as the decimal indicator for numeric values.* The default is the current IBM SPSS Statistics decimal indicator. This setting has no effect on the decimal indicator used with FORMAT=VARIABLE for comma, dollar, custom currency, and dot formats. (Comma and dollar always use the period as the decimal indicator; dot always uses the comma as the decimal indicator, custom currency formats honor the decimal indicator defined in the format) The value cannot be the same as the DELIMITER or QUALIFIER value. (If DECIMAL=DOT, the default delimiter is a comma; if DECIMAL=COMMA, the default delimiter is a semicolon.)

- **DOT.** *Use a period (.) as the decimal indicator.*
- **COMMA.** *Use a comma (,) as the decimal indicator.*

The default decimal indicator is the current IBM SPSS Statistics decimal indicator. The current IBM SPSS Statistics decimal indicator can be set with SET LOCALE (which uses the OS locale decimal indicator) or SET DECIMAL and can be shown with SHOW DECIMAL. The TEXTOPTIONS DECIMAL setting overrides the default

decimal indicator in the current SAVE TRANSLATE command but does not change the default/current IBM SPSS Statistics decimal indicator, and it has no effect on the determination of the default delimiter for TYPE=CSV.

**FORMAT=PLAIN|VARIABLE.** Specifies the data formats to use when writing out data values.

- **PLAIN.** Remove all "extraneous" formatting from numeric values. This is the default. For example, a dollar format value of \$12,345.67 is written simply as 12345.67 (or 12345.67, depending on the decimal indicator). The number of decimal positions for each value is the number of decimal positions necessary to preserve the entire value (and different values of the same variable may have a different number of decimal positions). Dates are written in the general format mm/dd/yyyy. Times are written in the general format hh:mm:ss.
- **VARIABLE.** Use the print format for each variable to write data values. For example, a value of 12345.67 with a print format of DOLLAR10.2 is written as \$12,345.67 (and is qualified with double quotes or the user-specified qualifier if a comma is the value delimiter).

Print formats can be set with the PRINT FORMATS or FORMATS commands and displayed with DISPLAY DICTIONARY.

---

## EXCELOPTIONS subcommand

For XLSX Excel files (TYPE=XLS, VERSION=12), you can use EXCELOPTIONS to specify a sheet name.

```
/EXCELOPTIONS SHEET='name'
```

- The name must be enclosed in quotation marks.
- The name cannot exceed 31 characters.
- The name cannot include the following characters: / \ ? [ ] .
- If the /APPEND subcommand is also specified, the sheet is appended to the file. If a sheet with that name exists in the file, it is replaced.

---

## EDITION Subcommand

The EDITION subcommand specifies the edition for Stata files. EDITION only applies to Stata version 7 or later.

**INTERCOOLED.** Saves the data file in Stata Intercooled format. This setting is the default. Only the first 2,047 variables are saved, and only the first 80 bytes of string values are saved.

**SE.** Saves the data file in Stata SE format. The first 32,767 variables are saved, and the first 244 bytes of string values are saved.

Example

```
SAVE TRANSLATE OUTFILE='/data/newdata.dta' /TYPE=STATA  
/VERSION=8 /EDITION=SE.
```

This subcommand is ignored for any file types other than Stata version 7 or later.

---

## PLATFORM Subcommand

The PLATFORM subcommand is required for all SAS file types, with the exception of SAS transport files. Enter the keyword corresponding to the platform for which the target SAS file is intended. There is no default value for this command. Choose from the following keywords: WINDOWS, ALPHA, UNIX.

Example

```
SAVE TRANSLATE OUTFILE='STAFF.SD7' /TYPE=SAS /VERSION=7  
/PLATFORM=WINDOWS /VALFILE='LABELS.SAS'.
```

---

## VALFILE Subcommand

The VALFILE subcommand, which is available only for SAS file formats, excluding the SAS transport file format, saves value labels to a SAS syntax file. This syntax file is used in conjunction with the saved SAS data file to re-create value labels in SAS.

- The syntax file has an *.sas* file extension.

### Example

```
SAVE TRANSLATE OUTFILE='STAFF.SD7' /TYPE=SAS /VERSION=7
/PLATFORM=WINDOWS /VALFILE='LABELS.SAS'.
```

- SAVE TRANSLATE saves the current data as a SAS v7 file and creates a SAS syntax file named *LABELS.SAS*, which contains the value labels for the data.

---

## ODBC Database Subcommands

The CONNECT, ENCRYPTED, TABLE, SQL, BULKLOADING, ODBCOPTIONS, and APPEND subcommands are used with TYPE=ODBC.

### CONNECT Subcommand

CONNECT identifies the database name and other parameters for TYPE=ODBC.

- The database must already exist. You cannot create a new database with SAVE TRANSLATE (although you can create new tables in an existing database).
- If you are unsure what the connect string should be, you can use the Export to Database Wizard to generate SAVE TRANSLATE command syntax. (See Export to Database Wizard for more information.) If the connection string is specified on multiple lines, each line must be enclosed in quotes.

### Example

```
SAVE TRANSLATE
/TYPE=ODBC
/CONNECT
'DSN=MS Access Database;DBQ=C:\examples\data\dm_demo.mdb;'
'DriverId=25;FIL=MS Access;MaxBufferSize=2048;PageTimeout=5;'
/TABLE='mytable'.
```

### ENCRYPTED and UNENCRYPTED Subcommands

The ENCRYPTED subcommand indicates that the password in the CONNECT string is encrypted. The default is UNENCRYPTED. (Both the Database Wizard and Export to Database Wizard generate encrypted passwords.)

The ENCRYPTED and UNENCRYPTED subcommands have no additional specifications.

### TABLE Subcommand

TABLE identifies the table name for TYPE=ODBC.

- Table names should be enclosed in quotes.
- You can replace an existing table or append new records to an existing table.
- You can create a new table in the database by specifying a table name that does not currently exist in the database.

### Example

```
SAVE TRANSLATE
/TYPE=ODBC
/CONNECT
'DSN=MS Access Database;DBQ=C:\examples\data\dm_demo.mdb;'
'DriverId=25;FIL=MS Access;MaxBufferSize=2048;PageTimeout=5;'
/TABLE='mytable'.
```

## SQL Subcommand

The SQL subcommand provides the ability to issue any SQL directives that are needed in the target database. It can be used, for example, to define joins or alter table properties in the database to include new columns or modify column properties.

- Each SQL statement must be enclosed in quotes.
- You can use multiple lines for a single SQL statement by using multiple quoted strings connected with plus signs (the standard string concatenation symbol).
- Each quoted line cannot exceed 256 characters.
- Multiple SQL statements can be included by using multiple SQL subcommands.
- Table and field specifications in SQL statements refer to tables and fields available in the database, not datasets and variables available in the IBM SPSS Statistics session (although in many cases the names may be the same).
- Regardless of the position of the SQL subcommand, the SQL statements are executed last, after all other actions executed by the SAVE TRANSLATE command.

Example: Adding New Columns to an Existing Table

```
SAVE TRANSLATE /TYPE=ODBC
/CONNECT=
'DSN=MS Access Database;DBQ=C:\examples\data\dm_demo.mdb;
'DriverId=25;FIL=MS Access;MaxBufferSize=2048;PageTimeout=5;'
/TABLE = 'NewColumn'
/KEEP ID income_score
/REPLACE
/SQL='ALTER TABLE CombinedTable ADD COLUMN income_score REAL'
/SQL='UPDATE CombinedTable INNER JOIN NewColumn ON ' +
'CombinedTable.ID=NewColumn.ID SET ' +
'CombinedTable.income_score=NewColumn.income_score'.
```

- The TABLE, KEEP, and REPLACE subcommands create or replace a table named *NewColumn* that contains two variables: a key variable (*ID*) and a computed score (*income\_score*).
- The first SQL subcommand, specified on a single line, adds a column to an existing table that will contain values of the computed variable *income\_score*. At this point, all we have done is create an empty column in the existing database table, and the fact that both database tables and the active dataset use the same name for that column is merely a convenience for simplicity and clarity.
- The second SQL subcommand, specified on multiple lines with the quoted strings concatenated with plus signs, adds the *income\_score* values from the new table to the existing table, matching rows (cases) based on the value of the key variable *ID*.

The end result is that an existing table is modified to include a new column containing the values of the computed variable.

Example: Specifying Data Types for a New Table

```
SAVE TRANSLATE /TYPE=ODBC
/CONNECT='DSN=MS Access Database;DBQ=c:\temp\temp.mdb;DriverId=25;FIL=MS'+
' Access;MaxBufferSize=2048;PageTimeout=5;'
/TABLE=tempTable /REPLACE
/SQL='CREATE TABLE NewTable(numVar double, intVar integer, dollarVar currency)'
/SQL='INSERT INTO NewTable(numVar, intVar, dollarVar) SELECT * FROM tempTable'
/SQL='DROP TABLE tempTable'.
```

- The TABLE subcommand creates a new table that contains variables in the active dataset with the default database data types. In this example, the original variables have IBM SPSS Statistics variable formats of F8.2, F4.0, and Dollar10.2 respectively, but the default database type for all three is double.
- The first SQL subcommand creates another new table with data types explicitly defined for each field. At this point, this new table contains no data.
- The second SQL subcommand inserts the data from the *tempTable* into *NewTable*. This does not affect the data types previously defined for *NewTable*, so *intVar* will have a data type of integer and *dollarVar* will have a data type of currency.
- The last SQL subcommand deletes *tempTable*, since it is no longer needed.

## BULKLOADING Subcommand

The BULKLOADING subcommand controls settings for bulk loading to a database. Bulk loading can make the export much faster, particularly for large data files.

### METHOD=OFF | BATCH | ODBC

Specifies the bulk loading method.

- OFF. Bulk loading is turned off. Records are committed to the database one at a time. This option is the default setting.
- BATCH. Commits records to the database in the batch size value that is specified for the BATCHSIZE keyword.
- ODBC. Uses the ODBC binding method to commit records in the specified batch size. This option is available only if the database supports ODBC binding. This option is not available on Mac OS.

### BATCHSIZE=integer

Specifies the batch size. The value must be a positive integer. The default value is 10000.

### BINDING=ROW | COLUMN

For ODBC binding, specifies row or column binding. This setting is ignored unless METHOD=ODBC.

- ROW. Row-wise binding typically improves speed compared to the use of parameterized inserts that insert data on a record-by-record basis. This option is the default setting.
- COLUMN. Column-wise binding improves performance by binding each database column to an array of  $n$  values.

## ODBCOPTIONS subcommand

You can use ODBCOPTIONS to export defined value labels instead of data values.

ODBCOPTIONS VALLABELS=NONE | varlist

- The default setting is VALLABELS=NONE.
- If a variable list is specified, the value label text is exported instead of the data values.
- For values that do not have a defined value label, the data value is exported as a text string.
- This option is ignored for date format variables and variables that do not have any defined value labels.
- This option is only available for creating a new table, replacing an existing table, and adding new fields to an existing table. You cannot use this option for appending rows to an existing table or modifying the content of existing fields in a table.

---

## APPEND Subcommand

### TYPE=ODBC

For TYPE=ODBC, APPEND appends rows (cases) to an existing database table after type and variable name validations. There must be a matching column in the table for each IBM SPSS Statistics variable. If a column that can correctly store a variable is not found, a failure is returned. If the table contains more columns than the number of IBM SPSS Statistics variables, the command still stores the data in the table. The variable names and column names must match exactly. A variable can be stored in a column as long as the column type is a type that can store values of the variable type. A column of any numeric type (short integer, integer, float, double, etc.) is valid for a numeric variable, and a column of any character type is valid for a string variable.

*Note:* APPEND can only add rows to a table, not columns. If you want to add columns (fields) to a database table, see the SQL subcommand.

## TYPE=XLS

For TYPE=XLS, APPEND can append a new sheet to an existing file.

- APPEND is valid only for VERSION=12.
- A sheet name must be specified on the EXCELOPTIONS subcommand.

---

## REPLACE Subcommand

REPLACE gives permission to overwrite an existing file (or database table) of the same name. REPLACE takes no further specifications.

- SAVE TRANSLATE will not overwrite an existing file without an explicit REPLACE subcommand. The default behavior is to not overwrite.
- For database tables (TYPE=ODBC), APPEND and REPLACE are mutually exclusive.

*Note:* For database tables, REPLACE destroys an existing table and replaces it with the data written by the SAVE TRANSLATE command, which may lead to loss of database-specific information, such as the designation of key variables (fields) and data formats. If you want to update an existing table with new values in some existing rows or by adding additional fields to the table, see the SQL subcommand.

---

## UNSELECTED Subcommand

UNSELECTED determines whether cases that were excluded on a previous FILTER or USE command are to be retained or deleted. The default is RETAIN. The UNSELECTED subcommand has no effect when the active dataset does not contain unselected cases.

**RETAIN.** *Retain the unselected cases.* All cases in the active dataset are saved. This setting is the default when UNSELECTED is specified by itself.

**DELETE.** *Delete the unselected cases.* Only cases that meet the FILTER or USE criteria are saved.

---

## DROP and KEEP Subcommands

Use DROP or KEEP to include only a subset of variables in the resulting file. DROP specifies a set of variables to exclude. KEEP specifies a set of variables to retain. Variables that are not specified on KEEP are dropped.

- Specify a list of variable, column, or field names separated by commas or spaces.
- KEEP does not affect the order of variables in the resulting file. Variables are kept in their original order.
- Specifying a variable that is not in the active dataset or that has been dropped because of a previous DROP or KEEP subcommand results in an error, and the SAVE command is not executed.

### Example

```
SAVE TRANSLATE OUTFILE='ADDRESS.DBF' /TYPE=DB4 /DROP=PHONENO, ENTRY.
```

- SAVE TRANSLATE creates a dBASE IV file named *ADDRESS.DBF*, dropping the variables *PHONENO* and *ENTRY*.

---

## RENAME Subcommand

RENAME changes the names of variables as they are copied into the resulting file.

- The specification on RENAME is a list of old variable names followed by an equals sign and a list of new variable names. The same number of variables must be specified on both lists. The keyword T0 can be used in the first list to refer to consecutive variables in the active dataset and can be in the second list to generate new variable names. The entire specification must be enclosed in parentheses.

- Alternatively, you can specify each old variable name individually, followed by an equals sign and the new variable name. Multiple sets of variable specifications are allowed. The parentheses around each set of specifications are optional.
- New names cannot exceed 64 bytes. Characters not allowed in IBM SPSS Statistics variable names can be used in new names for the target file, but if the name contains special characters (e.g., spaces, commas, slashes, plus signs) the name must be enclosed in quotes.
- RENAME does not affect the active dataset. However, if RENAME precedes DROP or KEEP, variables must be referred to by their new names on DROP or KEEP.
- Old variable names do not need to be specified according to their order in the active dataset.
- Name changes take place in one operation. Therefore, variable names can be exchanged between two variables.
- Multiple RENAME subcommands are allowed.

### Examples

```
SAVE TRANSLATE OUTFILE='STAFF.SYM' VERSION=2 /FIELDNAMES
/RENAME AGE=AGE88 JOBCAT=JOBCAT88.
```

- RENAME renames the variable *AGE* to *AGE88* and renames *JOBCAT* to *JOBCAT88* before they are copied to the first row of the spreadsheet.

```
SAVE TRANSLATE OUTFILE='STAFF.SYM' VERSION=2 /FIELDNAMES
/RENAME (AGE JOBCAT=AGE88 JOBCAT88).
```

- The name changes are identical to the changes in the previous example: *AGE* is renamed to *AGE88*, and *JOBCAT* is renamed to *JOBCAT88*. The parentheses are required with this method.

---

## MISSING Subcommand

The MISSING subcommand controls the treatment of user-missing values. By default, user-missing values are treated as regular valid values in the target file.

**IGNORE.** *Treat user-missing values as regular valid values.* This setting is the default.

**RECODE.** *Recode numeric user-missing values to system-missing, and recode string user-missing values to blank spaces.*

---

## COMPRESSED and UNCOMPRESSED Subcommands

For TYPE=PC, COMPRESSED saves the file in compressed form. UNCOMPRESSED saves the file in uncompressed form.

- The only specification is the keyword COMPRESSED or UNCOMPRESSED.
- The COMPRESSED and UNCOMPRESSED keywords are valid only for TYPE=PC.

---

## MAP Subcommand

MAP displays a list of the variables in the resulting file and their corresponding names in the active dataset.

- The only specification is the keyword MAP.
- Multiple MAP subcommands are allowed. Each MAP subcommand maps the results of subcommands that precede it but not the results of subcommands that follow it.

### Example

```
GET FILE=HUBEMPL.
SAVE TRANSLATE OUTFILE='STAFF.SYM' /VERSION=2 /FIELDNAMES
/RENAME=(AGE=AGE88)(JOBCAT=JOBCAT88).
```

- MAP is specified to confirm that the variable *AGE* is renamed to *AGE88* and *JOBCAT* is renamed to *JOBCAT88*.

---

## Chapter 239. SAVETM1

### SAVETM1

```
/CONNECTION PMSYSURL='string'  
  SERVER='string'  
[NAMESPACE='string']  
  USERNAME='string'  
  PASSWORD='string' ENCRYPTED={YES**}  
                                {NO  }  
  
/CUBE NAME='string'  
  
/MAPPINGS MEASURE_FIELDS = fieldname (MAPTO='element name' NEW={YES | NO}) ...  
          [DIMENSION_FIELDS = fieldname (MAPTO='dimension name') ... ]  
          [SLICES = 'dimension name' (LEAF='element name') ... ]
```

\*\*Default if keyword omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Release History

Release 22.0.0.1

- Command introduced.

### Example

```
SAVETM1  
/CONNECTION PMSYSURL='http://mypmsystem:9510/pmhub/pm'  
  SERVER='myserver'  
  USERNAME='tm1user'  
  PASSWORD='#o/B!a.],-./.-#(' ENCRYPTED=YES  
  
/CUBE NAME='mycube'  
  
/MAPPINGS MEASURE_FIELDS=PredictedSales (MAPTO='Predicted Sales' NEW=YES)  
  
          DIMENSION_FIELDS=Region (MAPTO='Region')  
                             Product (MAPTO='Product')  
                             Month (MAPTO='Month')  
  
          SLICES='Store Type' (LEAF='Department Store').
```

---

## Overview

SAVETM1 saves data from the active dataset to an IBM Cognos TM1 cube. This feature is particularly useful when you import data from TM1, transform or score the data in SPSS Statistics, and then want to export the results back to TM1. You must have access to a TM1 Performance Management system and an associated TM1 server to use this feature.

**Important:** To enable the exchange of data between SPSS Statistics and TM1, you must copy the following three processes from SPSS Statistics to the TM1 server: `ExportToSPSS.pro`, `ImportFromSPSS.pro`, and `SPSSCreateNewMeasures.pro`. To add these processes to the TM1 server, you must copy them to the

data directory of the TM1 server and restart the TM1 server. These files are available from the common/scripts/TM1 directory under the SPSS Statistics installation directory.

- All subcommands are required.
- The TM1 cube to which you export must include a measure dimension.
- System-missing and user-missing values of fields that are mapped to elements in the measure dimension of the TM1 cube are ignored on export. The associated cells in the TM1 cube are unchanged.
- Fields with a value of zero, that are mapped to elements in the measure dimension, are exported as a valid value.

**Related information:**

“Overview” on page 847

---

## **CONNECTION subcommand**

The required CONNECTION subcommand specifies the IBM Cognos TM1 Performance Management system and associated TM1 server and any credentials that are required to access data on the TM1 server.

### **PMSYSURL**

Specifies the URL for the Performance Management system where the TM1 server you want to connect to is installed. The Performance Management system is defined as a single URL for all TM1 servers. From this URL, all TM1 servers that are installed and running on your environment can be discovered and accessed. The keyword is followed by an equals sign (=) and a URL enclosed in quotation marks.

### **SERVER**

Specifies the TM1 server. The keyword is followed by an equals sign (=) and the name of the server enclosed in quotation marks.

### **MODE=SETCREDENTIALS**

Specifies that credentials are explicitly specified. This setting is the default. For SETCREDENTIALS, you must specify values for USERNAME and PASSWORD.

#### **USERNAME**

The TM1 user name with which to log on to the server. The keyword is followed by an equals sign (=) and a value that is enclosed in quotation marks.

#### **PASSWORD**

The password that is associated with the specified user name. The keyword is followed by an equals sign (=) and a value that is enclosed in quotation marks. By default, the password is assumed to be encrypted. If you do not want the password to be treated as encrypted, then specify ENCRYPTED=NO.

#### **NAMESPACE**

The IBM Cognos Business Intelligence security authentication provider that is used to log on to the server. This setting is only required when the server uses authentication mode 5 (IBM Cognos security). The keyword is followed by an equals sign (=) and a value that is enclosed in quotation marks. The keyword is ignored if the authentication mode is anything other than mode 5.

### **MODE=STOREDCREDENTIAL**

Specifies to use the login information from a stored credential. To use a stored credential, you must be connected to the IBM SPSS Collaboration and Deployment Services Repository that contains the credential. For STOREDCREDENTIAL, you must specify the CREDENTIAL keyword, followed by an equals sign (=) and the name of the credential in quotation marks.

---

## CUBE subcommand

The required CUBE subcommand specifies the IBM Cognos TM1 cube where the data is saved. The subcommand name is followed by the keyword NAME, an equals sign (=), and the name of the cube enclosed in quotation marks. The specified cube must include a measure dimension.

---

## MAPPINGS subcommand

The required MAPPINGS subcommand defines the mappings from the fields in the active dataset to the dimensions and measures in the specified IBM Cognos TM1 cube.

- The MEASURE\_FIELDS keyword is required.
- For each regular dimension in the cube, you must either map a field in the active dataset to the dimension or specify a slice for the dimension.

### MEASURE\_FIELDS

Required keyword that specifies the mappings from fields in the active dataset to elements in the measure dimension of the cube.

- The keyword is followed by an equals sign (=) and a list of fields.
- The form of a field specification is `fieldname (MAPTO='element name' NEW={YES | NO})`, where *fieldname* is the name of a field in the active dataset and '*element name*' is the name of the element in the measure dimension that it is mapped to, enclosed in quotation marks. The NEW keyword specifies whether the element is a new element in the measure dimension: YES specifies a new element, NO specifies an existing element.

#### Note:

- Only numeric fields can be specified on the MEASURE\_FIELDS keyword.
- Values that are exported to an existing element in the measure dimension overwrite the associated cells in the TM1 cube.

### DIMENSION\_FIELDS

Optional keyword that specifies the mappings from fields in the active dataset to regular dimensions in the cube.

- The keyword is followed by an equals sign (=) and a list of fields.
- The form of a field specification is `fieldname (MAPTO='dimension name')`, where *fieldname* is the name of a field in the active dataset and '*dimension name*' is the name of the dimension it is mapped to, enclosed in quotation marks.

#### Note:

- Only string fields can be specified on the DIMENSION\_FIELDS keyword.
- Cases with field values that do not match a leaf element in the specified dimension are not exported. In that regard, you can export only to leaf elements.

### SLICES

Optional keyword that specifies slices for one or more regular dimensions. A slice specifies a single leaf element of a dimension so that all exported cases are associated with the specified leaf element.

- The keyword is followed by an equals sign (=) and a list of fields.
- The form of a field specification is `'dimension name' (LEAF='element name')`, where '*dimension name*' is the name of a dimension and '*element name*' is the name of the leaf element that defines the slice. Both values must be enclosed in quotation marks.

## Example

```
/MAPPINGS MEASURE_FIELDS=PredictedSales (MAPTO='Predicted Sales' NEW=YES)
```

```
    DIMENSION_FIELDS=Region (MAPTO='Region')  
                      Product (MAPTO='Product')  
                      Month (MAPTO='Month')
```

```
    SLICES='Store Type' (LEAF='Department Store')
```

---

## Chapter 240. SCRIPT

```
SCRIPT 'filename' [(quoted string)] [PYTHONVERSION = {2**}]  
{3 }
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Release History

#### Release 16.0

- Scripts run from the SCRIPT command now run synchronously with the command syntax stream.

#### Release 17.0

- Ability to run Python scripts introduced.

#### Release 24.0

- PYTHONVERSION keyword introduced.

---

## Overview

SCRIPT runs a script to customize the program or automate regularly performed tasks. You can run a Basic script or a Python script.

### Basic Specification

The basic specification is keyword SCRIPT with a filename. The filename is required. The optional quoted string, enclosed in parentheses, can be passed to the script.

### PYTHONVERSION Keyword

The PYTHONVERSION keyword specifies whether to use the Python 2 or the Python 3 processor to run the script. By default, the Python 2 processor is used.

### Operations

- SCRIPT runs the specified script, and works in both local and distributed mode. The effect is the same as opening the script file in the script editor (Basic or Python) and running it from there.

### Limitations

- Python scripts run from the SCRIPT command cannot execute command syntax.
- The SCRIPT command is not supported in the IBM SPSS Statistics Batch Facility (available with IBM SPSS Statistics Server).

---

## Running Basic Scripts That Contain Syntax Commands

If a Basic script that is run via the SCRIPT command contains syntax commands, those commands must be run asynchronously. To run commands asynchronously, set the bSync parameter of the ExecuteCommands method to False, as in:

```
Dim objSpssApp As spsswinLib.Application16  
Dim strCommands As String  
Set objSpssApp=CreateObject("SPSS.Application16")
```

' Construct and execute syntax commands:

```
strCommands = "GET FILE = '/data/bank.sav'. " & vbCr
strCommands = strCommands & "Display Dictionary."
objSpssApp.ExecuteCommands strCommands, False
```

---

## Chapter 241. SEASON

SEASON is available in SPSS Statistics Professional Edition or the Forecasting option.

SEASON VARIABLES= series names

```
[/MODEL={MULTIPLICATIVE**}  
{ADDITIVE  
}]
```

```
[/MA={EQUAL  
{CENTERED  
}]
```

```
[/PERIOD=n]
```

```
[/APPLY [= 'model name']]
```

\*\*Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Example

```
SEASON VARIABLES = VARX  
/MODEL=ADDITIVE.
```

---

## Overview

SEASON estimates multiplicative or additive seasonal factors for time series by using any specified periodicity. SEASON is an implementation of the Census Method I, otherwise known as the ratio-to-moving-average method. See <sup>77</sup> and <sup>78</sup>.

### Options

**Model Specification.** You can specify either a multiplicative or additive model on the MODEL subcommand. You can specify the periodicity of the series on the PERIOD subcommand.

**Computation Method.** Two methods of computing moving averages are available on the MA subcommand for handling series with even periodicities.

**Statistical Output.** Specify TSET PRINT=BRIEF to display only the initial seasonal factor estimates. TSET PRINT=DETAILED produces the same output as the default.

**New Variables.** To evaluate the displayed averages, ratios, factors, adjusted series, trend-cycle, and error components without creating new variables, specify TSET NEWVAR=NONE prior to SEASON. This can result in faster processing time. To add new variables without erasing the values of previous Forecasting-generated variables, specify TSET NEWVAR=ALL. This saves all new variables that are generated during the current session to the active dataset and may require extra processing time. When the default (TSET NEWVAR=CURRENT) is in effect, only variables from the current procedure are saved to the active dataset, and the suffix #n is used to distinguish variables that are generated by different series. TSET MXNEWVAR specifies the maximum number of new variables that can be generated by a procedure. The default is 60. The order in which new variables are added to the active dataset's dictionary is *ERR*, *SAS*, *SAF*, and *STC*.

### Basic Specification

---

77. Makridakis, S., S. C. Wheelwright, and V. E. McGee. 1983. *Forecasting: Methods and applications*. New York: John Wiley and Sons.

78. McLaughlin, R. L. 1984. *Forecasting techniques for decision making*. Rockville, Md.: Control Data Management Institute.

The basic specification is one or more series names.

- By default, SEASON uses a multiplicative model to compute and display moving averages, ratios, seasonal factors, the seasonally adjusted series, the smoothed trend-cycle components, and the irregular (error) component for each specified series (variable). The default periodicity is the periodicity that is established with TSET PERIOD or DATE.
- Unless the default on TSET NEWVAR is changed prior to the procedure, SEASON creates four new variables, with the following prefixes, for each specified series (these variables are automatically named, labeled, and added to the active dataset):

**SAF.** *Seasonal adjustment factors.* These values indicate the effect of each period on the level of the series.

**SAS.** *Seasonally adjusted series.* These values are the values that are obtained after removing the seasonal variation of a series.

**STC.** *Smoothed trend-cycle components.* These values show the trend and cyclical behavior that are present in the series.

**ERR.** *Residual or "error" values.* These values are the values that remain after the seasonal, trend, and cycle components have been removed from the series.

#### Subcommand Order

- Subcommands can be specified in any order.

#### Syntax Rules

- VARIABLES can be specified only once.
- Other subcommands can be specified more than once, but only the last specification of each one is executed.

#### Operations

- The endpoints of the moving averages and ratios are displayed as system-missing in the output.
- Missing values are not allowed anywhere in the series. (You can use the RMV command to replace missing values, use TSET MISSING=INCLUDE to include user-missing values, and use USE to ignore missing observations at the beginning or end of a series. See RMV and USE for more information.)

If SPLIT FILE processing is on, SEASON ignores USE settings.

#### Limitations

- A maximum of one VARIABLES subcommand is allowed. There is no limit on the number of series that are named on the list.

---

## VARIABLES Subcommand

VARIABLES specifies the series names and is the only required subcommand.

- Each specified series must contain at least four full seasons of data.

---

## MODEL Subcommand

MODEL specifies whether the seasonal decomposition model is multiplicative or additive.

- The specification on MODEL is the keyword MULTIPLICATIVE or ADDITIVE.
- If more than one keyword is specified, only the first keyword is used.
- MULTIPLICATIVE is the default if the MODEL subcommand is not specified or if MODEL is specified without any keywords.

#### Example

```
SEASON VARIABLES = VARX  
/MODEL=ADDITIVE.
```

- This example uses an additive model for the seasonal decomposition of *VARX*.

---

## MA Subcommand

MA specifies how to treat an even-periodicity series when computing moving averages.

- MA should be specified only when the periodicity is even. When periodicity is odd, the EQUAL method is always used.
- For even-periodicity series, the keyword EQUAL or CENTERED can be specified. CENTERED is the default.
- EQUAL calculates moving averages with a span (number of terms) equal to the periodicity and all points weighted equally.
- CENTERED calculates moving averages with a span (number of terms) equal to the periodicity plus 1 and endpoints weighted by 0.5.
- The periodicity is specified on the PERIOD subcommand.

### Example

```
SEASON VARIABLES = VARY
/MA=CENTERED
/PERIOD=12.
```

- In this example, moving averages are computed with spans of 13 terms and endpoints weighted by 0.5.

---

## PERIOD Subcommand

PERIOD indicates the size of the period.

- The specification on PERIOD indicates how many observations are in one period or season and can be any positive integer.
- If PERIOD is not specified, the periodicity that is established on TSET PERIOD is in effect. If TSET PERIOD is not specified, the periodicity that is established on the DATE command is used. If periodicity was not established anywhere, the SEASON command will not be executed.

### Example

```
SEASON VARIABLES = SALES
/PERIOD=12.
```

- In this example, a periodicity of 12 is specified for *SALES*.

---

## APPLY Subcommand

APPLY allows you to use a previously defined SEASON model without having to repeat the specifications.

- The only specification on APPLY is the name of a previous model in quotation marks. If a model name is not specified, the model that was specified on the previous SEASON command is used. Model names are either the default *MOD\_n* names or the names that are assigned on the MODEL NAME command.
- To change one or more model specifications, specify the subcommands of only those portions that you want to change after the APPLY subcommand.
- If no series are specified on the command, the series that were originally specified with the model that is being reapplied are used.
- To change the series used with the model, enter new series names before or after the APPLY subcommand. If a series name is specified before APPLY, the slash before the subcommand is required.

### Example

```
SEASON VARIABLES = X1
/MODEL=ADDITIVE.
SEASON VARIABLES = Z1
/APPLY.
```

- The first command specifies an additive model for the seasonal decomposition of *X1*.
- The second command applies the same type of model to series *Z1*.

## Example

```
SEASON X1 Y1 Z1  
/MODEL=MULTIPLICATIVE.  
SEASON APPLY  
/MODEL=ADDITIVE.
```

- The first command specifies a multiplicative model for the seasonal decomposition of *X1*, *Y1*, and *Z1*.
- The second command applies an additive model to the same three variables.

---

## Chapter 242. SELECT IF

SELECT IF [(*logical expression*)]

The following relational operators can be used in logical expressions:

*Table 83. Relational operators*

Symbol	Definition
EQ or =	Equal to
NE or ~= or $\neq$ or <>	Not equal to
LT or <	Less than
LE or <=	Less than or equal to
GT or >	Greater than
GE or >=	Greater than or equal to

The following logical operators can be used in logical expressions:

*Table 84. Logical operators*

Symbol	Definition
AND or &	Both relations must be true
OR or	Either relation can be true
NOT	Reverses the outcome of an expression

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. See the topic “Command Order” on page 40 for more information.

### Example

```
SELECT IF (SEX EQ 'MALE').
```

---

## Overview

SELECT IF permanently selects cases for analysis based on logical conditions that are found in the data. These conditions are specified in a *logical expression*. The logical expression can contain relational operators, logical operators, arithmetic operations, and any functions that are allowed in COMPUTE transformations. For temporary case selection, specify a TEMPORARY command before SELECT IF.

### Basic Specification

The basic specification is simply a logical expression.

### Syntax Rules

- Logical expressions can be simple logical variables or relations, or these expressions can be complex logical tests involving variables, constants, functions, relational operators, and logical operators. The logical expression can use any of the numeric or string functions that are allowed in COMPUTE transformations (see COMPUTE and see ).
- Parentheses can be used to enclose the logical expression. Parentheses can also be used within the logical expression to specify the order of operations. Extra blanks or parentheses can be used to make the expression easier to read.

- A relation can compare variables, constants, or more complicated arithmetic expressions. Relations cannot be abbreviated. For example, (A EQ 2 OR A EQ 5) is valid while (A EQ 2 OR 5) is not valid. Blanks (not commas) must be used to separate relational operators from the expressions that are being compared.
- A relation cannot compare a string variable to a numeric value or variable, or vice versa. A relation cannot compare the result of the logical functions `SYSMIS`, `MISSING`, `ANY`, or `RANGE` to a number.
- String values that are used in expressions must be specified in quotation marks and must include any leading or trailing blanks. Lowercase letters are considered distinct from uppercase letters.

## Operations

- `SELECT IF` permanently selects cases. Cases that are not selected are dropped from the active dataset.
- The logical expression is evaluated as true, false, or missing. If a logical expression is true, the case is selected; if it is false or missing, the case is not selected.
- Multiple `SELECT IF` commands that are issued prior to a procedure command must all be true for a case to be selected.
- `SELECT IF` should be placed before other transformations for efficiency.
- Logical expressions are evaluated in the following order: numeric functions, exponentiation, arithmetic operators, relational operators, and logical operators. Use parentheses to change the order of evaluation.
- If `N OF CASES` is used with `SELECT IF`, the program reads as many records as required to build the specified *n* cases. It makes no difference whether `N OF CASES` precedes or follows `SELECT IF`.
- System variable `$CASENUM` is the sequence number of a case in the active dataset. Although it is syntactically correct to use `$CASENUM` on `SELECT IF`, it does not produce the expected results. To select a set of cases based on their sequence in a file, create your own sequence variable with the transformation language prior to making the selection (see the “Examples”).

## Missing Values

- If the logical expression is indeterminate because of missing values, the case is not selected. In a simple relational expression, a logical expression is indeterminate if the expression on either side of the relational operator is missing.
- If a compound expression is used in which relations are joined by the logical operator `OR`, the case is selected if either relation is true, even if the other relation is missing.
- To select cases with missing values for the variables within the expression, use the missing-value functions. To include cases with values that have been declared user-missing, along with other cases, use the `VALUE` function.

## Limitations

`SELECT IF` cannot be placed within a `FILE TYPE-END FILE TYPE` or `INPUT PROGRAM-END INPUT PROGRAM` structure. `SELECT IF` can be placed nearly anywhere following these commands in a transformation program. See the topic Chapter 304, “Commands and Program States,” on page 2187 for more information.

---

## Examples

### Working With Simple Logical Expressions

```
SELECT IF (SEX EQ 'MALE').
```

- All subsequent procedures will use only cases in which the value of `SEX` is `MALE`.
- Because uppercase and lowercase are treated differently in comparisons of string variables, cases for which the value of `SEX` is `male` are not selected.

```
SELECT IF (INCOME GT 75000 OR INCOME LE 10000).
```

- The logical expression tests whether a case has a value that is either greater than 75,000 or less than or equal to 10,000. If either relation is true, the case is used in subsequent analyses.

```
SELECT IF (V1 GE V2).
```

- This example selects cases where variable *V1* is greater than or equal to *V2*. If either *V1* or *V2* is missing, the logical expression is indeterminate, and the case is not selected.

```
SELECT IF (SEX = 'F' & INCOME <= 10000).
```

- The logical expression tests whether string variable *SEX* is equal to F and whether numeric variable *INCOME* is less than or equal to 10,000. Cases that meet both conditions are included in subsequent analyses. If either *SEX* or *INCOME* is missing for a case, the case is not selected.

```
SELECT IF (SYSMIS(V1)).
```

- The logical expression tests whether *V1* is system-missing. If it is system-missing, the case is selected for subsequent analyses.

```
SELECT IF (VALUE(V1) GT 0).
```

- Cases are selected if *V1* is greater than 0, even if the value of *V1* has been declared user-missing.

```
SELECT IF (V1 GT 0).
```

- Cases are not selected if *V1* is user-missing, even if the user-missing value is greater than 0.

```
SELECT IF ((V1-15) LE (V2*(-0.001))).
```

- The logical expression compares whether *V1* minus 15 is less than or equal to *V2* multiplied by  $-0.001$ . If it is true, the case is selected.

```
SELECT IF ((YRMODA(88,13,0) - YRMODA(YVAR,MVAR,DVAR)) LE 30).
```

- The logical expression subtracts the number of days representing the date (*YVAR*, *MVAR*, and *DVAR*) from the number of days representing the last day in 1988. If the difference is less than or equal to 30, the case is selected.

### Understanding and Changing the Order of Evaluation

```
SELECT IF (RECEIV GT DUE AND (REVNUS GE EXPNS OR BALNCE GT 0)).
```

- By default, AND is executed before OR. This expression uses parentheses to change the order of evaluation.
- The program first tests whether variable *REVNUS* is greater than or equal to variable *EXPNS*, or variable *BALNCE* is greater than 0. Second, the program tests whether *RECEIV* is greater than *DUE*. If one of the expressions in parentheses is true and *RECEIV* is greater than *DUE*, the case is selected.
- Without the parentheses, the program would first test whether *RECEIV* is greater than *DUE* and *REVNUS* is greater than or equal to *EXPNS*. Second, the program would test whether *BALNCE* is greater than 0. If the first two expressions are true *or* if the third expression is true, the case is selected.

### Selecting Cases Based on Their Sequence in a File

```
COMPUTE #CASESEQ=#CASESEQ+1.  
SELECT IF (MOD(#CASESEQ,2)=0).
```

- This example computes a scratch variable, *#CASESEQ*, containing the sequence numbers for each case. Every other case is selected, beginning with the second case.
- *#CASESEQ* must be a scratch variable so that it is not reinitialized for every case. An alternative is to use the LEAVE command.

### Using SELECT IF within a DO IF Structure

```
DO IF SEX EQ 'M'.  
+ SELECT IF PRESTIGE GT 50.  
ELSE IF SEX EQ 'F'.  
+ SELECT IF PRESTIGE GT 45.  
END IF.
```

- The SELECT IF commands within the DO IF structure select males with prestige scores above 50 and females with prestige scores above 45.

---

## Chapter 243. SELECTPRED

SELECTPRED is available in the Statistics Base Edition.

```
SELECTPRED dependent variable [(MLEVEL={S})]
                               {0}
                               {N}
      [BY factor list] [WITH covariate list]

[/EXCEPT VARIABLES=varlist]

[/SCREENING [STATUS={0N**}] [PCTMISSING={70** }]]
           {OFF }           {number}
           [PCTEQUAL={95** }] [PCTUNEQUAL={90** }]]
           {number}         {number}
           [STDDEV={0** } ]
           {number}
           [CV={0.001** }]]
           {number}

[/CRITERIA [SIZE={AUTO** } ] [PCUTOFF={0.05**}]

           [RANKING={PEARSONCHISQ**}] [TIMER={5** }]]
           {LRCHISQ }         {number}
           {CRAMERSV }
           {LAMBDA }
           [SHOWUNSELECTED={0** }]]
           {integer}

[/MISSING USERMISSING={EXCLUDE**}]
           {INCLUDE }

[/PRINT [CPS**] [EXCLUDED**] [SELECTED**] [NONE]]
        [SUMMARY**[([PEARSONCHISQ] [LRCHISQ] [CRAMERSV] [LAMBDA])]]]

[/PLOT SUMMARY]
```

\*\* Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

Release history

Release 14.0

- Command introduced.

Example

```
SELECTPRED response_01.
```

---

## Overview

The SELECTPRED procedure submits a large number of predictor variables and selects a smaller subset for use in predictive modeling procedures. This procedure uses a univariable method that considers each predictor in isolation, as opposed to the multivariable method of selecting procedures that is used by the NAIVEBAYES procedure. The SELECTPRED procedure supports both categorical and scale dependent variables and accepts very large sets of predictors. SELECTPRED is useful when rapid computing is required.

Options

**Methods.** The SELECTPRED procedure includes a screening step as well as the univariable predictor selection method.

**Missing values.** Cases with missing values for the dependent variable or for all predictors are excluded. The SELECTPRED procedure has an option for treating user-missing values of categorical variables as valid. User-missing values of scale variables are always treated as invalid.

**Output.** SELECTPRED displays pivot table output by default but offers an option for suppressing most such output. The procedure optionally displays lists of categorical and scale predictors—not a model—by way of global macro variables. These global macro variables can be used to represent the subset of selected predictors in subsequent procedures.

### Basic specification

The basic specification is the SELECTPRED command followed by a dependent variable.

By default, SELECTPRED determines the measurement level of the dependent variable based on its dictionary setting. All other variables in the dataset — except the weight variable if it is defined — are treated as predictors, with the dictionary setting of each predictor determining its measurement level. SELECTPRED performs the screening step and then selects a subset of predictors by using a univariable method. User-missing values are excluded, and default pivot table output is displayed.

### Syntax rules

- All subcommands are optional.
- Only a single instance of each subcommand is allowed.
- An error occurs if a keyword is specified more than once within a subcommand.
- Parentheses, equals signs, and slashes that are shown in the syntax chart are required.
- The command name, subcommand names, and keywords must be spelled in full.
- Empty subcommands are not honored.

### Operations

The SELECTPRED procedure begins by excluding the following types of cases and predictors.

- Cases with a missing value for the dependent variable.
- Cases with missing values for all predictors.
- Predictors with missing values for all cases.
- Predictors with the same value for all cases.

A further screening step can be used to exclude the following types of predictors:

- Predictors with a large percentage of missing values.
- Categorical predictors with a large percentage of cases representing a single category.
- Categorical predictors with a large percentage of categories containing one case.
- Scale predictors with a small coefficient of variation (standard deviation divided by mean).

The univariable predictor selection method also ranks each predictor based on its association with the dependent variable and selects the top subset of predictors to use in subsequent modeling procedures. The ranking criterion that is used for any given predictor depends on the measurement level of the dependent variable as well as the measurement level of the predictor.

Note: Since measurement level can affect the results, if any variables (fields) have an unknown measurement level, an initial data pass will be performed to determine default measurement level for any variables with an unknown measurement level. For information on the criteria used to determine default measurement level, see SET SCALEMIN.

### Categorical dependent variable.

- For categorical predictors, the ranking criterion can be the Pearson chi-square p-value, likelihood ratio chi-square p-value, Cramér's *V*, or Lambda.
- For scale predictors, the F p-value from a one-way ANOVA is always used as the criterion.
- For mixed predictors, the categorical predictors use the chi-square p-value or the likelihood ratio chi-square p-value, and the scale predictors use the F p-value from a one-way ANOVA.

#### Scale dependent variable.

- For categorical predictors, the F p-value from a one-way ANOVA is always used as the criterion.
- For scale predictors, the p-value for a Pearson correlation coefficient is always used.
- For mixed predictors, both types of p-values are used, depending on the predictor type.

#### Frequency weight

If a WEIGHT variable is specified, its values are used as frequency weights by the SELECTPRED procedure.

- Cases with missing weights or weights that are less than 0.5 are not used in the analyses.
- The weight values are rounded to the nearest whole numbers before use. For example, 0.5 is rounded to 1, and 2.4 is rounded to 2.

#### Limitations

SPLIT FILE settings are ignored by the SELECTPRED procedure.

---

## Examples

```
SELECTPRED response_01
/EXCEPT VARIABLES=custid response_02 response_03
/MISSING USERMISSING=INCLUDE.
```

- This analysis specifies *response\_01* as the dependent variable.
- All other variables are to be considered as possible predictors, with the exception of *custid*, *response\_02*, and *response\_03*.
- User-missing values of categorical variables are treated as valid for the purpose of selecting predictors.
- All other settings fall back to their default values.

For discussion of output from this syntax and to place the example in context, see

---

## Variable lists

The variable lists specify the dependent variable, any categorical predictors (also known as factors), and any scale predictors (also known as covariates).

- The dependent variable must be the first specification on SELECTPRED.
- The dependent variable may not be the weight variable.
- The dependent variable may be followed by the measurement-level specification, which contains, in parentheses, the MLEVEL keyword followed by an equals sign and then S for scale, O for ordinal, or N for nominal. SELECTPRED treats ordinal and nominal dependent variables equivalently as categorical.
- If a measurement level is specified, it temporarily overrides the dependent variable's setting in the data dictionary.
- If no measurement level is specified, SELECTPRED defaults to the dictionary setting.
- If a measurement level is not specified, and no setting is recorded in the data dictionary, a numeric variable is treated as scale and a string variable is treated as categorical.
- A string variable may be defined as ordinal or nominal only.
- The names of the factors, if any, must be preceded by the keyword BY. If BY is specified with no factors, a warning is issued, and the keyword is ignored.

- The names of the covariates, if any, must be preceded by the keyword WITH. If WITH is specified without covariates, a warning is issued, and the keyword is ignored.
- If the dependent variable or the weight variable is specified within a factor list or a covariate list, the variable is ignored in the list.
- All variables that are specified within a factor or covariate list must be unique. If duplicate variables are specified within a list, the duplicates are ignored.
- If duplicate variables are specified across the factor and covariate lists, an error is issued.
- The universal keywords T0 and ALL may be specified in the factor and covariate lists.
- If neither BY nor WITH is specified, all variables in the active dataset except the dependent variable, the weight variable, and any variables that are specified on the EXCEPT subcommand, are treated as predictors. If the dictionary setting of a predictor is nominal or ordinal, the predictor is treated as a factor. If the dictionary setting is scale, the predictor is treated as a covariate.
- The dependent variable and factor variables can be numeric or string.
- The covariates must be numeric.

---

## EXCEPT subcommand

The EXCEPT subcommand lists any variables that the SELECTPRED procedure should exclude from the factor or covariate lists on the command line. This subcommand is useful if the factor or covariate lists contain a large number of variables—specified by using the T0 or ALL keyword, for example—but there are a few variables (for example, Case ID) that should be excluded.

- The EXCEPT subcommand ignores duplicate variables, the dependent variable, and variables that are not specified on the command line's factor or covariate lists.
- There is no default variable list on the EXCEPT subcommand.

---

## SCREENING subcommand

The SCREENING subcommand specifies settings for the screening step, which excludes unsuitable predictors.

**STATUS=option.** *Perform the screening step.* Valid options are ON or OFF. If OFF is specified, any other SCREENING specifications are ignored. The default value is ON.

**PCTMISSING=number.** *Percentage of missing values in a predictor.* If the percentage of cases representing a single category in a predictor is greater than the specified value, the predictor is excluded. The specified value must be a positive number that is less than or equal to 100. The default value is 70.

**PCTEQUAL=number.** *Percentage of cases representing a single category in a categorical predictor.* If the percentage of cases representing a single category in a predictor is greater than the specified value, the predictor is excluded. This setting applies only to categorical predictors. The specified value must be a positive number that is less than or equal to 100. The default value is 95.

**PCTUNEQUAL=number.** *Percentage of categories containing one case in a categorical predictor.* If the percentage of a predictor's categories containing only one case is greater than the specified value, the predictor is excluded. This setting applies only to categorical predictors. The specified value must be a positive number that is less than or equal to 100. The default value is 90.

**STDDEV=number.** *Minimum standard deviation for a scale predictor.* If the standard deviation is less than the specified value, the predictor is excluded. This setting applies only to scale predictors. The specified value must be a non-negative number. The default value is 0, which turns off the standard deviation check.

**CV=number.** *Coefficient of variation for a scale predictor.* A predictor's coefficient of variation is defined as its standard deviation divided by its mean. If the absolute value of the coefficient of variation is less than

the specified value, the predictor is excluded. This setting applies only to scale predictors and applies only if the mean is not equal to 0. The specified value must be a positive number. The default value is 0.001.

---

## CRITERIA subcommand

The CRITERIA subcommand specifies computational settings for the SELECTPRED procedure.

### SIZE keyword

The SIZE keyword specifies the number of predictors to select. Value AUTO indicates that the number should be computed automatically. Alternatively, a positive integer less than the number of unique predictors on the SELECTPRED command may be specified. AUTO is the default.

### RANKING keyword

The RANKING keyword specifies the ranking criterion that is used for categorical predictors if the target is categorical.

**PEARSONCHISQ.** *Rank predictors based on Pearson chi-square p-value.* Predictors are sorted in ascending order of Pearson chi-square p-values. This criterion is the default.

**LRCHISQ.** *Rank predictors based on likelihood ratio chi-square p-value.* Predictors are sorted in ascending order of likelihood ratio chi-square p-values.

**CRAMERSV.** *Rank predictors based on Cramer's V.* Predictors are sorted in descending order of Cramer's V. If this criterion is used when the target is categorical but predictors are mixed (that is, some categorical, some scale), the PEARSONCHISQ default is used instead.

**LAMBDA.** *Rank predictors based on Lambda (asymmetric).* Predictors are sorted in descending order of Lambda. If this criterion is used when the target is categorical but predictors are mixed; that is, some categorical, some scale, then the PEARSONCHISQ default is used instead.

### PCUTOFF keyword

The PCUTOFF keyword specifies the cutoff whenever a p-value is used as a ranking criterion. More particularly, if p-values are used to rank predictors, only those predictors for which the p-value is less than the PCUTOFF value may be selected. A positive number that is less than or equal to 1 may be specified. Specifying 1 turns off the limit on p-values. The default is 0.05.

### SHOWUNSELECTED keyword

The SHOWUNSELECTED keyword specifies a limit on the number of unselected predictors to display in tables and charts. If the specified number  $n$  is greater than 0, the top  $n$  unselected predictors are displayed. A non-negative integer may be specified. The default is 0.

### TIMER keyword

The TIMER keyword specifies the maximum number of minutes during which the SELECTPRED procedure can be run. If the time limit is exceeded, the procedure is terminated, and no results are given. Any number that is greater than or equal to 0 may be specified. Specifying 0 turns the timer off completely. The default is 5.

---

## MISSING Subcommand

The MISSING subcommand controls whether user-missing values for categorical variables are treated as valid values. By default, user-missing values for categorical variables are treated as invalid.

- User-missing values for scale variables are always treated as invalid.
- System-missing values for any variables are always treated as invalid.

**USERMISSING=EXCLUDE.** *User-missing values for categorical variables are treated as invalid. This setting is the default.*

**USERMISSING=INCLUDE.** *User-missing values for categorical variables are treated as valid values.*

---

## PRINT subcommand

The PRINT subcommand indicates the tabular output to display. If PRINT is not specified, the default tables are displayed. If PRINT is specified, only the requested tables are displayed.

CPS Keyword

The CPS keyword displays the case processing summary table, which summarizes the number of cases that are included and excluded in the analysis.

EXCLUDED keyword

The EXCLUDED keyword displays a table of screened predictors. The table lists screened predictors by type (categorical or scale) and reason for being screened. The table includes predictors that are screened due to missing or constant values for all cases, as well as any additional screening that is requested on the SCREENING subcommand.

SUMMARY keyword

The SUMMARY keyword displays a statistical summary of selected and unselected predictors. Selected predictors are always displayed. The maximum number of unselected predictors that can be displayed is determined by the SHOWUNSELECTED option on the CRITERIA subcommand.

The SUMMARY keyword may be followed, optionally, by one or more ranking criterion keywords in parentheses. When the target is categorical, and predictors are categorical or of mixed type, the RANKING option on the CRITERIA subcommand specifies the ranking criterion actually used by the algorithm to select predictors. The parenthesized list that follows the SUMMARY keyword displays additional ranking criteria for comparative purposes. The criterion that is actually used is always displayed, irrespective of whether it is specified following SUMMARY.

If a parenthesized list follows SUMMARY, then keywords in the list may be given in any order. If a specified keyword is inapplicable, it is ignored, and a warning is issued.

**PEARSONCHISQ.** *Display the Pearson chi-square statistics.*

**LRCHISQ.** *Display the likelihood ratio chi-square statistics.*

**CRAMERSV.** *Display the Cramer's V statistics.*

**LAMBDA.** *Display the Lambda statistics.*

SELECTED keyword

The `SELECTED` keyword displays a table of selected predictors by type (categorical or scale).

`NONE` keyword

The `NONE` keyword suppresses all tabular output except the Notes table and any warnings. This keyword may not be specified with any other keywords.

---

## **PLOT subcommand**

The `PLOT` subcommand and `SUMMARY` keyword display a chart that summarizes the selected and unselected predictors. Selected predictors are always displayed. The maximum number of unselected predictors that can be displayed is determined by the `SHOWUNSELECTED` option on the `CRITERIA` subcommand.

---

## Chapter 244. SET

*Note:* Square brackets used in the SET syntax chart are required parts of the syntax and are not used to indicate optional elements. All subcommands are optional.

SET

```

\*\* Default setting at installation.

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

## Release History

### Release 13.0

- RNG and MTINDEX subcommands introduced.
- Default for MXERRS subcommand increased to 100.
- SORT subcommand introduced.
- LOCALE subcommand introduced.

### Release 14.0

- Default for WORKSPACE subcommand increased to 6144.

### Release 15.0

- LABELS replaces VALUES as the default for the TNUMBERS subcommand.
- JOURNAL subcommand is obsolete and no longer supported.
- Value EXTERNAL added to list for SORT subcommand, replacing the value INTERNAL as the default. Value SS is deprecated.

### Release 16.0

- MCACHE subcommand introduced.
- THREADS subcommand introduced.
- UNICODE subcommand introduced.

### Release 16.0.1

- BOTHLARGE keyword introduced for the TFIT subcommand.

### Release 17.0

- FUZZBITS subcommand introduced.
- MIOUTPUT subcommand introduced.

### Release 18.0

- ROWSBREAK, CELLSBREAK, and TOLERANCE subcommands introduced for controlling display of large pivot tables.
- ZCOMPRESSION subcommand introduced.
- COMPRESSION subcommand is obsolete and ignored.
- REPDEFER subcommand introduced.

#### Release 19.0

- XVERSION subcommand introduced.
- OATTRS subcommand introduced.
- DIGITGROUPING subcommand introduced.
- TABLERENDER subcommand introduced.
- CMPTRANS subcommand introduced.

#### Release 20.0

- FAST keyword introduced for the TABLERENDER subcommand, replacing the LIGHT keyword, which is deprecated.
- Value BPortugu (Brazilian Portuguese) added to list for OLANG subcommand.

#### Release 21.0

- ODISPLAY subcommand introduced.

#### Release 22.0

- OSLOCALE keyword added to LOCALE subcommand.
- BASETEXTDIRECTION subcommand added.
- SUMMARY subcommand added.

#### Release 24.0

- LEADZERO subcommand added.

---

## Overview

Many of the running options in the program can be tailored to your own preferences with the SET command. The default settings for these options vary from system to system. To display the current settings, use the SHOW command. A setting that is changed by SET remains in effect for the entire working session unless changed again by another SET command. The PRESERVE command saves the current settings so that you can return to them later in the session by using the RESTORE command. PRESERVE and RESTORE are especially useful with the macro facility.

### Options

**Memory Management.** Use the WORKSPACE subcommand to dynamically allocate memory when some procedures indicate memory shortage. Use the MXCELLS subcommand to increase maximum cell numbers for a pivot table.

**Output Format.** Use the FORMAT subcommand to change the default (F8.2) print and write formats used for numeric variables. Use the TLOOK and CTEMPLATE subcommands to specify a TableLook file and/or a chart template file. (*Note:* TableLooks created in earlier versions of IBM SPSS Statistics cannot be used in version 16.0 or later.) Use the ONUMBERS, OVARs, TNUMBERS, and TVARS subcommands to define default display of variables in the outline or pivot tables. Use the TFIT subcommand to specify default column widths. Use the DIGITGROUPING subcommand to specify whether the current IBM SPSS Statistics locale's digit grouping format is applied to numeric values in pivot tables, charts, and Model Viewer items, as well as in the Data Editor.

**Samples and Random Numbers.** You can use the RNG, SEED, and MTINDEX subcommands to change the random number generator and initialization value.

**Output Destination.** You can use the ERRORS, MESSAGES, PRINTBACK, and RESULTS subcommands to send error messages, resource-utilization messages, command printback, and the output from your commands to your screen and/or to a file. You can also suppress each of these items by using the keyword NONE.

**Journal Files.** The JOURNAL subcommand is obsolete. You can only set the journal location via the Options dialog (Edit menu>Options>File Locations tab).

**Macro Displays.** You can use the MEXPAND, MITERATE, and MNEST subcommands to control macro expansion, the maximum number of loop iterations, and nesting levels within a macro. You can also use the MPRINT subcommands to control the display of the variables, commands, and parameters that a macro uses.

**Blanks and Undefined Input Data.** You can use the BLANKS subcommand to specify the value that the program should use when it encounters a completely blank field for a numeric variable. You can also use UNDEFINED to turn off the warning message that the program issues when it encounters an invalid value for a numeric variable.

**Maximum Warnings.** You can use MXWARNS to limit the warning messages for each set of commands that read the data, after which further warnings are suppressed.

**Maximum Loops.** You can use MXLOOPS to raise or lower the maximum number of iterations that are allowed for the LOOP-END LOOP structure.

**Scratch File Compression.** You can specify whether scratch files are kept in compressed or uncompressed form using the ZCOMPRESSION subcommand.

**Custom Currency Formats.** You can customize currency formats for your own applications using the CCA, CCB, CCC, CCD, and CCE subcommands. For example, you can display currency as French francs rather than American dollars.

**Cache File.** The CACHE subcommand creates a complete copy of the active data file in temporary disk space after a specified number of changes in the active data file. Caching the active data file can improve performance.

**Large Pivot Table Display.** The ROWSBREAK, CELLSBREAK, and TOLERANCE subcommands control the display of large pivot tables in the Viewer. By default, tables with many rows are displayed in sections of 100 rows. To turn off this feature and always display the complete table regardless of size, specify ROWSBREAK=NONE. See the topic “CELLSBREAK, ROWSBREAK, and TOLERANCE Subcommands” on page 1788 for more information.

## Basic Specification

The basic specification is at least one subcommand.

## Subcommand Order

Subcommands can be specified in any order.

## Syntax Rules

- You can specify as many subcommands as needed. Subcommands must be separated by at least one space or slash.
- Only one keyword or argument can be specified for each subcommand.

- SET can be used more than once in the command sequence.
- YES and ON are aliases for each other. NO and OFF are aliases for each other.

### Operations

- Settings that are specified on SET remain in effect until they are changed by another SET command or until the current session is ended.
- Each time that SET is used, only the specified settings are changed. All other settings remain at their previous settings or the default.
- Where filenames are specified, they must include the full path. Relative file specifications, file handles, and filenames without a path are not allowed.

---

## Example

```
SET BLANKS=0/UNDEFINED=NOWARN.
```

- BLANKS specifies 0 as the value that the program should use when it encounters a completely blank field for a numeric variable.
- UNDEFINED=NOWARN suppresses the message that is displayed whenever anything other than a number or a blank is encountered as the value for a numeric variable.

---

## BASETEXTDIRECTION Subcommand

The BASETEXTDIRECTION subcommand controls the direction for text flow. Individual words will still flow in the correct direction, based on the language. This option controls only the text flow for complete blocks of text (for example, all the text that is entered in an edit field).

AUTOMATIC. Text flow is determined by characters that are used in each word. This option is the default.

RIGHTTOLEFT. Text flows right to left.

LEFTTORIGHT. Text flows left to right.

---

## BLANKS Subcommand

BLANKS specifies the value that the program should use when it encounters a completely blank field for a numeric variable. By default, the program uses the system-missing value.

- BLANKS controls only the translation of numeric fields. If a blank field is read with a string format, the resulting value is a blank.
- The value that is specified on BLANKS is not automatically defined as a missing value.
- The BLANKS specification applies to all numeric variables. You cannot use different specifications for different variables.
- BLANKS must be specified before data are read. Otherwise, blanks in numeric fields are converted to the system-missing value (the default) as they are read.

---

## BLOCK Subcommand

BLOCK specifies the character that is used for drawing icicle plots.

- You can specify any single character either as a quoted string or as a quoted hexadecimal pair preceded by the character X.
- The default is X'2A'.

### Example

```
SET BLOCK='#'.
```

- This command specifies a pound sign (#) as the character to be used for drawing bar charts. The character is specified as a quoted string.

---

## BOX Subcommand

BOX specifies the characters that are used to draw table borders in text output. The specification is either a 3-character or 11-character quoted string, in which the characters have the following representations: 1=horizontal line, 2=vertical line, 3=middle (cross), 4=lower left corner, 5=upper left corner, 6=lower right corner, 7=upper right corner, 8=left T, 9=right T, 10=Top T, 11=bottom T.

- The characters can be specified either as a quoted string or hexadecimal pairs. Specify an X before the quoted hexadecimal pairs.
- The defaults vary from system to system. To display the current settings, use the SHOW command.

---

## CACHE Subcommand

The CACHE subcommand creates a complete copy of the active data file in temporary disk space after a specified number of changes in the active data file. If you have the available disk space, this feature can improve performance. The default number of changes that can occur before the active file is cached is 5.

Example

```
SET CACHE 10.
```

---

## CCA, CCB, CCC, CCD, and CCE Subcommands

You can use the subcommands CCA, CCB, CCC, CCD, and CCE to specify up to five custom currency formats.

- Each custom currency subcommand defines one custom format and can include four specifications in the following order: a negative prefix, a prefix, a suffix, and a negative suffix.
- The specifications are delimited by either periods or commas, whichever you do not want to use as a decimal point in the format.
- If your custom currency format includes periods or commas that you need to distinguish from delimiters, use a single quotation mark as an escape character before the period or comma that is part of the custom currency format. For example, if the format includes a period but the decimal indicator is a comma, the period must also be used as the delimiter.
- Each currency specification must always contain three commas or three periods. All other specifications are optional.
- Use blanks in the specification only where you want blanks in the format.
- The entire specification must be enclosed in single or double quotation marks. If the format includes a single quotation mark as an escape character, the entire specification must be enclosed in double quotation marks.
- A specification cannot exceed 16 characters (excluding the apostrophes).
- Custom currency formats cannot be specified as input formats on DATA LIST. Use them only as output formats in the FORMATS, WRITE FORMATS, PRINT FORMATS, WRITE, and PRINT commands.

Specifying a Custom Currency Format

```
SET CCA='-,$,,'.
```

- A minus sign (-) preceding the first command is used as the negative prefix.
- A dollar sign is specified for the prefix.
- No suffixes are specified (there are two consecutive commas before the closing apostrophe).
- Because commas are used as separators in the specification, the decimal point is represented by a period.

Specifying Multiple Custom Currency Formats

```
SET CCA='(,,-)' CCB='(,%,)' CCC='(,$,)' CCD='-/-..Df1 ..-'.
FORMATS VARA(CCA9.0)/ VARB(CCB6.1)/ VARC(CCC8.0)/ VARD(CCD14.2).
```

- SET defines four custom currency formats.
- FORMATS assigns these formats to specific variables.

Table 85. Custom currency examples

	CCA	CCB	CCC	CCD
negative prefix	(	none	(	-/-
prefix	none	none	\$	Dfl
suffix	none	%	none	none
negative suffix	-)	none	)	-
separator	,	,	,	.
sample positive number	23,456	13.7%	\$352	Dfl 37.419,00
sample negative number	(19,423-)	13.7%	(\$189)	-/-Dfl 135,19-

---

## CELLSBREAK, ROWSBREAK, and TOLERANCE Subcommands

These subcommands control the display of large pivot tables in the Viewer. These settings have no effect on printing large pivot tables or exporting output to external formats with command such as OUTPUT EXPORT or OMS. They also have no effect on tables rendered with the fast tables engine.

**CELLSBREAK=n.** Sets the maximum number of cells to display. The default is 10000. The value must be an integer between 1000 and 100000. If ROWSBREAK=NONE, this setting is ignored.

**ROWSBREAK=n | NONE.** Sets the number of rows to display. The default is 100. The value must be an integer between 10 and 1000 or the keyword NONE, which turns off this feature and displays the entire table, regardless of size. When the feature is on and large tables are displayed in sections, navigation controls allow you to view different sections of the table.

**TOLERANCE=n.** Controls the maximum number of rows of the inner most row dimension of the table to split across displayed views of the table. For example, if there are six categories in each group of the inner most row dimension, specifying a value of six would prevent any group from splitting across displayed views. The value must be an integer and cannot be greater than the ROWSBREAK value. If ROWSBREAK=NONE, this setting is ignored.

Several factors can affect the actual number of rows displayed, including:

- If the CELLSBREAK value is reached before the ROWSBREAK value, then the table is split at that point. For example, if ROWSBREAK=1000 and CELLSBREAK=10000, a table with 20 columns will be displayed in blocks of 500 rows.
- The TOLERANCE setting can cause fewer or more rows than the ROWSBREAK value to be displayed.

---

## CMPTRANS Subcommand

*Note:* This command works only if you are connected to the IBM SPSS Statistics Server running on Windows Server.

CMPTRANS interacts with a setting on the IBM SPSS Statistics Server to determine whether transformation commands (such as COMPUTE and RECODE) are compiled to machine code when a syntax job is run.

- If the administrator of the IBM SPSS Statistics Server turns on compiled transformations with the IBM SPSS Statistics Server setting *and* CMPTRANS is set to YES, transformation commands are compiled to machine code when the syntax job is run. The compiled code is used for the subsequent execution of the transformations.
- If the administrator does not turn on compiled transformations, a warning message is displayed and the command is ignored.

- Compiling transformations may improve performance when there are a large number of cases and multiple transformation commands.
- Because there is an overhead involved in compiling the transformations, you should set CMPTRANS to YES only when there are a large number of cases and multiple transformation commands.
- CMPTRANS has no effect on transformation commands enclosed in INPUT PROGRAM and END INPUT PROGRAM commands.

**YES.** *Compile transformations to machine code.*

**NO.** *Do not compile transformations to machine code.*

---

## CTEMPLATE and TLOOK Subcommands

TLOOK and CTEMPLATE specify a file that is used to define the table and chart appearance in the output. The default for either command is NONE, which produces tables and charts that use the system defaults.

- TLOOK determines the properties of output tables that are produced. The properties include the borders, placement of titles, column and row labels, text font, and column and cell formats. (*Note:* TableLooks created in earlier versions of IBM SPSS Statistics cannot be used in version 16.0 or later.)
- CTEMPLATE determines the properties of output charts and plots. The properties include line style, color, fill pattern, and text font of relevant chart elements (such as frames, titles, labels, and legends).
- The specification on TLOOK or CTEMPLATE remains in effect until a new TLOOK or CTEMPLATE is specified.

**NONE.** *Use the system defaults.* The tables and charts in the output do not use customized properties.

**filename.** *Use the specified file as a template for tables/charts in the output.* For TLOOK you should specify a full path, enclosed in quotes (Directory settings on the CD and INSERT commands do not apply to the template file location for TLOOK).

---

## DECIMAL Subcommand

DECIMAL can be used to override the default decimal indicator for reading and writing text data. The default decimal indicator is the OS locale decimal indicator or the decimal indicator for the locale specified on the LOCALE subcommand.

**DOT.** The decimal indicator is a period.

**COMMA.** The decimal indicator is a comma.

- A subsequent LOCALE subcommand—either on the same or separate SET command—will override the DECIMAL setting. See the topic “LOCALE Subcommand” on page 1792 for more information.
- This setting only affects reading and writing text data. It has no effect on how data values are displayed in the Data Editor or in results displayed in the Viewer.

---

## DEFOLANG Subcommand

The DEFOLANG subcommand specifies the default output language (if the language that is specified on the OLANG subcommand is not available). The initial default setting is the language of the installed software version. For example, if you install the English version of the software on a Japanese operating system, the default output language is English.

Example

```
SET DEFOLANG = JAPANESE.
```

- The language keyword is not case-sensitive.
- Do *not* enclose the language keyword in quotation marks or other string delimiters.

---

## DIGITGROUPING Subcommand

DIGITGROUPING specifies whether the current IBM SPSS Statistics locale's digit grouping format will be applied to numeric values in pivot tables and charts as well as in the Data Editor. For example, in a French locale, with DIGITGROUPING set to YES the value 34419,57 is displayed as 34 419,57.

The grouping format does not apply to trees, Model Viewer items, numeric values with the DOT or COMMA format, or numeric values with a DOLLAR or custom currency format. It does, however, apply to the display of the days value for numeric values with a DTIME format--for example, to the value of ddd in the format ddd hh:mm.

**YES.** *Apply the current locale's digit grouping format.*

**NO.** *Do not apply the current locale's digit grouping format. This is the default.*

---

## EPOCH Subcommand

EPOCH defines the 100-year-span dates that are entered with two-digit years and date functions with a two-digit year specification.

**AUTOMATIC.** *100-year span beginning 69 years prior to the current date and ending 30 years after the current date.*

**begin year.** *First year of the 100-year span.*

Examples

SET EPOCH=1900.

- All dates that are entered with two-digit year values are read as years between 1900 and 1999. For example, a date that is entered as 10/29/87 is read as 10/29/1987.

SET EPOCH=1980.

- Dates that are entered with two-digit year values between 80 and 99 are read as years between 1980 and 1999.
- Dates that are entered with two-digit year values between 00 and 79 are read as years between 2000 and 2079.

---

## ERRORS, MESSAGES, RESULTS, and PRINTBACK Subcommands

ERRORS, MESSAGES, RESULTS, and PRINTBACK are used with keywords LISTING and NONE to route program output. ERRORS, MESSAGES, and RESULTS apply only to text output. PRINTBACK applies to all commands that are entered in a syntax window or generated from a dialog box during a session.

- ERRORS refers to both error messages and warning messages for text output.
- MESSAGES refers to resource-utilization messages that are displayed with text output, including the heading and the summaries (such as the amount of memory that is used by a command).
- RESULTS refers to the text output that is generated by program commands.
- PRINTBACK refers to command printback in the log in the Viewer window and in the journal file. Syntax is always displayed as part of the Notes in the syntax window.

**LISTING.** *Display output in the designated output window.* This alias is ON or YES. For PRINTBACK, the alias is BOTH. The executed commands are printed back in the journal and displayed in the log in the output window. You can either display an icon only or list all commands.

**NONE.** *Suppress the output.* The alias is NO or OFF.

---

## EXTENSIONS Subcommand

This subcommand is no longer supported.

---

## FORMAT Subcommand

FORMAT specifies the default print and write formats for numeric variables. This default format applies to numeric variables that are defined on DATA LIST in freefield format and to all numeric variables that are created by transformation commands (unless a format is explicitly specified).

- The specification must be a simple F format. The default is F8.2.
- You can use the PRINT FORMATS, WRITE FORMATS, and FORMATS commands to change print and write formats.
- Format specifications on FORMAT are output formats. When specifying the width, enough positions must be allowed so that any punctuation characters, such as decimal points, commas, and dollar signs, can be included.
- If a numeric data value exceeds its width specification, the program still attempts to display some value. The program rounds decimal values, removes punctuation characters, tries scientific notation, and finally, if there is still not enough space, produces asterisks indicating that a value is present but cannot be displayed in the assigned width.

---

## FUZZBITS Subcommand

FUZZBITS specifies the default setting of the *fuzzbits* argument for the RND and TRUNC functions. The value controls the number of least-significant bits by which the internal representation of the value to be rounded or truncated (expressed as a 64-bit floating point binary) may fall short of the nearest rounding boundary and be rounded up. See the topic “Arithmetic functions” on page 66 for more information.

- The value must be an integer between 0 and 20. The default is 6, which should be sufficient for most applications.
- A value of 0 produces the same results as in release 10. A value of 10 produces the same results as in releases 11 and 12.
- The FUZZBITS setting persists across sessions.

---

## HEADER Subcommand

HEADER controls whether the output includes headings. The HEADER subcommand applies to both default headings and headings that are specified on the TITLE and SUBTITLE commands. This command applies only to text output from this program. The default is NO.

**NO.** *Suppress headings in text output.* All general headings, including pagination, are replaced by a single blank line.

**YES.** *Display headings in text output.*

**BLANK.** *Suppress headings but start a new page.*

---

## JOURNAL Subcommand

This subcommand is obsolete and no longer supported. To set the location of the journal file, which contains a log of submitted commands and error and warning messages that are generated during a session, and turn the journal on and off:

1. From the menus in any IBM SPSS Statistics window, choose:  
**Edit > Options**
2. On the File Locations tab, specify the journal location and select journal options.

---

## LEADZERO Subcommand

LEADZERO specifies whether leading zeros are displayed for numeric values that consist only of a decimal part. For example, when leading zeros are displayed, the value .123 is displayed as 0.123.

- The LEADZERO setting does not apply to numeric values that have a currency or percent format.
- With the exception of fixed ASCII files (\*.dat), leading zeros are not included when the data are saved to an external file.

**NO** Do not display leading zeros. This setting is the default.

**YES** Display leading zeros.

---

## LENGTH and WIDTH Subcommands

LENGTH and WIDTH specify the maximum page length and width for the text output, respectively. These two subcommands apply only to text output.

- Length represents number of lines, and width represents number of characters.
  - You can specify any length from 40 through 999,999 lines. If a long page length is specified, the program continues to provide page ejects and titles at the start of each procedure and at logical points in the display, such as between crosstabulations.
  - To suppress page ejects, use keyword NONE on LENGTH. The program will insert titles at logical points in the display but will not supply page ejects.
  - You can specify any number of characters from 80 through 255 for WIDTH.
- 

## LOCALE Subcommand

The LOCALE subcommand allows you to change the locale used for data analysis. By default, the locale is set to the computer's system locale if possible. With the LOCALE subcommand, you can override the default behavior and process data files in other locales without changing your computer's system or user locale.

- The default locale is the current operating system locale.
- The LOCALE subcommand persists. The next time that IBM SPSS Statistics is started on your computer, IBM SPSS Statistics will run in that locale.
- The OSLOCALE keyword sets the locale to the operating system locale. The application gets this information from the operating system each time you start the application. This is the default.
- If the locale ID does not match the system locale, not all output will be rendered correctly.
- In code page mode, locale changes that also change the encoding can only be made when there are no open datasets. For information on code page mode and Unicode mode, see "UNICODE Subcommand" on page 1801.
- You can use SHOW LOCALE to view the current IBM SPSS Statistics locale.

### Example

```
SET LOCALE='Japanese'.
```

- When you are connecting to a server, the relevant locale ID is defined in the *loclmap.xml* file, which is located on the server computer. Check with your server administrator for available locale IDs.
- Locale ID values of the general form *Language\_Country.codepage#*, which were valid in previous releases, are not valid in release 16.0 or later. In most instances, the "Language" portion of the old locale specification should be a valid locale ID in release 16.0 or later. For example, instead of 'Japanese\_Japan.932', you could specify simply 'Japanese'. For a complete list of names and aliases that can be used to specify locale, go to <http://www.iana.org/assignments/character-sets>

Two-letter language abbreviations adhere to the ISO 639-1 standard:

Two-letter country codes adhere to the ISO 3166 standard: [http://en.wikipedia.org/wiki/ISO\\_3166-1](http://en.wikipedia.org/wiki/ISO_3166-1)

### Example

```
SET LOCALE='ja_JP.Shift_JIS'
```

- "ja" is the two-letter language code for Japanese.
- "JP" is the two-letter country code for Japan.
- "Shift\_JIS" is the name of the character set.

---

## MCACHE Subcommand

The MCACHE subcommand specifies the memory cache (in kilobytes) that multithreaded procedures use when calculating results. By default, IBM SPSS Statistics uses an internal algorithm to determine the memory cache for a particular computer. You can change this setting, but the default will often provide the best performance. The default also appears as the recommended setting when you run the SHOW command.

Using the memory cache is relevant only if your computer has multiple processors or each processor has multiple cores. Also, this setting affects only selected procedures that take advantage of it. These are:

- CORRELATIONS
- DISCRIMINANT
- FACTOR
- NOMREG
- PARTIAL CORR
- REGRESSION

*Note:* PRESERVE and RESTORE do not operate on this subcommand.

---

## MEXPAND and MPRINT Subcommands

MEXPAND and MPRINT control whether macros are expanded and whether the expanded macros are displayed. For more information about macros, see the DEFINE command and .

The specifications for MEXPAND are:

**ON.** *Expand macros.* This setting is the default.

**OFF.** *Do not expand macros.* The command line that calls the macro is treated like any other command line. If the macro call is a command, it will be executed; otherwise, it will trigger an error message.

The specifications for MPRINT are:

**ON.** *Include expanded macro commands in the output.*

**OFF.** *Exclude expanded macro commands from the output.* This is the default.

- MPRINT is effective only when MEXPAND is ON and is independent of the PRINTBACK subcommand.

---

## MIOUTPUT Subcommand

MIOUTPUT specifies the display of pooled output when a multiply imputed dataset is analyzed.

**OBSERVED.** *Show results for observed data.*

**IMPUTED.** *Show results for each imputed dataset.*

**POOLED.** *Show final pooled statistics.*

**DIAGNOSTICS.** *Display pooling diagnostics for parameters pooled by the univariate method.*

- At least one keyword must be specified in square brackets. If a keyword is not specified the corresponding output is suppressed.
- DIAGNOSTICS is ignored with a warning if POOLED is not specified.
- All options are on by default.
- The MIOUTPUT setting persists across sessions. It is ignored by tables that do not support splits. It is also ignored when analysis is performed without variable *Imputation\_* defined as a split variable.
- MIOUTPUT has no effect on charts or PMML.

See the topic for more information.

---

## MITERATE and MNEST Subcommands

MITERATE and MNEST control the maximum loop traversals and the maximum nesting levels permitted in macro expansions, respectively.

- The specification on MITERATE or MNEST is a positive integer. The default for MITERATE is 1000. The default for MNEST is 50.

---

## MTINDEX, RNG, and SEED Subcommands

Two random number generators are available. The generator that is currently in effect is set by the RNG subcommand:

**RNG=MC.** *The random number generator that is used in version 12 and previous releases. If you need to reproduce randomized results that were generated in previous releases based on a specified seed value, use this random number generator. This setting is the default.*

**RNG=MT.** *Mersenne Twister random number generator. This generator is a newer random number generator that is more reliable for simulation purposes. If reproducing randomized results from version 12 or earlier is not an issue, use this random number generator.*

If you need to reproduce the same randomized results in the future, you can set the initialization value for the random number generator. The initialization value applies to the current session only. It is automatically reset to the default at the start of each new session.

**SEED={integer | RANDOM}.** *Initialization value for MC random number generator. The value must be a positive integer that is less than 2,000,000,000 or the keyword RANDOM, which randomly sets the initialization value. The default is 2,000,000.*

**MTINDEX={value | RANDOM}.** *Initialization value for the MT random number generator. The value can be any positive or negative value, including fractional values (expressed as decimals), or the keyword RANDOM. The default is 2,000,000.*

Example

SET RNG=MT MTINDEX=-12345.678.

Some procedures have internal random number generators, including:

Chapter 139, "LINEAR," on page 1013

Chapter 109, "GENLINMIXED," on page 781

---

## MXCELLS and WORKSPACE Subcommands

WORKSPACE allocates more memory for some procedures when you receive a message indicating that the available memory has been used up or indicating that only a given number of variables can be processed. MXCELLS increases the maximum number of cells you can create for a new pivot table when you receive a warning that a pivot table cannot be created because it exceeds the maximum number of cells that are allowed.

- WORKSPACE allocates workspace memory in kilobytes for some procedures that allocate only one block of memory. The default and minimum value is 24576.
- Do not increase the workspace memory allocation unless the program issues a message that there is not enough memory to complete a procedure.
- Use MXCELLS with caution. Set MXCELLS at a number higher than the limit indicated in the warning message that you receive. After the table is created, restore the number to the default.
- The memory-allocation or cell maximum number increase takes effect as soon as you run the SET command.

*Note:* The MXMEMORY subcommand is no longer supported.

---

## MXERRS Subcommand

MXERRS controls the maximum number of errors that are allowed in a session. The default is 100.

- MXERRS applies only to command files that are submitted for execution through IBM SPSS Statistics Batch Facility (available with IBM SPSS Statistics Server).
- Eligible errors are errors that stop execution of a command but continue the session.
- When the MXERRS limit is exceeded, IBM SPSS Statistics stops processing commands but continues to scan for additional errors.
- In interactive mode or in IBM SPSS Statistics and other windowed environments, MXERRS does not apply.

---

## MXLOOPS Subcommand

MXLOOPS specifies the maximum number of times that a loop that is defined by the LOOP-END LOOP structure is executed for a single case or input record. The default is 40.

- MXLOOPS prevents infinite loops, which may occur if no cutoff is specified for the loop structure (see LOOP-END LOOP).
- MXLOOPS will limit the number of loops for any loop structure that doesn't have an indexing clause, including loops with conditional IF clauses. If a loop has an indexing clause (e.g., LOOP #i=1 to 1000), the indexing clause overrides the MXLOOPS setting.
- When a loop is terminated, control passes to the command immediately following the END LOOP command, even if the END LOOP condition is not yet met.

---

## MXWARNS Subcommand

MXWARNS controls the number of warnings that are issued. The default is 10. The behavior of this setting depends on mode of operation: interactive or IBM SPSS Statistics Batch Facility. In this context, "interactive" includes any mode of operation other than IBM SPSS Statistics Batch Facility.

**Interactive.** In interactive mode, MXWARNS limits the number of warnings that are issued for each set of commands that read the data (for example, a group of transformation commands followed by a statistical procedure).

- Exceeding the limit does not halt execution of commands; it simply suppresses further warnings.
- MXWARNS=0 suppresses all warnings except a warning that further warnings have been suppressed.
- MXWARNS does not affect the display of error messages, and errors do not count toward the warning limit.

**Batch Facility.** In the Batch Facility (available with IBM SPSS Statistics Server), MXWARNS limits the total number of warnings that are allowed in a job.

- When the MXWARNS limit is exceeded, IBM SPSS Statistics stops processing commands but continues to scan for errors.
- When the combined total number of warnings and errors exceeds the MXWARNS limit, IBM SPSS Statistics stops processing commands but continues to scan for errors.

---

## OATTRS and XVERSION Subcommands

XVERSION and OATTRS control aspects of OXML and SAV output from the Output Management System (OMS).

- XVERSION specifies the version of the Output XML schema used to generate OXML output from OMS.
- OATTRS specifies whether language invariant versions of text attributes are included in OXML and whether variable names in datasets generated from SAV output are in English. When specified, the English value of a text attribute is stored in the text\_eng attribute which either replaces the text attribute or is in addition to it. The text\_eng attribute allows you to write XPath expressions in a language invariant manner. See the topic for more information.

*Note:* The settings specified by XVERSION and OATTRS apply to subsequent OMS requests.

The specifications for XVERSION are:

**DEFAULT.** Use the schema associated with the version of IBM SPSS Statistics from which the SET command is executed. This is the default.

**'version'** . A quoted string specifying the output schema version--for example, '1.6'. The version string is the value of the version attribute of the xs:schema element from the associated output schema file. You can specify the version for any of the installed output schema files. Output schema files are located in the IBM SPSS Statistics installation folder.

The specifications for OATTRS are:

**OLANG.** The text\_eng attribute is not included in OXML output and variable names in datasets generated from SAV output are translated into the current output language (when available). This is the default.

**ENG.** The text attribute is replaced (other than in cell elements) with a text\_eng attribute whose value is the English value of the text attribute. Variable names in datasets generated from SAV output will be in English. The value ENG requires that the output schema version in use is 1.6 or higher, which is satisfied by the default setting of the XVERSION subcommand.

**BOTH.** A `text_eng` attribute is added to each element (other than a cell element) that has a text attribute. The value of the `text_eng` attribute is the English value of the text attribute. Variable names in datasets generated from SAV output will be in English. The value BOTH requires that the output schema version in use is 1.6 or higher, which is satisfied by the default setting of the XVERSION subcommand.

---

## ODISPLAY Subcommand

For procedures that can generate either Model Viewer output or pivot table and chart output, ODISPLAY specifies which type of output is generated. For version 25, ODISPLAY only applies to output from the Generalized Linear Mixed Models procedure (GENLINMIXED command) and the Nonparametric Tests procedure (NPTESTS command).

**MODELVIEWER.** Specifies that Model Viewer output will be generated.

**TABLES.** Specifies that pivot table and chart output will be generated. This is the default.

---

## OLANG Subcommand

The OLANG subcommand controls the language that is used in output. OLANG does not apply to simple text output. Available languages may vary. (The General tab in the Options dialog box displays a list of available output languages.) Valid language keywords include English, French, German, Spanish, Italian, Japanese, Korean, TChinese (traditional Chinese), SChinese (simplified Chinese), Polish, Russian, and BPortugu (Brazilian Portuguese).

Output that is produced after the command is executed will be in the specified language (if that language is available). Additional language materials may be available for downloading from the IBM Corp. web site.

Depending on the language, you may also need to switch to UNICODE mode or change the LOCALE setting to match the output language for characters to render properly.

### Example

```
SET OLANG = German.
```

- The language keyword is not case-sensitive.
  - Do *not* enclose the language keyword in quotation marks or other string delimiters.
- 

## ONUMBERS, OVARS, TNUMBERS, and TVARS Subcommands

ONUMBERS, OVARS, TNUMBERS, and TVARS control how variables are displayed in the outline for pivot table output and in the pivot tables.

- ONUMBERS controls the display of variable values in the outline for pivot tables. The default is LABELS.
- OVARS controls the display of variables in the outline for pivot tables. The default is LABELS.
- TNUMBERS controls the display of variable values and/or value labels in the pivot tables. The default is LABELS.
- TVARS controls the display of variable names and/or variable labels in the pivot tables. The default is LABELS.

**NAMES.** Display variable names.

**VALUES.** Display variable values.

**LABELS.** Display variable labels.

**BOTH.** Display both labels and values for variables or both names and labels for variables.

---

## REPDEFER Subcommand

REPDEFER specifies whether REPOSITORY CONNECT commands (connection requests to an IBM SPSS Collaboration and Deployment Services Repository) are deferred until a connection is required.

**YES.** *Defer connection requests until a connection is required.* This is the default when executing command syntax with the IBM SPSS Statistics Batch Facility (available with IBM SPSS Statistics Server).

**NO.** *Attempt to connect when a REPOSITORY CONNECT command is encountered.* This is the default unless executing command syntax with the IBM SPSS Statistics Batch Facility.

---

## SCALEMIN Subcommand

For IBM SPSS Statistics data files that were created prior to release 8.0 and data read from external sources, you can specify the minimum number of data values for a numeric variable that is used to classify the variable as continuous (scale) or nominal. Variables with fewer than the specified number of unique values are classified as nominal. All string variables are classified as nominal, regardless of the number of unique values.

There are numerous other conditions that are evaluated prior to applying the minimum number of data values rule when determining to apply the continuous (scale) or nominal measurement level. Conditions are evaluated in the order listed in the table below. The measurement level for the first condition that matches the data is applied.

*Table 86. Rules for determining default measurement level*

Condition	Measurement Level
Format is dollar or custom-currency	Continuous
Format is date or time (excluding Month and Wkday)	Continuous
All values of a variable are missing	Nominal
Variable contains at least one non-integer value	Continuous
Variable contains at least one negative value	Continuous
Variable contains no valid values less than 10,000	Continuous
Variable has $N$ or more valid, unique values*	Continuous
Variable has no valid values less than 10	Continuous
Variable has less than $N$ valid, unique values*	Nominal

\*  $N$  is the user-specified cut-off value. The default is 24.

---

## SMALL Subcommand

The SMALL subcommand controls the display of numbers in scientific notation in pivot tables for small decimal values.

This setting only affects output with the "general" format, which is determined by the application. This setting does not affect the display of significance levels or other statistics with a standard range of values. The format of many numeric values in pivot tables is based on the format of the variable associated with the numeric value.

### Example

```
SET SMALL = 0.
```

```
SET SMALL = .001.
```

- The first SET SMALL command suppresses the display of scientific notation in all output that uses the general format.
- The second SET SMALL command will only display scientific notation for values that are less than 0.001.

---

## **SORT Subcommand**

By default, IBM SPSS Statistics tries to use an external, third-party sorting mechanism, which may reduce processing time with large data sources. The third-party sorting option is available only if you have IBM SPSS Statistics Server. The specific sorting engine is defined by your server administrator. If you are not connected to the IBM SPSS Statistics Server or the IBM SPSS Statistics Server cannot find the third-party sort engine, the built-in sorting mechanism is used.

**EXTERNAL.** *Use the external, third-party sort engine if available.* This setting is the default. If the third-party sort engine is not available, this setting is ignored, and the built-in sorting mechanism is used. COXREG and CURVEFIT use built-in sorting regardless of the SORT setting.

**INTERNAL.** *Use the built-in sorting mechanism.*

**SS.** This setting is deprecated. It has the same effect as EXTERNAL.

---

## **SUMMARY Subcommand**

The SUMMARY subcommand adds comments to pivot tables.

- Comment text is displayed in a tooltip when you hover over a table in the Viewer.
- Screen readers read the comment text when the table has focus.
- The tooltip in the Viewer displays only the first 200 characters of the comment, but screen readers read the entire text.
- When you export output to HTML or a web report, the comment text is used as alt text.

The keyword is followed by an equals sign and the keyword NONE or a quoted value. The default option is NONE. You can also include special variables to insert date, time, and other values.

### **)DATE**

Current date in the form dd-mmm-yyyy.

### **)ADATE**

Current date in the form mm/dd/yyyy.

### **)SDATE**

Current date in the form yyyy/mm/dd.

### **)EDATE**

Current date in the form dd.mm.yyyy.

**)TIME** Current 12-hour clock time in the form hh:mm:ss.

### **)ETIME**

Current 24-hour clock time in the form hh:mm:ss.

### **)TITLE**

The text of the outline label for the table.

### **)PROCEDURE**

The name of the procedure that created the table.

### **)DATASET**

The name of the dataset used to create the table.

**\n** Inserts a line break.

---

## TABLERENDER Subcommand

You can specify whether tables are rendered as legacy tables. Legacy tables may render slowly and are only recommended if you require compatibility with IBM SPSS Statistics releases prior to 20. For release 20 and higher, all tables have full support for pivoting and editing.

- Tables, other than legacy tables, created in IBM SPSS Statistics release 20 or later and lightweight tables in output documents that are modified in release 20 or later (but created in release 19) cannot be viewed in releases prior to 19.0.0.2. Such tables are viewable in release 19.0.0.2, where they are rendered as lightweight tables; however, they may not render the same as in release 20 or later.
- Lightweight tables created in IBM SPSS Statistics release 19 automatically have full support for pivoting and editing in release 20 or later.

**FAST.** *Tables render much faster than legacy tables.* This is the default.

**FULL.** *Tables are rendered as legacy tables.*

**LIGHT.** This setting is deprecated. It has the same effect as FAST.

---

## TFIT Subcommand

TFIT controls the default column widths of the pivot tables. The default at installation is BOTH.

**BOTH.** *Adjust column widths to accommodate both labels and data.*

**LABELS.** *Adjust column widths to accommodate labels only.* This setting produces compact tables, but data values that are wider than labels may be truncated.

**BOTHLARGE.** *Adjust column widths to accommodate both labels and data, except for very large tables.* For very large tables (more than 10,000 cells), column widths are adjusted to accommodate labels only, and data values that are wider than the column labels may be truncated. *Note:* For tables that are not rendered as legacy tables, this setting is equivalent to BOTH.

---

## THREADS Subcommand

The THREADS subcommand specifies the number of threads that multithreaded procedures use when calculating results. By default, IBM SPSS Statistics uses an internal algorithm to determine the number of threads for a particular computer. You can change this setting, but the default (THREADS=AUTO) will often provide the best performance. The default also appears as the recommended setting when you run the SHOW command.

In local analysis mode, any changes to the setting persist across sessions until you explicitly change the setting to a different value. In distributed analysis mode (available with IBM SPSS Statistics Server), the setting does not persist across sessions, and the default value is AUTO. Any changes to the setting in distributed analysis mode remain in effect only for the duration of the current session. In distributed analysis mode, the maximum number of threads can be limited by the administrator.

Using more than one thread is relevant only if your computer has multiple processors or each processor has multiple cores. Also, this setting affects only selected procedures that take advantage of it. These are:

- CORRELATIONS
- CSCOXREG
- CSLOGISTIC
- CSORDINAL
- CSSELECT
- DISCRIMINANT

- FACTOR
- NOMREG
- PARTIAL CORR
- REGRESSION
- SIMRUN
- SORT CASES

*Note:* PRESERVE and RESTORE do not operate on this subcommand.

---

## UNDEFINED Subcommand

UNDEFINED controls whether the program displays a warning message when it encounters anything other than a number or a blank as the value for a numeric variable. The default is WARN.

**WARN.** *Display a warning message when an invalid value is encountered for a numeric variable. This setting is the default.*

**NOWARN.** *Suppress warning messages for invalid values.*

---

## UNICODE Subcommand

SET UNICODE NO|YES controls the default behavior for determining the encoding for reading and writing data files and syntax files.

**NO.** *Use the current locale setting to determine the encoding for reading and writing data and command syntax files. This is referred to as **code page mode**. The alias is OFF. For information on the current locale setting, see “LOCALE Subcommand” on page 1792.*

**YES.** *Use Unicode encoding (UTF-8) for reading and writing data and command syntax files. This is referred to as **Unicode mode**. The alias is ON. This is the default.*

- You can change the UNICODE setting only when there are no open data sources.
- The UNICODE setting persists across sessions and remains in effect until it is explicitly changed.

There are a number of important implications regarding Unicode mode and Unicode files:

- Data and syntax files saved in Unicode encoding should not be used in releases prior to 16.0.
- When code page data files are read in Unicode mode, the defined width of all string variables is tripled. You can use ALTER TYPE to automatically adjust the width of all string variables.
- The GET command determines the file encoding for IBM SPSS Statistics data files from the file itself, regardless of the current mode setting (and defined string variable widths in code page files are tripled in Unicode mode). See the topic Chapter 111, “GET,” on page 811 for more information.
- For syntax files, the encoding is changed *after* execution of the block of commands that includes SET UNICODE. For example, if you are currently in code page mode, you must run SET UNICODE=YES separately from subsequent commands that contain Unicode characters not recognized by the local encoding in effect prior to switching to Unicode.

---

## ZCOMPRESSION Subcommand

*Note:* This command works only if you are connected to the IBM SPSS Statistics Server.

ZCOMPRESSION is an override mechanism that works with a setting on the IBM SPSS Statistics Server to determine whether scratch files that are created during a session are in compressed or uncompressed form. Scratch files are created by CACHE, SORT, AGGREGATE, transformations, and any other procedure that adds columns to the data file.

- The administrator of the IBM SPSS Statistics Server must give you permission to override the IBM SPSS Statistics Server setting. If you don't have permission, a warning message is displayed and the command is ignored.
- A compressed scratch file reduces the amount of disk I/O compared to an uncompressed scratch file but requires more processing on the IBM SPSS Statistics Server.
- The extra overhead associated with compression is considerably greater when writing than reading a file. Consider using a higher value for SET CACHE to reduce the frequency of writing new scratch files containing the entire data set. A higher SET CACHE value will also increase the number of times a scratch file is read.
- If you are working with a very large data file (larger than half of the Server's RAM) and compression is on, you may consider issuing an explicit CACHE command before running other procedures. Doing this will ensure the procedures take full advantage of the disk I/O benefits.
- The override specification takes effect the next time that a scratch file is written and stays in effect until SET ZCOMPRESSION is specified again or until the end of the session.
- The default setting for compressing scratch files is set on the IBM SPSS Statistics Server. There is no syntax default.

**YES.** *Compress scratch files.*

**NO.** *Do not compress scratch files.*

---

## Chapter 245. SHIFT VALUES

```
SHIFT VALUES VARIABLE=varname RESULT=varname {LEAD=non-negative integer}
                                                {LAG=non-negative integer }
                                                {SHIFT=integer          }
[/VARIABLE=varname...]
```

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Release History

Release 17.0

- Command introduced.

### Example

```
SHIFT VALUES VARIABLE=01dVar RESULT=NewVar LEAD=1.
```

---

## Overview

The SHIFT VALUES command creates new variables that contain the values of existing variables from preceding or subsequent cases.

### Basic Specification

The basic specification is the command name followed by:

**VARIABLE=varname.** This must be a variable that already exists in the active dataset.

**RESULT=newname.** This must be a variable that does not currently exist in the active dataset.

One of the following alternative shift methods:

- **LEAD=n.** Get the value from a subsequent case in the dataset. The value must be a non-negative integer that indicates the number of cases. For example, LEAD=1 returns the value of the existing variable from the case immediately following the current case.
- **LAG=n.** Get the value from a preceding case in the dataset. The value must be a non-negative integer that indicates the number of cases. For example, LAG=1 returns the value of the existing variable from the case immediately before the current case.
- **SHIFT=n.** Get the value from a preceding or subsequent case. The value must be an integer that indicates the number of cases. For example, SHIFT=1 returns the value of the existing variable from the case immediately following the current case, and SHIFT=-1 returns the value of the existing variable from the case immediately before the current case.

To specify more than one variable on the same command, use a forward slash (/) to separate the full specification for each subsequent variable.

### Syntax Rules

- The RESULT keyword must specify a new variable name. The name cannot be a variable that already exists in the active dataset. For information on variable naming rules, see “Variable Names” on page 46.
- Each keyword must be followed by an equals sign (=) before the value. For example, RESULT=NewVar.

### Operations

- If split file processing is on, the scope of the shift is limited to each split group. A shift value cannot be obtained from a case in a preceding or subsequent split group.
- Filter status is ignored.
- The value of the result variable is set to system-missing for the first or last  $n$  cases in the dataset or split group, where  $n$  is the number of cases specified on LEAD, LAG, or SHIFT. For example, LAG=1 would set the result variable to system-missing for the first case in the dataset (or first case in each split group).
- A value of 0 for number of cases will copy the value of the original value to the same case for the new variable.
- User-missing values are preserved.
- Dictionary information from the original variable, including defined value labels and user-missing value assignments, is applied to the new variable. (Note: Custom variable attributes are not included.)
- A variable label is automatically generated for the new variable that describes the shift operation that created the variable.

### Example

```
DATA LIST FREE /Var1 (F1).
BEGIN DATA
0 1 9 0 1
END DATA.
VARIABLE LABEL Var1 'Original Variable'.
VALUE LABELS Var1 0 'No' 1 'Yes' 9 'Missing'.
MISSING VALUES Var1(9).
SHIFT VALUES VARIABLE=Var1 RESULT=Var1_Lead LEAD=1
/VARIABLE=Var1 RESULT=Var1_Lag LAG=1
/VARIABLE=Var1 RESULT=Var1_Shift SHIFT=-1.
```

Var1	Var1_Lead	Var1_Lag	Var1_Shift
0	1	.	.
1	9	0	0
9	0	1	1
0	1	9	9
1	.	0	0

Figure 86. Results displayed in Data View

Name	Type	Width	Decimals	Label	Values	Missing
Var1	Numeric	1	0	Original Variable	{0, No}...	9
Var1_Lead	Numeric	1	0	Lead(Var1,1)	{0, No}...	9
Var1_Lag	Numeric	1	0	Lag(Var1,1)	{0, No}...	9
Var1_Shift	Numeric	1	0	Shift(Var1,-1)	{0, No}...	9

Figure 87. Dictionary information displayed in Variable View

---

## Chapter 246. SHOW

SHOW [ALL] [BASETEXTDIRECTION] [BLANKS] [BOX] [BLOCK] [CC] [CCA] [CCB]  
[CCC] [CCD] [CCE] [CACHE] [CTEMPLATE] [DECIMAL] [DEFOLANG] [DIGITGROUPING]  
[DIRECTORY] [ENVIRONMENT] [EPOCH] [ERRORS] [EXTPATHS] [FILTER] [FORMAT] [FUZZBITS]  
[HANDLES] [HEADER] [LEADZERO] [LENGTH] [LICENSE] [LOCALE] [MESSAGES] [MEXPAND] [MIOOUTPUT]  
[MITERATE] [MNEST] [MPRINT] [MXCELLS] [MXERRS] [MXLOOPS] [MXWARNS]  
[N] [OATTRS] [ODISPLAY] [OLANG] [ONUMBERS] [OVARs] [PLUGINS] [PRINTBACK] [REPDEFER] [RESULTS]  
[RNG] [SCALEMIN] [SCOMPRESSION] [SEED] [SMALL] [SORT] [SPLIT] [SYSMIS] [TABLERENDER]  
[TFIT] [TLOOK] [TMSRECORDING] [TNUMBERS] [TVARS] [UNDEFINED] [UNICODE] [VERSION]  
[WEIGHT] [WIDTH] [WORKSPACE] [XVERSION] [ZCOMPRESSION] [\$VARS]

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Release History

#### Release 13.0

- BLKSIZE and BUFNO subcommands are obsolete and no longer supported.
- HANDLES subcommand introduced.
- SORT subcommand introduced.

#### Release 15.0

- TMSRECORDING subcommand introduced.

#### Release 16.0

- UNICODE subcommand introduced.
- MCACHE subcommand introduced.
- THREADS subcommand introduced.

#### Release 17.0

- FUZZBITS subcommand introduced.

#### Release 18.0

- EXTPATHS subcommand introduced.
- ZCOMPRESSION subcommand introduced.
- COMPRESSION subcommand removed because it is obsolete.
- REPDEFER subcommand introduced.

#### Release 19.0

- TABLERENDER subcommand introduced.
- XVERSION subcommand introduced.
- OATTRS subcommand introduced.
- DIGITGROUPING subcommand introduced.
- CMPTRANS subcommand introduced.

#### Release 21.0

- ODISPLAY subcommand introduced.

Release 22.0

- PLUGINS subcommand introduced.

Release 24.0

- LEADZERO subcommand introduced.

Example

SHOW.

---

## Overview

SHOW displays current settings for running options. Most of these settings can be changed by using the SET command.

### Basic Specification

The basic specification is simply the command keyword, which displays important current settings (keyword ALL). Some displayed option settings are applicable only when you have options such as Tables and Categories.

### Subcommand Order

Subcommands can be named in any order.

### Syntax

- If any subcommands are specified, only the requested settings are displayed.
- SHOW can be specified more than once.

---

## Example

SHOW BLANKS /UNDEFINED /MXWARNS.

- BLANKS shows the value to which a completely blank field for a numeric variable is translated.
- UNDEFINED indicates whether a message is displayed whenever the program encounters anything other than a number or a blank as the value for a numeric variable.
- MXWARNS displays the maximum number of warnings that are allowed before a session is terminated.

---

## Subcommands

The following alphabetical list shows the available subcommands.

**ALL.** Display important settings that are applicable to your system. This setting is the default.

**BASETEXTDIRECTION.** The direction for text flow. The setting is AUTOMATIC, RIGHTTOLEFT, or LEFTTORIGHT. The default setting is AUTOMATIC

**BLANKS.** Value to which a blank field for a numeric variable is translated. The default is the system-missing value.

**BOX.** Characters that are used to draw boxes. Both character and hexadecimal representations are displayed. The default is X'2D7C2B2B2B2B2B2B2B2B'. This setting applies only to text output from the program.

**BLOCK.** Character that is used to draw bar charts. Both character and hexadecimal representations are displayed. The default is X'2A'. This setting applies only to the text output from the program.

**CC.** Custom currency formats. CC shows the current custom currency formats that are defined for CCA, CCB, CCC, CCD, and CCE on SET. In Windows environments, the formats reflect the Regional Settings Properties. You can also request any of these keywords individually.

**CACHE.** Cache active data file. This setting shows the number of changes in the active data file before a cache file is created. The default is 5.

**CMPTTRANS.** Override IBM SPSS Statistics Server setting for compiled transformations. The setting is either ON or OFF (alias YES or NO). There is no default because the default behavior is determined by the IBM SPSS Statistics Server.

**CTEMPLATE.** Chart template file. The setting is either NONE or a file name.

**DECIMAL.** Decimal indicator. This setting indicates the current character that is used as the decimal indicator. DOT indicates that a period is the decimal indicator; COMMA indicates that a comma is the decimal indicator.

**DEFOLANG.** Default output language. This setting indicates the default output language to use if the language that is specified on the OLANG subcommand is not available. The initial default setting is the language version of the installed software.

**DIGITGROUPING.** Whether the current IBM SPSS Statistics locale's digit grouping format is applied to numeric output. The setting is YES (alias ON) or NO (alias OFF). The default is NO.

**DIRECTORY.** Default directory. This setting indicates the root directory that is used to determine the locations of files that are specified with no paths or relative paths. A wide variety of actions can change the current default directory during a session.

**ENVIRONMENT.** Operating system and computer information. This setting includes information about environment variables, defined paths, and domain.

**EPOCH.** Range of years for date-format variables and date functions that are entered with a two-digit year value. AUTOMATIC indicates a 100-year range that begins 69 years before the current year and 30 years after the current year.

**ERRORS.** Error messages for text output. The setting can be LISTING (alias YES or ON) or NONE (alias NO or OFF).

**EXTENSIONS.** No longer supported.

**EXTPATHS.** Displays the locations for installing and searching for custom dialogs, extension commands, and R packages. When more than one location exists, location 1 takes precedence over location 2, and so on. The location R\_HOME (in R\_HOME\library) specifies the directory where R is installed.

**FILTER.** Filter status. This setting indicates whether filtering is in effect (FILTER command) and indicates the filter variable that is in use (if any).

**FORMAT.** Default print and write formats for numeric variables that are defined on DATA LIST in freefield format and all numeric variables that are created by transformation commands. The default is F8.2.

**FUZZBITS.** Default setting of the fuzzbits argument for the RND and TRUNC functions. The default is 6.

HANDLES. Displays a list of all file handles currently in effect. File handles are created with the FILE HANDLE command.

HEADER. Headings for text output. The setting is YES, NO, or BLANK. The default is NO.

JOURNAL. No longer supported.

LEADZERO. Whether leading zeros are displayed for numeric values that consist only of a decimal part. The setting is either YES or NO.

LENGTH. Maximum page length for output. The default is 59. This setting applies only to the text output from the program.

LICENSE. Licensed components, expiration date, release number, and maximum number of users who are allowed by the license.

LOCALE. Operating system locale setting and code page. In Windows operating systems, locale is set in the Regional Options of the Control Panel.

MCACHE. Memory cache size in kilobytes. The default and recommended setting are based on your specific hardware.

MESSAGES. Resource-utilization messages for text output. The setting can be LISTING (alias YES or ON) or NONE (alias NO or OFF).

MEXPAND. Macro expansion. The setting is either ON (alias YES) or OFF (alias NO). The default is ON.

MIOOUTPUT. Displays the settings for pooled output when a multiply imputed dataset is analyzed.

MITERATE. Maximum loop iterations that are allowed in macro expansions. The default is 1000.

MNEST. Maximum nesting level for macros. The default is 50.

MPRINT. Inclusion of expanded macros in the output. The setting is either ON (alias YES) or OFF (alias NO). The default is OFF.

MXCELLS. Maximum number of cells that are allowed for a new pivot table. The default is AUTOMATIC, which allows the number to be determined by the available memory.

MXERRS. Maximum number of errors that are allowed and number of errors so far in current session. In most implementations of IBM SPSS Statistics, the maximum number of errors that are defined on SET MXERRS is ignored. However, the information that SHOW MXERRS provides about number of errors in the current session can be useful.

MXLOOPS. Maximum executions of a loop on a single case. The default is 40.

MXMEMORY. No longer supported.

MXWARNS. Maximum number of warnings and errors that are shown for text output. The default is 10.

N. Unweighted number of cases in the active dataset. N displays UNKNOWN if there is no active dataset. N cannot be changed with SET.

OATTRS. Whether OXML and SAV output from OMS contains English-only attribute values and English-only variable names respectively. The setting is OLANG, ENG, or BOTH. The default is OLANG.

ODISPLAY. Displays what type of output is generated for procedures that can generate either Model Viewer output or pivot table and chart output. The setting is MODELVIEWER or TABLES. The default is MODELVIEWER. For version 25, ODISPLAY applies only to output from the Generalized Linear Mixed Models procedure (GENLINMIXED command).

OLANG. Output language for pivot tables.

ONUMBERS. Display of variable values in the outline for pivot tables. The settings can be LABELS, VALUES, and BOTH.

OVARs. Display of variables as headings. The settings can be LABELS, NAMES, and BOTH.

PLUGINS. Displays which programmability plug-ins are installed. For Python and R, the path to the Python or R home directory is also shown.

PRINTBACK. Command print back. The setting can be BOTH (alias LISTING, YES, or ON) or NONE (alias NO or OFF). The default is BOTH at system installation.

REPDEFER. Whether connection requests to an IBM SPSS Collaboration and Deployment Services Repository are deferred until needed. The setting is YES (alias ON) or NO (alias OFF). The default is NO unless you are running command syntax with the IBM SPSS Statistics Batch Facility (available with IBM SPSS Statistics Server), in which case the default is YES.

RESULTS. Output from commands. This setting is not applicable to output that is displayed in pivot tables. The setting can be LISTING (alias YES or ON) or NONE (alias NO or OFF).

RNG. Random number generator. Indicates which random number generator is being used.

SCALEMIN. For data files that were created in versions before version 8.0, the minimum number of unique values for a numeric variable that is used to classify the variable as scale. This setting affects only data files created in versions before version 8.0 that are opened in later versions.

SCOMPRESSION . Compression of IBM SPSS Statistics data files. This setting can be overridden by the COMPRESSED or UNCOMPRESSED subcommands on the SAVE or XSAVE commands. The default setting varies by system. SCOMPRESSION cannot be changed with SET.

SEED. Seed for the random-number generator. The default is generally 2,000,000 but might vary by system.

SMALL. Decimal value to control display of scientific notation in output.

SORT. Sorting mechanism that is in effect: IBM SPSS Statistics or external, third-party (if available).

SPLIT. Split file status.

SYSMIS. The system-missing value. SYSMIS cannot be changed with SET.

TABLERENDER. Method for rendering tables. The settings can be FULL or LIGHT. Lightweight tables render faster but cannot be pivoted or edited.

TFIT. Adjust column widths in pivot tables. The settings can be BOTH (label and data) and LABELS.

THREADS. Number of threads. The default and recommended setting are based on your specific hardware.

TLOOK. Pivot table template file. The setting can be either NONE or a file name.

TMSRECORDING. TMS recording status. Yes indicates that a TMS block for writing transformations to PMML is in effect. No indicates that TMS is not currently in effect. For more information, see Chapter 271, "TMS BEGIN," on page 1979.

TNUMBERS. Display of variable values in pivot tables. The settings can be VALUES, LABELS, and BOTH.

TVARS. Display of variables as headings. The settings can be NAMES, LABELS, and BOTH.

UNDEFINED. Warning message for undefined data. YES is the value that is associated with the default setting of SET UNDEFINED=WARN.NO is the value that is associated with SET UNDEFINED=NOWARN, which suppresses messages but does not alter the count of warnings toward the MXWARNS total.

UNICODE. Unicode mode status. The setting is either YES (alias ON) or NO (alias OFF).

VERSION. Version number and creation date.

WEIGHT. Variable that is used to weight cases. WEIGHT can be specified for SHOW only and cannot be changed with SET.

WIDTH. Maximum page width for the output. The default is 132 columns for batch mode and 80 for interactive mode. This setting applies only to text output from the program.

WORKSPACE. Special workspace memory limit in kilobytes. The default is 6148.

XVERSION. Version of Output XML schema that is used to generate OXML output from OMS. The setting is DEFAULT or the version number (if the version differs from the default one). The default is the value DEFAULT.

ZCOMPRESSION . Override Server setting for compression of scratch files. The setting is either ON or OFF (alias YES or NO). There is no default because the default behavior is determined by the IBM SPSS Statistics Server.

\$VARS. Values of system variables. \$VARS cannot be changed with SET.

---

## Chapter 247. SIMPLAN

SIMPLAN is available in the Statistics Base Edition.

```
SIMPLAN CREATE [SOURCE=AUTOFIT** | 'filespec']
```

```
[/MODEL
  FILE='filespec'
  [CUSTOM={YES }
    {NO**}]

[/TARGETOPTS

SIMPLAN CREATE reads the active dataset and causes execution of any pending transformations.

### Display an existing plan

```

SIMPLAN VIEW
/PLAN FILE='filespec'

```

SIMPLAN VIEW causes execution of any pending transformations.

\*\* Default if the subcommand or keyword is omitted.

### Release History

#### Release 21.0

- Command introduced.

#### Release 22.0

- LOCK keyword introduced on FIXEDINPUT subcommand.
- CONTINGENCY subcommand added.
- CONTINGENCY keyword added to specifications for CATEGORICAL distribution on SIMINPUT subcommand.
- Added global SOURCE keyword and deprecated SOURCE keyword for DISTRIBUTION=EMPIRICAL.
- MISSING subcommand added.
- VALUELABELS subcommand added.

### Example

```

SIMPLAN CREATE
/MODEL FILE='/models/mymodel.xml'
/SIMINPUT INPUT=labor materials
/PLAN FILE='/simulations/myplan.splan'.

SIMPLAN VIEW
/PLAN FILE='/simulations/myplan.splan'.

```

---

## Overview

The SIMPLAN command creates a simulation plan that contains all of the specifications required to run a simulation. The simulation plan is used as input to the SIMRUN command, which runs the simulation.

Simulation in IBM SPSS Statistics refers to simulating input data to predictive models, evaluating the model based on the simulated data and using the distribution of predicted target values to evaluate the likelihood of various outcomes. Inputs to the model are specified as fixed or simulated. Values for simulated inputs are drawn from a specified probability distribution. Fixed inputs are those whose values

are known and remain constant when evaluating the model. The simulation plan specifies the model to be simulated, probability distributions for simulated inputs and values for fixed inputs, as well as various other settings.

You can also simulate data in the absence of a predictive model by specifying probability distributions for variables that are to be simulated. The simulation plan then specifies those probability distributions, as well as various other settings.

## Options

**Probability distributions for simulated inputs.** You can automatically determine the probability distribution that most closely fits the data, in the active dataset, associated with each simulated input. You can also manually specify distributions if historical data are not available or you require specific distributions.

**Correlations.** You can automatically determine correlations between simulated inputs from historical data for each input in the active dataset. You can also manually specify correlations between simulated inputs if historical data are not available or you require specific correlations.

**Associations for categorical inputs.** You can automatically compute a multiway contingency table, from the historical data, that describes the associations between inputs with a categorical distribution. The contingency table is then used when generating data for those inputs.

**Input and target filtering.** You can specify the valid range of values for both simulated inputs and targets. For simulated inputs, only values in the specified range will be used in simulated data. For targets, values outside of the specified range are excluded from all output and analyses.

**Specify sensitivity analysis.** Sensitivity analysis allows you to investigate the effect of systematic changes in a fixed input or in a distribution parameter for a simulated input by generating an independent set of simulated data—effectively, a separate simulation—for each specified value.

**Stopping criteria.** You can specify criteria for stopping the simulation, potentially before the maximum number of allowable cases of simulated data have been generated. In particular, you can specify to continue generating cases until the confidence interval of the mean of a target is within a specified threshold, or you can specify to continue generating cases until one of the tails of a target has been sampled to a specified degree.

## Creating a simulation plan that includes a predictive model

The basic specification is the SIMPLAN command with the CREATE keyword, followed by the MODEL subcommand, one or more SIMINPUT subcommands for simulated inputs and the PLAN subcommand specifying where the simulation plan should be saved.

## Creating a simulation plan without a predictive model

The basic specification is the SIMPLAN command with the CREATE keyword, followed by one or more SIMINPUT subcommands for simulated inputs and the PLAN subcommand specifying where the simulation plan should be saved.

## Displaying an existing plan

The basic specification is the SIMPLAN command with the VIEW keyword, followed by the PLAN subcommand which specifies the simulation plan to be displayed.

## Syntax rules

- The PLAN subcommand, and at least one SIMINPUT subcommand are required. All other subcommands are optional.
- Subcommands can be specified in any order.
- There can be multiple instances of SIMINPUT, FIXEDINPUT, TARGETOPTS, and VALUETAGS subcommands. Only a single instance of any other subcommand is allowed.
- A keyword cannot be specified more than once within a subcommand.
- Only one SIMINPUT subcommand can specify iterations of distribution parameters.
- If multiple input fields are specified for a SIMINPUT subcommand, then you cannot specify iterations of distribution parameters for that subcommand.
- Only one FIXEDINPUT subcommand can contain the ITERATIONS keyword.
- If multiple input fields are specified for a FIXEDINPUT subcommand, then the subcommand cannot contain the ITERATIONS keyword.
- If a FIXEDINPUT subcommand contains the ITERATIONS keyword, then iterations of distribution parameters cannot be specified for a SIMINPUT subcommand.
- Parentheses, equals signs, and slashes shown in the syntax chart are required.
- The command name, subcommand names, and keywords must be spelled in full.
- Empty subcommands are not allowed.

#### Limitations

- SPLIT FILE is ignored by this command.

---

## Examples

### Automatically fitting distributions and correlations

```
SIMPLAN CREATE
/MODEL FILE='/models/sales_model.xml'
/SIMINPUT INPUT=advert agents cci(MAPTO=confidence_index)
/PLAN FILE='/simulations/sales.splan'.
```

- The MODEL subcommand specifies the model file. Since the CUSTOM keyword is omitted, the model file is assumed to be an IBM SPSS model file (an XML file that contains model PMML created from IBM SPSS Statistics or IBM SPSS Modeler).
- The SIMINPUT subcommand specifies that the model fields *advert*, *agents* and *cci* are simulated inputs. Since the TYPE keyword on SIMINPUT is omitted, the default of TYPE=AUTOFIT is used. This results in automatically finding the distribution that most closely fits the data in the active dataset associated with each of the simulated inputs.
- The MAPTO keyword for the specification of *cci* indicates that *cci* maps to the field named *confidence\_index* in the active dataset. Data for *confidence\_index* will then be used to find the closest fitting distribution for *cci*.
- Since the CORRELATIONS subcommand is omitted, correlations between the simulated inputs will be determined from the data for those inputs in the active dataset. The mapping of the model field *cci* to the dataset field *confidence\_index* applies to calculations of correlations, as well as to distribution fitting.
- The PLAN subcommand specifies that the simulation plan will be saved to the file */simulations/sales.splan*.

### Manually specifying distributions

```
SIMPLAN CREATE
/MODEL FILE='/models/profitmodel.xml' CUSTOM=YES
/SIMINPUT INPUT=volume
  TYPE=MANUAL DISTRIBUTION=TRIANGULAR(MIN=5000 MAX=7500 MODE=6250)
/SIMINPUT INPUT=unit_cost_materials
  TYPE=MANUAL DISTRIBUTION=TRIANGULAR(MIN=10 MAX=15 MODE=13)
/FIXEDINPUT INPUT=price VALUE=89
/FIXEDINPUT INPUT=fixed VALUE=7500
/FIXEDINPUT INPUT=unit_cost_labor VALUE=14
/PLAN FILE='/simulations/profitmodel.splan'.
```

- The setting `CUSTOM=YES` on the `MODEL` subcommand specifies that this is a custom model created from a `SIMPREP BEGIN-SIMPREP END` block.
- The setting `TYPE=MANUAL` on the two `SIMINPUT` subcommands specifies that the probability distributions for *volume* and *unit\_cost\_materials* will be explicitly specified. The `DISTRIBUTION` keyword specifies that both inputs have Triangular distributions.
- The three `FIXEDINPUT` subcommands specify that the model inputs *price*, *fixed* and *unit\_cost\_labor* are fixed inputs. The `VALUE` keyword specifies the fixed value.

### Specifying sensitivity analysis for a fixed input

```
SIMPLAN CREATE
/MODEL FILE='/models/profitmodel.xml' CUSTOM=YES
/SIMINPUT INPUT=volume
  TYPE=MANUAL DISTRIBUTION=TRIANGULAR(MIN=5000 MAX=7500 MODE=6250)
/SIMINPUT INPUT=unit_cost_materials
  TYPE=MANUAL DISTRIBUTION=TRIANGULAR(MIN=10 MAX=15 MODE=13)
/FIXEDINPUT INPUT=price VALUE=89
/FIXEDINPUT INPUT=fixed VALUE=7500
/FIXEDINPUT INPUT=unit_cost_labor ITERATIONS=VALUES(14 17 19)
/PLAN FILE='/simulations/profitmodel.splan'.
```

- The `ITERATIONS` keyword on the `FIXEDINPUT` subcommand for *unit\_cost\_labor* specifies that sensitivity analysis will be carried out and will be based on varying values of this fixed input. The `VALUES` keyword specifies the three values 14, 17 and 19. An independent set of simulated data will be generated for each of these three values of *unit\_cost\_labor*.

### Generating data without a predictive model

```
SIMPLAN CREATE
/SIMINPUT INPUT=age glucose income
/PLAN FILE='/simulations/diabetes_data.splan'.
```

- The `SIMINPUT` subcommand specifies that data are to be generated for the variables *age*, *glucose* and *income*. Since the `TYPE` keyword on `SIMINPUT` is omitted, the default of `TYPE=AUTOFIT` is used. This results in automatically finding the distribution that most closely fits the data in the active dataset associated with each of the variables.
- Since the `CORRELATIONS` subcommand is omitted, correlations between the specified variables will be determined from the data for those variables in the active dataset.
- The `PLAN` subcommand specifies that the simulation plan will be saved to the file */simulations/diabetes\_data.splan*.

---

## MODEL subcommand

The `MODEL` subcommand specifies the file containing the model that is to be simulated. You can specify an IBM SPSS model file (an XML file or a compressed file archive (.zip file) that contains model PMML created from IBM SPSS Statistics or IBM SPSS Modeler) or a file created from a `SIMPREP BEGIN-SIMPREP END` block. `SIMPREP BEGIN-SIMPREP END` blocks create a model, for use with `SIMPLAN`, based on a set of custom equations that you define.

**FILE = 'filespec'.** *Specifies the model file.* File specifications should be enclosed in quotation marks and fully qualified paths are recommended to avoid ambiguity. The file is assumed to be a model file unless it has an extension of `.splan`, in which case it is treated as a simulation plan file from which the model file will be extracted.

*Note:* The optional combination of an asterisk (\*) and a backslash (\) preceding the model file name specifies that the file is a temporary file. This only applies in the case that `SIMPLAN CREATE` follows a `SIMPREP BEGIN-SIMPREP END` block. See the topic “`OUTFILE` subcommand” on page 1829 for more information.

**CUSTOM = YES | NO.** *Specifies whether the model consists of a set of custom equations.* Models for sets of custom equations are created using a `SIMPREP BEGIN-SIMPREP END` block. The default is `NO`, which specifies that the model was not created by a `SIMPREP BEGIN-SIMPREP END` block.

## PMML models supported by Simulation

- Linear Regression
- Automatic Linear Model
- Generalized Linear Model
- Generalized Linear Mixed Model
- General Linear Model
- Binary Logistic Regression
- Multinomial Logistic Regression
- Ordinal Multnomial Regression
- Cox Regression
- Tree
- Boosted Tree (C5)
- Discriminant
- Two-step Cluster
- K-Means Cluster
- Neural Net
- Ruleset (Decision List)

### Note:

- PMML models that have multiple target fields (variables) or splits are not supported for use in Simulation.
- Values of string inputs to binary logistic regression models are limited to 8 bytes in the model. If you are fitting such string inputs to the active dataset, make sure that the values in the data do not exceed 8 bytes in length. Data values that exceed 8 bytes are excluded from the associated categorical distribution for the input, and are displayed as unmatched in the Unmatched Categories output table.

---

## TARGETOPTS subcommand

The TARGETOPTS subcommand specifies optional settings for targets.

### TARGET keyword

The TARGET keyword specifies names and optional settings for one or more targets. The TARGET keyword is required when TARGETOPTS is specified. The specification for each target is the field name with an optional qualifier of the form (FORMAT=format), where the parentheses are required. Use a blank space to separate specifications for multiple targets. For example:

```
TARGET=target1(FORMAT=DOLLAR) target2(FORMAT=F,4)
```

- **FORMAT.** *Specifies the output format of the field.* The format consists of a format type, such as F, optionally followed by a comma and the number of decimal places. If the number of decimal places is omitted then it is assumed that there are 0 decimal places. The following formats are supported:

Table 87. Format specifications.

Format Specification	Definition
F,d	Numeric
E,d	Scientific notation
N,d	Restricted numeric
DOT,d	Numeric with dots
COMMA,d	Numeric with commas

Table 87. Format specifications (continued).

Format Specification	Definition
DOLLAR,d	Numeric with commas and dollar sign
PCT,d	Numeric with percent sign
CCA,d	Custom currency
CCB,d	Custom currency
CCC,d	Custom currency
CCD,d	Custom currency
CCE,d	Custom currency

If no format is specified, then the Numeric format F is used for numeric inputs.

**COMMENT = 'string'.** Specifies a description that will be associated with the targets listed on the *TARGET* keyword. Use separate *TARGETOPTS* subcommands for targets requiring different descriptions. The *COMMENT* keyword is only supported for models with *CUSTOM=YES* on the *MODEL* subcommand. Comments are displayed on the Model tab of the Simulation Builder, when the simulation plan has been loaded into the Simulation Builder.

**OUTPUT.** Specifies whether the targets listed on the *TARGET* keyword are included in table and chart output. The default is YES.

*TARGETFILTER* keyword

The *TARGETFILTER* keyword specifies a filter to apply to the specified targets. The filter allows you to specify the range of valid values for one or more targets. Values outside of the specified range are excluded from all output and analyses associated with the targets.

- **MIN.** Specifies the minimum value for the range. You can use the keywords *L0* or *LOWEST*. The default is *L0*. By default, the value specified for *MIN* is included in the range. You can exclude the value from the range by using the *EXCLUSIVE* keyword.
- **MAX.** Specifies the maximum value for the range. You can use the keywords *HI* or *HIGHEST*. The default is *HI*. By default, the value specified for *MAX* is included in the range. You can exclude the value from the range by using the *EXCLUSIVE* keyword.

---

## SIMINPUT subcommand

The *SIMINPUT* subcommand specifies input fields whose values will be simulated. It is a required subcommand. When the *MODEL* subcommand is used, each input in the associated model file must be specified as either simulated or fixed. Use the *FIXEDINPUT* subcommand to specify fixed inputs.

*INPUT* keyword

The *INPUT* keyword specifies names and optional settings for one or more simulated inputs. The *INPUT* keyword is required. The specification for each input is the field name with an optional qualifier of the form (*MAPTO=name FORMAT=format*), where the parentheses are required. Use a blank space to separate specifications for multiple inputs. The keywords *T0* and *ALL* are not supported for variable lists specified on the *INPUT* keyword. For example:

```
INPUT=input1(MAPTO=field1 FORMAT=F,4) input2(FORMAT=DOLLAR)
```

- **MAPTO.** *Maps a simulated field to a field in the active dataset.* The MAPTO keyword is only needed when you are automatically fitting to data in the active dataset and the name of a simulated field differs from the name of the associated field in the active dataset. The value of MAPTO should be the name of the field in the active dataset.
- **FORMAT.** *Specifies the output format of the field.* The format consists of a format type, such as F, optionally followed by a comma and the number of decimal places. If the number of decimal places is omitted then it is assumed that there are 0 decimal places. The following formats are supported:

Table 88. Format specifications.

Format Specification	Definition
F,d	Numeric
E,d	Scientific notation
N,d	Restricted numeric
DOT,d	Numeric with dots
COMMA,d	Numeric with commas
DOLLAR,d	Numeric with commas and dollar sign
PCT,d	Numeric with percent sign
CCA,d	Custom currency
CCB,d	Custom currency
CCC,d	Custom currency
CCD,d	Custom currency
CCE,d	Custom currency

If no format is specified, then the Numeric format F is used for numeric inputs.

**OUTPUT.** *Specifies whether the inputs listed on the INPUT keyword are included in table and chart output.* The default is YES.

#### TYPE keyword

The TYPE keyword specifies whether the probability distribution for this simulated input field is determined by automatically fitting to the data for this field in the active dataset or by manually specifying the distribution.

- **MANUAL(LOCK = YES | NO SAVEASFITTED = YES | NO).** *Indicates that the probability distribution is manually specified.* When MANUAL is specified, the DISTRIBUTION keyword must be used unless the global SOURCE keyword specifies a simulation plan file (for more information, see the topic “SOURCE Keyword” on page 1827).

The LOCK keyword specifies whether the distribution for this simulated input field will be locked. Locked distributions will not be modified when automatically fitting distributions interactively in the user interface, using the Simulation Builder or the Run Simulation dialog. If you are creating a simulation plan that you or someone else will work with in the user interface and you want to prevent refitting a simulated input to historical data, then be sure to specify LOCK=YES for that input. Users who open the plan in the Run Simulation dialog will not be able to make any modifications to the distribution of the input. Users who open the plan in the Simulation Builder will be able to make changes to the distribution once they unlock the input.

The SAVEASFITTED keyword occurs when pasting syntax for a simulated input whose distribution was automatically fitted to historical data and then locked in the user interface. The keyword allows the state of the input to be stored in the plan file so that it can be restored in the user interface when re-opening the plan file. The default is SAVEASFITTED=NO.

- **AUTOFIT.** Indicates that the probability distribution associated with this input field will be automatically determined from the data for the associated field in the active dataset. By default, the measurement level of the field is used to determine the set of distributions that are considered.

For nominal input fields, the default set of distributions only includes the categorical distribution.

For ordinal input fields, the default set of distributions includes the following: binomial, negative binomial and Poisson. The chi-square test is used to determine the distribution that most closely fits the data.

For continuous input fields, the default set of distributions includes the following: beta, exponential, gamma, lognormal, normal, triangular, uniform and Weibull. By default, the Anderson-Darling test for goodness of fit is used to determine the distribution that most closely fits the data. Optionally, you can specify the Kolmogorov-Smirnoff test for goodness of fit. See the topic “AUTOFIT Subcommand” on page 1824 for more information.

You can override the default set of distributions by explicitly specifying one or more distributions on the AUTOFIT keyword, but you cannot mix distributions belonging to different measurement levels. For example, you can specify one or more of the distributions for ordinal data (BINOM, NEGBIN and POISSON) but you cannot specify those in conjunction with distributions for continuous data such as NORMAL.

*Note:* For the negative binomial distribution (NEGBIN), AUTOFIT uses the form of the distribution that describes the probability of a given number of failures before a given number of successes occur. If you require the alternate parameterization that describes the probability of a given number of trials before a given number of successes occur, then manually specify the distribution with the DISTRIBUTION keyword. Also note that for the Weibull distribution, AUTOFIT only considers the case where the location parameter C equals 0.

The DISTRIBUTION keyword specifies the probability distribution for a simulated input field and is used when you want to explicitly specify the probability distribution rather than have it automatically determined from the data for the associated field in the active dataset. The DISTRIBUTION keyword can only be used with TYPE = MANUAL.

**BERNOULLI(PROB=value).** *Bernoulli distribution.*

**BETA(SHAPE1=value SHAPE2=value).** *Beta distribution.*

**BINOM(N=value PROB=value).** *Binomial distribution.*

**CATEGORICAL(CATS=valuelist PROBS=valuelist CONTINGENCY=YES | NO\*\*).** *Categorical distribution.* The Categorical distribution describes an input field that has a fixed number of values, referred to as categories. Each category has an associated probability such that the sum of the probabilities over all categories equals one.

- The CATS keyword specifies a list of the categories and the PROBS keyword specifies a list of the probabilities associated with each category. The n-th item in each list specifies the associated value for the n-th category. The number of values in each of the lists must be the same.
- For string inputs with a Categorical distribution, the category values can be specified with or without quotation marks; however, numeric categories for such inputs must be enclosed in quotation marks.
- The CONTINGENCY keyword specifies whether the input is included in a multiway contingency table that is computed from the active dataset and that describes associations between inputs with categorical distributions. By default, the input is not included in a contingency table. When CONTINGENCY=YES, MULTIWAY=YES must be specified on the CONTINGENCY subcommand.

Because the contingency table is computed from the active dataset, inputs with CONTINGENCY=YES must either exist in the active dataset or be mapped to a field in the active dataset with the MAPTO keyword. In addition, when CONTINGENCY=YES values specified for the CATS and PROBS keywords are ignored because the categories and category probabilities are determined from the contingency table.

Inputs specified as TYPE=AUTOFIT that are fit to a categorical distribution are automatically included in the contingency table when MULTIWAY=YES is specified on the CONTINGENCY subcommand.

**Note:** If the source of your predictive model is a PMML model file and you are specifying a categorical distribution for an input that is categorical in the model (such as gender), then you should specify the same category values as used in the model (or a subset of those values).

**EMPIRICAL([SOURCE=AUTOFIT\*\* | 'filespec']).** *Empirical distribution.* The empirical distribution is calculated from the data in the active dataset corresponding to the input field. EMPIRICAL is only supported for inputs with a continuous or ordinal measurement level.

- For continuous inputs, the empirical distribution is the cumulative distribution function of the data.
- For ordinal inputs, the empirical distribution is the categorical distribution of the data.
- For nominal input fields, use TYPE=AUTOFIT(CATEGORICAL).
- The SOURCE keyword is deprecated. Use the global SOURCE keyword instead, which has the same specifications but applies to both contingency tables and parameters for empirical distributions. See the topic “SOURCE Keyword” on page 1827 for more information.

**EXP(SCALE=value).** *Exponential distribution.*

**GAMMA(SHAPE=value SCALE=value).** *Gamma distribution.*

**LNORMAL(A=value B=value).** *Lognormal distribution.*

**NEGBIN(TYPE=FAILURES | TRIALS THRESHOLD=value PROB=value).** *Negative Binomial distribution.* Two parameterizations of the negative binomial distribution are supported.

- TYPE=FAILURES specifies a distribution that describes the probability of a given number of failures before a given number of successes occur.
- TYPE=TRIALS specifies a distribution that describes the probability of a given number of trials before a given number of successes occur, and is the parameterization used in the command syntax function PDF.NEGBIN.

**NORMAL(MEAN=value STDDEV=value).** *Normal distribution.*

**POISSON(MEAN=value).** *Poisson distribution.*

**TRIANGULAR(MIN=value MAX=value MODE=value).** *Triangular distribution.*

**UNIFORM(MIN=value MAX=value).** *Uniform distribution.*

**USER\_RANGES(MIN=valuelist MAX=valuelist PROBS=valuelist).** *User-defined ranges.* This distribution consists of a set of intervals with a probability assigned to each interval such that the sum of the probabilities over all intervals equals 1. Values within a given interval are drawn from a uniform distribution defined on that interval.

- The MIN keyword specifies a list of the left endpoints of each interval, the MAX keyword specifies a list of the right endpoints of each interval, and the PROBS keyword specifies a list of the probabilities associated with each interval. The n-th item in each list specifies the associated value for the n-th interval. The number of values in each of the lists must be the same. The specified endpoints are included in the intervals.
- Intervals can be overlapping. For example, you can specify MIN = 10 12 and MAX = 15 20, which defines the two intervals [10,15] and [12,20].

**WEIBULL(A=value B=value [C=value]).** *Weibull distribution.* The parameter C is an optional location parameter, which specifies where the origin of the distribution is located. Omitting the value of C is equivalent to setting its value to 0. When C equals 0, the distribution reduces to the Weibull distribution function in command syntax (PDF.WEIBULL).

Iterating distribution parameters

For any of the above distributions, you can specify multiple values for one of the distribution parameters. An independent set of simulated cases--effectively, a separate simulation--is generated for each specified value, allowing you to investigate the effect of varying the input. This is referred to as **Sensitivity Analysis**, and each set of simulated cases is referred to as an **iteration**.

- The set of specified values for a given distribution parameter should be separated by spaces.
- For the CATEGORICAL distribution, the CATS parameter can only specify a single set of category values, but you can specify multiple sets of values for the PROBS parameter, allowing you to vary the set of probabilities associated with the categories. Each set of probabilities should be separated by a semicolon.
- For the USER\_RANGES distribution, the MIN and MAX parameters can only specify a single set of intervals, but you can specify multiple sets of values for the PROBS parameter, allowing you to vary the set of probabilities associated with the specified intervals. Each set of probabilities should be separated by a semicolon.
- You can only iterate distribution parameters for a single simulated input. An error results if you specify iterations of distribution parameters and there are multiple fields on the INPUT keyword.

Example: Normal distribution with iterated parameters

The following specification results in two iterations, one with NORMAL (MEAN=15 STDDEV=2) and one with NORMAL (MEAN=15 STDDEV=3).

```
DISTRIBUTION= NORMAL (MEAN=15 STDDEV=2 3)
```

Example: Categorical distribution with iterated sets of probabilities

The example shows three iterations for the set of probabilities associated with the specified set of categories.

```
DISTRIBUTION= CATEGORICAL (CATS=1 2 3 PROBS=0.5 0.25 0.25; 0.4 0.3 0.3; 0.2 0.6 0.2)
```

The CATS keyword specifies the set of categories. The probabilities for the first iteration are specified by the set of values up to the first semi-colon following the PROBS keyword. Thus the category with value 1 has probability 0.5, the category with value 2 has probability 0.25 and the category with value 3 has probability 0.25. The probabilities for the second and third iterations are (0.4, 0.3, 0.3) and (0.2, 0.6, 0.2) respectively.

Example: User Ranges distribution with iterated sets of probabilities

The example shows two iterations for the set of probabilities associated with the specified intervals.

```
DISTRIBUTION= USER_RANGES (MIN=10 13 17 MAX=12 16 20 PROBS=0.3 0.3 0.4; 0.2 0.3 0.5)
```

The MIN and MAX keywords specify the three intervals [10-12], [13-16] and [17-20]. For the first iteration, the interval from 10 to 12 has probability 0.3, the interval from 13 to 16 has probability 0.3 and the interval from 17 to 20 has probability 0.4. The probabilities for the second iteration are (0.2, 0.3, 0.5).

MINVAL Keyword

The MINVAL keyword specifies the minimum allowed value for the simulated input field. If MINVAL is omitted, the minimum value is determined by the range of the associated probability distribution. If the specified value is less than the minimum allowed for the associated probability distribution, then the minimum for the probability distribution is used. MINVAL is not supported for the following distributions: Bernoulli, categorical, empirical, triangular, uniform and user ranges.

MAXVAL Keyword

The MAXVAL keyword specifies the maximum allowed value for the simulated input field. If MAXVAL is omitted, the maximum value is determined by the range of the associated probability distribution. If the

specified value is greater than the maximum allowed for the associated probability distribution, then the maximum for the probability distribution is used. MAXVAL is not supported for the following distributions: Bernoulli, categorical, empirical, triangular, uniform and user ranges.

## FIXEDINPUT Subcommand

The FIXEDINPUT subcommand specifies input fields whose values are fixed. When the MODEL subcommand is used, each input in the model file must be specified as either simulated or fixed. Use the SIMINPUT subcommand to specify simulated inputs.

### INPUT Keyword

The INPUT keyword specifies names and optional settings for one or more fixed inputs. The INPUT keyword is required. The specification for each input is the field name with an optional qualifier of the form (FORMAT=format), where the parentheses are required. Use a blank space to separate specifications for multiple inputs. The keywords T0 and ALL are not supported for variable lists specified on the INPUT keyword. For example:

```
INPUT=fixed1(FORMAT=PCT)
```

- **FORMAT.** *Specifies the output format of the field.* The format consists of a format type, such as F, optionally followed by a comma and the number of decimal places. If the number of decimal places is omitted then it is assumed that there are 0 decimal places. The following formats are supported:

Table 89. Format specifications.

Format Specification	Definition
F,d	Numeric
E,d	Scientific notation
N,d	Restricted numeric
DOT,d	Numeric with dots
COMMA,d	Numeric with commas
DOLLAR,d	Numeric with commas and dollar sign
PCT,d	Numeric with percent sign
CCA,d	Custom currency
CCB,d	Custom currency
CCC,d	Custom currency
CCD,d	Custom currency
CCE,d	Custom currency

If no format is specified, then the Numeric format F is used for numeric inputs.

**VALUE.** *Specifies the fixed value for the fields listed on the INPUT keyword.* Use separate FIXEDINPUT subcommands for fixed inputs that have different values. VALUE cannot be used with the ITERATIONS keyword. String values should be enclosed in quotation marks.

### ITERATIONS keyword

The ITERATIONS keyword specifies a set of values for a fixed input. An independent set of simulated cases--effectively, a separate simulation--is generated for each specified value, allowing you to investigate the effect of varying the input. This is referred to as sensitivity analysis, and each set of simulated cases is referred to as an iteration.

- ITERATIONS cannot be used with the VALUE keyword.

- You can only iterate values for a single fixed input field. An error results if the ITERATIONS keyword is specified and there are multiple fields on the INPUT keyword.

**VALUES(value list).** Specifies an explicit set of values for the fixed input. Values should be separated by spaces and string values should be enclosed in quotation marks. The list cannot contain a mixture of string and numeric values.

**RANGE(MIN=value MAX=value N=integer).** Specifies a range of equally spaced discrete numeric values for the fixed input. The parameter N specifies the number of values, including the values specified for MIN and MAX. For example, to specify the list [20, 30, 40, 50], use RANGE(MIN=20 MAX=50 N=4).

**LOCK = YES | NO.** Specifies whether the fixed input will be locked. If you are creating a simulation plan for use in the Run Simulation dialog and you want to prevent users from changing the value of the fixed input then specify LOCK=YES. The default is LOCK=NO. Locked inputs can be modified in the Simulation Builder but not in the Run Simulation dialog.

---

## CORRELATIONS Subcommand

The CORRELATIONS subcommand specifies the correlation matrix that describes any correlations between the simulated input fields. Correlations between inputs that will be simulated must be accounted for in order to ensure that the simulated values preserve those correlations. If the CORRELATIONS subcommand is omitted, correlations will be automatically determined from the fields in the active dataset associated with the simulated input fields. In that case, correlations for fields that do not exist in the active dataset are set to 0.

**VARORDER.** A list of variable names specifying the variable associated with each row in the correlation matrix. The n-th row in the correlation matrix specifies the correlations associated with the n-th variable in the list. The list must contain all input fields, except any fields that meet one of the following conditions:

- The field has a nominal measurement level and its distribution is to be automatically determined (TYPE=AUTOFIT).
- The distribution for the field has been explicitly set to the categorical distribution.
- The field has been specified as a fixed input.

**CORRMATRIX.** A set of lists of values specifying the lower triangular portion of the correlation matrix. The n-th list specifies the n-th row of the lower triangular portion of the correlation matrix, including the diagonal element which always has the value 1. The number of lists must equal the number of fields specified on the VARORDER keyword. In the case that two input fields are uncorrelated, the associated element in the correlation matrix should be set to 0. Specified values must be between -1 and 1.

**LOCK = YES | NO.** Specifies whether the correlation matrix will be locked. If you are creating a simulation plan that you or someone else will work with in the user interface (in the Simulation Builder or the Run Simulation dialog) and you want to prevent recalculation of correlations from historical data (carried out as part of distribution fitting), then specify LOCK=YES. The default is LOCK=NO.

### Example

Consider a model with continuous inputs *input1*, *input2* and *input3*, all of which will be simulated. Assume the correlation matrix for these inputs is:

	input1	input2	input3
input1	1	0.091	0.011
input2	0.091	1	-0.105
input3	0.011	-0.105	1

The following specification represents this correlation matrix:

```
/CORRELATIONS
VARORDER= input1 input2 input3
CORRMATRIX= 1; 0.091, 1; 0.011, -0.105 1
```

---

## CONTINGENCY Subcommand

The CONTINGENCY subcommand specifies whether a multiway contingency table that describes associations between inputs with a categorical distribution is to be used when data are generated for those inputs. The multiway contingency table is computed from the active dataset and includes all inputs that are fit to a categorical distribution. It ensures that associations between those inputs in the historical data are preserved when simulating data for those inputs.

### **MULTIWAY = YES | NO**

Specifies whether a multiway contingency table is used. The default is NO, which specifies that inputs with a categorical distribution are independent of each other.

**Note:** You can use the global SOURCE keyword to specify a simulation plan file that contains a multiway contingency table that is to be used instead of computing the table from the active dataset. For more information, see the topic “SOURCE Keyword” on page 1827.

---

## AUTOFIT Subcommand

The AUTOFIT subcommand specifies options for automatic fitting of probability distributions and correlations to fields in the active dataset.

**NCASES.** *Specifies the number of cases in the active dataset to be used for automatic fitting of probability distributions and correlations.* For a specification NCASES = n, the first n cases will be used. The default is all cases.

**FIT = AD | KS.** *Specifies whether to use the Anderson-Darling or Kolmogorov-Smirnoff test for goodness of fit when automatically fitting probability distributions for simulated input fields.* Only applies to simulated input fields with a continuous measurement level. The default is Anderson-Darling (FIT = AD). For input fields with ordinal or nominal measurement levels, a chi-square test is used.

**MAXITERATIONS.** *Specifies the maximum number of iterations SIMPLAN can go through in its computations when automatically fitting probability distributions.* The default is 100.

**BINS.** *Specifies the number of bins used when fitting the empirical distribution for a continuous input field.* The default is 100 and the maximum is 1000. The empirical distribution is the cumulative distribution function of the historical data.

---

## STOPCRITERIA subcommand

The STOPCRITERIA subcommand specifies criteria for stopping the simulation, potentially before the maximum number of allowable cases has been generated.

**MAXCASES.** *Specifies the maximum number of cases of simulated data to generate.* The default is 100000. A larger value for MAXCASES will allow for more accurate predictions but will also require a longer execution time to complete the simulation.

- When the TARGET and TYPE keywords are omitted, this is the number of cases that will be generated.
- When sensitivity analysis is specified, this is the maximum number of cases for each iteration.
- When the MODEL subcommand is omitted, MAXCASES is the only option.

**TARGET.** *The name of the target to which the criteria specified on the TYPE keyword are applied.*

### TYPE Keyword

The TYPE keyword specifies the criteria for stopping the simulation. The TYPE keyword is ignored if the TARGET keyword is omitted.

**MEAN.** Specifies to continue generating cases until the confidence interval of the mean of the target distribution is within a specified threshold. To use this option, you specify a confidence level and a threshold. For example, you can use this option to specify that cases are generated until the confidence interval of the mean at the 95% confidence level is within 5% of the mean value.

- The keyword THRESH specifies the threshold value for the confidence interval at the confidence level specified by the CILEVEL keyword. The default for CILEVEL is 95, representing a confidence level of 95%.
- The keyword UNIT indicates whether the value specified for THRESH represents a percentage of the mean value of the target (UNIT=PERCENT) or a numeric value (UNIT=VALUE). For example, if your target is revenue and you want to ensure that the width of the 95% confidence interval of the mean is less than \$1000 then you would specify THRESH=1000 UNIT=VALUE. When UNIT=PERCENT, THRESH is specified as an integer, as in the value 5 for 5%.
- Generation of cases will continue until the criteria specified in MEAN is reached or the maximum number of allowed cases (MAXCASES keyword) has been reached

**TAIL.** Specifies to continue generating cases until a given number of cases have been generated in one of the tails of the distribution for the specified target.

- For UNIT=VALUE, the THRESH keyword specifies the value of the target that defines the boundary of the tail region. By default, the value is assumed to specify the right tail region. To specify the left tail region, use SIDE=LEFT.
- For UNIT=PERCENTILE, the THRESH keyword specifies the boundary of the tail region as a percentile of the target distribution. The SIDE keyword is ignored when UNIT=PERCENTILE, since the side is implicit in the specified value of THRESH--for example, a value of 99 implies the right tail and a value of 1 implies the left tail.
- The FREQUENCY keyword specifies the number of cases that must be generated in the specified tail region.
- Generation of cases will continue until the criteria specified in TAILS is reached or the maximum number of allowed cases (MAXCASES keyword) has been reached

## Examples

This example specifies that exactly 1,000,000 cases of simulated data will be generated.

```
/STOPCRITERIA MAXCASES=1000000
```

This example specifies that cases will be generated until either the width of the 99% confidence interval of the mean of the target *profit* is within 1% of the mean value, or 1,000,000 cases have been generated.

```
/STOPCRITERIA MAXCASES=1000000  
TARGET=profit  
TYPE=MEAN(THRESH=1 UNIT=PERCENT CILEVEL=99)
```

This example specifies that the boundary of the right tail region for the target *loss* is at the value 50,000,000. Cases will be generated until either 500 cases have a target value greater than 50,000,000 or 10,000,000 cases have been generated.

```
/STOPCRITERIA MAXCASES=1000000  
TARGET=loss  
TAIL(UNIT=VALUE THRESH=50000000 FREQUENCY=500)
```

---

## MISSING Subcommand

The MISSING subcommand specifies how missing values are handled. Cases with invalid values for any input are excluded from the following analyses: distribution fitting; computation of correlations; and computation of the contingency table, if requested. System missing values are always invalid. User-missing values are invalid except for inputs that are fit to a categorical distribution when CLASSMISSING=INCLUDE.

The CLASSMISSING keyword specifies whether user-missing values of inputs that are fit to a categorical distribution are treated as valid.

#### EXCLUDE

Exclude user-missing values. Treat user-missing values for these inputs as invalid data. This setting is the default.

#### INCLUDE

Include user-missing values. Treat user-missing values for these inputs as valid data

---

## VALUELABELS Subcommand

The VALUELABELS subcommand specifies value labels for simulated inputs and fixed inputs. It applies only in the case of simulating data without a predictive model.

#### VARIABLES

A list of variables to which the value labels are applied.

#### VALUES

A list of pairs that consist of a value followed by the associated label.

- Each value label must be enclosed in quotation marks. For string variables, the values themselves must also be quoted.
- Value labels can contain any characters, including blanks.
- To enter an apostrophe as part of a label, enclose the label in double quotation marks or enter two apostrophes (two single quotation marks).
- Each value label can be up to 120 bytes long.
- To continue a label from one command line to the next, specify a plus (+) sign before the continuation of the label. Each string segment of the label must be enclosed in quotation marks. To insert a blank between the strings, the blank must be included in the label specification.
- To control line-wrapping of labels in pivot tables and charts, insert \n as part of the label wherever you want a line break. The \n is not displayed in output; it is interpreted as a line-break character.

**Note:** Labels always wrap wherever \n occurs in the defined label even if there is enough space to display the label without wrapping.

#### Example

```
/VALUELABELS VARIABLES=vehicletype VALUES= 0 'economy' 1 'compact' 2 'midsize' 3 'standard' 4 'fullsize'
```

---

## PLAN Subcommand

The PLAN subcommand specifies the name of a simulation plan file to be written or displayed by SIMPLAN. The file contains all of the specifications required to run a simulation. The PLAN subcommand is required.

**FILE = 'filespec'.** *Specifies the simulation plan file.* File specifications should be enclosed in quotation marks and fully qualified paths are recommended to avoid ambiguity.

*Note:* The optional combination of an asterisk (\*) and a backslash (\) preceding the plan file name specifies that the file is a temporary file--for example, FILE='\*\SimulationPlan.splan'. You would then use this file specification on the PLAN subcommand of a subsequent SIMRUN command.

**DISPLAY.** *Specifies whether the details of the plan file are displayed in the output.* The default is YES.

---

## SOURCE Keyword

The SOURCE keyword specifies whether associations between inputs with categorical distributions (specified by a contingency table) and parameters for inputs with empirical distributions are automatically calculated from the active dataset or whether they can be taken from a simulation plan file, which is given by 'filespec'. The default is SOURCE=AUTOFIT, which specifies that empirical distributions and contingency tables are calculated from the active dataset.

Specifying TYPE=MANUAL, without the DISTRIBUTION keyword, for an input on the SIMINPUT subcommand indicates that the specifications for the input are to be taken from the simulation plan file that is designated by SOURCE='filespec'. This specification is only valid for the following types of inputs: inputs that are described by an empirical distribution in the plan file; inputs that are described by a categorical distribution and included in a contingency table in the plan file.

The following rules apply to inputs with a categorical distribution and that are included in a contingency table in the plan file:

- When TYPE=MANUAL is specified without the DISTRIBUTION keyword, MULTIWAY=YES must be specified on the CONTINGENCY subcommand.
- You cannot specify TYPE=MANUAL (without the DISTRIBUTION keyword) for a subset of inputs that are included in the contingency table. You must either specify TYPE=MANUAL for all such inputs or for none of them.

**Note:** The contingency table in the plan file determines both the associations between the included inputs and the categories and category probabilities for those inputs.

---

## Chapter 248. SIMPREP BEGIN-SIMPREP END

SIMPREP BEGIN and SIMPREP END are deprecated for release 23 and higher. The command names are changed to BEGIN EXPR and END EXPR.

**Related information:**

Chapter 29, “BEGIN EXPR-END EXPR,” on page 245

---

### OUTFILE subcommand

The OUTFILE subcommand of SIMPREP BEGIN saves an XML-format file that specifies the custom model. This file can be used as the model file for creating a simulation plan with the SIMPLAN command.

**PREPXML = 'filespec'.** *Specifies the XML-format file.* File specifications should be enclosed in quotation marks and file names must be specified in full. SIMPREP BEGIN does not supply file extensions. If the file specification refers to an existing file, then the file is overwritten.

*Note:* The optional combination of an asterisk (\*) and a backslash (\) preceding the XML file name specifies that the file is a temporary file--for example, PREPXML='\*\SIMPREP\_transformation.xml'. You would then use this file specification on the MODEL subcommand of the subsequent SIMPLAN command.

---

## Chapter 249. SIMRUN

SIMRUN is available in the Statistics Base Edition.

```
SIMRUN
/PLAN FILE=file

[/CRITERIA
  [REPRESENTS = {TRUE**}]
                {FALSE }
  [SEED = {629111597**}]
                {number  }
[/DISTRIBUTION
  [DISPLAY = [CDF] [PDF**] [NONE] ]
  [CDFORDER = [ASCENDING**] [DESCENDING] ]
  [SCALE= [MEAN] [MEDIAN] [PCT[({5** 95**  })]] [SIGMAS(integer)]
                {value [value]}
  [CUSTOM(value [value [...] ] )] [PDFVIEW([CURVE**] [HISTOGRAM])]
  [OVERLAYTARGETS({NO**})]
                {YES }
  [REFLINES([LOWER={DEFAULT**}] [UPPER={DEFAULT**}])]
                {value  }      {value  }
                {LO    }      {HI    }
  [CATEGORICAL= [PREVDVAL**] [PREDPROB] [GROUP([CATS**] [ITERS])] ]

[/SCATTERPLOT
  [DISPLAY = {YES }]
                {NO**}
  [ROWSIZE={DEFAULT**}]
                {integer }
[/BOXPLOT
  [DISPLAY = {YES }]
                {NO**}
  [OVERLAYTARGETS= {NO**}
                {YES }[(GROUP=[TARGETS**] [ITERS])]
[/TORNADO
  [DISPLAY = {YES**}]
                {NO  }
  [TYPE= [CORR**] [DELTASTDDEV(number)] [VARIANCE] ]
[/PRINT
  [DESCRIPTIVES = {YES**}[(CILEVEL={95** })] ]
                {value }
                {NO  }
  [PERCENTILES = {YES }([NTILES = integer] [PTILES = valueList]) ]
                {NO**}
  [ASSOCIATIONS={YES }]
                {NO**}
[/OPTIONS
  [VIZSTYLESHEET="style sheet name"[LOCATION={LOCAL**
                {repository folderspec"}] ]
[/OUTFILE
  FILE={'filespec' | 'dataset'}
```

\*\* Default if the subcommand or keyword is omitted.

This command does not read the active dataset or execute pending transformations.

Release History

Release 21.0

- Command introduced.

Release 22.0

- Added support for saving the simulated data to the active dataset by specifying an asterisk (\*) on the FILE keyword of the OUTFILE subcommand.
- REFLINES keyword added to DISTRIBUTION subcommand.
- ASSOCIATIONS keyword added to PRINT subcommand.
- OPTIONS subcommand added.

Example

```
SIMRUN  
/PLAN FILE='/simulations/myplan.splan'.
```

---

## Overview

The SIMRUN command runs a simulation based on a simulation plan created from the SIMPLAN command. All settings required to run the simulation are specified in the simulation plan file. The SIMRUN command only provides options for customizing the output.

Simulation in IBM SPSS Statistics refers to simulating input data to predictive models using the Monte Carlo method and evaluating the model based on the simulated data. The distribution of predicted target values can then be used to evaluate the likelihood of various outcomes.

Uncertain inputs are modeled with probability distributions and simulated values for those inputs are generated by drawing from those distributions. Inputs whose values are known are held fixed at the known values. The predictive model is evaluated using a simulated value for each uncertain input and fixed values for the known inputs to calculate the target (or targets) of the model. The process is repeated many times (typically tens of thousands or hundreds of thousands of times), resulting in a distribution of target values. Each repetition of the process generates a separate data record that consists of the set of simulated values for the uncertain inputs, the values of the fixed inputs, and the predicted target (or targets) of the model.

You can also simulate data in the absence of a predictive model by specifying probability distributions for variables that are to be simulated. Each generated data record consists of the set of simulated values for the specified variables.

Options

**Distributions of target values.** For continuous targets you can display the probability density function and the cumulative distribution function of the predicted values. For categorical targets, you can display the percentage of simulated cases that fall in each category of the target. For categorical targets of PMML models, you can also display histograms of the probability distribution (over the simulated cases) for each of the categories of the target. For Two-Step cluster models and K-Means cluster models, you can display a bar chart of cluster membership.

**Scatterplots and boxplots.** You can display scatterplots of each target with each of its simulated inputs, and you can display boxplots of the distribution of predicted values for each continuous target.

**Tornado charts.** You can create tornado charts (horizontal bar charts) that display relationships between targets and simulated inputs using a variety of metrics.

**Associations.** You can display a table of correlation coefficients between simulated inputs. When simulated inputs with categorical distributions are generated from a contingency table, you can display the contingency table of the simulated data for those inputs.

**Customizing results from sensitivity analysis.** When the simulation plan contains specifications for sensitivity analysis, independent sets of simulated data are generated, allowing you to investigate the effect of systematic changes in a fixed input or in a distribution parameter for a simulated input. The SIMRUN command provides options for displaying the results from the different sets of simulated data.

## Basic Specification

The basic specification is the SIMRUN command with a PLAN subcommand that specifies the simulation plan file.

## Syntax Rules

- The PLAN subcommand is required. All other subcommands are optional.
- Subcommands can be specified in any order.
- An error occurs if a keyword is specified more than once within a subcommand.
- Parentheses, equals signs, and slashes shown in the syntax chart are required.
- The command name, subcommand names, and keywords must be spelled in full.
- Empty subcommands are not allowed.

---

## Example

```
SIMRUN
/PLAN FILE='/simulations/myplan.splan'
/CRITERIA REPRESULTS=TRUE SEED=498654860
/DISTRIBUTION DISPLAY=PDF CDF
/BOXPLOT DISPLAY=YES
/SCATTERPLOT DISPLAY=YES
/TORNADO DISPLAY=YES TYPE=CORR VARIANCE
/PRINT DESCRIPTIVES=YES PERCENTILES=YES(NTILES=4).
```

- The CRITERIA subcommand specifies an explicit seed value so that results of this simulation can be reproduced by using the same seed.
- The DISTRIBUTION subcommand specifies that both probability density functions and cumulative distribution functions of the predicted target values will be displayed.
- The BOXPLOT subcommand specifies that a boxplot of the distribution of predicted target values will be displayed.
- The SCATTERPLOT subcommand specifies that scatterplots of each target with each of its simulated inputs will be displayed.
- The TORNADO subcommand specifies that two tornado charts will be displayed. One chart will display the correlation coefficients between a target and its simulated inputs, and the other will display the contribution to the variance of the target from each of its simulated inputs.
- The PRINT subcommand specifies that tables of descriptive statistics of targets and inputs will be generated as well as a table of the quartiles for continuous targets.

---

## PLAN Subcommand

The PLAN subcommand identifies the plan file whose specifications are to be used for running the simulation. It is a required subcommand.

**FILE = 'filespec'.** *Specifies the simulation plan file.* File specifications should be enclosed in quotation marks and fully qualified paths are recommended to avoid ambiguity. Simulation plan files have the file extension *.splan*.

*Note:* The optional combination of an asterisk (\*) and a backslash (\) preceding the plan file name specifies that the file is a temporary file. This only applies in the case that SIMRUN follows the SIMPLAN command that creates the simulation plan. See the topic “PLAN Subcommand” on page 1826 for more information.

---

## CRITERIA Subcommand

**REPRESENTS.** *Specifies whether the results for this simulation are reproducible.* The default is TRUE. When TRUE is specified, use the SEED keyword to specify the seed value for generating random numbers, or simply accept the default value. When FALSE is specified, a seed value will be randomly generated and the results of the simulation will not be reproducible.

**SEED.** *Specifies the value of the random seed.* Specify an integer. The default is 629111597. The SEED keyword is ignored if REPRESENTS=FALSE.

**Note:** For a particular random seed, results are replicated unless the number of threads is changed. On a particular computer, the number of threads is constant unless you change it by running SET THREADS command syntax. The number of threads might change if you run the simulation on a different computer because an internal algorithm is used to determine the number of threads for each computer.

---

## DISTRIBUTION Subcommand

The DISTRIBUTION subcommand provides settings for displaying the distributions of predicted target values. For continuous targets, you can display cumulative distribution functions (CDF) and probability density functions (PDF). For categorical targets (targets with a measurement level of nominal or ordinal), a bar chart is generated that displays the percentage of cases that fall in each category of the target. Additional options for categorical targets of PMML models are available with the CATEGORICAL keyword. For Two-Step cluster models and K-Means cluster models, a bar chart of cluster membership is produced.

**DISPLAY.** Specifying DISPLAY=PDF displays the probability density function for continuous targets, the bar chart of the predicted values for categorical targets, and the bar chart of cluster membership for cluster models. You can display the cumulative distribution function for continuous targets by specifying CDF. Specifying DISPLAY=NONE suppresses all charts generated from the DISTRIBUTION subcommand.

**CDFORDER.** *Specifies the default view for cumulative distribution functions.* By default, cumulative distribution functions are displayed as ascending functions. Use CDFORDER=DESCENDING to display them as descending functions. When displayed as a descending function, the value of the function at a given point on the horizontal axis is the probability that the target lies to the right of that point. You can change the view in the Output Viewer by activating the chart. Specifying both ASCENDING and DESCENDING will generate two charts, one in ascending order and the other in descending order.

### SCALE Keyword

The SCALE keyword specifies settings for continuous targets. With the exception of the PDFVIEW keyword, all keywords below apply to charts of both cumulative distribution functions and probability density functions.

**MEAN.** Displays a vertical reference line at the mean of the target.

**MEDIAN.** Displays a vertical reference line at the median of the target.

**PCT.** Displays fixed vertical reference lines at one or two specified percentiles of the target distribution. You can specify one or two values for PCT, as in PCT(10) or PCT(25 75). If PCT is specified without values, reference lines will be displayed at the 5-th and 95-th percentiles.

**SIGMAS.** Displays vertical reference lines at the specified number of standard deviations above and below the mean of the target distribution. Specify a numeric value between 1 and 10.

**CUSTOM.** Displays vertical reference lines at the specified positions along the horizontal axis. Use spaces to separate values, for example: CUSTOM(50000 100000).

**PDFVIEW.** By default, probability density functions are displayed as a continuous curve. Use PDFVIEW=HISTOGRAM to display them as histograms. You can change the view in the Output Viewer by activating the chart. Specifying both HISTOGRAM and CURVE will generate two charts, one for each of the two views.

**OVERLAYTARGETS.** In the case of multiple continuous targets, this specifies whether distribution functions for all continuous targets are displayed on a single chart (separate charts for cumulative distribution functions and probability density functions). The default is NO and results in a separate chart for each target.

- If the plan file contains specifications for sensitivity analysis, OVERLAYTARGETS=YES will overlay all targets for a given iteration of the analysis on a single chart, with a separate chart for each iteration; and OVERLAYTARGETS=NO (the default) will overlay all iterations for a given target on a single chart, with a separate chart for each target.
- OVERLAYTARGETS is ignored for probability density functions when PDFVIEW=HISTOGRAM.

**REFLINES.** Controls the initial positions of the moveable reference lines on PDF and CDF charts. Values specified for the lower and upper lines refer to positions along the horizontal axis, not percentiles. You can remove the lower line by specifying LOWER=L0, effectively setting the position to negative infinity; and you can remove the upper line by specifying UPPER=HI, effectively setting the position to infinity. You cannot specify both LOWER=L0 and UPPER=HI. By default, the lines are positioned at the 5-th and 95-th percentiles. When multiple distributions are displayed on a single chart, the default refers to the distribution for the first iteration or first target.

*Note:* If the plan file contains specifications for sensitivity analysis and there is only one continuous target, then results for all iterations of the analysis will be displayed on the same chart. This applies to cumulative distribution functions and to probability density functions when PDFVIEW=CURVE. In addition, when multiple distributions are displayed on a single chart, vertical reference lines will only be applied to the distribution for the first iteration or first target. You can add reference lines to the other distributions from the Chart Options dialog, accessed from the PDF or CDF chart.

#### CATEGORICAL Keyword

The CATEGORICAL keyword specifies settings for categorical targets (targets with a measurement level of nominal or ordinal) and cluster models (Two-Step and K-Means models), and is in effect when PDF is specified on the DISPLAY keyword, or the DISPLAY keyword is omitted. It is ignored otherwise.

**PREDVAL.** For categorical targets, this option generates a bar chart that displays the percentage of simulated cases that fall in each category of the target. If the plan file contains specifications for sensitivity analysis, a clustered bar chart is displayed. By default, results are clustered by each iteration of the sensitivity analysis, with results for all categories (for a given iteration) grouped together (GROUP=CATS). You can cluster by category by specifying GROUP=ITERS. You can change the grouping in the Output Viewer by activating the chart. Specifying GROUP=CATS ITERS will generate two charts, one for each of the two groupings.

For Two-Step cluster models and K-Means cluster models, a bar chart of cluster membership is produced. When the plan file contains specifications for sensitivity analysis, the result is a clustered bar chart. The same choices for groupings, as for categorical targets, applies except categories are now replaced by the clusters from the predictive model.

**PREDPROB.** For categorical targets of PMML models, this option displays histograms of the probability distribution (over the simulated cases) for each of the categories of the target (one histogram for each category). If the plan file contains specifications for sensitivity analysis, the histograms for each iteration of the sensitivity analysis are grouped together by default (GROUP=CATS). You can group all histograms (one for each iteration) for each category together by specifying GROUP=ITERS. Specifying GROUP=CATS ITERS will generate the charts for each of the two groupings.

**Note:** The DISTRIBUTION subcommand is ignored when data are generated in the absence of a predictive model.

---

## SCATTERPLOT Subcommand

The SCATTERPLOT subcommand generates scatterplots of each target with each of its simulated inputs.

**DISPLAY.** Controls whether scatterplots are displayed. The default is NO, which specifies that scatterplots are not displayed.

**ROWSIZE.** Scatterplots for a given target are grouped together. The ROWSIZE keyword specifies the number of scatterplots to display in each row.

**Note:** The SCATTERPLOT subcommand is ignored when data are generated in the absence of a predictive model.

---

## BOXPLOT Subcommand

The BOXPLOT subcommand generates boxplots of the distribution of each continuous target. If the plan file contains specifications for sensitivity analysis and there is only one continuous target, then results for all iterations of the sensitivity analysis (one boxplot for each iteration) will be displayed on the same chart. Boxplots are not available for categorical targets.

**DISPLAY.** Controls whether boxplots are displayed. The default is NO, which specifies that boxplots are not displayed.

**OVERLAYTARGETS.** Specifies the behavior when there are multiple continuous targets. By default, results for each target are displayed on a separate chart. To overlay results for all targets on a single chart, specify OVERLAYTARGETS=YES.

- If the plan file contains specifications for sensitivity analysis and there are multiple continuous targets, then OVERLAYTARGETS=YES will produce a clustered boxplot. In that case, the GROUP keyword controls the clustering. By default, the chart is clustered by sensitivity analysis iteration with results for a given iteration (the boxplots for the targets) grouped together (GROUP=TARGETS). You can cluster by targets by specifying GROUP=ITERS. You can change the grouping in the Output Viewer by activating the chart. Specifying GROUP=TARGETS ITERS will generate two charts, one for each of the two groupings.

**Note:** The BOXPLOT subcommand is ignored when data are generated in the absence of a predictive model.

---

## TORNADO Subcommand

The TORNADO subcommand generates tornado charts. Tornado charts are horizontal bar charts that display relationships between targets and simulated inputs using a variety of metrics.

**DISPLAY.** Controls whether tornado charts are displayed. The default is YES, which specifies that tornado charts are displayed.

TYPE Keyword

The TYPE keyword specifies the metrics for the tornado charts. Each specified metric generates a separate chart.

- **CORR.** Displays a tornado chart of the correlation coefficient between a target and its simulated inputs, and is the default tornado chart. This type of tornado chart does not support targets with a nominal or ordinal measurement level or simulated inputs with a categorical distribution.

- **DELTASTDDEV(number)**. Displays a tornado chart of the effect on the target of modulating each simulated input by plus or minus a specified number of standard deviations of the distribution associated with the input. For example, DELTASTDDEV(0.5) displays the change in the target when the input changes by +/- 0.5 standard deviations. The multiplier must be a numeric value greater than 0 and less than or equal to 10. This type of tornado chart does not support targets with ordinal or nominal measurement levels, or simulated inputs with any of the following distributions: categorical, Bernoulli, binomial, Poisson, or negative binomial.
- **VARIANCE**. Displays a tornado chart of the contribution to the variance of a target from each of its simulated inputs, allowing you to assess the degree to which each input contributes to the overall uncertainty in the target. This type of tornado chart does not support targets with ordinal or nominal measurement levels, or simulated inputs with any of the following distributions: categorical, Bernoulli, binomial, Poisson, or negative binomial.

**Note:** The TORNADO subcommand is ignored when data are generated in the absence of a predictive model.

---

## PRINT Subcommand

The PRINT subcommand controls tabular output.

**DESCRIPTIVES.** By default, descriptive statistics are displayed for continuous and categorical targets as well as for continuous inputs.

- For continuous targets the table includes the mean, standard deviation, median, minimum and maximum, confidence interval of the mean at the specified level, and the 5-th and 95-th percentiles of the target distribution. By default, the confidence interval of the mean is calculated for a confidence level of 95%. You can specify the confidence level using the CILEVEL keyword. *Note:* In the absence of a predictive model, the CILEVEL keyword is ignored.
- For categorical targets the table includes the percentage of cases that fall in each category of the target. For Two-Step cluster models and K-Means cluster models the table includes the percentage of cases that fall in each cluster of the model. For categorical targets of PMML models, the table also includes the mean probability of each category of the target.
- For continuous inputs, the table includes the mean, standard deviation, minimum and maximum.

**ASSOCIATIONS.** Displays a table of correlation coefficients between simulated inputs. When inputs with categorical distributions are generated from a contingency table, the contingency table of the data generated for those inputs is also displayed.

### PERCENTILES Keyword

The PERCENTILES keyword displays percentiles of the distribution of each continuous target. This is in addition to the 5-th and 95-th percentiles, which are always displayed.

- **NTILES.** Calculates the percentages that divide the distribution into the specified number of categories and displays the values below which the requested percentages of cases fall. The value must be an integer between 2 and 100 inclusive.
- **PTILES.** Displays the values below which the specified percentages of cases fall. Specify one or more values separated by spaces.

*Note:* In the absence of a predictive model, the PERCENTILES and CILEVEL keywords are ignored.

---

## VIZSTYLESHEET Keyword

The VIZSTYLESHEET keyword specifies an existing visualization style sheet and applies it to all charts that are generated from the current SIMRUN command.

The keyword is followed by an equals sign (=) and the name of the style sheet in quotation marks. By default, SIMRUN looks for a built-in or imported template that is stored on the local workstation. This default behavior is equivalent to appending the qualifier [LOCATION=LOCAL] to the quoted style sheet name. To use a style sheet in a IBM SPSS Collaboration and Deployment Services Repository, append the qualifier [LOCATION="repository folderspec"] to the quoted style sheet name. For more information about IBM SPSS Collaboration and Deployment Services Repository file specifications, see Chapter 308, "File Specifications for IBM SPSS Collaboration and Deployment Services Repository Objects," on page 2217. The IBM SPSS Collaboration and Deployment Services Repository file specification is enclosed in quotation marks.

**Note:** The square brackets that are shown in the specification for the LOCATION keyword are required and are not used to indicate an optional element.

New Style sheets can be created with the separate IBM SPSS Visualization Designer product. The SIMRUN command can reference these style sheets if they are stored in the IBM SPSS Collaboration and Deployment Services Repository or if they are imported by using the Graphboard Template Chooser. You can access the Template Chooser by selecting **Graphboard Template Chooser** from the **Graphs** menu.

**"style sheet name"**

Apply the specified style sheet.

**Note:** The VIZSTYLESHEET keyword is ignored when data are generated in the absence of a predictive model.

---

## OUTFILE Subcommand

The OUTFILE subcommand specifies the name of a file or dataset where the simulated data and predicted target values will be written. The results include all targets and all inputs (both simulated and fixed) regardless of whether they were excluded from chart and table output. Each case of the data file consists of the predicted values of the targets along with the simulated inputs and fixed inputs that generate the target values. When sensitivity analysis is specified, each iteration of the analysis gives rise to a contiguous set of cases that are labeled with the iteration number.

**FILE = 'filespec' | dataset.** *Specifies a file or the name of a previously declared dataset.* File specifications should be enclosed in quotation marks and fully qualified paths are recommended to avoid ambiguity. You can use an asterisk (\*) to specify that the simulated data will be written to the active dataset, replacing the current active dataset.

---

## Chapter 250. SORT CASES

```
SORT CASES [BY] varlist[({A**})] [varlist...]
           {D }
           [/OUTFILE='filespec' [INDEX={NO**} [SIZE={DEFAULT**}]]]
           {YES } {value }
           [/PASSPROTECT PASSWORD={'password'} [ENCRYPTEDPW={NO**}] ]
           {NONE** } {YES }
```

\*\*Default if keyword omitted

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Release History

#### Release 17.0

- Added support for SET THREADS.

#### Release 20.0

- Added OUTFILE subcommand.

#### Release 21.0

- Added INDEX keyword to OUTFILE subcommand.
- Added SIZE keyword to OUTFILE subcommand..
- PASSPROTECT subcommand added.

### Example

```
SORT CASES BY DIVISION (A) STORE (D).
```

---

## Overview

SORT CASES reorders the sequence of cases in the active dataset based on the values of one or more variables. You can optionally sort cases in ascending or descending order, or you can use combinations of ascending and descending order for different variables.

### Basic Specification

The basic specification is a variable or list of variables that are used as sort keys. By default, cases are sorted in ascending order of each variable, starting with the first variable that is named. For each subsequent variable, cases are sorted in ascending order within categories of the previously named variables.

### Syntax Rules

- Keyword BY is optional.
- BY variables can be numeric or string but not scratch, system, or temporary variables.
- You can explicitly request the default sort order (ascending) by specifying A or UP in parentheses after the variable name. To sort cases in descending order, specify D or DOWN.
- An order specification (A or D) applies to all variables in the list, up to the previous order specification. If you combine ascending and descending order on the same SORT CASES command, you may need to specify the default A explicitly.

### Operations

- SORT CASES first sorts the file according to the first variable that is named. For subsequent variables, cases are sorted within categories of the previously named variables.
- The sort sequence is based on the locale-defined order (and is not necessarily the same as the numerical order of the character codes). The default locale is the operating system locale. You can change the locale with SET LOCALE. Use SHOW LOCALE to display the current locale.
- This procedure uses the multithreaded options specified by SET THREADS.

#### Limitations

- You cannot specify more than 64 sort variables.

---

## OUTFILE Subcommand

OUTFILE specifies the data file to be saved when the active dataset is sorted. This subcommand is optional and is provided as a convenience. It will avoid the extra data pass that occurs if you follow SORT CASES with the SAVE command to save the sorted data. Reducing the number of data passes can improve performance.

- Filenames should be enclosed in quotes and are stored in the working directory unless a path is included as part of the file specification.
- If OUTFILE is specified more than once, only the last OUTFILE is in effect.

**INDEX=NO|YES.** The optional INDEX keyword indicates if the file should be indexed. Indexing table lookup files can improve performance when merging data files with STAR JOIN. The default is NO.

Note: Sorting and saving with an index may take longer and result in a different sort order than sorting and saving without an index. The resulting file will usually take more disk space.

**SIZE=DEFAULT|value.** For indexed files, the optional SIZE keyword specifies the memory (in megabytes) to allocate for the index. The default is DEFAULT, which is  $\text{SQRT}(N)*4$ , where  $N$  is the number of cases in the file. For example, if there are 100 cases, the memory allocation is 40 MB.

---

## PASSPROTECT Subcommand

The PASSPROTECT subcommand specifies the settings for saving a data file as an encrypted file. Once encrypted, the file can only be opened by providing the correct password.

**PASSWORD.** Specifies the password required to open this file. Passwords are limited to 10 characters and are case-sensitive. The specified value must be enclosed in quotation marks. The keyword NONE specifies that the file will not be encrypted and is the default.

*Warning:* Passwords cannot be recovered if they are lost. If the password is lost the file cannot be opened.

#### ENCRYPTEDPW Keyword

The ENCRYPTEDPW keyword specifies whether the password is encrypted.

**NO.** The password is not encrypted. It is treated as plain text. This is the default.

**YES.** The password is encrypted. Passwords are always encrypted when pasting syntax from the Sort Cases dialog. *Note:* ENCRYPTEDPW=YES should only be used when the password is known to be encrypted.

#### Creating strong passwords

- Use eight or more characters.
- Include numbers, symbols and even punctuation in your password.

- Avoid sequences of numbers or characters, such as "123" and "abc", and avoid repetition, such as "111aaa".
- Do not create passwords that use personal information such as birthdays or nicknames.
- Periodically change the password.

*Note:* Encrypted data files and output documents cannot be opened in versions of IBM SPSS Statistics prior to version 21. Encrypted syntax files cannot be opened in versions prior to version 22.

---

## Examples

`SORT CASES BY DIVISION (A) STORE (D).`

- Cases are sorted in ascending order of variable *DIVISION*. Cases are further sorted in descending order of *STORE* within categories of *DIVISION*. A must be specified so that D applies to *STORE* only.

`SORT CASES DIVISION STORE (A) AGE (D).`

- Cases are sorted in ascending order of *DIVISION*. Keyword *BY* is not used in this example.
- Cases are further sorted in ascending order of *STORE* within values of *DIVISION*. Specification A applies to both *DIVISION* and *STORE*.
- Cases are further sorted in descending order of *AGE* within values of *STORE* and *DIVISION*.

---

## **SORT CASES with Other Procedures**

- In *AGGREGATE*, cases are sorted in order of the break variable or variables. You do not have to use *SORT CASES* prior to running *AGGREGATE*, because the procedure does its own sorting.
- You can use *SORT CASES* in conjunction with the *BY* keyword in *ADD FILES* to interleave cases with the same variables but from different files.
- With *MATCH FILES*, cases must be sorted in the same order for all files that you combine.
- With *UPDATE*, cases must be sorted in ascending order of the key variable or variables in both the master file and all transaction files.
- You can use the *PRINT* command to check the results of a *SORT CASES* command. To be executed, *PRINT* must be followed by a procedure or *EXECUTE*.

---

## Chapter 251. SORT VARIABLES

```
SORT VARIABLES [BY] {NAME           } [{(A)}]
                   {TYPE            } {D}
                   {FORMAT          }
                   {LABEL           }
                   {VALUES          }
                   {MISSING         }
                   {MEASURE         }
                   {ROLE            }
                   {COLUMNS        }
                   {ALIGNMENT       }
                   {ATTRIBUTE name}
```

If there are any pending transformations, this command reads the active dataset and causes execution of any pending commands. Otherwise, it takes effect immediately without reading the active dataset.

### Release History

Release 16.0.

- Command introduced.

Release 18.0.

- ROLE keyword introduced.

### Example

```
SORT VARIABLES BY NAME (A).
```

---

## Overview

SORT VARIABLES sorts the variables in the active dataset based on the values of the selected dictionary attribute.

### Basic Specification

The basic specification is the command name SORT VARIABLES followed by the name of a single dictionary attribute.

### Syntax Rules

- Only one dictionary attribute can be specified.
- The BY keyword is optional.
- You can explicitly request the default sort order (ascending) by specifying A or UP in parentheses after the attribute name. To sort variables in descending order, specify D or DOWN.

### Sorting Options

Variables can be sorted based on the values of any one of the following dictionary attributes:

**NAME.** *Sort variables by variable names.* The primary sort is alphabetical, but trailing digits are sorted numerically within ties on the preceding part. For example, V2 comes before V10 in ascending order.

**TYPE.** *Group variables by type (numeric or string) and sort string variables by defined width.* In default ascending order, numeric variables come before string variables, and shorter string variables come before longer string variables.

**FORMAT.** *Group variables by format (for example, Date, Dollar, String).*

**LABEL.** *Sort variables in alphabetical order by variable labels.* In default ascending order, all variables without defined variable labels come before variables with defined variable labels. See the topic Chapter 291, "VARIABLE LABELS," on page 2129 for more information.

**VALUES.** *Sort variables by value labels.* In default ascending order, all variables without defined value labels come before variables with defined value labels. See the topic Chapter 287, "VALUE LABELS," on page 2115 for more information.

**MISSING.** *Group variables by defined missing values.* In default ascending order, all variables without defined missing values come before variables with defined missing values. See the topic Chapter 153, "MISSING VALUES," on page 1165 for more information.

**MEASURE.** *Sort variables by measurement level.* The default ascending order is: nominal, ordinal, scale. See the topic Chapter 292, "VARIABLE LEVEL," on page 2131 for more information.

**ROLE.** *Sort variables by role.* Some dialogs support predefined roles that can be used to pre-select variables for analysis. See the topic "Overview" on page 2133 for more information.

**COLUMNS.** *Sort variables by column width.* Column width is the width of the column that displays the variable in Data View of the Data Editor. See the topic Chapter 294, "VARIABLE WIDTH," on page 2135 for more information.

**ALIGNMENT.** *Group variables by alignment.* The default ascending order is: left, right, center. See the topic Chapter 289, "VARIABLE ALIGNMENT," on page 2125 for more information.

**ATTRIBUTE name.** *Sort variables by values of the specified custom variable attribute name.* In default ascending order, all variables without values for the named attribute come before variables with values for the named attribute. See the topic Chapter 290, "VARIABLE ATTRIBUTE," on page 2127 for more information.

## Release History

### Release 23.0

- Command introduced.

## Example

### SPATIAL ASSOCIATION RULES

```

/MAPSPEC FILE="/MyFolder/MyFile.xml"
/DATASET DATAID=EventData
EVENTDATA=YES
PREDICTIONS=EVar1 EVar2 EVar3
CONDITIONS=EVar2 EVar3 EVar4 EVar5
/DATASET DATAID=ContextDataA
EVENTDATA=NO
PREDICTIONS=AVar1 AVar2
CONDITIONS=AVar2 AVar3
/DATASET DATAID=ContextDataB
EVENTDATA=NO
PREDICTIONS=BVar1 BVar2
CONDITIONS=BVar2 BVar3
/SAVE SOURCESTOSCORE=EventData(EventData)
BESTNAME="BestRules".

```

---

## Overview

The SPATIAL ASSOCIATION RULES command finds associations based on event and geospatial data (geospatial association rules).

### Basic specifications

- MAPSPEC subcommand that specifies the map specification file.
- DATASET subcommand that specifies the data source that contains event data.
- One or more DATASET subcommands that specify the data sources that contain map information.
- All other subcommands are optional.

## Operations

Unlike most statistical procedure commands, this command does not require an active dataset that is open in the current session. All data sources used by the procedure must be specified in a map specification file defined with the SPATIAL MAPSPEC command.

### Syntax rules

- Subcommands can be specified in any order.
- Parentheses, equals signs, and slashes shown in the syntax chart are required.
- The command name, subcommand names, and keywords must be spelled in full.
- Empty subcommands are not allowed.

### Limitations

SPLIT FILE is ignored by SPATIAL ASSOCIATION RULES.

---

## MAPSPEC subcommand

The MAPSPEC subcommand specifies the map specification file that identifies the required maps and data.

- A map specification file is a .mplan file created with the SPATIAL MAPSPEC command.
- The file specification must be enclosed in quotation marks.

---

## AUTOBINNING subcommand

The AUTOBINNING subcommand specifies the number of bins for continuous fields.

- The BINS keyword specifies the number of bins.
- The default value is BINS=5.
- The value must be an integer between 1 and 10.

---

## AGGREGATION subcommand

The AGGREGATION subcommand specifies the aggregation methods for data and maps.

- Aggregation is necessary when there are more records in the data than there are features in the map. For example, you have data records for individual counties but you have a map of states.
- You can specify the aggregation method for continuous and ordinal fields. Nominal fields are aggregated based on the modal value.

### AGGMAP=NO | YES

The AGGMAP keyword specifies if aggregation is applied to both data and maps. The default value is NO, and aggregation is applied only to data.

### CONTINUOUS=MEAN | MEDIAN | SUM

The aggregation method for continuous fields. The default value is MEAN.

### ORDINAL=MODE | MEDIAN | HIGHEST | LOWEST

The aggregation method for ordinal fields. The default value is MODE.

## Measurement level

For data sources that are not IBM SPSS Statistics format data files, measurement level is automatically assigned based on the rules in the following table.

Table 90. Rules for determining default measurement level

Condition	Measurement Level
Format is dollar or custom-currency	Continuous
Format is date or time (excluding Month and Wkday)	Continuous
All values of a variable are missing	Nominal
Variable contains at least one non-integer value	Continuous
Variable contains at least one negative value	Continuous
Variable contains no valid values less than 10,000	Continuous
Variable has <i>N</i> or more valid, unique values*	Continuous
Variable has no valid values less than 10	Continuous
Variable has less than <i>N</i> valid, unique values*	Nominal

\* *N* is the user-specified cut-off value. The default is 24.

## DATASET subcommand

The DATASET subcommand identifies the data sources used in the analysis. The datasets are defined in a map specification file created by the SPATIAL MAPSPEC command.

- You can specify multiple DATASET subcommands for multiple data sources.
- Only one DATASET subcommand can specify event data.

### DATAID=id

The IDENTIFIER value of the dataset, specified on a DATA subcommand of the SPATIAL MAPSPEC command.

- If EVENTDATA=YES and more than one data source provides event data, you can specify multiple ID values .

### KEEP=fieldname (id id [id...] [type] [measurement level]) fieldname...

Required for multiple event data sources, KEEP creates a single data source from the different data sources. For each field, specify the datasets that contain that field.

**ALL** ALL can be used in place of a list of dataset ID values. This keyword includes all fields from all datasets specified on the DATAID keyword.

### STRING | NUMERIC

You can optionally specify the data type as STRING or NUMERIC. Data type for each field must be the same in all datasets. The type specification on KEEP treats all instances of the field as the same type. If a type keyword is specified, you must also specify the measurement level.

### NOMINAL | ORDINAL | SCALE

You can optionally specify the measurement level as NOMINAL, ORDINAL, or SCALE. This keyword must be preceded by a type keyword. SCALE cannot be specified with STRING.

### PREDICTIONS=fieldlist

Specifies the fields that are predictions in the rules.

- For multiple event data sources, all fields specified for PREDICTIONS must also be specified on KEEP.
- Fields specified as predictions can also be specified as conditions.

### CONDITIONS=fieldlist

Specifies the fields that are conditions. Fields specified as conditions can also be specified as predictions.

**BINEXCEPTIONS=fieldname(value list); fieldname(value list);...**

For the specified continuous fields, overrides the AUTOBINNING setting and uses the specified list of cut points for binning.

- The value list is enclosed in parentheses.
- Specifications for multiple fields are separated by semi-colons.

**AGGEXCEPTIONS=fieldname(MEAN | MEDIAN | MODE | SUM | HIGH | LOW); fieldname...**

For the specified fields, overrides the aggregation method specified on the AGGREGATION subcommand and uses the specified method.

- The method name is enclosed in parentheses.
- Specifications for multiple fields are separated by semi-colons.

---

## **RULEGENERATION subcommand**

The RULEGENERATION subcommand specifies parameters for how rules are generated. A rule consists of conditions and predictions. A rule can have multiple conditions and multiple predictions.

**MAXCONDITION=integer**

Maximum number of field values that can occur in the conditions for a rule. The value must be a positive integer between 1 and 9. The default value is 5. The sum of MAXCONDITION and MAXPREDICTION cannot exceed 10.

**MAXPREDICTION=integer**

Maximum number of field values that can occur in the predictions for a rule. The value must be a positive integer between 1 and 5. The default value is 1. The sum of MAXCONDITION and MAXPREDICTION cannot exceed 10.

**MINSUPPORT=value**

Minimum rule support a rule must have to be included in the output. The value represents the proportion of cases for which the rule is true in the observed data. For example, if the rule is "If  $x=1$  and  $y=2$ , then  $z=3$ ," rule support is the actual proportion of cases in the data for which  $x=1$ ,  $y=2$ , and  $z=3$ . The value must be greater than 0 and less than 1. The default value is 0.05. Using the default value, a rule must be true at least 5% of the time in the observed data.

**MINCONDITIONSUPPORT=value**

Minimum condition support a rule must have to be included in the output. The value represents the proportion of cases for which the condition exists. For example, if the rule is "If  $x=1$  and  $y=2$ , then  $z=3$ ," condition support is the proportion of cases in the data for which  $x=1$  and  $y=2$ . The value must be greater than 0 and less than 1. The default value is 0.05. Using the default value, a condition must occur in 5% of the cases.

**MINCONFIDENCE=value**

Minimum confidence a rule must have to be included in the output. Confidence is the proportion of correct predictions. The value must be greater than 0 and less than 1. The default value is 0.1. Using the default value, the prediction of the rule must be correct at least 10% of the time.

**MINLIFT=value**

Minimum lift a rule must have to be included in the output. Lift is a measure of how much the rule improves prediction compared to random chance. It is the ratio of correct predictions to the overall occurrence of the predicted value. The value must be greater than 1. The default value is 1.2. For example, if the predicted value occurs 20% of the time and the confidence in the prediction is 80%, then the lift value is 4. The default value of 1.2 means that prediction must be correct 20% more often than the overall occurrence of the predicted value.

**EXCLUDE=fieldname(id) fieldname(id); fieldname(id) fieldname(id);...**

Excludes the specified pairs of fields from being included in the same rule.

- Each field name is followed by the ID value of the data source it comes from.

- The ID value is the IDENTIFIER value that is specified on the DATA subcommand of the SPATIAL MAPSPEC command.
- If there are multiple event data sources, use the keyword EVENT for the ID value.
- Each pair of field names is separated by a semi-colon.

**ENCODEASSAME=fieldname(id) fieldname(id); fieldname(id) fieldname(id);...**

Identifies pairs of fields that should be treated as the same field.

- Each field name is followed by the ID value of the data source it comes from.
- The ID value is the IDENTIFIER value that is specified on the DATA subcommand of the SPATIAL MAPSPEC command.
- If there are multiple event data sources, use the keyword EVENT for the ID value.
- Each pair of field names is separated by a semi-colon.

## MODELTABLES subcommand

The MODELTABLES subcommand specifies the model evaluation tables to display in the output.

**RECORDSUMMARY=YES | NO**

Number and percentage of included and excluded records. The default display setting is YES.

**EVALUATION=YES | NO**

Summary statistics for condition support, confidence, rule support, lift and deployability. The statistics include mean, minimum, maximum, and standard deviation. The default display setting is YES.

**FIELDFREQ=YES | NO**

Fields that occur most frequently in the rules. The default display setting is YES.

**FIELDTRANSFORMATIONS=NO | YES**

Describes the transformations that are applied to fields used in the analysis. The default display setting is NO.

**ITEMFREQ=NO | YES**

Items that occur most frequently. An item is a condition or a prediction in a rule. For example, age < 18 or gender=female. The default display setting is NO.

**EXCLUDEDINPUTS=NO | YES**

Fields excluded from the analysis and the reason each field was excluded. The default display setting is NO.

## MAPOUTPUT subcommand

The MAPOUTPUT subcommand controls the display of interactive map output, based on the specified criterion. To display results for multiple criteria, use multiple MAPOUTPUT subcommands.

**DISPLAY=YES | NO**

Controls the display of the interactive map output. The default display setting is YES.

**NUMRULES=integer**

The maximum number of rules to include in the output.

- The value must be an integer between 2 and 10.
- The specified value is the maximum number of rules. The final number of rules included could be lower than that.
- The default value is 5.

**CRITERION=value**

The criterion to use for rules.

- Only one criterion can be specified on each subcommand.

- To display rules for more than one criterion, use multiple subcommands.

**CONFIDENCE**

The percentage of correct rule predictions. This is the default setting.

**RULESUPPORT**

The percentage of cases for which the rule is true. For example, if the rule is "If  $x=1$  and  $y=2$ , then  $z=3$ ," rule support is the actual percentage of cases in the data for which  $x=1$ ,  $y=2$ , and  $z=3$ .

**LIFT** Lift is a measure of how much the rule improves prediction compared to random chance. It is the ratio of correct predictions to the overall occurrence of the predicted value. The value must be greater than 1. For example, if the predicted value occurs 20% of the time and the confidence in the prediction is 80%, then the lift value is 4.

**CONDSUPPORT**

The percentage of cases for which the rule condition exists. For example, if the rule is "If  $x=1$  and  $y=2$ , then  $z=3$ ," condition support is the proportion of cases in the data for which  $x=1$  and  $y=2$ .

**DEPLOYABILITY**

The percentage of incorrect predictions when the conditions are true. Deployability is equal to  $(1-\text{confidence})$  multiplied by condition support or condition support minus rule support.

## **WORDCLOUD subcommand**

The WORDCLOUD subcommand controls the display of a word cloud of rules for the specified criterion. The size and position of the text indicates its relative importance. To display results for multiple criteria, use multiple WORDCLOUD subcommands.

**DISPLAY=NO | YES**

Controls the display of the word cloud. The default display setting is NO.

**NUMRULES=integer**

The number of rules to include in the output. The value must be an integer between 2 and 30. The default value is 10.

**CRITERION=value**

The criterion to use for rules.

- Only one criterion can be specified on each subcommand.
- To display rules for more than one criterion, use multiple subcommands.

**CONFIDENCE**

The percentage of correct rule predictions. This is the default setting.

**RULESUPPORT**

The percentage of cases for which the rule is true. For example, if the rule is "If  $x=1$  and  $y=2$ , then  $z=3$ ," rule support is the actual percentage of cases in the data for which  $x=1$ ,  $y=2$ , and  $z=3$ .

**LIFT** Lift is a measure of how much the rule improves prediction compared to random chance. It is the ratio of correct predictions to the overall occurrence of the predicted value. The value must be greater than 1. For example, if the predicted value occurs 20% of the time and the confidence in the prediction is 80%, then the lift value is 4.

**CONDSUPPORT**

The percentage of cases for which the rule condition exists. For example, if the rule is "If  $x=1$  and  $y=2$ , then  $z=3$ ," condition support is the proportion of cases in the data for which  $x=1$  and  $y=2$ .

## DEPLOYABILITY

The percentage of incorrect predictions when the conditions are true. Deployability is equal to (1-confidence) multiplied by condition support or condition support minus rule support.

---

## RULESTABLE subcommand

The RULESTABLE subcommand controls the display of a table of rules, sorted by the value of the specified criterion.

- The table displays the top  $n$  rules (based on NUMRULES), based on the selected criterion.
- The table displays values for all criteria.
- To display results sorted by different criteria, use multiple RULESTABLE subcommands.

### DISPLAY=NO | YES

Controls the display of the rules. The default display setting is NO.

### NUMRULES=integer

The maximum number of rules to include in the output.

- The value must be an integer between 2 and 50.
- The specified value is the maximum number of rules. The final number of rules included could be lower than that.
- The default value is 30.

### CRITERION=value

The criterion to use for rules.

- Only one criterion can be specified on each subcommand.
- To display rules for more than one criterion, use multiple subcommands.

### CONFIDENCE

The percentage of correct rule predictions. This is the default setting.

### RULESUPPORT

The percentage of cases for which the rule is true. For example, if the rule is "If  $x=1$  and  $y=2$ , then  $z=3$ ," rule support is the actual percentage of cases in the data for which  $x=1$ ,  $y=2$ , and  $z=3$ .

**LIFT** Lift is a measure of how much the rule improves prediction compared to random chance. It is the ratio of correct predictions to the overall occurrence of the predicted value. The value must be greater than 1. For example, if the predicted value occurs 20% of the time and the confidence in the prediction is 80%, then the lift value is 4.

### CONDSUPPORT

The percentage of cases for which the rule condition exists. For example, if the rule is "If  $x=1$  and  $y=2$ , then  $z=3$ ," condition support is the proportion of cases in the data for which  $x=1$  and  $y=2$ .

## DEPLOYABILITY

The percentage of incorrect predictions when the conditions are true. Deployability is equal to (1-confidence) multiplied by condition support or condition support minus rule support.

---

## SAVE subcommand

The SAVE subcommand saves score values as new fields in a data file or new dataset.

**SOURCESTOSCORE=id ('filespec'| dataset)**

New fields containing score values are written to the specified data source. The ID value is the value of DATAID on the DATASET subcommand. If the data source is not open in the current session, it is opened in the current session. You must explicitly save the modified file to save the new fields.

**BESTRULE=integer**

Saves the best  $n$  rules. Three new fields are saved for each rule: rule ID, predicted value, and confidence. The default number of best rules is 3.

**BESTNAME='name'**

Root name for the new fields. Names must conform to variable naming rules. The default root name is "BestRule".

**TARGETS=fieldname(id) fieldname(id)...**

Create new fields for the selected target (prediction) fields.

- Two new fields are created for each target field: predicted value and confidence value.
- For continuous (scale) target fields, the predicted value is string that describes a value range. A value of the form "(value1, value2]" means "greater than value1 and less than or equal to value2."

---

## Release History

### Release 23.0

- Command introduced.

---

## Overview

The SPATIAL MAPSPEC command defines map specification files for use with SPATIAL TEMPORAL PREDICTION and SPATIAL ASSOCIATION RULES.

### Syntax rules

- Subcommands can be specified in any order.
- You can specify multiple MAP and DATA subcommands. The order of MAP subcommands determines the layer order of the maps.
- Parentheses, equals signs, and slashes shown in the syntax chart are required.
- The command name, subcommand names, and keywords must be spelled in full.
- Empty subcommands are not allowed.

---

## MAPPROJECTION subcommand

The optional MAPPROJECTION subcommand specifies the type of projection that is used to read and display maps.

- All maps specified in the SPATIAL MAPSPEC command must use the same map projection.
- If both WKID and PROJECTION are specified, the WKID value is used.

### WKID=code

"Well known ID" for common projections. For more information, go to <http://resources.arcgis.com>

### PROJECTION

The PROJECTION keyword identifies the type of projection.

**name** A valid projection name. For more information, go to <http://help.arcgis.com/en/webapi/javascript/gmaps/help/topics/pcs.html>

### CARTESIAN

The coordinate system is simple X and Y coordinates.

### DISPLAY

The DISPLAY keyword sets the display projection.

### SIMPLE

Use the projection from the WKID or the PROJECTION value. This setting is the default value.

### MERCATOR

A cylindrical map projection that preserves the angles and the shapes of small objects. The Mercator projection distorts the size and shape of large objects, as the scale increases from the Equator to the poles, where it becomes infinite.

### STEREOGRAPHIC

A projection recommended for maps close to the poles.

### WINKELTRIPEL

Winkel tripel projection. This projection is a modified azimuthal map projection.

---

## MAP subcommand

Each optional MAP subcommand represents a map and layer in the model. The z-order of the maps is determined by the order of the MAP subcommands. The first MAP subcommand represents the map furthest back in map order.

- If specified, the MAP subcommand must include TYPE, SOURCE, and IDENTIFIER keywords.
- This subcommand is not required if you are using a dataset in the current session or an IBM SPSS Statistics data file that includes fields that contain X and Y coordinates.

### TYPE=FILE | SERVICE

Specifies the type of map. FILE indicates that the source is a shape file (.shp). SERVICE indicates that the source is an online map service.

### SOURCE='filespec' | 'url'

- If TYPE=FILE, the SOURCE value must be a shape file (.shp) with a corresponding dBase (.dbf) file in the same directory location. The name of the .dbf file must be the same as the name of the .shp file. The source file can also be a .zip archive. The name of the .shp file, .dbf file, and any other supporting files (.shx, .sbx, .sbn, .prj) must be the same as the name of the .zip archive.
- If TYPE=SERVICE, the SOURCE value must be an internet address (URL) for the service. The value must be enclosed in quotation marks.

### LAYER=number

If the source is a map service, the index number of the layer. The default value is the first layer of the map. You can specify LAYER or LAYERNAME.

### LAYERNAME='name'

If the source is a map service, the name of the layer. The name must be enclosed in quotation marks. The default value is the first layer of the map. You can specify LAYER or LAYERNAME.

### IDENTIFIER=name

A unique name that identifies the map. The name must conform to variable name rules.

### COORDSYSTEM

If there is no projection (.prj) file associated with the map, COORDSYSTEM specifies the coordinate system.

#### GEOGRAPHIC

The coordinate system is latitude and longitude. This option is the default setting.

#### WKID (value)

The coordinate system is based on the WKID value. The value is enclosed in parentheses.

#### PROJECTION (name)

The coordinate system is based on the named projection. The name is enclosed in parentheses. For more information, go to <http://help.arcgis.com/en/webapi/javascript/gmaps/help/topics/pcs.html>

### SPATIALRELATION

The geospatial relationship is used by the model to determine how the events relate to the features in the map.

- This setting is used only for maps that are used in the SPATIAL ASSOCIATION RULES procedure.
- This setting only applies to data sources associated with maps where ROLE=CONTEXT is specified on the DATA subcommand.

### CLOSE

The event occurs close to a specified point on the map. The CLOSERADIUS keyword determines the area that is "close".

**WITHIN**

The event occurs within a specified region on the map.

**CONTAINS**

The event area contains geographic context object.

**INTERSECTS**

Locations where lines or regions from the different maps intersect each other.

**CROSS**

Locations where lines (for roads, rivers, railroads) from different lines cross each other.

**NORTH, SOUTH, EAST, WEST**

The event occurs within an area north, south, east, or west of a specified point on the map. The CLOSERADIUS keyword determines the area.

**CLOSERADIUS=value**

The radius for what is considered "close" to the features in the map. This setting is used only when the spatial relation value is CLOSE, NORTH, SOUTH, EAST, or WEST.

**CLOSEMEASURE=MILE | KILOMETER | METER | CENTIMETER**

The measurement unit that is used for the CLOSERADIUS value. The default measurement unit is MILE.

**MAXRELATIONS=integer**

The maximum number of relationships between the features on the map and the events. The default value is 5.

---

**DATA subcommand**

The DATA subcommand specifies data sources to include.

- You can specify multiple DATA subcommands.

**TYPE=FILE | MAP | DATASET**

Specifies the type for the data source.

- FILE. An IBM SPSS Statistics format data file (.sav).
- MAP. A DBF (.dbf) file associated with a shape file (.shp) specified on the MAP subcommand.
- DATASET. A dataset that is open in the current session.

**SOURCE='file spec' | map id | dataset | \***

Specifies the name of the data source.

- For TYPE=FILE, the name must be a file specification enclosed in quotation marks.
- For TYPE=MAP, the name must be the value of IDENTIFIER specified on the MAP subcommand.
- For TYPE=DATASET, the name must be the name of a dataset that is open in the current session. You can use an asterisk (\*) to refer to the active dataset.

**IDENTIFIER=name**

A unique name that identifies the dataset. The name must conform to variable name rules.

**ROLE=EVENTDENSITY | CONTEXT | SCORE**

Specifies the role of the data source.

**EVENTDENSITY**

- For SPATIAL ASSOCIATION RULES, this value indicates that the data source contains event data. Event data contain information on events that occur, such as crimes, accidents, or individual addresses.
- For SPATIAL TEMPORAL PREDICTION, this value indicates that the data source contains data for computing kernel density estimates. This data source must use coordinates, specified with the XCOORDINATE, YCOORDINATE and optional ZCOORDINATE keywords.

## CONTEXT

A context data identifies features on the map. A context data can also contain fields that can be used as inputs for the model. To use a context dBase (.dbf) file that is associated with a map shape (.shp) file, the context dBase file must be in the same location as the shape file and must have the same root name. For example, if the shape file is geodata.shp, the dBase file must be named geodata.dbf.

## SCORE

For SPATIAL TEMPORAL PREDICTION, fields that contain values for predicted values, variance, and upper and lower confidence bounds are written to the specified data source. You must include a SCORE specification if SCORE=YES on the SAVE subcommand of the SPATIAL TEMPORAL PREDICTION command.

**KEY** For TYPE=MAP, an optional list of hierarchical key fields. For example, a map could have a region for every county and every state. Since county names are not unique, you need to specify state and county as hierarchical keys.

## SHAPEID

A unique internal ID value. This is the default.

## DEFINED (field list)

A list of field names that define the hierarchical keys. The list of field names is enclosed in parentheses.

## MAPID, DATAKEY, and MAPKEY

For TYPE=FILE and TYPE=DATASET, the DATA subcommand must specify either key values associated with a map or coordinate values.

### MAPID=id

This setting specifies the map associated with the data. The ID value for the map is the IDENTIFIER value specified on the MAP subcommand.

### DATAKEY=fieldlist

The key fields in the data source that match the data with the map. Fields specified on DATAKEY are matched with fields specified on MAPKEY in the order specified. Both keywords must contain the same number of fields.

### MAPKEY=fieldlist

The key fields in the map that match the map with the data. Fields specified on MAPKEY are matched with fields specified on DATAKEY in the order specified. Both keywords must contain the same number of fields.

## XCOORDINATE, YCOORDINATE, and ZCOORDINATE

For TYPE=FILE and TYPE=DATASET, the DATA subcommand must specify either key values associated with a map or coordinate values. If the data source contains coordinate values, these settings specify the X, Y, and Z coordinates. The Z coordinate is optional and is ignored by the SPATIAL ASSOCIATION RULES command.

## COORDSYSTEM

Specifies the coordinate system.

### GEOGRAPHIC

The coordinate system is latitude and longitude. This option is the default setting.

### CARTESIAN

The coordinate system is simple X and Y coordinates.

### WKID (value)

The coordinate system is based on the WKID value. The value is enclosed in parentheses.

**PROJECTION (name)**

The coordinate system is based on the named projection. The name is enclosed in parentheses. For more information, go to <http://help.arcgis.com/en/webapi/javascript/gmaps/help/topics/pcs.html>

**DATATOMAP='data value' TO 'map value'**

Maps specified unmatched data key values to specified map key values.

- Multiple pairs of values are separated by semi-colons.
- Quotation marks are optional for numeric values.

---

**SPECFILE subcommand**

The SPECFILE subcommand specifies the name and location for the map specification file defined by the SPATIAL MAPSPEC command.

**FILE='filespec'**

Specifies the name and location of the file.

- The file specification must be enclosed in quotation marks.
- The output file is .zip archive with the default file extension .mplan.
- You can use "\*" as a directory path to specify the SPSS Statistics temporary directory. The temporary file is deleted at the end of the session.
- If you do not specify a file, a temporary file named mapspec.zip is created in the temporary directory. This file is deleted at the end of the session.

**DISPLAY=YES | NO**

Controls the display of an output table that contains the details of the map specification. The default setting is YES.

**SAVEDATA=NO | YES**

Controls whether data from the files are saved with the map specification.

- NO. The map specification contains only references to the files. This option is the default setting.
- YES. Data from map shape files, external data files, and datasets used in the map specification are saved in the .zip archive.
- Data from unsaved datasets in the map specification are always saved.
- Only references are saved for map services and databases.

---

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

## Release History

Release 23.0

- Command introduced.

---

## Overview

SPATIAL TEMPORAL PREDICTION is a time series modeling procedure that include spatial aspects in the analysis.

## Syntax rules

- Parentheses, equals signs, and slashes shown in the syntax chart are required.
- The command name, subcommand names, and keywords must be spelled in full.
- Empty subcommands are not allowed.
- A maximum of two DATASET subcommands are allowed.

## Limitations

SPLIT FILE is ignored by SPATIAL TEMPORAL PREDICTION.

## Data requirements

Spatial temporal modeling requires data values that define both time and location, including:

- One or more fields that define time intervals. These fields can be dates or times or numbers that represent cyclic time periods.
- One or more fields that define location. These fields can be key values that match key values in a map file, or coordinates such as longitude and latitude.
- For each time interval, there is an instance of each location.
  - For regular time data, it is assumed that there are instances of each location for each time interval. If some locations are missing for some time intervals, those locations are treated as missing data.
  - For point occurrence data used for calculating kernel density estimates, it is assumed that the number of locations changes over time.

---

## MAPSPEC subcommand

The MAPSPEC subcommand specifies the map specification file that identifies the required maps and data.

**FILE='filespec'**

A map specification file is a .mplan file created with the SPATIAL MAPSPEC command.  
The file specification must be enclosed in quotation marks.

---

## AGGREGATION subcommand

The AGGREGATION subcommand specifies the aggregation methods for any fields specified as INPUTS on the DATASET subcommand.

- Aggregation is necessary when there is more than one record in a defined time interval. For example, if the time interval is month, then multiple dates in the same month are aggregated together.
- You can specify the aggregation method for continuous and ordinal fields. Nominal fields are aggregated based on the modal value.

**CONTINUOUS=MEAN | MEDIAN | SUM**

The aggregation method for continuous fields. The default value is MEAN.

**ORDINAL=MEDIAN | MODE | HIGHEST | LOWEST**

The aggregation method for ordinal fields. The default value is MEDIAN.

## Measurement level

For data sources that are not IBM SPSS Statistics format data files, measurement level is automatically assigned based on the rules in the following table.

*Table 91. Rules for determining default measurement level*

Condition	Measurement Level
Format is dollar or custom-currency	Continuous
Format is date or time (excluding Month and Wkday)	Continuous
All values of a variable are missing	Nominal
Variable contains at least one non-integer value	Continuous
Variable contains at least one negative value	Continuous
Variable contains no valid values less than 10,000	Continuous
Variable has $N$ or more valid, unique values*	Continuous
Variable has no valid values less than 10	Continuous
Variable has less than $N$ valid, unique values*	Nominal

\*  $N$  is the user-specified cut-off value. The default is 24.

---

## DATASET subcommand

The DATASET subcommand identifies the data sources that are used in the analysis. The datasets are defined in a map specification file that is created by the SPATIAL MAPSPEC command. You can specify a maximum of two DATASET subcommands.

The following requirements apply when there are two data sources:

- Kernel density estimates (KDE) are calculated and used as the target.
- The map specification file must include a map (SPATIAL MAPSPEC command, MAP subcommand).
- Both data sources must contain a time field.

- One of the data sources must specify `ROLE=EVENTDENSITY` on the `DATA` subcommand of the `SPATIAL MAPSPEC` command. This data source must contain coordinates.
- The other data source must specify `ROLE=CONTEXT` on the `DATA` subcommand of the `SPATIAL MAPSPEC` command. This data source must be matched to the map with key values.

**DATAID=id**

The IDENTIFIER value of the dataset, which is specified on a `DATA` subcommand of the `SPATIAL MAPSPEC` command.

**KDENAME=rootname**

Root field name for calculated kernel density estimates. If a field name with that name exists, a unique new name is generated by appending an integer value to the name.

**TARGET=fieldname**

The name of the target field.

- If there is only one `DATASET` subcommand, a single target field is required.
- If there are two `DATASET` subcommands, the `TARGET` keyword is not valid.

**INPUTS=fieldlist**

The inputs (predictors) in the dataset. Inputs for each dataset are specified on separate `DATASET` subcommands.

**TIMEINDEX=fieldlist**

The fields that define time periods. Multiple fields can be specified to define periodicity. Each `DATASET` subcommand must contain a `TIMEINDEX` specification, and they must define the same time interval.

**AGGEXCEPTIONS=fieldname(MEAN | MEDIAN | MODE | SUM | HIGH | LOW); fieldname...**

For the specified fields, overrides the aggregation method specified on the `AGGREGATION` subcommand and uses the specified method.

- The method name is enclosed in parentheses.
- Specifications for multiple fields are separated by semi-colons.

## TIMEFIELDS subcommand

The `TIMEFIELDS` subcommand defines the time intervals for `TIMEINDEX` fields specified on the `DATASET` subcommand.

- The procedure assumes that all cases (records) represent equally spaced intervals.
- Based on the selected time interval, the procedure can detect missing observations or multiple observations in the same time interval that need to be aggregated together. For example, if the time interval is days and the date 2014-10-27 is followed by 2014-10-29, then there is a missing observation for 2014-10-28. If the time interval is month, then multiple dates in the same month are aggregated together.
- For some time intervals, the additional setting can define breaks in the normal equally spaced intervals. For example, if the time interval is days, but only week days are valid, you can specify that there are five days in a week, and the week begins on Monday.

**INPUTINTERVAL=keyword**

The basic time interval. The value can be: `YEAR`, `QUARTER`, `MONTH`, `WEEK`, `DAY`, `HOUR`, `MINUTE`, `SECOND`, `DURATION`, or `PERIOD`.

- `DURATION` applies to time values (hours, minutes, seconds) that represent length of time from a starting time, rather than clock time.
- Time fields must be date format or time format fields unless the input interval is `PERIOD`.

**INTERVAL=HOUR | MINUTE | SECOND**

For `DURATION`, this setting specifies what the duration interval represents. This setting is valid only for `DURATION`.

**INCREMENT=integer**

The increment for the input interval. For example, if the input interval is years and the increment is 2, the time interval between observations is two years. The value must be a positive integer. The default value is 1. This setting is valid for YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, DURATION, and PERIOD.

**DAYSWK=integer**

Number of days in a week. The value must be a positive integer. The default setting is 7. This setting is valid for DAY, HOUR, MINUTE, and SECOND.

**WKSTART=MON | TUE | WED | THU | FRI | SAT | SUN**

The starting day of the week value. The default value is MON. This setting is valid for DAY, HOUR, MINUTE, and SECOND.

**HRSDAY=integer**

Number of hours in a day. The value must be a positive integer. The default value is 24. This setting is valid for HOUR, MINUTE, and SECOND.

**DAYSTART=hh:mm**

Starting time for the day. The value must be a time value in format hh:mm. The default value is 00:00. This setting is valid for HOUR, MINUTE, and SECOND.

**START=value list**

List of starting values for cyclic periods. The value must be a positive integer. This setting is valid only with PERIOD.

**LENGTH=value list**

List of cycle lengths of cyclic periods. The value must be a positive integer. This setting is valid only with PERIOD.

**INPUTINTERVAL=PERIOD**

- If there is only one time field, START and LENGTH are not valid. For a single time field, the input interval PERIOD defines the time interval for a non-cyclic time field that is not a date format or time format field.
- If there are multiple time fields, the fields represent cyclic periods, such as years, quarters within years, and months within quarters.
- If there are multiple time fields, START and LENGTH are required. If there are n time fields, the number of START and LENGTH values must be n-1, where the values correspond to the last n-1 fields specified for TIMEINDEX.
- INCREMENT represents the input interval at the lowest cycle level, which is the last field specified for TIMEINDEX.

For example, if TIMEFIELDS=year quarter month, the INPUTINTERVAL specification could be:

```
INPUTINTERVAL=PERIOD START=1 1 LENGTH=4 3
```

- The START and LENGTH values apply to quarter and month.
- LENGTH specifies that there are four quarters in each year and 3 months in each quarter.

---

**MODELBUILDING subcommand**

The MODELBUILDING subcommand specifies parameters for building the model.

**SIGNIFICANCE=value**

The significance level for determining if a parametric variogram-based model is appropriate. The value must be greater than 0 and less than 1. The default value is 0.05. If the significance level is higher than the specified value, an empirical model is used, regardless of the setting on the COVARIANCE keyword. The results of one of the tests used to make this determination are displayed in the test of spatial covariance table (MODELTABLES subcommand, COVARIANCE keyword).

**INTERCEPT=NO | YES**

Include the intercept in the model. The default setting value is NO.

**COVARIANCE=VARIOGRAM (value) | EMPIRICAL**

The covariance method for the model. The default method is VARIOGRAM. The keyword VARIOGRAM is followed by a value enclosed in parentheses. The value must be between 1 and 2.

**AUTOREGRESSIONLAG=value**

The maximum autoregression lag. The value must be an integer between 1 and 5. The default value is 1. The number of time intervals in the data must be at least double the autoregression lag value.

**MISSINGRECORDS=value**

Maximum allowed proportion of records (cases) with missing values. If a record has a missing value for the target field or a predictor field, it is not included in the analysis. If the total number of records with missing target or predictor values exceeds the specified proportion, the procedure does not run. The value must be greater than 0 and less than 1. The default value is 0.05.

**UNCERTAINTY=value**

The uncertainty factor is a proportion value that represents the growth in uncertainty when forecasting into the future. The upper and lower limits of forecast uncertainty increase by the specified proportion for each step into the future. The value must be greater than 0 and less than 1. The default value is 0.05.

---

**MODELTABLES subcommand**

The MODELTABLES subcommand specifies the tables to include in the output.

**SPECIFICATIONS=YES | NO**

Summary of specifications used to run the analysis, including target, input, and location fields. The default setting is YES.

**TEMPORALINFO=YES | NO**

Identifies the time field and time intervals used in the model. The default setting is YES.

**LOCATIONS=YES | NO**

Number of locations included and excluded. The default setting is YES.

**COVARIANCE=YES | NO**

For variogram-based parametric models, displays the results of the test of decay over space. If the test result is not significant, a nonparametric, empirical model is used instead of a parametric model. The default setting is YES.

**QUALITY=NO | YES**

Model quality statistics including mean squared error, pseudo R-squared and pseudo adjusted R-squared. The default setting is NO.

**EFFECTS=NO | YES**

Tests of effects in the mean structure model. The output includes test statistics value, degrees of freedom, and significance level for the corrected model and each effect. The default setting is NO.

**MEANSTRUCTURE=NO | YES**

Mean structure model coefficients. The output includes the coefficient value, standard error, test statistics value, significance level, and confidence intervals for each model term. The default setting is NO.

**COEFFICIENTS=NO | YES**

Autoregressive coefficients. The output includes the coefficient value, standard error, test statistics value, significance level, and confidence intervals for each lag. The default setting is NO.

**PARAMETRIC=NO | YES**

For variogram-based parametric models, displays parameter estimates for parametric spatial covariance. The default setting is NO.

---

## MAPOUTPUT subcommand

The MAPOUTPUT subcommand controls the display of interactive map output

### TARGETVALUES=YES | NO

Map of target values. The default setting is YES.

### CORRELATIONS=YES | NO

Map of correlations. The default setting is YES.

### CLUSTER=YES | NO

Map that highlights clusters of locations that are similar to each other. The default setting is YES. Maps of clusters are displayed only for non-parametric empirical models.

#### sub

### SIMILARITY=value

Specifies the similarity required to create clusters. The value must be a number greater than zero and less than 1. The default value is 0.2.

### MAXCLUSTERS=integer

The maximum number of clusters to include. The value must be an integer greater than 1. The default value is 10.

---

## SAVE subcommand

The SAVE subcommand saves predicted values to an open dataset in the current session or an IBM SPSS Statistics- format data file.

- The data source cannot be a data source used in the model.
- The data source must contain all the time fields and predictors used in the model.
- The time values must be greater than the time values used in the model.
- The data source must also be specified on the SPATIAL MAPSPEC command with ROLE=SCORE.

### SCORE=NO | YES

Specifies if predicted values are saved. The default setting is NO.

### SOURCESTOSCORE=id ('filespec' | dataset)

New fields containing predicted values, variance, and upper and lower confidence bounds are written to the specified data source.

- The ID value is the value of IDENTIFIER on the DATA subcommand of the SPATIAL MAPSPEC command. The DATA subcommand must also include ROLE=SCORE for this data source.
- If you are writing scores to an external file (instead of an open dataset), you must use the ID value specified on the SPATIAL MAPSPEC command with a different file specification. You cannot write scores to the file specified on SPATIAL MAPSPEC.

---

## Chapter 255. SPCHART

SPCHART is available in the Statistics Base Edition.

```
SPCHART
[/TEMPLATE='filename']

[/TITLE='line 1' ['line 2']]

\*\*Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

## Release History

### Release 15.0

- (XBARONLY) keyword introduced on XR and XS subcommands.
- RULES subcommand introduced.
- ID subcommand introduced.

### Release 19.0

- CPCHART subcommand introduced.
- NORMAL subcommand introduced.
- REFERENCE subcommand introduced.
- Following keywords introduced on STATISTICS subcommand: N, MEAN, STDDEV, CAPSIGMA, LSL, USL, TARGET, AZLOUT, AZUOUT, CZLOUT, CZUOUT, PZLOUT, PZUOUT.

## Example

```
SPCHART /TEMPLATE='cntr.sgt'  
/IR=subsize.
```

---

## Overview

SPCHART generates several types of high-resolution control charts. A control chart plots a quality characteristic that is measured or computed from a sample versus the sample number or time. This technique is a widely used process-control technique for testing the hypothesis that the process is in a state of statistical control. All control charts display four series:

- The process line representing the quality characteristic for each sample.
- The center line indicating the average value of the quality characteristic that corresponds to the in-control state.
- Two horizontal lines showing the upper control limit and lower control limit.

Control charts are used for improving productivity, preventing defects and unnecessary process adjustments, and gathering information about process capability.

SPCHART produces X-bar, R, s, individuals, and moving range charts as well as np, p, c, and u charts. It also produces a process capability chart. You may need to transform your data to conform to the required data organization that is described under each chart type subcommand.

Control charts are available only on systems where high-resolution display is available.

## Options

**Titles and Footnotes.** You can use the TITLE, SUBTITLE, and FOOTNOTE subcommands to specify a title, subtitle, and footnote for the chart.

**Chart Type.** You can request a specific type of chart by using the XR, XS, IR, I, NP, P, C, U, or CPCHART subcommand.

**Templates.** You can specify a template, using the TEMPLATE subcommand, to override the default chart attribute settings on your system.

**Control Limits.** You can specify a sigma value on the SIGMAS subcommand to modify the calculated upper and lower control limits. You can also use the USL and LSL subcommands to specify fixed limits. The upper and lower limits that you specify will be displayed simultaneously with the calculated control limits. *Note:* Calculated control limits are not displayed on process capability charts.

**Control Rules.** You can specify control rules that help you quickly identify out-of-control points.

### Basic Specification

The basic specification is a chart type subcommand with a variable specification that describes the process data.

### Subcommand Order

Subcommands can be specified in any order.

### Syntax Rules

- Only one chart type subcommand can be specified.
- Keyword SPAN is used only with IR and I subcommands.
- Keyword CONFORM or NONCONFORM is used only with NP and P subcommands.
- Keywords NORMAL and REFERENCE are used only with the CPCHART subcommand.
- Keywords LSL and USL are required when the CPCHART subcommand is specified.

### Operations

- All control charts generated by SPCHART contain four basic series: the process, the center line, the upper control line, and the lower control line.
- The chart title, subtitle, and footnote are assigned as they are specified on TITLE, SUBTITLE, and FOOTNOTE subcommands. For control charts, the default chart title is **Control Chart**, followed by the label of the process variable, and a one-line default footnote displays the sigma level. For a process capability chart, the default chart title is **Process Capability** and there is no default footnote. For all chart types, if split-file processing is in effect then a default subtitle is added that provides split-file information.
- For control charts, the category variable label is used as the title for the *category axis*. If no variable label is defined, the variable name is used. If no category variable is defined, the title is null.
- For control charts, the category variable value labels are used as the *category axis* labels. If no value labels are defined, values are used. If no category variable is defined, integer values from 1 to  $n$  are used, where  $n$  is the number of subgroups or units plotted.
- For control charts, all series are plotted as lines. When a series has a constant value across all samples, the value is reported in the legend entry for the series.
- For all chart types, case weights are not honored when each case is a subgroup. Case weights are honored when each case is a unit and when the weights are integers. When weighted data are used in an individuals chart, replicated cases are plotted on the control chart.
- For control charts, the calculated control limits are always displayed and can be suppressed only by editing the chart in a chart window.
- You can specify preset control limits for an X-bar or I chart, as some industries often do. The specified control limits are displayed simultaneously with the calculated limits.

### Limitations

- Control charts cannot have fewer than 2 points or more than 3000 points.
- The subgroup size in X-bar and range charts cannot exceed 100.
- The span for individuals charts is limited to 100.

- For process capability charts, the subgroup size cannot exceed 100 when /CAPSIGMA=RBAR, and the span cannot exceed 100 when /CAPSIGMA=MRBAR. In addition, the subgroup size or span cannot be less than 2.

---

## Example

```
SPCHART /TEMPLATE='cntr.sgt'  
/IR=subsize.
```

- This command generates an individuals chart and a moving range chart. The process variable *subsize* is a numeric variable that measures the size variation of the product.
- Both charts use the attributes that are defined for the template that is saved in *cntr.sgt*.
- The default span (2) and sigma value (3) are used.
- Because no BY variable is specified, the *x* axis is labeled by sequence numbers.

---

## TEMPLATE Subcommand

TEMPLATE uses an existing file as a template and applies it to all charts generated by the current SPCHART command. The template overrides the default settings that are used to create any charts, and the specifications on the current SPCHART command override the template. Templates are created in the Chart Editor by saving an existing chart as a template.

### Example

```
SPCHART /TEMPLATE='/templates/cntr.sgt'  
/IR=subsize.
```

---

## TITLE, SUBTITLE, and FOOTNOTE Subcommands

TITLE, SUBTITLE, and FOOTNOTE specify lines of text that are placed at the top or bottom of the control chart.

- One or two lines of text can be specified for TITLE or FOOTNOTE, and one line of text can be specified for SUBTITLE.
- Each line of text must be enclosed in quotes. The maximum length of any line is 72 characters.
- The default font sizes and types are used for the title, subtitle, and footnote.
- By default, the title, subtitle, and footnote are left-aligned with the *y* axis.
- For control charts, if you do not specify TITLE the default is **Control Chart** followed by the label of the process variable. For a process capability chart the default title is **Process Capability**.
- If you do not specify SUBTITLE, the subtitle provides the split-file information if split-file processing is in effect; otherwise, it is null, which leaves more space for the chart.
- For control charts, if you do not specify FOOTNOTE the sigma level is identified as the first line of the footnote. There is no default footnote for a process capability chart.

### Example

```
SPCHART TITLE = 'Wheel Production'  
/SUBTITLE = 'Process Control'  
/IR=SUBSIZE.
```

---

## XR and XS Subcommands

XR produces an X-bar chart and an R chart. XS produces an X-bar chart and an s chart. X-bar, R, and s charts are control charts for continuous variables, such as size, weight, length, and temperature.

An X-bar chart plots the mean of each subgroup. The center line indicates the mean of subgroup means. The control limits are calculated from subgroup means, numbers, standard deviations, and the user-specified SIGMAS value. The following figure shows an X-bar chart.

Figure 88. X-bar chart

An R chart plots range values (maximum-minimum) of successive subgroups. The center line indicates the mean of subgroup ranges. The control limits are calculated from subgroup ranges, numbers, and the user-specified SIGMAS value. The R chart tests whether the process variability is in control. When the subgroup size is relatively small (4, 5, or 6), the range method yields almost as good an estimator of the variance as does the subgroup variance. The following figure shows an R chart.

Figure 89. R chart

An s chart plots subgroup standard deviations. The center line indicates the mean of subgroup standard deviations. The control limits are calculated from subgroup standard deviations, numbers, and the user-specified SIGMAS value. The s chart tests whether the process variability is in control, especially when

the subgroup size is moderate to large. The following figure shows an s chart.

Figure 90. An s chart

## Data Organization

For X-bar, R, or s charts, data can be organized where each case is a unit or where each case is a subgroup.

- If each case is a unit with a subgroup identifier, cases are assigned to a category according to the value of the identifier. Table 92 is an example of this type of data organization. The data do not have to be sorted by subgroup. A BY variable (the subgroup identifier) is required to sort and aggregate data and label the process variable.
- If each case is a subgroup, there are as many variables as individuals within one sample. A sample identifier is not required. When there is a sample identifier, it is used for labeling. Table 93 shows this type of organization.

Table 92. Each case is a unit for X-bar, R, and s charts

Subgroup	Length
8:50	6.35
11:30	6.39
8:50	6.40
11:30	6.46
8:50	6.32
11:30	6.37
8:50	6.39
11:30	6.36
...	...

Table 93. Each case is a subgroup for X-bar, R, and s charts

Subgroup	N1	N2	N3	N4
8:50	6.35	6.40	6.32	6.39
11:30	6.39	6.46	6.37	6.36
...	...	...	...	...

## Variable Specification

If data are organized as shown in Table 92, the variable specifications on XR and XS subcommands are  
VAR BY VAR

The variable that is specified before BY is the process variable, which is the variable that contains values for all instances to be plotted (for example, *LENGTH* in Table 92). The variable that is specified after BY is

the category variable or the BY variable, which is the subgroup identifier (for example, *SUBGROUP* in Table 92 on page 1874). The process variable must be numeric, while the category variable can be of any type. The chart is sorted by the category variable.

If data are organized as shown in Table 93 on page 1874, the variable specifications on XR and XS subcommands are

```
VAR VAR [VAR...] [BY VAR]
```

Each of the variables that is specified before BY represents an instance to be plotted (for example, *N1* to *N3* in Table 93 on page 1874). At least two variables are required, and each variable must be numeric. Keyword BY and the category variable (for example, *SUBGROUP* in Table 93 on page 1874) are optional; if specified, the category variable provides labels for the *category axis* and can be any type of variable. If omitted, the *category axis* is labeled from 1 to the number of variables that are specified before keyword BY.

### Example

```
SPCHART /TEMPLATE='ctrl.sgt'  
/XR SUBSIZE BY SHIFT.
```

- The data are organized as shown in Table 92 on page 1874. *SUBSIZE* is a numeric variable that measures the part size. *SHIFT* contains the subgroup identifier (work shift number).
- The chart template is stored in the chart file *ctrl.sgt*.

## (XBARONLY) Keyword

(XBARONLY) suppresses the R or s secondary charts. If this keyword is omitted, the R or s chart will be generated with the X-bar chart.

### Example

```
SPCHART  
/XR=ph BY time (XBARONLY)  
/CAPSIGMA=RBAR  
/SIGMAS=3  
/MINSAMPLE=2.
```

---

## I and IR Subcommands

I produces an individuals chart, and IR produces an individuals chart and a moving range chart. Both types are control charts for continuous variables, such as size, weight, length, and temperature.

An individuals chart plots each individual observation on a control chart. The center line indicates the mean of all individual values, and the control limits are calculated from the mean of the moving ranges, the span, and the user-specified SIGMAS value. Individuals charts are often used with moving range charts to test process variability when the subgroup size is 1. This situation occurs frequently when automated inspection and measurement technology is used and every manufactured unit is analyzed. The situation also occurs when the process is so slow that a larger subgroup size becomes impractical. The following figure shows an individuals chart.

Figure 91. Individuals chart

A moving range chart plots moving ranges of  $n$  successive observations on a control chart, where  $n$  is the specified span (see ). The center line is the mean of moving ranges, and the control limits are calculated from the ranges, the span, and the user-specified SIGMAS value (see ). The following figure shows a moving range chart.

Figure 92. Moving range chart

## Data Organization

For individuals charts and moving range charts, data must be organized so that each case is a unit. Cases are not sorted or aggregated before plotting.

## Variable Specification

The variable specification for I or IR subcommand is

VAR [BY VAR]

You must specify the process variable that contains the value for each individual observation. Each observation is plotted for the individuals chart. The range of  $n$  consecutive observations (where  $n$  is the value that is specified on the SPAN subcommand) is calculated and plotted for the moving range chart. The range data for the first  $n-1$  cases are missing, but the mean and the limit series are not missing.

Keyword BY and the category variable are optional. When specified, the category variable is used for labeling the *category axis* and can be any type of variable. If omitted, the *category axis* is labeled 1 to the number of individual observations in the process variable.

## Example

```
SPCHART /TEMPLATE='ctrl1.sgt'  
/IR=SUBSIZE.
```

- This command requests an individuals chart and a moving range chart.
- The default span (2) and sigma value (3) are used.

## P and NP Subcommands

P produces a p chart and NP produces an np chart. Both charts are control charts for attributes. That is, these charts use data that can be counted, such as the number of nonconformities and the percentage of defects.

A p chart plots the **fraction nonconforming** on a control chart. Fraction nonconforming is the proportion of nonconforming or defective items in a subgroup to the total number of items in that subgroup. This measurement is expressed as a decimal or, occasionally, as a percentage. The center line of the control chart is the mean of the subgroup fractions, and the control limits are based on a binomial distribution and can be controlled by the user-specified SIGMAS value.

Figure 93. A p chart

An np chart plots the number nonconforming rather than the fraction nonconforming. The center line is the mean of the numbers of nonconforming or defective items. The control limits are based on the binomial distribution and can be controlled by the user-specified SIGMAS value. When the subgroup sizes are unequal, np charts are not recommended.

Figure 94. A np chart

## Data Organization

Data for p and np charts can be organized where each case is a unit or where each case is a subgroup.

- If each case is a unit with a conformity status variable and a subgroup identifier, cases are assigned to a category by the value of the subgroup identifier. Table 94 is an example of this type of data organization. The data do not have to be sorted. A BY variable (the subgroup identifier) is required to sort and aggregate data and label the *category axis*.
- If each case is a subgroup, one variable contains the total number of items within a subgroup, and one variable contains the total number of nonconforming or defective items in the subgroup. The subgroup identifier is optional. If specified, the subgroup identifier is used for labeling purposes. Table 95 is an example of this type of data organization. The data are the same as the data that are used in Table 94.

Table 94. Each case is a unit for p and np charts

Subgroup	Outcome
January	Cured
January	Cured
January	Cured
January	Relapse
February	Relapse
February	Cured
February	Relapse
February	Relapse
...	...

Table 95. Each case is a subgroup for p and np charts

Subgroup	Relapse	N
January	1	4
February	3	4
...	...	...

## Variable Specification

If data are organized as illustrated in Table 94, the variable specification on P or NP subcommands is

```
VAR BY VAR
```

The variable that is specified before BY is the status variable (for example, *OUTCOME* in Table 94). The value of this variable determines whether an item is considered conforming or nonconforming. The status variable can be any type, but if it is a string, the value that is specified on CONFORM (or NONCONFORM) must

be enclosed in quotes (see ). The variable that is specified after BY is the category variable and can be any type of variable. The chart is sorted by values of the category variable.

If data are organized as shown in Table 95 on page 1878, the variable specification on P or NP is

```
COUNT(VAR) N({VAR}) [BY VAR]
                {VAL}
```

The variable that is specified on keyword COUNT is the variable that contains the number of nonconforming or defective items (for example, *RELAPSE* in Table 95 on page 1878). The specification on keyword N is either the variable that contains the sample size or a positive integer for a constant size across samples (for example, *N* in Table 95 on page 1878). The COUNT variable cannot be larger than the N variable for any given subgroup; if it is larger, the subgroup is dropped from calculation and plotting. Keyword BY and the category variable are optional. When specified, the category variable is used for *category axis* labels; otherwise, the *category axis* is labeled 1 to the number of subgroups. Cases are unsorted for the control chart.

## C and U Subcommands

C produces a c chart and U produces a u chart. Both charts are control charts for attributes. That is, the charts use data that can be counted.

A c chart plots the total number of defects or nonconformities in each subgroup. A defect or nonconformity is one specification that an item fails to satisfy. Each nonconforming item has at least one defect, but any nonconforming item may have more than one defect. The center line of the c chart indicates the mean of the defect numbers of all subgroups. The control limits are based on the Poisson distribution and can be controlled by the user-specified SIGMAS value. When the sample sizes are not equal, c charts are not recommended.

Figure 95. A c chart

A u chart plots the average number of defects or nonconformities per inspection unit within a subgroup. Each subgroup contains more than one inspection unit. The center line of the u chart indicates the average number of defects per unit of all subgroups. The control limits are based on Poisson distribution and can be controlled by the user-specified SIGMAS value.

Control Chart: Total number of blemishes

Figure 96. A u chart

## Data Organization

Data for c and u charts can be organized where each case is a unit or where each case is a subgroup.

- If each case is a unit with a variable containing the number of defects for that unit and a subgroup identifier, cases are assigned to each subgroup by the value of the identifier. Table 96 is an example of this type of data organization. Data do not have to be sorted by subgroup. A BY variable (the subgroup identifier) is required to sort and aggregate data and to label the *category axis*.
- If each case is a subgroup, one variable contains the total number of units within the subgroup, and one variable contains the total number of defects for all units within the subgroup. The subgroup identifier is optional. When specified, the subgroup identifier is used as *category axis* labels; otherwise, the number 1 to the number of subgroups are used to label the *category axis*. Table 97 is an example of this method of data organization. The data are the same as the data in Table 96.

Table 96. Each case is a unit for c and u charts

ID	Subgroup	Count
1	January	0
2	January	2
3	January	0
4	January	0
5	February	5
6	February	1
7	February	0
8	February	0
...	...	...

Table 97. Each case is a subgroup for c and u charts

Subgroup	Relapses	N
JANUARY	1	4
FEBRUARY	3	4
...	...	...

## Variable Specification

If data are organized as shown in Table 96, the variable specification on C and U subcommands is

VAR BY VAR

The variable that is specified before keyword **BY** contains the number of defects in each unit (for example, *COUNT* in Table 96 on page 1880). The variable must be numeric. The variable that is specified after keyword **BY** is the subgroup identifier (for example, *SUBGROUP* in Table 96 on page 1880). This variable can be any type of variable. The chart is sorted by values of the subgroup identifier.

If data are organized as shown in Table 97 on page 1880, the variable specification on **C** and **U** subcommands is

```
COUNT(VAR) N({VAR}) [BY VAR]
                {VAL}
```

The specification is the same as the specification for **p** and **np** charts.

## CPCHART Subcommand

CPCHART produces a process capability chart. The default process capability chart consists of a histogram of the process values, a superimposed normal curve based on the capability sigma and the process mean, and vertical reference lines at the fixed upper and lower control limits and target value (if specified). It also displays the process capability indices, the process performance indices, and process data such as the process mean and process standard deviation.

- When CPCHART is specified the LSL and USL subcommands are required. The TARGET subcommand is optional with CPCHART.
- You can control which normal curves are superimposed on the histogram with the NORMAL subcommand.
- You can display vertical reference lines at the plus or minus three sigma level, or a user-specified sigma level, with the REFERENCE subcommand.
- All of the statistics displayed on the process capability chart are available in table form from the STATISTICS subcommand.
- Process capability charts have a default title of **Process Capability**. You can specify your own title using the TITLE and SUBTITLE subcommands.

Figure 97. Process capability chart

## Data Organization

The data can be organized in the following ways:

- Each case is a unit with a subgroup identifier that is specified with a BY variable. Table 98 is an example of this type of data organization. The data do not have to be sorted by subgroup.
- Each case is a subgroup and there are as many variables as individuals within one sample. Table 99 shows this type of organization.
- Each case is a unit and there are no subgroups. Table 100 shows this type of organization. Cases are not sorted or aggregated before plotting.

Table 98. Each case is a unit with a subgroup identifier

Subgroup	Length
8:50	6.35
11:30	6.39
8:50	6.40
11:30	6.46
8:50	6.32
11:30	6.37
8:50	6.39
11:30	6.36
...	...

Table 99. Each case is a subgroup

N1	N2	N3	N4
6.35	6.40	6.32	6.39
6.39	6.46	6.37	6.36
...	...	...	...

Table 100. Each case is a unit and there are no subgroups

pH
4.9
4.5
4.7
5.1
4.6
5.1
4.9
4.8
...

## Variable Specification

If data are organized as shown in Table 98, the variable specification on the CPCHART subcommand is

```
var BY var
```

The variable that is specified before BY is the process variable, which is used to generate the histogram (for example, *length* in Table 98). The variable that is specified after BY is the subgroup identifier (for example, *subgroup* in Table 98). The process variable must be numeric, while the subgroup identifier variable can be of any type.

If data are organized as shown in Table 99, the variable specification on the CPCHART subcommand is

```
var var [var...]
```

Each variable contains process values for a particular subgroup. Values from all subgroups are used to generate the histogram. At least two variables are required, and each variable must be numeric.

If data are organized as shown in Table 100 on page 1882, the variable specification on the CPCHART subcommand is

var

The specified variable contains the process values used to generate the histogram, and must be numeric.

#### Example

```
SPCHART /TEMPLATE='cpchart.sgt'  
/CPCHART length BY shift.
```

- The data are organized as shown in Table 98 on page 1882. *length* is a numeric variable that measures the length of a part. *shift* contains the subgroup identifier (work shift number).
- The chart uses the chart template from *cpchart.sgt*.

---

## STATISTICS Subcommand

Any keyword may be specified in any place in the subcommand, but for conceptual clarity, the keywords are organized as follows: the Process Capability Indices, the Process Performance Indices, the Process Data, and the Measure(s) for Assessing Normality.

- This subcommand is silently ignored if the chart is not an XR, XS, IR, I, or CPCHART chart.
- A duplicated subcommand name causes a syntax error.
- A duplicated keyword is silently ignored.
- There is no default keyword or parameter value.

### The Process Capability Indices

**CP.** *Capability of the process.*

**CPU.** *The distance between the process mean and the upper specification limit scaled by capability sigma.*

**CPL.** *The distance between the process mean and the lower specification limit scaled by capability sigma.*

**K.** *The deviation of the process mean from the midpoint of the specification limits. This measurement is computed independently of the estimated capability sigma.*

**CPK.** *Capability of the process related to both dispersion and centeredness. It is the minimum of CpU and CpL. If only one specification limit is provided, we compute and report a unilateral CpK instead of taking the minimum.*

**CR.** *The reciprocal of CP.*

**CPM.** *An index relating capability sigma and the difference between the process mean and the target value. A target value must be specified on the TARGET subcommand by the user.*

**CZU.** *The number of capability sigmas between the process mean and the upper specification limit.*

**CZL.** *The number of capability sigmas between the process mean and the lower specification limit.*

**CZMIN.** *The minimum number of capability sigmas between the process mean and the specification limits.*

**CZMAX.** *The maximum number of capability sigmas between the process mean and the specification limits.*

**CZOUT.** *The estimated percentage outside the specification limits. The standard normal approximation is based on CZ<sub>U</sub> and CZ<sub>L</sub>.*

**CZLOUT.** *The estimated percentage outside the lower specification limit. The standard normal approximation is based on CZ<sub>L</sub>.*

**CZUOUT.** *The estimated percentage outside the upper specification limit. The standard normal approximation is based on CZ<sub>U</sub>.*

- For each of the keywords (other than CPK), both the LSL subcommand and the USL subcommand must be specified. Otherwise, the keyword(s) are ignored, and a syntax warning is issued. For CPK, at least one of the LSL and USL subcommands must be specified.
- If the TARGET subcommand is not specified, the keyword CPM is ignored, and a syntax warning is issued.

## The Process Performance Indices

**PP.** *Performance of the process.*

**PPU.** *The distance between the process mean and the upper specification limit scaled by process standard deviation.*

**PPL.** *The distance between the process mean and the lower specification limit scaled by process standard deviation.*

**PPK.** *Performance of the process related to both dispersion and centeredness. It is the minimum of PpU and PpL. If only one specification limit is provided, we compute and report a unilateral PpK instead of taking the minimum.*

**PR.** *The reciprocal of PP.*

**PPM.** *An index relating process variance and the difference between the process mean and the target value. A target value must be specified on the TARGET subcommand by the user.*

**PZU.** *The number of standard deviations between the process mean and the upper specification limit.*

**PZL.** *The number of standard deviations between the process mean and the lower specification limit.*

**PZMIN.** *The minimum number of standard deviations between the process mean and the specification limits.*

**PZMAX.** *The maximum number of standard deviations between the process mean and the specification limits.*

**PZOUT.** *The estimated percentage outside the specification limits. The standard normal approximation is based on PZ<sub>U</sub> and PZ<sub>L</sub>.*

**PZLOUT.** *The estimated percentage outside the lower specification limit. The standard normal approximation is based on PZ<sub>L</sub>.*

**PZUOUT.** *The estimated percentage outside the upper specification limit. The standard normal approximation is based on PZ<sub>U</sub>.*

- For each of the keywords (other than PPK), both the LSL subcommand and the USL subcommand must be specified. Otherwise, we ignore the keyword(s) and issue a syntax warning. For PPK, at least one of the LSL and USL subcommands must be specified.
- If the TARGET subcommand is not specified, the keyword PPM is ignored, and a syntax warning is issued.

## Process Data

**N.** *Total sample size.*

**MEAN.** *The process mean.*

**STDDEV.** *The process standard deviation.*

**CAPSIGMA.** *The capability sigma.*

**LSL.** *The fixed lower control limit.*

**USL.** *The fixed upper control limit.*

**TARGET.** *The target value.*

## Measure(s) for Assessing Normality

**AZOUT.** *The observed percentage outside the specification limits.* A point is defined outside the specification limits when its value is greater than or equal to the upper specification limit or is less than or equal to the lower specification limit.

**AZLOUT.** *The observed percentage outside the lower specification limit.* A point is defined outside the lower specification limit when its value is less than or equal to the lower specification limit.

**AZUOUT.** *The observed percentage outside the upper specification limit.* A point is defined outside the upper specification limit when its value is greater than or equal to the upper specification limit.

- For each of the keywords, both the LSL subcommand and the USL subcommand must be specified. Otherwise, we ignore the keyword and issue a syntax warning.

---

## RULES Subcommand

RULES specifies the rules for identifying out-of-control points. If a point violates any rule, it appears in the primary chart with a different shape and color compared to in-control points. Note that only the last point in a discovered pattern shall be marked for a rule violation, and any and all overlapping patterns are treated as separate patterns. A table of rule violations is also included in the output that displays the points marked in the control chart. If desired, use the ID keyword to specify the variable that identifies points in this table.

- Any keyword may be specified in any place in the subcommand.
- A duplicated subcommand name causes a syntax error.
- A duplicated keyword is silently ignored.
- The default keyword is ALL.
- If the subcommand is omitted, no control rules are used.
- RULES does not apply when generating a process capability chart (CPCHART subcommand).

**ALL.** *All rules.*

**UCL.** *Greater than +3 sigma.*

**R2UPPER.** *2 points out of the last 3 greater than +2 sigma.*

**R4UPPER.** *4 points out of the last 5 greater than +1 sigma.*

**R8UPPER.** *8 consecutive points above the center line.*

**R8LOWER.** *8 consecutive points below the center line.*

**R4LOWER.** *4 points out of the last 5 less than -1 sigma.*

**R2LOWER.** *2 points out of the last 3 less than -2 sigma.*

**LCL.** *Less than -3 sigma.*

**TRUP.** *6 consecutive points trending up.*

**TRDOWN.** *6 consecutive points trending down.*

**ALTERNATING.** *14 consecutive points alternating.*

---

## ID Subcommand

ID specifies a variable that identifies points in the table of rule violations. If this subcommand is omitted, the BY variable is used. Without the RULES subcommand, ID has no effect.

---

## CAPSIGMA Subcommand

This subcommand defines the capability sigma estimator, which is required in computing all the Process Capability Indices except K. There are four options:

**RBAR.** *Mean sample range.* The estimated capability sigma is based on the mean of the sample group ranges.

**SBAR.** *Mean sample standard deviation.* The estimated capability sigma is based on the mean of the sample group standard deviations.

**MRBAR.** *Mean sample moving range.* The estimated capability sigma is based on the mean of the sample moving ranges. The span that is defined by the SPAN subcommand is used. (Recall that its passive default value is 2.)

**WITHIN.** *Sample within-group variance.* The estimated capability sigma is the square root of the sample within-group variance.

The validity of specification depends on the chart specification (i.e., /XR, /XS, /I, /IR, or /CPCHART).

*Table 101. Valid CAPSIGMA options by chart specification*

<b>Chart Specification</b>	<b>Valid CAPSIGMA Options</b>
XR	RBAR (default), SBAR, WITHIN
XS	RBAR, SBAR (default), WITHIN
I	MRBAR (default)
IR	MRBAR (default)
CPCHART	RBAR, SBAR, WITHIN, MRBAR

- When this subcommand is omitted or specified without a keyword by the user, the default conditional on the chart specification is implicitly assumed (see the table above). When the chart specification is /CPCHART, the default is RBAR when the data are organized in subgroups, and MRBAR otherwise.
- An invalid specification (e.g., /I and /CAPSIGMA = RBAR) causes a syntax error when the chart specification is /XR, /XS, /I, or /IR and an applicable STATISTICS keyword is specified. An invalid specification (for those same chart types) without an applicable STATISTICS keyword generates a syntax warning.
- When the chart specification is /CPCHART, an invalid specification (e.g., /CAPSIGMA = RBAR when the data are not organized in subgroups) causes a syntax error.
- When the chart specification is /XR, /XS, /I, or /IR, CAPSIGMA is silently ignored if the subcommand specification is valid (with respect to the chart specification) but an applicable STATISTICS keyword is not specified.
- CAPSIGMA is silently ignored if the chart specification is not /XR, /XS, /I, /IR, or /CPCHART.
- A duplicated subcommand name causes a syntax error.

- A duplicated keyword is silently ignored, but if two or more keywords are specified and they do not have identical meanings, a syntax error message is issued.

---

## SPAN Subcommand

SPAN specifies the span from which the moving range for an individuals chart or process capability chart (when the data are specified in the form `var`) is calculated. The specification must be an integer value that is greater than 1. The default is 2. SPAN applies only to I, IR, and CPCHART chart specifications.

### Example

```
SPCHART /IR=SUBSIZE /SPAN=5.
```

- The SPAN subcommand specifies that the moving ranges are computed from every five individual samples.

---

## CONFORM and NONCONFORM Subcommands

Either CONFORM or NONCONFORM is required when you specify a status variable on the P or NP subcommand. You make that specification when data are organized so that each case is an inspection unit (see ).

- Either subcommand requires a value specification. The value can be numeric or string. String values must be enclosed within quotes.
- If CONFORM is specified, all values for the status variable (other than the specified value) are tabulated as nonconformities. If NONCONFORM is specified, only the specified value is tabulated as a nonconformity.
- CONFORM and NONCONFORM apply only to P and NP chart specifications.

---

## SIGMAS Subcommand

SIGMAS allows you to define the sigma level for a control chart. The value specified on SIGMAS is used in calculating the upper and lower control limits on the chart. It also determines the placement of reference lines on a process capability chart (/CPCHART) when the REFERENCE subcommand includes the keyword SIGMAS. You can specify a number larger than 1 but less than or equal to 10. A larger SIGMAS value means a greater range between the upper and the lower control limits. The default is 3.

---

## MINSAMPLE Subcommand

MINSAMPLE specifies the minimum sample size for X-bar, R, or s charts, as well as process capability charts when the data are organized in subgroups. When you specify XR, XS, or CPCHART on SPCHART, any subgroup with a size that is smaller than the size that is specified on MINSAMPLE is excluded from the chart and from all computations. If each case is a subgroup, there must be at least as many variables named as the number that is specified on MINSAMPLE. The default, as well as the minimum, is 2.

---

## LSL and USL Subcommand

LSL and USL allow you to specify fixed lower and upper control limits. Fixed control limits are often used in manufacturing processes as designer-specified limits.

- For chart types other than CPCHART, these limits are displayed on the chart, along with the calculated limits. If you do not specify LSL and USL, no fixed control limits are displayed. However, if you want only the specified control limits, you must edit the chart in a chart window to suppress the calculated series.
- For a chart type of CPCHART (process capability chart), LSL and USL are required. The REFERENCE subcommand controls whether these limits are displayed on the process capability chart. By default, they are displayed.

### Example

```
SPCHART /TEMPLATE='ctr1.sgt'  
/XS=SUBSIZE  
/USL=74.50  
/LSL=73.50.
```

- The USL and LSL subcommands specify the control limits according to the designing engineer. The center line is probably at 74.00.
- The specified upper and lower limits are displayed together with the control limits that are calculated from the observed standard deviation and the sigma value.

---

## TARGET Subcommand

This subcommand defines the target value that is used in computing CpM and PpM requested by the STATISTICS subcommand. It is also the target value that is displayed by default on a process capability chart (/CPCHART). The value may be any real number that is less than or equal to the USL value and greater than or equal to the LSL value.

- This subcommand is silently ignored if no applicable STATISTICS keyword is specified or the chart type is not CPCHART.
- If the value is numeric but out of the valid range, we issue a warning and ignore the CPM and/or PPM keyword(s), if any, in the STATISTICS subcommand.

---

## MISSING Subcommand

MISSING controls the treatment of missing values.

- The default is NOREPORT and EXCLUDE.
- REPORT and NOREPORT are alternatives and apply only to category variables. REPORT and NOREPORT control whether categories (subgroups) with missing values are created. They do not apply to process capability charts (/CPCHART).
- INCLUDE and EXCLUDE are alternatives and apply to process variables.

**NOREPORT.** *Suppress missing-value categories.* This setting is the default.

**REPORT.** *Report and plot missing-value categories.*

**EXCLUDE .** *Exclude user-missing values.* Both user-missing and system-missing values for the process variable are excluded from computation and plotting. This setting is the default.

**INCLUDE .** *Include user-missing values.* Only system-missing values for the process variable are excluded from computation and plotting.

---

## NORMAL Subcommand

NORMAL controls which normal curves are superimposed on a process capability chart. It only applies when the chart specification is /CPCHART. Specify one of the following values:

**CAPABILITY.** *Superimposes a normal curve with mean equal to the process mean and standard deviation equal to the capability sigma.* This is the default.

**PERFORMANCE .** *Superimposes a normal curve with mean equal to the process mean and standard deviation equal to the process standard deviation.*

**BOTH .** *Superimposes both the CAPABILITY and PERFORMANCE normal curves.*

**NONE.** *Specifies that no normal curves will be displayed.*

---

## REFERENCE Subcommand

REFERENCE controls which vertical reference lines are displayed on a process capability chart. It only applies when the chart specification is /CPCHART.

**SL.** *Vertical reference lines are displayed at the specified values of LSL and USL as well as at the value of TARGET if specified. This is the default.*

**SIGMAS.** *Vertical reference lines are displayed at the process mean and at a specified number of capability sigmas above and below the mean. The number of capability sigmas is given by the value of the SIGMAS subcommand, which is 3 by default.*

**NONE.** *Specifies that no reference lines will be displayed. This is an alternative to SL and/or SIGMAS and cannot be used in combination with them.*

---

## Chapter 256. SPECTRA

SPECTRA is available in SPSS Statistics Professional Edition or the Forecasting option.

SPECTRA VARIABLES= series names

```
[/{CENTER NO**}]
  {CENTER      }

[/{CROSS NO**}]
  {CROSS      }

[/WINDOW={HAMMING** [( {5  }) ]}]
  {          {span}      }
  {BARTLETT [(span)]    }
  {PARZEN [(span)]      }
  {TUKEY [(span)]       }
  {UNIT or DANIELL [(span)]}
  {NONE                 }
  {w-p, ..., w0, ..., wp }

[/PLOT= {P} [S] [CS] [QS] [PH] [A]
        {G} [K] [ALL] [NONE]
        [BY {FREQ  }]
        {PERIOD}]

[/SAVE = {FREQ (name)} {PER (name)} {SIN (name)}
         {COS (name)} {P (name)} {S (name)}
         {RC (name)} {IC (name)} {CS (name)}
         {QS (name)} {PH (name)} {A (name)}
         {G (name)} {K (name)}]

[/APPLY [= 'mode1 name']]
```

\*\*Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Example

```
SPECTRA VARIABLES = HSTARTS.
```

---

## Overview

SPECTRA plots the periodogram and spectral density function estimates for one or more series. You can also request bivariate spectral analysis. Moving averages, termed *windows*, can be used for smoothing the periodogram values to produce spectral densities.

### Options

**Output.** In addition to the periodogram, you can use the PLOT subcommand to produce a plot of the estimated spectral density. You can use the keyword BY on PLOT to suppress the display of the plot by frequency or the plot by period. To reduce the range of values that are displayed in the plots, you can center the data by using the CENTER subcommand.

**Cross-Spectral Analysis.** You can specify cross-spectral (bivariate) analysis with the CROSS subcommand and select which bivariate plots are produced by using PLOT.

**New Variables.** Variables that are computed by SPECTRA can be saved to the active dataset for use in subsequent analyses with the SAVE subcommand. TSET MXNEWVAR specifies the maximum number of new variables that can be generated by a procedure. The default is 60.

**Spectral Windows.** You can specify a spectral window and its span for calculation of the spectral density estimates.

#### Basic Specification

The basic specification is one or more series names.

- By default, SPECTRA plots the periodogram for each specified series. The periodogram is shown first by frequency and then by period. No new variables are saved by default.

#### Subcommand Order

- Subcommands can be specified in any order.

#### Syntax Rules

- VARIABLES can be specified only once.
- Other subcommands can be specified more than once, but only the last specification of each subcommand is executed.

#### Operations

- SPECTRA cannot process series with missing observations. (You can use the RMV command to replace missing values, use TSET MISSING=INCLUDE to include user-missing values, and use USE to ignore missing observations at the beginning or end of a series. See RMV and USE for more information.)
- If the number of observations in the series is odd, the first case is ignored.
- If the SAVE subcommand is specified, new variables are created for each specified series. For bivariate analyses, new variables are created for each series pair.
- SPECTRA requires memory both to compute variables and to build plots. Requesting fewer plots may enable you to analyze larger series.

#### Limitations

- A maximum of one VARIABLES subcommand is allowed. There is no limit on the number of series named on the list.

---

## Example

```
SPECTRA VARIABLES = HSTARTS  
/CENTER  
/PLOT P S BY FREQ.
```

- This example produces a plot of the periodogram and spectral density estimate for series *HSTARTS*.
- CENTER adjusts the series to have a mean of 0.
- PLOT specifies that the periodogram (P) and the spectral density estimate (S) should be plotted against frequency (BY FREQ).

---

## VARIABLES Subcommand

VARIABLES specifies the series names and is the only required subcommand.

- VARIABLES must be specified before the other subcommands.
- Each specified series is analyzed separately unless the CROSS subcommand is specified.
- The series must contain at least six cases.

#### Example

```
SPECTRA VARIABLES = VARX VARY.
```

- This command produces the default display for two series, *VARX* and *VARY*.

---

## CENTER Subcommand

CENTER adjusts the series to have a mean of 0. This process reduces the range of values that are displayed in the plots.

- If CENTER is not specified, the ordinate of the first periodogram value is  $2n$  times the square of the mean of the series, where  $n$  is the number of cases.
- You can specify CENTER NO to suppress centering when applying a previous model with APPLY.

### Example

```
SPECTRA VARIABLES = VARX VARY  
/CENTER.
```

- This example produces the default display for VARX and VARY. The plots are based on the series after their means have been adjusted to 0.

---

## WINDOW Subcommand

WINDOW specifies a spectral window to use when the periodogram is smoothed to obtain the spectral density estimate. If WINDOW is not specified, the Tukey-Hamming window with a span of 5 is used.

- The specification on WINDOW is a window name and a span in parentheses, or a sequence of user-specified weights.
- The window name can be any one of the keywords listed below.
- Only one window keyword is accepted. If more than one keyword is specified, the first keyword is used.
- The span is the number of periodogram values in the moving average and can be any integer. If an even number is specified, it is decreased by 1.
- Smoothing near the end of series is accomplished via reflection. For example, if the span is 5, the second periodogram value is smoothed by averaging the first, third, and fourth values and twice the second value.

The following data windows can be specified. Each formula defines the upper half of the window. The lower half is symmetric with the upper half. In all formulas,  $p$  is the integer part of the number of spans divided by 2,  $D_p$  is the Dirichlet kernel of order  $p$ , and  $F_p$  is the Fejer kernel of order  $p$ <sup>79</sup>.

**HAMMING.** *Tukey-Hamming window.*

**TUKEY.** *Tukey-Hanning window.*

**PARZEN.** *Parzen window.*

**BARTLETT.** *Bartlett window.*

**UNIT.** *Equal-weight window.* The weights are  $w_k = 1$  where  $k=0, \dots, p$ . DANIELL is an alias for UNIT.

**NONE.** *No smoothing.* If NONE is specified, the spectral density estimate is the same as the periodogram.

**w.** *User-specified weights.*  $W_0$  is applied to the periodogram value that is being smoothed, and the weights on either side are applied to preceding and following values. If the number of weights is even, it is assumed that  $w_p$  is not supplied. The weight after the middle one is applied to the periodogram value being smoothed.  $W_0$  must be positive.

### Example

---

79. Priestley, M. B. 1981. *Spectral analysis and time series, volumes 1 and 2*. London: Academic Press.

```
SPECTRA VARIABLES = VAR01
/WINDOW=TUKEY(3)
/PLOT=P S.
```

- In this example, the Tukey window weights with a span of 3 are used.
- The PLOT subcommand plots both the periodogram and the spectral density estimate, both by frequency and period.

---

## PLOT Subcommand

PLOT specifies which plots are displayed.

- If PLOT is not specified, only the periodogram is plotted for each specified series. Each periodogram is shown both by frequency and by period.
- You can specify more than one plot keyword.
- Keywords can be specified in any order.
- The plot keywords K, CS, QS, PH, A, and G apply only to bivariate analyses. If the subcommand CROSS is not specified, these keywords are ignored.
- The period (horizontal) axis on a plot by period (BY PERIOD) is scaled in natural logarithms from 0.69 to  $\ln(n)$ , where  $n$  is the number of cases.
- The frequency (horizontal) axis on a plot by frequency (BY FREQ) is scaled from 0 to 0.5, expressing the frequency as a fraction of the length of the series.
- The periodogram and estimated spectrum (vertical axis) are scaled in natural logs.

The following plot keywords are available:

**P.** *Periodogram.* This setting is the default.

**S.** *Spectral density estimate.*

**K.** *Squared coherency.* Applies only to bivariate analyses.

**CS.** *Cospectral density estimate.* Applies only to bivariate analyses.

**QS.** *Quadrature spectrum estimate.* Applies only to bivariate analyses.

**PH.** *Phase spectrum.* Applies only to bivariate analyses.

**A.** *Cross amplitude.* Applies only to bivariate analyses.

**G.** *Gain.* Applies only to bivariate analyses.

**ALL.** *All plots.* For bivariate analyses, this setting includes all plots listed above. For univariate analyses, this setting includes the periodogram and the spectral density estimate.

## BY Keyword

By default, SPECTRA displays both frequency and period plots. You can use BY to produce only frequency plots or only period plots.

- BY FREQ indicates that all plots are plotted by frequency only. Plots by period are not produced.
- BY PERIOD indicates that all plots are plotted by period only. Plots by frequency are not produced.

### Example

```
SPECTRA VARIABLES = SER01
/PLOT=P S BY FREQ.
```

- This command plots both the periodogram and the spectral density estimate for *SER01*. The plots are shown by frequency only.

---

## CROSS Subcommand

CROSS is used to specify bivariate spectral analysis.

- When CROSS is specified, the first series named on the VARIABLES subcommand is the independent variable. All remaining variables are dependent.
- Each series after the first series is analyzed with the first series independently of other series that is named.
- Univariate analysis of each specified series is still performed.
- You can specify CROSS NO to turn off bivariate analysis when applying a previous model with APPLY.

### Example

```
SPECTRA VARIABLES = VARX VARY VARZ  
/CROSS.
```

- In this example, bivariate spectral analyses of series VARX with VARY and VARX with VARZ are requested in addition to the usual univariate analyses of VARX, VARY, and VARZ.

---

## SAVE Subcommand

SAVE saves computed SPECTRA variables to the active dataset for later use. SPECTRA displays a list of the new variables and their labels, showing the type and source of those variables.

- You can specify any or all of the output keywords listed below.
- A name to be used for generating variable names must follow each output keyword. The name must be enclosed in parentheses.
- For each output keyword, one variable is created for each series named on SPECTRA and for each bivariate pair.
- The keywords RC, IC, CS, QS, PH, A, G, and K apply only to bivariate analyses. If CROSS is not specified, these keywords are ignored.
- SAVE specifications are not used when models are reapplied by using APPLY. They must be specified each time variables are to be saved.
- The output variables correspond to the Fourier frequencies. They do not correspond to the original series.
- Because each output variable has only  $(n/2 + 1)$  cases (where  $n$  is the number of cases), the values for the second half of the series are set to system-missing.
- Variable names are generated by adding  $_n$  to the specified name, where  $n$  ranges from 1 to the number of series specified.
- For bivariate variables, the suffix is  $_n_n$ , where the  $ns$  indicate the two variables that are used in the analysis.
- The frequency (FREQ) and period (PER) variable names are constant across all series and do not have a numeric suffix.
- If the generated variable name is longer than the maximum variable name length, or if the specified name already exists, the variable is not saved.

The following output keywords are available:

**FREQ** . *Fourier frequencies.*

**PER** . *Fourier periods.*

**SIN** . *Value of a sine function at the Fourier frequencies.*

**COS** . *Value of a cosine function at the Fourier frequencies.*

**P.** *Periodogram values.*

**S.** *Spectral density estimate values.*

**RC.** *Real part values of the cross-periodogram.* Applies only to bivariate analyses.

**IC.** *Imaginary part values of the cross-periodogram.* Applies only to bivariate analyses.

**CS.** *Cospectral density estimate values.* Applies only to bivariate analyses.

**QS.** *Quadrature spectrum estimate values.* Applies only to bivariate analyses.

**PH.** *Phase spectrum estimate values.* Applies only to bivariate analyses.

**A.** *Cross-amplitude values.* Applies only to bivariate analyses.

**G.** *Gain values.* Applies only to bivariate analyses.

**K.** *Squared coherency values.* Applies only to bivariate analyses.

### Example

```
SPECTRA VARIABLES=STRIKES RUNS  
  /SAVE= FREQ (FREQ) P (PGRAM) S (SPEC).
```

- This example creates five variables: *FREQ*, *PGRAM\_1*, *PGRAM\_2*, *SPEC\_1*, and *SPEC\_2*.

---

## APPLY Subcommand

APPLY allows you to use a previously defined SPECTRA model without having to repeat the specifications.

- The only specification on APPLY is the name of a previous model in quotation marks. If a model name is not specified, the model that was specified on the previous SPECTRA command is used. Model names are either the default *MOD\_n* names that are assigned by Forecasting or the names that are assigned on the MODEL NAME command.
- To change one or more model specifications, specify the subcommands of only those portions you want to change after the APPLY subcommand.
- If no series are specified on the command, the series that were originally specified with the model that is being reapplied are used.
- To change the series that are used with the model, enter new series names before or after the APPLY subcommand. If a variable name is specified before APPLY, the slash before the subcommand is required.
- The SAVE specifications from the previous model are *not* reused by APPLY. They must be specified each time that variables are to be saved.

### Examples

```
SPECTRA VARIABLES = VAR01  
  /WINDOW=DANIELL (3)  
  /CENTER  
  /PLOT P S BY FREQ.  
SPECTRA APPLY  
  /PLOT P S.
```

- The first command plots both the periodogram and the spectral density estimate for *VAR01*. The plots are shown by frequency only.
- Because the PLOT subcommand is respecified, the second command produces plots by both frequency and period. All other specifications remain the same as in the first command.

---

## Chapter 257. SPLIT FILE

```
SPLIT FILE [{LAYERED }] {BY varlist}
           {SEPARATE}
           {OFF }
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Example

```
SPLIT FILE BY SEX.
```

---

## Overview

SPLIT FILE splits the active dataset into subgroups that can be analyzed separately. These subgroups are sets of adjacent cases in the file that have the same values for the specified split variables. Each value of each split variable is considered a break group, and cases within a break group must be grouped together in the active dataset. If they are not grouped together, the SORT CASES command must be used before SPLIT FILE to sort cases in the proper order.

### Basic Specification

The basic specification is keyword BY followed by the variable or variables that define the split-file groups.

- By default, the split-file groups are compared within the same table(s).
- You can turn off split-file processing by using keyword OFF.

### Syntax Rules

- SPLIT FILE can specify both numeric and string split variables, including variables that are created by temporary transformations. SPLIT FILE cannot specify scratch or system variables.
- SPLIT FILE is in effect for all procedures in a session unless you limit it with a TEMPORARY command, turn it off, or override it with a new SPLIT FILE or SORT CASES command.

### Operations

- SPLIT FILE takes effect as soon as it is encountered in the command sequence. Therefore, pay special attention to the position of SPLIT FILE among commands. See the topic “Command Order” on page 40 for more information.
- The file is processed sequentially. A change or break in values on any one of the split variables signals the end of one break group and the beginning of the next break group.
- AGGREGATE ignores the SPLIT FILE command. To split files by using AGGREGATE, name the variables that are used to split the file as break variables ahead of any other break variables on AGGREGATE. AGGREGATE still produces one file, but the aggregated cases are in the same order as the split-file groups.
- If SPLIT FILE is in effect when a procedure writes matrix materials, the program writes one set of matrix materials for every split group. If a procedure reads a file that contains multiple sets of matrix materials, the procedure automatically detects the presence of multiple sets.
- If SPLIT FILE names any variable that was defined by the NUMERIC command, the program prints page headings that indicate the split-file grouping.

### Limitations

- SPLIT FILE can specify or imply up to eight variables.
- Each eight bytes of a string variable counts as a variable toward the limit of eight variables. So a string variable with a defined width of greater than 64 bytes cannot be used as a split file variable.

---

## LAYERED and SEPARATE Subcommands

LAYERED and SEPARATE specify how split-file groups are displayed in the output.

- Only one of these subcommands can be specified. If neither subcommand is specified with the BY variable list, LAYERED is the default.
- LAYERED and SEPARATE do not apply to the text output.

**LAYERED.** *Display split-file groups in the same table in the outermost column.*

**SEPARATE.** *Display split-file groups as separate tables.*

---

## Examples

### Sorting and Splitting a File

```
SORT CASES BY SEX.  
SPLIT FILE BY SEX.  
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.
```

- SORT CASES arranges cases in the file according to the values of variable *SEX*.
- SPLIT FILE splits the file according to the values of variable *SEX*, and FREQUENCIES generates separate median income tables for men and women.
- By default, the two groups (men and women) are compared in the same Frequency and Statistics tables.

### Applying a Temporary Split File

```
SORT CASES BY SEX.  
TEMPORARY.  
SPLIT FILE SEPARATE BY SEX.  
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.  
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.
```

- Because of the TEMPORARY command, SPLIT FILE applies to the first procedure only. Thus, the first FREQUENCIES procedure generates separate tables for men and women. The second FREQUENCIES procedure generates tables that include both sexes.

### Turning Off a Split File

```
SORT CASES BY SEX.  
SPLIT FILE SEPARATE BY SEX.  
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.  
SPLIT FILE OFF.  
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.
```

- SPLIT FILE does not apply to the second FREQUENCIES procedure because it is turned off after the first FREQUENCIES procedure. This example produces the same results as the example above.

### Overriding a Previous Split File

```
SORT CASES BY SEX RACE.  
SPLIT FILE BY SEX.  
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.  
SPLIT FILE BY SEX RACE.  
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.
```

- The first SPLIT FILE command applies to the first FREQUENCIES procedure. The second SPLIT FILE command overrides the first command and splits the file by sex and race. This split is in effect for the second FREQUENCIES procedure.

---

## Chapter 258. STAR JOIN

```
STAR JOIN
/SELECT {* | alias0.field [AS newname], alias1.field [AS newname],...}
/FROM {'data file' [PASSWORD='password'] | dataset | *} AS alias0
/JOIN {'data file' [PASSWORD='password'] | dataset | *} AS alias1
  ON alias0.key1=alias1.key1
  [AND alias0.key2=alias1.key2] [AND...]
  [IN=field]
[/JOIN...] [/JOIN...]
/OUTFILE FILE={'data file' | dataset | *}
[/PASSPROTECT]
  PASSWORD={'password'|NONE**}
  [ENCRYPTEDPW={NO**|YES}]
```

\*\*Default if subcommand or keyword omitted

- All subcommands except PASSPROTECT are required.
- All subcommands must be in the order indicated in the syntax chart.
- Multiple JOIN subcommands are allowed, up to a maximum of the operating system limit for file handles or until you run out of memory.
- All command specifications must be spelled out in full; three letter abbreviation is not allowed.
- The syntax for SELECT, FROM, and JOIN is based on standard SQL syntax, but this is not SQL. You cannot include any SQL not explicitly specified in the syntax chart.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Release History

#### Release 21.0

- Command introduced.

#### Release 22.0

- PASSWORD keyword introduced on the FROM and JOIN subcommands.

### Example

```
STAR JOIN
/SELECT t1.Name1, t1.Name2, t1.Field1, t1.Field2, t1.Field3,
  t2.Value1, t3.Value2
/FROM '/myfiles/fact.sav' AS t1
/JOIN '/myfiles/field1_values.sav' AS t2
  ON t1.Field1 = t2.Field1
/JOIN '/myfiles/field2_values.sav' AS t3
  ON t1.Field2 = t3.Field2
/OUTFILE FILE='/myfiles/merged.sav'.
```

---

## Overview

STAR JOIN performs the equivalent of an SQL left outer join. The FROM subcommand specifies the case data file (fact table). The JOIN subcommands specify the table lookup files (dimension tables).

- All cases (records) from the case data file are included in the merged file.
- Cases from the table lookup files are included only if they have key values that match key values in the case data file.
- The merged file contains all fields specified on the SELECT subcommand and all fields specified as keys on the JOIN subcommand(s).

This is similar to MATCH FILES with one or more TABLE lookup subcommands, but STAR JOIN provides several features not available in MATCH FILES:

- The files do not have to be presorted in order of the key values.
- Different keys can be specified for each table lookup file.
- The defined width of string keys does not have to be the same in both the case data file and the table lookup file.

Note: Unlike MATCH FILES, STAR JOIN reads the active dataset and causes execution of any pending transformations.

#### Syntax

- All subcommands except PASSPROTECT are required.
- All subcommands must be in the order indicated in the syntax chart: SELECT, FROM, JOIN, OUTFILE, PASSPROTECT.
- Key values in files specified on the JOIN subcommand must be unique. Duplicate key values within the same file will result in an error. If there are multiple keys, each combination of keys must be unique.

#### Operations

The merged dataset contains complete dictionary information from the input files, including variable names, labels, print and write formats, and missing-value indicators.

- For key variables or other variables with the same name in more than one file, variable dictionary information is taken from the first file containing value labels, missing values, or a variable label for the common variable. If the case data file has no such information, the first lookup table specified is checked, and so on. This includes custom variable attributes.
- Custom file attributes (DATAFILE ATTRIBUTES command) are taken from the first file that contains custom file attributes. If the case data file has none, the first table lookup file is checked, and so on.
- The merged file includes all documents from all files (documents are created with the DOCUMENT and ADD DOCUMENTS commands).
- No file labels (FILE LABEL command) from any of the files are preserved.

---

## SELECT subcommand

The SELECT subcommand specifies the fields to be included from all data sources specified on the FROM and JOIN subcommands, with the exception of the key fields specified on the JOIN subcommand.

- The SELECT subcommand is required and must be the first subcommand.
- All field specifications take the general form of *alias.fieldname*, where *alias* is a stand-in name for each data source specified on the FROM and JOIN subcommands.
- Field specifications must be separated by commas.
- An asterisk (\*) can be used to specify all fields in all the data sources.

Note: In SQL the asterisk convention will cause duplicate entries for key fields in the merged result. For STAR JOIN, asterisk means “everything that isn’t a key”.

- Only one SELECT subcommand is allowed.
- Any fields specified as keys on the JOIN subcommand(s) that are also specified on the SELECT subcommand are ignored on the SELECT subcommand.
- Duplicate field names in different data sources are made unique by including the table alias and a period as a prefix (for example, *t1.field1*, *t2.field1*).
- Duplicate field names specified for the same data source are ignored.

---

## FROM subcommand

The FROM subcommand specifies the name of the case data file (fact table). It is followed by the keyword AS, followed by the alias used to identify the file source when specifying fields.

- The FROM subcommand is required and must immediately follow the SELECT subcommand.
- The data file name can be an external data file in IBM SPSS Statistics format or a dataset in the current session.
- External data file names must be quoted.
- An asterisk can be used to specify the currently active dataset.
- Alias names must follow standard variable naming rules. See the topic “Variable Names” on page 46 for more information.
- Only one FROM subcommand is allowed.

### PASSWORD Keyword

The PASSWORD keyword specifies the password required to open an encrypted IBM SPSS Statistics data file. The specified value must be enclosed in quotation marks and can be provided as encrypted or as plain text. Encrypted passwords are created when pasting command syntax from the Save Data As dialog. The PASSWORD keyword is ignored if the file is not encrypted.

---

## JOIN subcommand

The JOIN subcommand specifies the table lookup file (dimension table). It is followed by the keyword AS, followed by the alias used to identify the file source when specifying fields, followed by the keyword ON, which specifies the key(s) to use to match the file with the case data file.

- At least one JOIN subcommand is required, and all JOIN subcommands must follow the FROM subcommand.
- The maximum number of JOIN subcommands is determined by the operating system limit for file handles or available memory.
- The data file name can be an external data file in IBM SPSS Statistics format or a dataset in the current session.
- External data file names must be quoted.
- An asterisk can be used to specify the currently active dataset.
- Alias names must follow standard variable naming rules. See the topic “Variable Names” on page 46 for more information.
- To specify the same lookup table on multiple JOIN subcommands, use different alias names for each instance.
- Key values within each file must be unique. Duplicate key values within the same file will result in an error. If there are multiple keys, each combination of keys must be unique.

### ON Keyword

The ON keyword specifies the keys(s) used to match cases in the table lookup file with cases in the case data file. The general form is:

```
ON alias0.field=alias1.field
```

- Each key or key combination that identifies each case must be unique in the table lookup file.
- The basic data type (string or numeric) for each key comparison must be the same in both files.
- To specify multiple keys that identify each unique case in the table lookup file, use the keyword AND, as in:

```
ON alias0.field1=alias1.field1 AND alias0.field2=alias1.field2
```

- The field names do not have to be the same in the two files. If they are different, both fields are included in the merged data file.
- The only comparison that is allowed is equality between field values. Other comparisons (for example,  $>=$ ,  $<=$ ,  $<>$ ) are not allowed, and arithmetic expressions (for example,  $t1.field1 = t2.field1 + t2.field2$ ) are not allowed.
- Comparisons can only be evaluated between the current table lookup file and the case data file. For example, if the case data file is *t1*, and you have two lookup files, *t2* and *t3*,  $t2.field1=t3.field1$  is not valid.

### IN Keyword

The optional IN keyword creates a new variable (field) in the merged file that indicates if the case (based on the key values) is present in that table lookup file. A value 1 indicates that the case is present; a value of 0 indicates that it is not. You can use this to identify cases in the case data file that have no matching cases in the table lookup file.

The keyword is followed by an equals sign (=) and the name of the new variable. The name must conform to variable naming rules.

### PASSWORD Keyword

The PASSWORD keyword specifies the password required to open an encrypted IBM SPSS Statistics data file. The specified value must be enclosed in quotation marks and can be provided as encrypted or as plain text. Encrypted passwords are created when pasting command syntax from the Save Data As dialog. The PASSWORD keyword is ignored if the file is not encrypted.

---

## OUTFILE subcommand

The OUTFILE subcommand specifies the name of the new, merged dataset.

- The subcommand has one required keyword, FILE, which must be followed by an equals sign (=) and the name of an external data file, a previously declared dataset, or an asterisk.
- The data file name can be an external data file in IBM SPSS Statistics format or a dataset in the current session.
- External data file names must be quoted.
- An asterisk can be used to specify the currently active dataset. The currently active dataset will be replaced by the merged dataset.
- If you specify the name of an existing dataset in the current session, the merged dataset will replace the existing dataset.
- To specify a new dataset name in the current session, you must first declare the new dataset name with the DATASET DECLARE command.

---

## PASSPROTECT subcommand

The optional PASSPROTECT subcommand saves the file in encrypted format.

- PASSPROTECT is ignored unless OUTFILE specifies an external file.
- The PASSWORD keyword is required. The password can be up to 10 characters long.
- By default, passwords are not encrypted. Use the optional ENCRYPTEDPW=YES to encrypt the password.

## Example: STAR JOIN with two lookup table files

In this example, the case data file contains numeric codes for *Field1* and *Field2*, and descriptive values for each of those fields are contained in two separate lookup tables.

Data

Table 102. Case data file: *fact.sav*.

Name1	Name2	Field1	Field2	Field3
Barney	Jones	1	1	10/29/1987
Fred	Smith	1	3	10/28/1986
Barney	Jones	2	2	12/1/2001
Joe	Smith	5	4	12/1/2011
Nancy	Jones	99		

Table 103. Lookup table: *field1\_values.sav*.

Field1	Value1
1	One
2	Two
3	Three
99	Missing

Table 104. Lookup table: *field2\_values.sav*.

Field2	Value2
1	A
2	B
3	C
5	E

## Syntax

```
STAR JOIN
/SELECT t1.Name1, t1.Name2, t1.Field1, t1.Field2, t1.Field3,
t2.Value1, t3.Value2
/FROM '/myfiles/fact.sav' AS t1
/JOIN '/myfiles/field1_values.sav' AS t2
ON t1.Field1 = t2.Field1
/JOIN '/myfiles/field2_values.sav' AS t3
ON t1.Field2 = t3.Field2
/OUTFILE FILE='/myfiles/merged_data.sav'.
```

## Result

Table 105. Merged files.

Name1	Name2	Field1	Field2	Field3	Value1	Value2
Barney	Jones	1	1	10/29/1987	One	A
Fred	Smith	1	3	10/28/1986	One	C
Barney	Jones	2	2	12/1/2001	Two	B
Joe	Smith	5	4	12/1/2011	(blank)	(blank)
Nancy	Jones	99	(sysmis)	(sysmis)	Missing	

- All records from the case data file are included; so the fourth record (Joe Smith) is included even though the *Field1* value of 5 and the *Field2* value of 4 are not present in either lookup table.
- Only records from the lookup tables that have matching keys in the case data file are included; so the *Field1* record with a value of 3 in *field1\_values.sav* and the *Field2* record with a value of 5 in *field2\_values.sav* are not included.
- In this example, since the SELECT statement includes all fields in all three tables other than those specified as key fields with ON, an asterisk (\*) instead of the explicit list of fields would yield the same result.

---

## Example: STAR JOIN with two key-value pairs in the same file

This is similar to the previous example, except both key-value pairs are contained in the same lookup table. This syntax is less complex than standard SQL.

Data

Table 106. Case data file: *fact.sav*.

Name1	Name2	Field1	Field2	Field3
Barney	Jones	1	1	10/29/1987
Fred	Smith	1	3	10/28/1986
Barney	Jones	2	2	12/1/2001
Joe	Smith	5	4	12/1/2011
Nancy	Jones	99		

Table 107. Lookup table: *mixed\_values.sav*.

Field1	Value1	Field2	Value2
1	One	1	A
2	Two	2	B
3	Three	3	C
99	Missing	5	E

Syntax

```
STAR JOIN
/SELECT t1.Name1, t1.Name2, t1.Field1, t1.Field2, t1.Field3,
t2.Value1, t3.Value2
/FROM '/myfile/fact.sav' AS t1
/JOIN '/myfiles/mixed_values.sav' AS t2
ON t1.Field1 = t2.Field1
/JOIN '/myfiles/mixed_values.sav' AS t3
ON t1.Field2 = t3.Field2
/OUTFILE FILE='/myfiles/merged_file.sav'.
```

Result

- The result is exactly the same as the previous example.
- The syntax is very similar to the previous example. The only difference is that both of the JOIN statements refer to the same lookup table, but each one assigns a different alias to the same lookup table.

## Example: STAR JOIN with two keys required to match cases

This is similar to the previous example, except both key/value pairs are contained in the same lookup table. This syntax is less complex than standard SQL.

Data

Table 108. Case data file: fact.sav.

Name1	Name2	Field1	Field2	Field3
Barney	Jones	1	1	10/29/1987
Fred	Smith	1	3	10/28/1986
Barney	Jones	2	2	12/1/2001
Joe	Smith	5	4	12/1/2011
Nancy	Jones	99		

Table 109. Lookup table: two\_keys.sav.

Name1	Name2	City
Barney	Jones	Anytown
Fred	Smith	Centerville
Nancy	Jones	Metropolis
Joe	Jones	Anytown

Syntax

```
STAR JOIN
/SELECT t1.Name1, t1.Name2, t1.Field1, t1.Field2, t1.Field3, t2.City
/FROM '/myfiles/fact.sav' AS t1
/JOIN '/myfiles/two_keys.sav' AS t2
ON t1.Name1 = t2.Name1 AND t1.Name2 = t2.Name2
/OUTFILE FILE=*
```

Result

Table 110. Merged file.

Name1	Name2	Field1	Field2	Field3	City
Fred	Smith	1	3	10/29/1987	Centerville
Barney	Jones	1	1	10/28/1986	Anytown
Joe	Smith	5	4	12/1/2001	(blank)
Barney	Jones	2	2	12/1/2011	Anytown
Nancy	Jones	99	(sysmis)	(sysmis)	Metropolis

- All records from the case data file are included; so “Joe Smith” is included even though there is no matching record in the lookup table.
- Only records from the lookup table that match both keys in the case data file are included; so “Joe Jones” is not included.

---

## Chapter 259. STRING

STRING varlist (An) [/varlist...]

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Example

```
STRING STATE1 (A2).
```

---

## Overview

STRING declares new string variables that can be used as target variables in data transformations.

### Basic Specification

The basic specification is the name of the new variables and, in parentheses, the variable format.

### Syntax Rules

- If keyword T0 is used to create multiple string variables, the specified format applies to each variable that is named and implied by T0.
- To declare variables with different formats, separate each format group with a slash.
- STRING can be used within an input program to determine the order of string variables in the dictionary of the active dataset. When used for this purpose, STRING must precede DATA LIST in the input program. See the Examples for the NUMERIC command .
- STRING cannot be used to redefine an existing variable.
- String variables cannot have zero length; A0 is an illegal format.
- All implementations of the program allow the A format. Other string formats may be available on some systems. In addition, the definition of a long string depends on your operating system. Use keyword LOCAL on the INFO command to obtain documentation for your operating system.

### Operations

- STRING takes effect as soon as it is encountered in the command sequence. Therefore, pay special attention to the position of STRING among commands. See the topic “Command Order” on page 40 for more information.
- New string variables are initialized as blanks.
- Variables that are declared on STRING are added to the active dataset in the order in which they are specified. This order is not changed by the order in which the variables are used in the transformation language.
- To change the defined width of a string variable use the ALTER TYPE command. See the topic Chapter 12, “ALTER TYPE,” on page 159 for more information.

---

## Examples

```
STRING STATE1 (A2).  
RECODE STATE ('IO'='IA') (ELSE=COPY) INTO STATE1.
```

- STRING declares variable *STATE1* with an A2 format.
- RECODE specifies *STATE* as the source variable and specifies *STATE1* as the target variable. The original value IO is recoded to IA. Keywords ELSE and COPY copy all other state codes unchanged. Thus, *STATE* and *STATE1* are identical except for cases with the original value IO.

```
STRING V1 TO V6 (A8) / V7 V10 (A16).
```

- `STRING` declares variables `V1`, `V2`, `V3`, `V4`, `V5`, and `V6`, each with an `A8` format, and variables `V7` and `V10`, each with an `A16` format.

---

## Chapter 260. SUBTITLE

SUBTITLE [']text[']

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Example

```
SUBTITLE "Children's Training Shoes Only".
```

---

## Overview

SUBTITLE inserts a subtitle on the second line from the top of each page of the output. The default subtitle contains the installation name and information about the hardware and operating system.

### Basic Specification

The only specification is the subtitle itself.

### Syntax Rules

- The subtitle can include any characters. To specify a blank subtitle, enclose a blank within quotes.
- The subtitle can be up to 60 characters. Subtitles that are longer than 60 characters are truncated.
- The quotes enclosing the subtitle are optional; using them allows you to include single or double quotes in the subtitle.
- More than one SUBTITLE command is allowed in a single session.
- A subtitle cannot be placed between a procedure command and BEGIN DATA-END DATA or within data records when the data are inline.

### Operations

- Each SUBTITLE command overrides the previous command and takes effect on the next output page.
  - SUBTITLE is independent of TITLE and each command can be changed separately.
  - The subtitle will not be displayed if HEADER=NO is specified on SET.
- 

## Examples

### Using Single and Double Quotes

```
TITLE 'Running Shoe Study from Runner''s World Data'.  
SUBTITLE "Children's Training Shoes Only".
```

- The title is enclosed in single quotes, so the single quote (apostrophe) in *Runner's* must be specified as a two single quotes.
- The subtitle is enclosed in double quotes, so the apostrophe in *Children's* is simply specified as a single quote.

### Suppressing the Default Subtitle

```
TITLE 'Running Shoe Study from Runner''s World Data'.  
SUBTITLE ' '.
```

- This subtitle is specified as a blank, which suppresses the default subtitle.

---

## Chapter 261. SUMMARIZE

SUMMARIZE is available in Statistics Base Edition.

```
SUMMARIZE [TABLES={varlist} [BY varlist] [BY...] [/varlist...]  
          {ALL      }  
  
[/TITLE ='string']    [/FOOTNOTE= 'string']  
  
[/CELLS= [COUNT**] [MEAN ] [STDDEV]  
          [MEDIAN] [GMEDIAN] [SEMEAN] [SUM ]  
          [MIN] [MAX] [RANGE] [VARIANCE]  
          [KURT] [SEKURT] [SKEW] [SESKEW]  
          [FIRST] [LAST]  
          [NPCT] [SPCT] [NPCT(var)] [SPCT(var)]  
          [HARMONIC] [GEOMETRIC]  
          [DEFAULT]  
          [ALL] [NONE] ]  
  
[/MISSING=[{EXCLUDE**}] [{VARIABLE** }]  
          {INCLUDE } {TABLE }  
          {DEPENDENT}  
  
[/FORMAT=[{NOLIST** } ] [{CASENUM } ] [{TOTAL**}] [MISSING='string']  
          {LIST [LIMIT=n]} {NOCASENUM } {NOTOTAL}  
          {VALIDLIST }  
  
[/STATISTICS=[ANOVA] [{LINEARITY}] [NONE**] ]  
          {ALL      }]
```

\*\*Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Example

```
SUMMARIZE SALES.
```

---

## Overview

SUMMARIZE produces univariate statistics for specified variables. You can break the variables into groups defined by one or more control (independent) variables. Another procedure that displays univariate statistics is FREQUENCIES.

### Options

**Cell Contents.** By default, SUMMARIZE displays means, standard deviations, and cell counts. You can also use the CELLS subcommand to display aggregated statistics, including sums, variances, median, range, kurtosis, skewness, and their standard error.

**Statistics.** In addition to the statistics that are displayed for each cell of the table, you can use the STATISTICS subcommand to obtain a one-way analysis of variance and test of linearity.

**Format.** By default, SUMMARIZE produces a Summary Report with a total category for each group that is defined by the control variables. You can use the FORMAT subcommand to request a Listing Report with or without case numbers. You can also remove the total category from each group. You can use the TITLE and FOOTNOTE subcommands to specify a title and a caption for the Summary or Listing Report.

### Basic Specification

The basic specification is TABLES with a variable list. Each variable creates a category. The actual keyword TABLES can be omitted.

- The minimum specification is a dependent variable.
- By default, SUMMARIZE displays a Case Processing Summary table, showing the number and percentage of cases included, excluded, and their total. SUMMARIZE also displays a Summary Report, showing means, standard deviations, and number of cases for each category.

### Syntax Rules

- Both numeric and string variables can be specified. String variables can be short or long.
- If there is more than one TABLES subcommand, FORMAT=LIST or VALIDLIST results in an error.
- String specifications for TITLE and FOOTNOTE must be enclosed in quotes and cannot exceed 255 bytes. When the specification breaks on multiple lines, enclose each line in quotes, and separate the specifications for each line by at least one blank.
- Each subcommand (except TABLES) can be specified only once. If a subcommand is specified multiple times, a warning results, and the last specification is used.
- Multiple TABLES subcommands are allowed, but multiple specifications use a lot of computer resources and time.
- There is no limit on the number of variables that you can specify on each TABLES subcommand.
- When a variable is specified more than once, only the first occurrence is honored. If the same variables are specified after different BY keywords, an error results.

### Limitations

- Only 10 BY keywords can be specified.

### Operations

- The data are processed sequentially. It is not necessary to sort the cases before processing. If a BY keyword is used, the output is always sorted.
- A Case Processing Summary table is always generated, showing the number and percentage of the cases included, excluded, and the total.
- For each combination of control variables specified after different BY keywords, SUMMARIZE produces a group in the Summary Report (depending on the specification on the FORMAT subcommand). By default, mean, standard deviation, and number of cases are displayed for each group and for the total.
- An ANOVA table and a Measure of Association table are produced if additional statistics are requested.

---

## Example

### Creating a Grouped Summary Report

```
SUMMARIZE
  /TABLES=value BY street
  /FORMAT=NOLIST TOTAL
  /TITLE='Home Sale Statistics' /FOOTNOTE 'Grouped by Street'
  /MISSING=VARIABLE
  /CELLS=COUNT MEAN MEDIAN MIN MAX .
```

- The procedure produces summaries of *value* by values of *street*.
- FORMAT specifies that no case listing should be produced but that summary statistics should be produced.
- TITLE produces the requested title for the summary report and FOOTNOTE produces the specified table footnote.
- CELLS requests the cell counts, means, medians, minimums, and maximums.
- All other options are set to their default values.

For discussion of output from this syntax and to place the example in context, see .

### Displaying Individual Cases

```
SUMMARIZE
/TABLES=address value marktime
/FORMAT=VALIDLIST NOCASENUM MISSING='Unavailable' TOTAL
/TITLE='Case Listing' /FOOTNOTE 'Only homes selling for $335,000 or more'
/MISSING=VARIABLE
/CELLS=COUNT MEAN MEDIAN .
```

- The procedure produces summaries of *address*, *value*, and *marktime*.
- `FORMAT` specifies that the case listing report should contain only valid cases, without the case numbers, and with system-missing values displayed with the label *Unavailable*.
- `TITLE` produces the requested title for the summary report and `FOOTNOTE` produces the specified table footnote.
- `CELLS` requests the cell counts, means, and medians.
- All other options are set to their default values.

For discussion of output from this syntax and to place the example in context, see .

---

## TABLES Subcommand

`TABLES` specifies the dependent and control variables.

- You can specify multiple `TABLES` subcommands on a single `SUMMARIZE` command.
- For `FORMAT=LIST` or `VALIDLIST`, only one `TABLES` subcommand is allowed. Multiple dependent and control variables add more breaks to the Listing Report. Total statistics are displayed at the end for each combination that is defined by different values of the control variables.
- For `FORMAT=NOLIST`, which is the default, each use of keyword `BY` adds a dimension to the requested table. Total statistics are displayed with each group.
- The order in which control variables are displayed is the same as the order in which they are specified on `TABLES`. The values of the first control variable that is defined for the table appear in the leftmost column of the table and change the most slowly in the definition of groups.
- Statistics are displayed for each dependent variable in the same report.
- More than one dependent variable can be specified in a table list, and more than one control variable can be specified in each dimension of a table list.

---

## TITLE and FOOTNOTE Subcommands

`TITLE` and `FOOTNOTE` provide a title and a caption for the Summary or Listing Report.

- `TITLE` and `FOOTNOTE` are optional and can be placed anywhere.
- The specification on `TITLE` or `FOOTNOTE` is a string enclosed in quotes. To specify a multiple-line title or footnote, use `"\n"` to specify line breaks.
- The string that you specify cannot exceed 255 characters.

---

## CELLS Subcommand

By default, `SUMMARIZE` displays the means, standard deviations, and cell counts in each cell. Use `CELLS` to modify cell information.

- If `CELLS` is specified without keywords, `SUMMARIZE` displays the default statistics.
- If any keywords are specified on `CELLS`, only the requested information is displayed.
- `MEDIAN` and `GMEDIAN` use a lot of computer resources and time. Requesting these statistics (via these keywords or `ALL`) may slow down performance.

**DEFAULT.** *Means, standard deviations, and cell counts.* This setting is the default if `CELLS` is omitted.

**MEAN.** *Cell means.*

**STDDEV.** *Cell standard deviations.*

**COUNT.** *Cell counts.*

**MEDIAN.** *Cell median.*

**GMEDIAN.** *Grouped median.*

**SEMEAN.** *Standard error of cell mean.*

**SUM.** *Cell sums.*

**MIN.** *Cell minimum.*

**MAX.** *Cell maximum.*

**RANGE.** *Cell range.*

**VARIANCE.** *Variances.*

**KURT.** *Cell kurtosis.*

**SEKURT.** *Standard error of cell kurtosis.*

**SKEW.** *Cell skewness.*

**SESKEW.** *Standard error of cell skewness.*

**FIRST.** *First value.*

**LAST.** *Last value.*

**SPCT.** *Percentage of total sum.*

**NPCT.** *Percentage of total number of cases.*

**SPCT(var).** *Percentage of total sum within specified variable. The specified variable must be one of the control variables.*

**NPCT(var).** *Percentage of total number of cases within specified variable. The specified variable must be one of the control variables.*

**HARMONIC.** *Harmonic mean.*

**GEOMETRIC.** *Geometric mean.*

**ALL.** *All cell information.*

---

## **MISSING Subcommand**

MISSING controls the treatment of cases with missing values. There are two groups of keywords.

- EXCLUDE, INCLUDE, and DEPENDENT specify the treatment of user-missing values. The default is EXCLUDE.  
**EXCLUDE.** *All user-missing values are excluded. This setting is the default.*  
**INCLUDE.** *User-missing values are treated as valid values.*

**DEPENDENT.** *User-missing values are considered missing in a dependent variable and valid in a grouping variable (variables that are specified after a BY keyword).*

- VARIABLE and TABLE specify how cases with missing values for dependent variables are excluded. The default is VARIABLE.
- Cases with missing values for any control variables are always excluded.

**VARIABLE.** *A case is excluded when all values for variables in that table are missing. This setting is the default.*

**TABLE.** *A case is excluded when any value is missing within a table.*

---

## FORMAT Subcommand

FORMAT specifies whether you want a case listing for your report and whether you want case numbers displayed for the listing. FORMAT also determines whether your reports will display a total category for each group and how the reports will indicate missing values.

**NOLIST.** *Display a Summary Report without a case listing. This setting is the default.*

**LIST.** *Display a Listing Report.* By default, LIST shows all cases. It can be followed by the optional keyword LIMIT, an equals sign, and a positive integer to limit the number of cases in the report. For example, /FORMAT LIST LIMIT=10 will limit the report to the first 10 cases.

**VALIDLIST.** *Display a Listing Report showing only valid cases.*

**CASENUM.** *Display case numbers as a category in the Listing Reports. This setting is the default when FORMAT=LIST or VALIDLIST.*

**NOCASENUM.** *Do not display case numbers.*

**TOTAL.** *Display the summary statistics for the total of each group with the label Total. This is the default.*

**NOTOTAL.** *Display the total category without a label.*

**MISSING='string'.** *Display system-missing values as a specified string.*

---

## STATISTICS Subcommand

Use STATISTICS to request a one-way analysis of variance and a test of linearity for each table list.

- Statistics that are requested on STATISTICS are computed in addition to the statistics that are displayed in the Group Statistics table.
- If STATISTICS is specified without keywords, SUMMARIZE computes ANOVA.
- If two or more dimensions are specified, the second and subsequent dimensions are ignored in the analysis-of-variance table.

**ANOVA.** *Analysis of variance.* ANOVA displays a standard analysis-of-variance table and calculates eta and eta squared (displayed in the Measures of Association table). This setting is the default if STATISTICS is specified without keywords.

**LINEARITY.** *Test of linearity.* LINEARITY (alias ALL) displays additional statistics to the tables that are created by the ANOVA keyword—the sums of squares, degrees of freedom, and mean square associated with linear and nonlinear components, the *F* ratio, and the significance level for the ANOVA table and Pearson's *r* and *r*<sup>2</sup> for the Measures of Association table. LINEARITY is ignored if the control variable is a string.

**NONE.** *No additional statistics.* This setting is the default if `STATISTICS` is omitted.

#### Example

```
SUMMARIZE TABLES=INCOME BY SEX BY RACE  
/STATISTICS=ANOVA.
```

- `SUMMARIZE` produces a Group Statistics table of *INCOME* by *RACE* within *SEX* and computes an analysis of variance only for *INCOME* by *SEX*.

---

## Chapter 262. SURVIVAL

SURVIVAL is available in SPSS Statistics Standard Edition or the Advanced Statistics Option.

```
SURVIVAL TABLE=survival varlist
    [BY varlist (min, max)...][BY varlist (min, max)...]

/INTERVAL=THRU n BY a [THRU m BY b ...]

/STATUS=status variable({min, max}) FOR {ALL      }
    {value  }      {survival varlist}
[/STATUS=...]

[/PLOTS ({ALL      })={ALL      } BY {ALL      } BY {ALL      }]
    {LOGSURV } {survival varlis} {varlist} {varlist}
    {SURVIVAL}
    {HAZARD  }
    {DENSITY }
    {OMS      }

[/PRINT={TABLE**}]
    {NOTABLE}

[/COMPARE={ALL**      } BY {ALL** } BY {ALL** }]
    {survival varlist} {varlist} {varlist}

[/CALCULATE=[{EXACT**  }] [PAIRWISE] [COMPARE] ]
    {CONDITIONAL}
    {APPROXIMATE}

[/MISSING={GROUPWISE**} [INCLUDE] ]
    {LISTWISE  }

[/WRITE=[{NONE**}] ]
    {TABLES   }
    {BOTH     }
```

\*\*Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Example

```
SURVIVAL TABLE=MOSFREE BY TREATMNT(1,3)
/STATUS = PRISON (1) FOR MOSFREE
/INTERVAL=THRU 24 BY 3.
```

---

## Overview

SURVIVAL produces actuarial life tables, plots, and related statistics for examining the length of time to the occurrence of an event, often known as **survival time**. Cases can be classified into groups for separate analyses and comparisons. Time intervals can be calculated with the IBM SPSS Statistics date- and time-conversion functions—for example, `CTIME.DAYS` or `YRMODEA`. For a closely related alternative nonparametric analysis of survival times using the product-limit Kaplan-Meier estimator, see the `KM` command. For an analysis of survival times with covariates, including time-dependent covariates, see the `COXREG` command.

### Options

**Life Tables.** You can list the variables to be used in the analysis, including any control variables on the `TABLE` subcommand. You can also suppress the life tables in the output with the `PRINT` subcommand.

**Intervals.** SURVIVAL reports the percentage alive at various times after the initial event. You can select the time points for reporting with the `INTERVAL` subcommand.

**Plots.** You can plot the survival functions for all cases or separately for various subgroups with the PLOTS subcommand.

**Comparisons.** When control variables are listed on the TABLE subcommand, you can compare groups based on the Wilcoxon (Gehan) statistic using the COMPARE subcommand. You can request pairwise or approximate comparisons with the CALCULATE subcommand.

**Writing a File.** You can write the life tables, including the labeling information, to a file with the WRITE subcommand.

#### Basic Specification

- The basic specification requires three subcommands: TABLE, INTERVAL, and STATUS. TABLE identifies at least one survival variable from the active dataset, INTERVAL divides the time period into intervals, and STATUS names a variable that indicates whether the event occurred.
- The basic specification prints one or more life tables, depending on the number of survival and control variables specified.

#### Subcommand Order

- TABLE must be first.
- Remaining subcommands can be named in any order.

#### Syntax Rules

- Only one TABLE subcommand can be specified, but multiple survival variables can be named. A survival variable cannot be specified as a control variable on any subcommands.
- Only one INTERVAL subcommand can be in effect on a SURVIVAL command. The interval specifications apply to all of the survival variables listed on TABLE. If multiple INTERVAL subcommands are used, the last specification supersedes all previous ones.
- Only one status variable can be listed on each STATUS subcommand. To specify multiple status variables, use multiple STATUS subcommands.
- You can specify multiple control variables on one BY keyword. Use a second BY keyword to specify second-order control variables to interact with the first-order control variables.
- All variables, including survival variables, control variables, and status variables, must be numeric. SURVIVAL does not process string variables.

#### Operations

- SURVIVAL computes time intervals according to specified interval widths, calculates the survival functions for each interval, and builds one life table for each group of survival variables. The life table is displayed unless explicitly suppressed.
- When the PLOTS subcommand is specified, SURVIVAL plots the survival functions for all cases or separately for various groups.
- When the COMPARE subcommand is specified, SURVIVAL compares survival-time distributions of different groups based on the Wilcoxon (Gehan) statistic.

#### Limitations

- Maximum 20 survival variables.
- Maximum 100 control variables total on the first- and second-order control-variable lists combined.
- Maximum 20 THRU and BY specifications on INTERVAL.
- Maximum 35 values can appear on a plot.

---

## Examples

```
SURVIVAL TABLE=MOSFREE BY TREATMNT(1,3)
/STATUS = PRISON (1) FOR MOSFREE
/INTERVAL = THRU 24 BY 3.
```

- The survival analysis is used to examine the length of time between release from prison and return to prison for prisoners in three treatment programs. The variable *MOSFREE* is the length of time in months a prisoner stayed out of prison. The variable *TREATMNT* indicates the treatment group for each case.
- A value of 1 on the variable *PRISON* indicates a terminal outcome—that is, cases coded as 1 have returned to prison. Cases with other non-negative values for *PRISON* have not returned. Because we don't know their final outcome, such cases are called censored.
- Life tables are produced for each of the three subgroups. *INTERVAL* specifies that the survival experience be described every three months for the first two years.

---

## TABLE Subcommand

TABLE identifies the survival and control variables to be included in the analysis.

- The minimum specification is one or more survival variables.
- To specify one or more first-order control (or factor) variables, use the keyword *BY* followed by the control variable(s). First-order control variables are processed in sequence. For example, *BY A(1,3) B(1,2)* results in five groups (*A=1, A=2, A=3, B=1, and B=2*).
- You can specify one or more second-order control variables following a second *BY* keyword. Separate life tables are generated for each combination of values of the first-order and second-order controls. For example, *BY A(1,3) BY B(1,2)* results in six groups (*A=1 B=1, A=1 B=2, A=2 B=1, A=2 B=2, A=3 B=1, and A=3, B=2*).
- Each control variable must be followed by a value range in parentheses. These values must be integers separated by a comma or a blank. Non-integer values in the data are truncated, and the case is assigned to a subgroup based on the integer portion of its value on the variable. To specify only one value for a control variable, use the same value for the minimum and maximum.
- To generate life tables for all cases combined, as well as for control variables, use *COMPUTE* to create a variable that has the same value for all cases. With this variable as a control, tables for the entire set of cases, as well as for the control variables, will be produced.

### Example

```
SURVIVAL TABLE = MOSFREE BY TREATMNT(1,3) BY RACE(1,2)
/STATUS = PRISON(1)
/INTERVAL = THRU 24 BY 3.
```

- *MOSFREE* is the survival variable, and *TREATMNT* is the first-order control variable. The second *BY* defines *RACE* as a second-order control group having a value of 1 or 2.
- Six life tables with the median survival time are produced, one for each pair of values for the two control variables.

---

## INTERVAL Subcommand

*INTERVAL* determines the period of time to be examined and how the time will be grouped for the analysis. The interval specifications apply to all of the survival variables listed on *TABLE*.

- *SURVIVAL* always uses 0 as the starting point for the first interval. Do not specify the 0. The *INTERVAL* specification *must* begin with the keyword *THRU*.
- Specify the terminal value of the time period after the keyword *THRU*. The final interval includes any observations that exceed the specified terminal value.
- The grouping increment, which follows the keyword *BY*, must be in the same units as the survival variable.

- The period to be examined can be divided into intervals of varying lengths by repeating the THRU and BY keywords. The period must be divided in ascending order. If the time period is not a multiple of the increment, the endpoint of the period is adjusted upward to the next even multiple of the grouping increment.
- When the period is divided into intervals of varying lengths by repeating the THRU and BY specifications, the adjustment of one period to produce even intervals changes the starting point of subsequent periods. If the upward adjustment of one period completely overlaps the next period, no adjustment is made and the procedure terminates with an error.

#### Example

```
SURVIVAL TABLE = MOSFREE BY TREATMNT(1,3)
/STATUS = PRISON(1) FOR MOSFREE
/INTERVAL = THRU 12 BY 1 THRU 24 BY 3.
```

- INTERVAL produces life tables computed from 0 to 12 months at one-month intervals and from 13 to 24 months at three-month intervals.

#### Example

```
SURVIVAL ONSSURV BY TREATMNT (1,3)
/STATUS = OUTCOME (3,4) FOR ONSSURV
/INTERVAL = THRU 50 BY 6.
```

- On the INTERVAL subcommand, the value following BY (6) does not divide evenly into the period to which it applies (50). Thus, the endpoint of the period is adjusted upward to the next even multiple of the BY value, resulting in a period of 54 with 9 intervals of 6 units each.

#### Example

```
SURVIVAL ONSSURV BY TREATMNT (1,3)
/STATUS = OUTCOME (3,4) FOR ONSSURV
/INTERVAL = THRU 50 BY 6 THRU 100 BY 10 THRU 200 BY 20.
```

- Multiple THRU and BY specifications are used on the INTERVAL subcommand to divide the period of time under examination into intervals of different lengths.
- The first THRU and BY specifications are adjusted to produce even intervals as in the previous example. As a result, the following THRU and BY specifications are automatically readjusted to generate 5 intervals of 10 units (through 104), followed by 5 intervals of 20 units (through 204).

---

## STATUS Subcommand

To determine whether the terminal event has occurred for a particular observation, SURVIVAL checks the value of a status variable. STATUS lists the status variable associated with each survival variable and the codes that indicate that a terminal event occurred.

- Specify a status variable followed by a value range enclosed in parentheses. The value range identifies the codes that indicate that the terminal event has taken place. All cases with non-negative times that do not have a code in the value range are classified as **censored cases**, which are cases for which the terminal event has not yet occurred.
- If the status variable does not apply to all the survival variables, specify FOR and the name of the survival variable(s) to which the status variable applies.
- Each survival variable on TABLE must have an associated status variable identified by a STATUS subcommand.
- Only one status variable can be listed on each STATUS subcommand. To specify multiple status variables, use multiple STATUS subcommands.
- If FOR is omitted on the STATUS specification, the status-variable specification applies to all of the survival variables not named on another STATUS subcommand.
- If more than one STATUS subcommand omits the keyword FOR, the final STATUS subcommand without FOR applies to all survival variables not specified by FOR on other STATUS subcommands. No warning is printed.

## Example

```
SURVIVAL ONSSURV BY TREATMNT (1,3)
/INTERVAL = THRU 50 BY 5, THRU 100 BY 10
/STATUS = OUTCOME (3,4) FOR ONSSURV.
```

- STATUS specifies that a code of 3 or 4 on *OUTCOME* means that the terminal event for the survival variable *ONSSURV* occurred.

## Example

```
SURVIVAL TABLE = NOARREST MOSFREE BY TREATMNT(1,3)
/STATUS = ARREST (1) FOR NOARREST
/STATUS = PRISON (1)
/INTERVAL=THRU 24 BY 3.
```

- STATUS defines the terminal event for *NOARREST* as a value of 1 for *ARREST*. Any other value for *ARREST* is considered censored.
- The second STATUS subcommand defines the value of 1 for *PRISON* as the terminal event. The keyword FOR is omitted. Thus, the status-variable specification applies to *MOSFREE*, which is the only survival variable not named on another STATUS subcommand.

---

## PLOTS Subcommand

PLOTS produces plots of the cumulative survival distribution, the hazard function, and the probability density function. The PLOTS subcommand can plot only the survival functions generated by the TABLE subcommand; PLOTS cannot eliminate control variables.

- When specified by itself, the PLOTS subcommand produces all available plots for each survival variable. Points on each plot are identified by values of the first-order control variables. If second-order controls are used, a separate plot is generated for every value of the second-order control variables.
- To request specific plots, specify, in parentheses following PLOTS, any combination of the keywords defined below.
- Optionally, generate plots for only a subset of the requested life tables. Use the same syntax as used on the TABLE subcommand for specifying survival and control variables, omitting the value ranges. Each survival variable named on PLOTS must have as many control levels as were specified for that variable on TABLE. However, only one control variable needs to be present for each level. If a required control level is missing on the PLOTS specification, the default BY ALL is used for that level. The keyword ALL can be used to refer to an entire set of survival or control variables.
- To determine the number of plots that will be produced, multiply the number of functions plotted by the number of survival variables times the number of first-order controls times the number of distinct values represented in all of the second-order controls.

**ALL.** *Plot all available functions.* ALL is the default if PLOTS is used without specifications.

**LOGSURV.** *Plot the cumulative survival distribution on a logarithmic scale.*

**SURVIVAL.** *Plot the cumulative survival distribution on a linear scale.*

**HAZARD.** *Plot the hazard function.*

**DENSITY.** *Plot the density function.*

**OMS.** *Plot the one-minus-survival function.*

## Example

```
SURVIVAL TABLE = NOARREST MOSFREE BY TREATMNT(1,3)
/STATUS = ARREST (1) FOR NOARREST
/STATUS = PRISON (1) FOR MOSFREE
/INTERVAL = THRU 24 BY 3
/PLOTS (SURVIVAL,HAZARD) = MOSFREE.
```

- Separate life tables are produced for each of the survival variables (*NOARREST* and *MOSFREE*) for each of the three values of the control variable *TREATMNT*.
- *LOTS* produces plots of the cumulative survival distribution and the hazard rate for *MOSFREE* for the three values of *TREATMNT* (even though *TREATMNT* is not included on the *LOTS* specification).
- Because plots are requested only for the survival variable *MOSFREE*, no plots are generated for the variable *NOARREST*.

---

## PRINT Subcommand

By default, *SURVIVAL* prints life tables. *PRINT* can be used to suppress the life tables.

**TABLE.** *Print the life tables.* This is the default.

**NOTABLE.** *Suppress the life tables.* Only plots and comparisons are printed. The *WRITE* subcommand, which is used to write the life tables to a file, can be used when *NOTABLE* is in effect.

### Example

```
SURVIVAL TABLE = MOSFREE BY TREATMNT(1,3)
/STATUS = PRISON (1) FOR MOSFREE
/INTERVAL = THRU 24 BY 3
/PLOTS (ALL)
/PRINT = NOTABLE.
```

- *PRINT NOTABLE* suppresses the printing of life tables.

---

## COMPARE Subcommand

*COMPARE* compares the survival experience of subgroups defined by the control variables. At least one first-order control variable is required for calculating comparisons.

- When specified by itself, the *COMPARE* subcommand produces comparisons using the *TABLE* variable list.
- Alternatively, specify the survival and control variables for the comparisons. Use the same syntax as used on the *TABLE* subcommand for specifying survival and control variables, omitting the value ranges. Only variables that appear on the *TABLE* subcommand can be listed on *COMPARE*, and their role as survival, first-order, and second-order control variables cannot be altered. The keyword *T0* can be used to refer to a group of variables, and the keyword *ALL* can be used to refer to an entire set of survival or control variables.
- By default, *COMPARE* calculates exact comparisons between subgroups. Use the *CALCULATE* subcommand to obtain pairwise comparisons or approximate comparisons.

### Example

```
SURVIVAL TABLE = MOSFREE BY TREATMNT(1,3)
/STATUS = PRISON (1) FOR MOSFREE
/INTERVAL = THRU 24 BY 3
/COMPARE.
```

- *COMPARE* computes the Wilcoxon (Gehan) statistic, degrees of freedom, and observed significance level for the hypothesis that the three survival curves based on the values of *TREATMNT* are identical.

### Example

```
SURVIVAL TABLE=ONSSURV,RECSURV BY TREATMNT(1,3)
/STATUS = RECURSIT(1,9) FOR RECSURV
/STATUS = STATUS(3,4) FOR ONSSURV
/INTERVAL = THRU 50 BY 5 THRU 100 BY 10
/COMPARE = ONSSURV BY TREATMNT.
```

- *COMPARE* requests a comparison of *ONSSURV* by *TREATMNT*. No comparison is made of *RECSURV* by *TREATMNT*.

---

## CALCULATE Subcommand

CALCULATE controls the comparisons of survival for subgroups specified on the COMPARE subcommand.

- The minimum specification is the subcommand keyword by itself. EXACT is the default.
- Only one of the keywords EXACT, APPROXIMATE, and CONDITIONAL can be specified. If more than one keyword is used, only one is in effect. The order of precedence is APPROXIMATE, CONDITIONAL, and EXACT.
- The keywords PAIRWISE and COMPARE can be used with any of the EXACT, APPROXIMATE, or CONDITIONAL keywords.
- If CALCULATE is used without the COMPARE subcommand, CALCULATE is ignored. However, if the keyword COMPARE is specified on CALCULATE and the COMPARE subcommand is omitted, an error message is generated.
- Data can be entered into SURVIVAL for each individual case or aggregated for all cases in an interval. The way in which data are entered determines whether an exact or an approximate comparison is most appropriate. See the topic “Using Aggregated Data” on page 1926 for more information. .

**EXACT.** *Calculate exact comparisons.* This is the default. You can obtain exact comparisons based on the survival experience of each observation with individual data. While this method is the most accurate, it requires that all of the data be in memory simultaneously. Thus, exact comparisons may be impractical for large samples. It is also inappropriate when individual data are not available and data aggregated by interval must be used.

**APPROXIMATE.** *Calculate approximate comparisons only.* Approximate comparisons are appropriate for aggregated data. The approximate-comparison approach assumes that all events occur at the midpoint of the interval. With exact comparisons, some of these midpoint ties can be resolved. However, if interval widths are not too great, the difference between exact and approximate comparisons should be small.

**CONDITIONAL.** *Calculate approximate comparisons if memory is insufficient.* Approximate comparisons are produced only if there is insufficient memory available for exact comparisons.

**PAIRWISE.** *Perform pairwise comparisons.* Comparisons of all pairs of values of the first-order control variable are produced along with the overall comparison.

**COMPARE.** *Produce comparisons only.* Survival tables specified on the TABLE subcommand are not computed, and requests for plots are ignored. This allows all available workspace to be used for comparisons. The WRITE subcommand cannot be used when this specification is in effect.

### Example

```
SURVIVAL TABLE = MOSFREE BY TREATMNT(1,3)
/STATUS = PRISON (1) FOR MOSFREE
/INTERVAL = THRU 24 BY 3
/COMPARE /CALCULATE = PAIRWISE.
```

- PAIRWISE on CALCULATE computes the Wilcoxon (Gehan) statistic, degrees of freedom, and observed significance levels for each pair of values of *TREATMNT*, as well as for an overall comparison of survival across all three *TREATMNT* subgroups: group 1 with group 2, group 1 with group 3, and group 2 with group 3.
- All comparisons are exact comparisons.

### Example

```
SURVIVAL TABLE = MOSFREE BY TREATMNT(1,3)
/STATUS = PRISON (1) FOR MOSFREE
/INTERVAL = THRU 24 BY 3
/COMPARE /CALCULATE = APPROXIMATE COMPARE.
```

- APPROXIMATE on CALCULATE computes the Wilcoxon (Gehan) statistic, degrees of freedom, and probability for the overall comparison of survival across all three *TREATMNT* subgroups using the approximate method.
- Because the keyword COMPARE is specified on CALCULATE, survival tables are not computed.

---

## Using Aggregated Data

When aggregated survival information is available, the number of censored and uncensored cases at each time point must be entered. Up to two records can be entered for each interval, one for censored cases and one for uncensored cases. The number of cases included on each record is used as the weight factor. If control variables are used, there will be up to two records (one for censored and one for uncensored cases) for each value of the control variable in each interval. These records must contain the value of the control variable and the number of cases that belong in the particular category as well as values for survival time and status.

### Example

```
DATA LIST / SURVEVAR 1-2 STATVAR 4 SEX 6 COUNT 8.
VALUE LABELS STATVAR 1 'DECEASED' 2 'ALIVE'
              /SEX 1 'FEMALE' 2 'MALE'.
BEGIN DATA
  1 1 1 6
  1 1 1 1
  1 2 2 2
  1 1 2 1
  2 2 1 1
  2 1 1 2
  2 2 2 1
  2 1 2 3
  ...
END DATA.
WEIGHT COUNT.
SURVIVAL TABLE = SURVEVAR BY SEX (1,2)
/INTERVAL = THRU 10 BY 1
/STATUS = STATVAR (1) FOR SURVEVAR.
```

- This example reads aggregated data and performs a SURVIVAL analysis when a control variable with two values is used.
- The first data record has a code of 1 on the status variable *STATVAR*, indicating that it is an uncensored case, and a code of 1 on *SEX*, the control variable. The number of cases for this interval is 6, the value of the variable *COUNT*. Intervals with weights of 0 do not have to be included.
- *COUNT* is not used in SURVIVAL but is the weight variable. In this example, each interval requires four records to provide all of the data for each *SURVEVAR* interval.

---

## MISSING Subcommand

MISSING controls missing-value treatments. The default is GROUPWISE.

- Negative values on the survival variables are automatically treated as missing data. In addition, cases outside of the value range on a control variable are excluded.
- GROUPWISE and LISTWISE are mutually exclusive. However, each can be used with INCLUDE.

**GROUPWISE.** *Exclude missing values groupwise.* Cases with missing values on a variable are excluded from any calculation involving that variable. This is the default.

**LISTWISE.** *Exclude missing values listwise.* Cases missing on any variables named on TABLE are excluded from the analysis.

**INCLUDE.** *Include user-missing values.* User-missing values are included in the analysis.

---

## WRITE Subcommand

WRITE writes data in the survival tables to a file. This file can be used for further analyses or to produce graphics displays.

- When WRITE is omitted, the default is NONE. No output file is created.
- When WRITE is used, a PROCEDURE OUTPUT command must precede the SURVIVAL command. The OUTFILE subcommand on PROCEDURE OUTPUT specifies the output file.

- When WRITE is specified without a keyword, the default is TABLES.

**NONE.** *Do not write procedure output to a file.* This is the default when WRITE is omitted.

**TABLES.** *Write survival-table data records.* All survival-table statistics are written to a file.

**BOTH.** *Write out survival-table data and label records.* Variable names, variable labels, and value labels are written out along with the survival table statistics.

## Format

WRITE writes five types of records. The keyword TABLES writes record types 30, 31, and 40. The keyword BOTH writes record types 10, 20, 30, 31, and 40. The format of each record type is described in the following tables.

*Table 111. Record type 10, produced only by keyword BOTH*

Columns	Content	Format
1-2	Record type (10)	F2.0
3-7	Table number	F5.0
8-47	Variable label of survival variable	A40
48	Number of BY's (0, 1, or 2)	F1.0
49-52	Number of rows in current survival table	F4.0
53-116	Name of survival variable	A64

- One type-10 record is produced for each life table.
- Column 48 specifies the number of orders of control variables (0, 1, or 2) that have been applied to the life table.
- Columns 49-52 specify the number of rows in the life table. This number is the number of intervals in the analysis that show subjects entering; intervals in which no subjects enter are not noted in the life tables.

*Table 112. Record type 20, produced by keyword BOTH*

Columns	Content	Format
1-2	Record type (20)	F2.0
3-7	Table number	F5.0
8-47	Variable label of control variable	A40
48-52	Value of control variable	F5.0
53-72	Value label for this value	A20
73-136	Name of control variable	A64

- One type-20 record is produced for each control variable in each life table.
- If only first-order controls have been placed in the survival analysis, one type-20 record will be produced for each table. If second-order controls have also been applied, two type-20 records will be produced per table.

*Table 113. Record type 30, produced by both keywords TABLES and BOTH*

Columns	Content	Format
1-2	Record type (30)	F2.0
3-7	Table number	F5.0
8-13	Beginning of interval	F6.2
14-21	Number entering interval	F8.2
22-29	Number withdrawn in interval	F8.2
30-37	Number exposed to risk	F8.2
38-45	Number of terminal events	F8.2

- Information on record type 30 continues on record type 31. Each pair of type-30 and type-31 records contains the information from one line of the life table.

Table 114. Record type 31, continuation of record type 30

Columns	Content	Format
1-2	Record type (31)	F2.0
3-7	Table number	F5.0
8-15	Proportion terminating	F8.6
16-23	Proportion surviving	F8.6
24-31	Cumulative proportion surviving	F8.6
32-39	Probability density	F8.6
40-47	Hazard rate	F8.6
48-54	S.E. of cumulative proportion surviving	F7.4
55-61	S.E. of probability density	F7.4
62-68	S.E. of hazard rate	F7.4

- Record type 31 is a continuation of record type 30.
- As many type-30 and type-31 record pairs are output for a table as it has lines (this number is noted in columns 57-60 of the type-10 record for the table).

Table 115. Record type 40, produced by both keywords TABLES and BOTH

Columns	Content	Format
1-2	Record type (40)	F2.0

- Type-40 records indicate the completion of the series of records for one life table.

## Record Order

The SURVIVAL output file contains records for each of the life tables specified on the TABLE subcommand. All records for a given table are produced together in sequence. The records for the life tables are produced in the same order as the tables themselves. All life tables for the first survival variable are written first. The values of the first- and second-order control variables rotate, with the values of the first-order controls changing more rapidly.

### Example

```
PROCEDURE OUTPUT OUTFILE = SURVTBL.
SURVIVAL TABLE = MOSFREE BY TREATMNT(1,3)
/STATUS = PRISON (1) FOR MOSFREE
/INTERVAL = THRU 24 BY 3
/WRITE = BOTH.
```

- WRITE generates a procedure output file called *SURVTBL*, containing life tables, variable names and labels, and value labels stored as record types 10, 20, 30, 31, and 40.

---

## Chapter 263. SYSDFILE INFO

`SYSDFILE INFO [FILE=] 'file specification' [PASSWORD='password']`

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Release History

#### Release 22.0

- `PASSWORD` keyword introduced.

### Example

```
SYSDFILE INFO FILE='PERSONL.SAV'.
```

---

## Overview

`SYSDFILE INFO` displays complete dictionary information for all variables in an external IBM SPSS Statistics data file. You do not have to retrieve the file with `GET` to use `SYSDFILE INFO`. If the file has already been retrieved, use `DISPLAY DICTIONARY` to display dictionary information.

### Basic Specification

The basic specification is the command keyword and a complete file specification that is enclosed in quotes.

### Syntax Rules

- Only one file specification is allowed per command. To display dictionary information for more than one IBM SPSS Statistics data file, use multiple `SYSDFILE INFO` commands.
- The file extension, if there is one, must be specified, even if it is the default.
- The subcommand keyword `FILE` is optional. When `FILE` is specified, the equals sign is required.

### Operations

- No procedure is needed to execute `SYSDFILE INFO`, because `SYSDFILE INFO` obtains information from the dictionary alone.
- `SYSDFILE INFO` displays file and variable information. File information includes number of variables and cases in the file; file label; file documents; defined multiple response sets; variable sets; and information that is used by other applications (such as IBM SPSS Modeler, Data Entry for Windows, and TextSmart). Variable information includes the variable name; label; sequential position in the file; print and write format; missing values; and value labels for each variable in the specified file.

### `PASSWORD` Keyword

The `PASSWORD` keyword specifies the password required to open an encrypted IBM SPSS Statistics data file. The specified value must be enclosed in quotation marks and can be provided as encrypted or as plain text. Encrypted passwords are created when pasting command syntax from the Save Data As dialog. The `PASSWORD` keyword is ignored if the file is not encrypted.

---

## Chapter 264. TCM ANALYSIS

TCM ANALYSIS is available in SPSS Statistics Professional Edition or the Forecasting option.

```
TCM ANALYSIS
  /MODELSYSTEM FILE=file

  [/EXPRESSIONS FILE=file

  /SCENARIOPERIOD
    TIMES = {ABSOLUTE}
           {RELATIVE}

    FORMAT = {VARIABLE}
            {ISO8601 }

    START={datetime }  END={datetime }  [PREDICTTHRU = {datetime } ]
          {integerList} {integerList}          {integerList}

  [/SCENARIO
    ID = string

    VALUES = {ACTUAL(valueList) }
             {EXPRESSION(variable)}

    ROOTFIELD = field

    [DIMVALUES = dimField(VALUE=dimValue) dimField(VALUE=dimValue) ...]

    [EFFECTS = {AUTOMATIC** }
              {TARGETLIST[(listID)]}]

  [/SCENARIOGROUP
    IDPREFIX = string

    EXPRESSION = variable

    ROOTFIELD = field

    [DIMVALUES = dimField(VALUE=dimValueList) dimField(VALUE=dimValueList) ...]

    [EFFECTS = {AUTOMATIC** }
              {TARGETLIST[(listID)]}]

  [/TARGETLIST
    [LISTID = string
     FIELDS = fieldList
     [DIMVALUES = dimField(VALUE=dimValueList) dimField(VALUE=dimValueList) ...]

  [/OPTIONS

    [CILEVEL = {95** } ]
              {number}

    [PREDICTEDCI = {YES } ]
                  {NO**}

    [PRINT = FORECASTS ]

    [PLOT = [IMPACTDIAGRAM**] [SERIESPLOT] [NONE] ]

    [MAXTARGETS = {25** } ]
                 {integer}

    [MAXLEVELS = {3** } ]
                 {integer}
```

\*\*Default if keyword omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

Syntax for the TCM ANALYSIS command can be generated from the dialog.

## Release History

Release 23.0

- Command introduced.

## Example

```
TCM ANALYSIS
  /MODELSYSTEM FILE='/models/mymodel.zip'
  /SCENARIOPERIOD
    TIMES = ACTUAL
    FORMAT = VARIABLE
    START = '10/01/2013'
    END = '12/01/2013'
    PREDICTTHRU = '03/01/2014'
  /SCENARIO
    ID = advert_1
    VALUES = ACTUAL(5000 5500 6000)
    ROOTFIELD = advert.
```

### Related information:

Chapter 266, “TCM MODEL,” on page 1951

Chapter 265, “TCM APPLY,” on page 1939

---

## Overview

The TCM ANALYSIS procedure runs user-defined scenarios for a temporal causal model system, with the data from the active dataset. A *scenario* is defined by a time series, that is referred to as the *root series*, and a set of user-defined values for that series over a specified time range. The specified values are then used to generate predictions for the time series that are affected by the root series. The procedure requires a model system file that was created by the TCM MODEL procedure. It is assumed that the active dataset is the same data as was used to create the model system file.

## Basic Specification

For column-based data, the basic specification is the MODELSYSTEM subcommand, the SCENARIOPERIOD subcommand and at least one SCENARIO subcommand. For multidimensional data, the basic specification is the MODELSYSTEM subcommand, the SCENARIOPERIOD subcommand and at least one SCENARIO subcommand or SCENARIOGROUP subcommand.

## Syntax Rules

- Multiple SCENARIO subcommands are allowed.
- Multiple SCENARIOGROUP subcommands are allowed. SCENARIOGROUP subcommands apply only to multidimensional data.
- Multiple TARGETLIST subcommands are allowed.
- Each keyword can be specified only once within a subcommand.
- Empty subcommands are not allowed.
- Parentheses, equals signs, and slashes that are shown in the syntax chart are required.
- The command name, subcommand names, and keywords must be spelled in full.

## Operations

- The procedure does not honor the PREDICT command. The TCM ANALYSIS procedure provides an option to specify how far to forecast.

## Limitations

- The SPLIT FILE setting is ignored by this procedure.
- Case weighting is ignored by this procedure.

---

## MODELSYSTEM Subcommand

The MODELSYSTEM subcommand is required and specifies the external file that contains the model system that you want.

**FILE** Specifies the compressed file archive (.zip file) that contains the model system.

---

## EXPRESSIONS Subcommand

The EXPRESSIONS subcommand specifies an external file that was created by BEGIN EXPR-END EXPR and that contains XML representations of expressions for computing scenario values. The EXPRESSIONS subcommand is required when a SCENARIOGROUP subcommand is used or when VALUES=EXPRESSION on a SCENARIO subcommand.

**FILE** Specifies the external XML file that contains the expressions.

**Note:** The combination of an asterisk (\*) and a backslash (\) preceding the XML file name specifies that the file is a temporary file.

### Related information:

“Specifying expressions” on page 246

---

## SCENARIOPERIOD subcommand

The SCENARIOPERIOD subcommand defines the period over which you specify the values that are used to run your scenarios. This period is referred to as the *scenario period*. The subcommand also specifies how far into the future to predict the effects of the scenario values. All scenarios use the same scenario period and the same specification for how far to predict into the future.

- The scenario period can start before or after the end of the estimation period. The estimation period is the same as was used to build the model system. The keyword START specifies the start of the scenario period and is required. The keyword END specifies the end of the scenario period and is required.
- The PREDICTTHRU keyword specifies how far to predict beyond the end of the scenario period. If PREDICTTHRU is omitted, then predictions are generated through the end of the scenario period.

**Note:** Predictions start at the first time period after the beginning of the scenario period. For example, if the scenario period starts on 2014-11-01 and the time interval is months, then the first prediction is for 2014-12-01.

### TIMES=ABSOLUTE

Specifies that START, END, and PREDICTTHRU are defined by date/time values or by lists of integers (for observations that are not defined by date/time values).

- For observations that are defined by a date, datetime, time, or string field, the FORMAT keyword is required (and ignored otherwise). It specifies the format of the values for START, END, and PREDICTTHRU. Values for START, END, and PREDICTTHRU must be quoted in this case.

### VARIABLE

Specifies to use the variable format for the variable that defines the observations; for example, mm/dd/yyyy. This option applies only when observations are defined by a date, datetime, or time field.

## ISO8601

Specifies that values for START, END, and PREDICTTHRU are in the general form of yyyy-mm-dd hh:mm:ss. FORMAT=ISO8601 must be specified when the observations are defined by a string field.

- Dates are specified in the form yyyy-mm-dd. Datetimes are specified in the form yyyy-mm-dd hh:mm:ss. Times are specified in the form hh:mm:ss.
  - Two digits are not required for month, day, hours, minutes or seconds specifications. For example, 2014-1-1 is interpreted as 2014-01-01 and 3:2:1 is interpreted as 03:02:01.
  - Values can be specified with reduced precision. For example, 2014-10 is interpreted as 2014-10-01 and 03:02 is interpreted as 03:02:00.
- For observations that are defined by cyclic period fields, START, END, and PREDICTTHRU are lists of integers, consisting of one value for each of the cyclic period fields. The first value is the value for the highest level cycle field, followed by the next highest cycle field, and so on.

For example, the following syntax specifies the start, end, and predict through time when there are two cycle levels, in addition to a period field:

```
START = 3 6 2  END = 3 6 4  PREDICTTHRU = 3 6 5
```

The start of the scenario period is defined by a value of 3 for the second-level cycle, a value of 6 for the first-level cycle, and a value of 2 for the period field. The end of the scenario period is defined by a value of 3 for the second-level cycle, a value of 6 for the first-level cycle, and a value of 4 for the period field. The predict through time is specified by a value of 3 for the second-level cycle, a value of 6 for the first-level cycle, and a value of 5 for the period field.

- For observations that are defined by record number, START, END, and PREDICTTHRU consist of a single value that specifies the starting record number, the ending record number, and how far to predict beyond the ending record number. For example, the following syntax specifies a scenario period that starts at record 58 and ends at record 60. Predictions are generated for one more time period beyond the end of the scenario period.

```
START = 58  END = 60  PREDICTTHRU = 61
```

- For observations that are defined by a date specification (DATE command), START, END, and PREDICTTHRU are lists of integers that consist of one value for each of the components of the date specification. For example, if the date specification is YEAR and MONTH, then the lists consist of two items, one for the year and one for the month. The order of the values is from the highest level component to the lowest level component. For example, the following syntax specifies start, end, and predict through times for a date specification that is defined by YEAR and MONTH:

```
START = 2013 10  END = 2013 12  PREDICTTHRU = 2014 3
```

The start of the scenario period is defined by a value of 2013 for the year and 10 for the month. The end of the scenario period is defined by a value of 2013 for the year and 12 for the month. Predictions are generated through to a value of 2014 for the year and 3 for the month.

## TIMES=RELATIVE

Specifies that START and END are defined by time intervals that are relative to the end of the estimation period. The time interval refers to the interval at which the data were modeled. For example, if the observations are daily but the data are aggregated to months, then the time interval is months.

- The end of the estimation period is defined as interval 0. Negative values represent intervals prior to the end of the estimation period and positive values represent intervals after the end of the estimation period.
- PREDICTTHRU must be a non-negative integer and represents the number of intervals past the time that is specified for the END keyword.

---

## SCENARIO subcommand

The SCENARIO subcommand defines a single scenario. Multiple SCENARIO subcommands are allowed.

**ID** Specifies an identifier for the scenario. The identifier is displayed in output associated with the scenario. The value must be a quoted string. The ID keyword is required.

### VALUES

Specifies the values of the root field that are used for the scenario.

### ACTUAL

Specifies that explicit values are provided for the scenario. The specification is a list of numeric values that defines the values for the scenario. The list must have the same number of values as the number of time intervals in the scenario period (as defined by the SCENARIOPERIOD subcommand).

### EXPRESSION

Specifies that the scenario values are computed from an expression. The specification is the name of the variable, from the expressions file (specified on the EXPRESSIONS subcommand), that defines the expression.

**Note:** Expressions are specified with COMPUTE statements in a BEGIN EXPR-END EXPR block. The variable that is specified on the EXPRESSION keyword is a target of one of those COMPUTE statements.

### ROOTFIELD

Specifies the root field for the scenario. For multidimensional data, the ROOTFIELD keyword must be accompanied by the DIMVALUES keyword which specifies the set of dimension values that (along with ROOTFIELD) uniquely defines the root time series.

### DIMVALUES

Specifies the list of dimension field values that (along with ROOTFIELD) uniquely defines the root time series. The keyword is required for multidimensional data and ignored otherwise. The form of the specification for a particular dimension field is `dimField(VALUE=dimValue)`, where `dimField` is the name of the field and `dimValue` is the value for that field. A value must be specified for each dimension field.

- Fields that are specified on the DIMVALUES keyword do not support ALL and TO.
- String values do not need to be quoted.

### EFFECTS

Specifies how to determine the set of series that are affected by the root series.

### AUTOMATIC

Specifies that the procedure automatically determines the series that are affected by the root series. This is the default. You can specify the breadth of the series that are affected by the scenario with settings on the OPTIONS subcommand.

### TARGETLIST

Specifies that the effects of the root series are limited to a specified set of series.

- If TARGETLIST is specified without *listID*, then the set of affected targets is given by the TARGETLIST subcommands that do not have a LISTID keyword.
- If TARGETLIST is specified with a value for *listID*, then the set of affected targets is given by the TARGETLIST subcommands whose LISTID keyword equals the specified value. The *listID* value is not quoted.

### Related information:

“Specifying expressions” on page 246

“OPTIONS subcommand” on page 1937

“TARGETLIST subcommand” on page 1937

---

## SCENARIOGROUP subcommand

The SCENARIOGROUP subcommand defines a group of scenarios that are based on a single root field and multiple sets of dimension values for that root field. Each set of dimension values (one value per dimension field) defines a time series. An individual scenario is then generated for each such time series, whose values in the scenario period are then replaced by the scenario values. Scenario values are specified by an expression, which is applied to each time series in the group. The SCENARIOGROUP subcommand applies only to the case of multidimensional data. Multiple SCENARIOGROUP subcommands are allowed.

### IDPREFIX

Specifies a prefix that is used to generate an identifier for each scenario in the scenario group. The identifier is displayed in output associated with each scenario. The value must be a quoted string. The identifier for a particular scenario contains the prefix and the set of dimension values that define the series for that scenario. Specifically, the identifier is the prefix, followed by an underscore, followed by the value of the first dimension field, followed by an underscore, followed by the value of the second dimension field, and so on. The IDPREFIX keyword is required.

### EXPRESSION

Specifies the name of the variable, from the expressions file (specified on the EXPRESSIONS subcommand), that defines the expression that is used to compute the scenario values.

**Note:** Expressions are specified with COMPUTE statements in a BEGIN EXPR-END EXPR block. The variable that is specified on the EXPRESSION keyword is a target of one of those COMPUTE statements.

### ROOTFIELD

Specifies the root field which, along with a set of dimension values, defines a root series.

### DIMVALUES

Specifies optional lists of dimension field values that define the sets of dimension values that, together with the root field, define the set of root series for the scenario group. The form of the specification for a particular dimension field is `dimField(VALUEs=dimValueList)`, where `dimField` is the name of the field and `dimValueList` is the list of values for that field.

- If a dimension field is not specified on DIMVALUES then all values in that dimension are included.
- Fields that are specified on the DIMVALUES keyword do not support ALL and TO.
- String values do not need to be quoted.

### EFFECTS

Specifies how to determine the set of series that are affected by each root series in the scenario group.

#### AUTOMATIC

Specifies that the procedure automatically determines the series that are affected by the root series. This is the default. You can specify the breadth of the series that are affected by each scenario with settings on the OPTIONS subcommand.

#### TARGETLIST

Specifies that the effects of the root series are limited to a specified set of series. Each root series in the group has the same set of affected targets

- If TARGETLIST is specified without *listID*, then the set of affected targets is given by the TARGETLIST subcommands that do not have a LISTID keyword.
- If TARGETLIST is specified with a value for *listID*, then the set of affected targets is given by the TARGETLIST subcommands whose LISTID keyword equals the specified value. The *listID* value is not quoted.

### Related information:

“Specifying expressions” on page 246

“OPTIONS subcommand”

“TARGETLIST subcommand”

---

## TARGETLIST subcommand

The TARGETLIST subcommand defines a set of target series that is used to limit the set of series that are affected by one or more scenarios. Multiple TARGETLIST subcommands can be specified.

### LISTID

Optional setting that identifies a particular group of TARGETLIST subcommands. Multiple TARGETLIST subcommands can have the same LISTID parameter. The LISTID parameter is not quoted.

### FIELDS

Specifies the fields for the current TARGETLIST subcommand.

### DIMVALUES

Specifies optional lists of dimension field values that define a subset of series for the fields that are specified on the FIELDS keyword. The DIMVALUES keyword applies only to multidimensional data. The form of the specification for a particular dimension field is `dimField(VALUEs=dimValueList)`, where `dimField` is the name of the field and `dimValueList` is the list of values for that field.

- If a dimension field is not specified on DIMVALUES then all values in that dimension are included.
- Fields that are specified on the DIMVALUES keyword do not support ALL and TO.
- String values do not need to be quoted.

### Related information:

“SCENARIO subcommand” on page 1935

“SCENARIOGROUP subcommand” on page 1936

---

## OPTIONS subcommand

### CILEVEL

Specifies the confidence level for the scenario predictions. The value is a positive number that is greater than 0 and less than 100. The default is 95.

### PREDICTEDCI

Specifies whether confidence intervals for scenario predictions are included in both chart and table output. The default is NO, which specifies that confidence intervals are not included.

### PRINT=FORECASTS

Tables of predicted values and scenario values for each scenario. These tables contains the same information as the tables in the impact diagram (PLOT=IMPACTDIAGRAM). These tables support all standard features for pivoting and editing tables. By default, these tables are not generated.

### PLOT

#### IMPACTDIAGRAM

Displays a graphical representation of the causal relations between the root series for each scenario and the target series that it affects. Tables of both the predicted values for the affected targets and the scenario values are included as part of the output item. The graph includes plots of the predicted values of the affected targets. Single-clicking any node in the impact diagram opens a detailed sequence diagram for the series that is associated with the node. A separate impact diagram is generated for each scenario. Impact diagrams are generated by default.

**SERIESPLOT**

Generates series plots of the predicted values for each of the affected targets in each scenario. By default, series plots are not generated.

**NONE**

Specifies that no plots are generated. NONE cannot be specified with any other keywords.

**MAXTARGETS**

Specifies the maximum number of targets that are automatically detected when EFFECTS=AUTOMATIC is specified. The value is a positive integer and the default is 25. Increasing the value of this setting increases the complexity of the computation and might affect performance.

**MAXLEVELS**

Specifies the maximum number of levels of affected targets that are considered. Each successive level includes targets that are more indirectly affected by the root series. Specifically, the second level includes targets that have the root series as a direct input. Targets in the third level have targets in the second level as a direct input, and so on. The allowed values are the integers from 1 to 5. The default is 3. Increasing the value of this setting increases the complexity of the computation and might affect performance.

---

```

\*\*Default if keyword omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

Syntax for the TCM APPLY command can be generated from the dialog.

#### Release History

Release 23.0

- Command introduced.

### Example

```

TCM APPLY
  /MODELSYSTEM FILE='/models/mymodel.zip'
  /OPTIONS REESTIMATE = YES FORECASTPERIODS = 3
  /SAVE TARGETS(ALL)

```

#### Related information:

Chapter 264, “TCM ANALYSIS,” on page 1931

---

## Overview

The TCM APPLY procedure loads a model system file that was created by the TCM MODEL procedure and applies the models to the active dataset. You can use this procedure to obtain forecasts for series for which more current data is available, without rebuilding your models. You can also generate any of the output that is available with the TCM MODEL procedure.

### Assumptions

- The structure of the data in the active dataset, either column-based or multidimensional, must be the same structure that was used when the model system was built. For multidimensional data, the dimension fields must be the same as used to build the model system. Also, the dimension values that were used to build the model system must exist in the active dataset.
- Models are applied to fields in the active dataset with the same names as the fields specified in the model system.
- The field, or fields, that defined the observations when the model system was built must exist in the active dataset. The time interval between observations is assumed to be the same as when the models

were built. If the observations were defined by a date specification, then the same date specification must exist in the active dataset. Date specifications are created from the Define Dates dialog or the DATE command.

- The time interval of the analysis and any settings for aggregation, distribution, and missing values are the same as when the models were built.

## Basic Specification

The basic specification is the MODELSYSTEM subcommand that specifies the model system file. This specification generates the Overall Model System visualization for the 10 best-fitting models, a histogram of model fit for all models, and a table of any transformations that were applied to the series in the model system. Also, forecasts are produced for the 10 best-fitting models, for one time interval beyond the end of the original estimation period. The forecasts are saved as new variables.

## Syntax Rules

- Multiple SERIESFILTER subcommands are allowed.
- Multiple FILTEREDOUTPUT subcommands are allowed. If the same value of the INCLUDE keyword appears on multiple FILTEREDOUTPUT subcommands, then the specifications for only the last such subcommand are honored.
- Each keyword can be specified only once within a subcommand.
- Empty subcommands are not allowed.
- Parentheses, equals signs, and slashes that are shown in the syntax chart are required.
- The command name, subcommand names, and keywords must be spelled in full.

## Operations

- The procedure honors the USE command but it also has settings for specifying the estimation period. Settings on the ESTIMATIONPERIOD keyword are applied after any case selection that is specified with the USE command.
- The procedure does not honor the PREDICT command. The TCM APPLY procedure provides an option to specify the forecast period.
- The procedure does not honor the TSET command.
- The procedure does not honor the following commands: MODEL NAME or SAVE MODEL. The TCM APPLY procedure provides the option to save the model system when model parameters are reestimated.
- The TDISPLAY command does not display model systems that are saved from TCM APPLY.

## Limitations

- The SPLIT FILE setting is ignored by this procedure.
- Case weighting is ignored by this procedure.

---

## MODELSYSTEM Subcommand

The MODELSYSTEM subcommand is required and specifies the external file that contains the model system that you want.

**FILE** Specifies the compressed file archive (.zip file) that contains the model system.

---

## OPTIONS subcommand

### REESTIMATE

Specifies whether model parameters are reestimated. The default is NO, which specifies that the parameters from the model system file are used to generate forecasts.

## ESTIMATIONPERIOD

Specifies the estimation period that defines the set of observations that are used for the analysis.

### MODEL

Specifies to use the estimation period that was used for building the model system. This setting is the default.

**ALL** Specifies that all observations are used. When ALL is specified, the estimation period starts at the time of the earliest observation and ends at the time of the latest observation across all series.

### TIMES

Specifies a range of observations by start and end time.

- If START is specified without END, then all observations from START to the last observation are used. If END is specified without START, then the first observation through END is used.
- For observations that are defined by a date, datetime, time, or string field, the FORMAT keyword is required (and ignored otherwise). It specifies the format of the values for START and END. Values for START and END must be quoted in this case.

### VARIABLE

Specifies to use the variable format for the variable that defines the observations; for example, mm/dd/yyyy. This option only applies when observations are defined by a date, datetime, or time field.

### ISO8601

Specifies that values for START and END are in the general form of yyyy-mm-dd hh:mm:ss. FORMAT=ISO8601 must be specified when the observations are defined by a string field.

- Dates are specified in the form yyyy-mm-dd. Datetimes are specified in the form yyyy-mm-dd hh:mm:ss. Times are specified in the form hh:mm:ss.
  - Two digits are not required for month, day, hours, minutes or seconds specifications. For example, 2014-1-1 is interpreted as 2014-01-01 and 3:2:1 is interpreted as 03:02:01.
  - Values can be specified with reduced precision. For example, 2014-10 is interpreted as 2014-10-01 and 03:02 is interpreted as 03:02:00.
- For observations that are defined by cyclic period fields, START and END are lists of integers, consisting of one value for each of the cyclic period fields. The first value is the value for the highest level cycle field, followed by the next highest cycle field, and so on.

For example, the following syntax specifies the start and end time when there are two cycle levels, in addition to a period field:

```
START = 3 6 2  END = 5 1 4
```

The start of the estimation period is defined by a value of 3 for the second-level cycle, a value of 6 for the first-level cycle, and a value of 2 for the period field. The end of the estimation period is defined by a value of 5 for the second-level cycle, a value of 1 for the first-level cycle, and a value of 4 for the period field.

- For observations that are defined by record number, START and END consist of a single value that specifies the starting record number and the ending record number. For example, the following syntax specifies an estimation period that starts at record 1 and ends at record 60:

```
START = 1  END = 60
```

- For observations that are defined by a date specification (DATE command), then START and END are lists of integers that consist of one value for each of the components of the date specification. For example, if the date specification is YEAR and MONTH, then

the lists consist of two items, one for the year and one for the month. The order of the values is from the highest level component to the lowest level component. For example, the following syntax specifies start and end time for a date specification that is defined by YEAR and MONTH:

```
START = 2008 1 END = 2013 12
```

The start of the estimation period is defined by a value of 2008 for the year and 1 for the month. The end of the estimation period is defined by a value of 2013 for the year and 12 for the month.

### **OBSERVATIONS**

Defines the estimation period as a specified number of time intervals that start at the earliest time interval or end at the latest time interval in the data, with an optional offset. In this context, the time interval refers to the interval at which the data were modeled. For example, if the observations are daily but the data are aggregated to months, then the time interval that is associated with OBSERVATIONS is months.

**TYPE** TYPE=NEWEST specifies to use the most recent time intervals. TYPE=OLDEST specifies to use the earliest time intervals.

### **OFFSET**

Specifies an offset from the earliest time interval (when TYPE=OLDEST) or the most recent time interval (when TYPE=NEWEST). The value of OFFSET must be an integer greater than or equal to 0. The default is 0 and specifies to start at the earliest time interval or end at the most recent time interval.

### **NUMBER**

Specifies the number of time intervals to include. The value must be an integer that is greater than or equal to 2. The default is 1000. If the specified value exceeds the number of time intervals in the data, then all time intervals, starting from the optional offset, are included.

### **FORECASTPERIODS**

Specifies the number of time intervals to forecast beyond the end of the estimation period. The default value is 1. In this context, the time interval refers to the interval at which the data were modeled. For example, if the observations are daily but the data are aggregated to months, then specifying 3 for FORECASTPERIODS means 3 months.

### **CILEVEL**

Specifies the confidence level for computing confidence intervals for forecasts and parameter estimates. The value must be positive number that is greater than 0 and less than 100. The default is 95.

### **OUTLIERTHRESH**

An observation is flagged as an outlier if the probability, as calculated from the model, that it is an outlier exceeds this threshold. You can specify a value in the range 50 - 100. The default value is 95.

---

## **TARGETFILTER subcommand**

The TARGETFILTER subcommand specifies a set of target series for which output is displayed. The content of the output for the specified series is determined by the FILTEREDOUTPUT subcommand. You can specify particular series, for which output is displayed, from the SERIESFILTER subcommand.

### **BESTFIT**

Specifies to generate output for the target series that have the best-fitting models. By default, output is generated for the top 10 models according to the value of the root mean square percentage error.

- The N keyword specifies the number of models to include, as an integer. If the count exceeds the number of models, all models are shown. The default is 10.
- The PCT keyword specifies the number of models to include, as a percentage of the total number of models. The percentage value must be an integer between 1 and 100.
- The FITSTAT keyword specifies the fit statistic that is used to determine the best-fitting models. The default is RSQUARE.

#### **RSQUARE**

Goodness-of-fit measure of a linear model, sometimes called the coefficient of determination. It is the proportion of variation in the target variable explained by the model. It ranges in value from 0 to 1. Small values indicate that the model does not fit the data well.

#### **RMSPE**

Root Mean Square Percentage Error. A measure of how much the model-predicted values differ from the observed values of the series. It is independent of the units that are used and can therefore be used to compare series with different units.

**RMSE** Root Mean Square Error. The square root of mean square error. A measure of how much a dependent series varies from its model-predicted level, expressed in the same units as the dependent series.

**BIC** Bayesian Information Criterion. A measure for selecting and comparing models based on the -2 reduced log likelihood. Smaller values indicate better models. The BIC also "penalizes" overparameterized models (complex models with a large number of inputs, for example), but more strictly than the AIC.

**AIC** Akaike Information Criterion. A measure for selecting and comparing models based on the -2 reduced log likelihood. Smaller values indicate better models. The AIC "penalizes" overparameterized models (complex models with a large number of inputs, for example).

#### **ALLTARGETS**

Specifies that output is generated for all target series.

#### **TARGETSNOINPUTS**

Specifies that only target series with no inputs (other than lagged values of the target itself) are included.

---

## **SERIESFILTER subcommand**

The SERIESFILTER subcommand specifies particular series for which output is displayed. The content of the output for the specified series is determined by the FILTEREDOUTPUT subcommand. You can specify multiple SERIESFILTER subcommands.

#### **FIELDS**

The FIELDS keyword is required and specifies the list of fields that contain the series that you want. The keyword T0 is supported but the keyword ALL is not supported. For multidimensional data, all series that are contained in each specified field are included by default. You can specify a subset of series by specifying particular sets of values for one or more dimension fields on the DIMVALUES keyword.

#### **DIMVALUES**

Specifies optional lists of dimension field values that define a subset of series for the fields that are specified on the FIELDS keyword. The DIMVALUES keyword applies only to multidimensional data. The form of the specification for a particular dimension field is `dimField(INCLUDE|EXCLUDE=dimValueList)`, where `dimField` is the name of the field and `dimValueList` is a list of values for that field.

- The INCLUDE or EXCLUDE keyword is required.

- INCLUDE specifies a list of values, from the associated dimension field, to include.
- EXCLUDE specifies a list of values, from the associated dimension field, to exclude.
- You can specify included or excluded values for one or more dimension fields. For dimension fields that are not specified on DIMVALUES, all values of the associated field are included.
- Fields that are specified on the DIMVALUES keyword do not support ALL and T0.
- String values do not need to be quoted, unless the string contains apostrophes or quotation marks. If the string contains apostrophes or single quotes, then enclose the string in double quotes. If the string contains double quotes, then enclose the string in single quotes.

---

## **FILTEREDOUTPUT subcommand**

The FILTEREDOUTPUT subcommand controls the output that is displayed for the series that are specified on the TARGETFILTER and SERIESFILTER subcommands.

### **INCLUDE**

Specifies the set of series to which the current FILTEREDOUTPUT subcommand applies. You can specify up to three FILTEREDOUTPUT subcommands, one for each of the values of INCLUDE.

- TARGETS specifies that the current settings apply to the targets that are specified by the TARGETFILTER subcommand.
- SERIES specifies that the current settings apply to the series that are specified by the SERIESFILTER subcommands.
- BOTH specifies that the current settings apply to the targets that are specified by the TARGETFILTER subcommand and the series that are specified by the SERIESFILTER subcommands.

### **NETWORKGRAPH**

Specifies whether the Overall Model System output item is generated. The default is YES. The Overall Model System item displays a graphical representation of the causal relations between series in the model system. Tables of both model fit statistics and outliers for the displayed targets are included as part of the output item. When this option is specified with INCLUDE=SERIES or INCLUDE=BOTH, a separate output item is created for each series that is specified on a SERIESFILTER subcommand.

- The SIGLEVEL keyword specifies the significance level threshold for hiding causal connections between series in the Overall Model System graph. A smaller significance level indicates a more significant connection. Connections with significance levels that are higher than the threshold are hidden. Specify a numeric value in the range 0-1. The default is 0.05.

### **PRINT**

Controls the display of tabular output. One or more of the following keyword values can be specified. By default, none of this tabular output is displayed.

#### **MODELFIT**

Tables of model fit statistics for the target series that are selected for display. The tables contain the same information as the model fit statistics table in the Overall Model System item. The tables support all standard features for pivoting and editing tables.

#### **OUTLIERS**

Tables of outliers for the target series that are selected for display. The tables contain the same information as the outliers table in the Overall Model System item. The tables support all standard features for pivoting and editing tables.

#### **MODELEFFECTS**

Tables of model effects tests for the target series that are selected for display. Model effects tests include the F statistic and associated significance value for each input included in the model.

## PARAMETERS

Tables of model parameters for the target series that are selected for display.

## FORECASTS

Tables of forecasted values and confidence intervals of those forecasts for the target series that are selected for display. The FORECASTS keyword is ignored if forecasts are not requested. Forecasts are requested with the FORECASTPERIODS keyword on the OPTIONS subcommand.

**PLOT** Controls the display of chart output. One or more of the following keyword values can be specified. By default, none of this chart output is displayed.

## SERIESPLOT

Plots of observed and predicted values for the target series that are selected for display. When forecasts are requested, the plot also shows the forecasted values and the confidence intervals for the forecasts.

## TOPINPUTS

Plots of each displayed target, over time, along with the top 3 inputs for the target. The top inputs are the inputs with the lowest significance value. To accommodate different scales for the inputs and target, the y axis represents the z score for each series.

## NRESIDUAL

Plots of the model residuals for the target series that are selected for display.

## IMPACTDIAGRAMS

Specifies whether impact diagrams are generated. An impact diagram displays a graphical representation of the causal relations between a series of interest and other series that it affects or that affect it. Series that affect the series of interest are referred to as *causes*. When the IMPACTDIAGRAMS keyword is specified, impact diagrams are generated for all series that are selected for display. By default, impact diagrams are not generated.

## EFFECTS

Creates an impact diagram that is initialized to show the series that are affected by the series of interest. You can specify the number of levels of effects to display, as in EFFECTS(4) for four levels of effects. The first level represents the series of interest. Each additional level shows more indirect effects of the series of interest. For example, the third level consists of the series that contain series in the second level as a direct input. Series in the third level are then indirectly affected by the series of interest since the series of interest is a direct input to the series in the second level. By default, 3 levels of effects are displayed. You can specify any number of levels up to a maximum of 99.

## CAUSES

Creates an impact diagram that is initialized to show the series that affect the series of interest. You can specify the number of levels of causes to display, as in CAUSES(4) for four levels of causes. The concept of levels for causes is the same as for levels of effects. By default, 3 levels of causes are displayed. You can specify any number of levels up to a maximum of 99.

**Note:** You can interactively toggle between causes and effects in the output item that displays the impact diagram.

## OUTLIER\_ROOTCAUSES

Specifies whether outlier root cause analysis is done. Outlier root cause analysis determines which series are most likely to be the cause of each outlier in a series of interest. The analysis is done for each series that is specified on a SERIESFILTER subcommand and that has outliers. By default, outlier root cause analysis is not done.

**Note:** Outliers are detected based on the active dataset and the temporal causal model system.

## LEVELS

Specifies the number of causal levels that are searched for root causes of outliers. By default, 3 causal levels are searched. The maximum number of levels is 5. The concept of levels that is used here is the same as described for impact diagrams.

## DISPLAY

- The value `INTERACTIVE` creates an interactive visualization that contains a table and chart of outliers and root causes of those outliers for each series of interest. The table contains a single row for each outlier. The chart is an impact diagram. Selecting a row in the table highlights the path, in the impact diagram, from the series of interest to the series that most likely causes the associated outlier.
- The value `TABLE` creates a table of outliers and root causes of those outliers for each series of interest. This table contains the same information as the table in the interactive display. This table supports all standard features for pivoting and editing tables.
- The value `BOTH` generates the interactive visualization and the separate table.

---

## SYSTEMOUTPUT subcommand

The `SYSTEMOUTPUT` subcommand controls output associated with the entire temporal causal model system.

### MODELFIT

Controls the display of histograms of model fit for all models. One or more fit statistics can be specified. A single histogram that is based on `RSQUARE` is generated by default. When `REESTIMATE=NO`, the fit statistics are taken from the model system file.

### RSQUARE

Goodness-of-fit measure of a linear model, sometimes called the coefficient of determination. It is the proportion of variation in the target variable explained by the model. It ranges in value from 0 to 1. Small values indicate that the model does not fit the data well.

### RMSPE

Root Mean Square Percentage Error. A measure of how much the model-predicted values differ from the observed values of the series. It is independent of the units that are used and can therefore be used to compare series with different units.

**RMSE** Root Mean Square Error. The square root of mean square error. A measure of how much a dependent series varies from its model-predicted level, expressed in the same units as the dependent series.

**BIC** Bayesian Information Criterion. A measure for selecting and comparing models based on the  $-2 \log$  likelihood. Smaller values indicate better models. The BIC also "penalizes" overparameterized models (complex models with a large number of inputs, for example), but more strictly than the AIC.

**AIC** Akaike Information Criterion. A measure for selecting and comparing models based on the  $-2 \log$  likelihood. Smaller values indicate better models. The AIC "penalizes" overparameterized models (complex models with a large number of inputs, for example).

### NONE

Specifies that histograms are not generated. `NONE` cannot be specified with any other keywords.

### TRANSFORMATIONS

Table of any transformations that were applied to the series in the model system. The possible transformations are missing value imputation, aggregation, and distribution. The default is `YES`, which specifies that the table is generated.

## OUTLIERPLOT

Bar chart of the number of outliers, across all targets, for each time interval in the estimation period. The default is NO, which specifies that the bar chart is not generated.

**Note:** Outliers are detected based on the active dataset and the temporal causal model system.

---

## SAVE subcommand

The SAVE subcommand saves new variables that represent predicted values, residuals, and confidence intervals. By default, no new variables are saved.

- Specify one or more keywords, along with optional rootnames to be used as the prefix for new variable names.
- The rootname, if specified, must conform to the rules for valid variable names.
- If the DATA keyword of the OUTFILE subcommand is specified, then the new variables are written to that location. If the DATA keyword is not specified and the new variables cannot be written to the active dataset, then they are written to an autogenerated dataset. New variables can be written to the active dataset only if the observations are defined by a date specification, or record order, and the data are not aggregated.

### TARGETS

**ALL** Specifies that new variables are created for all targets in the model system.

### FILTERED

Specifies that new variables are created just for the targets that are specified by the TARGETFILTER and SERIESFILTER subcommands. This option is the default.

### PREDICTED(rootname)

Saves model fit and forecast values. The default rootname is *Predicted*.

### CL(LCLROOT=rootname UCLROOT=rootname)

Saves upper and lower confidence limits. LCLROOT specifies the root name for the lower confidence limit and UCLROOT specifies the root name for the upper confidence limit. The default root name for the lower confidence limit is *LCL* and the default root name for the upper confidence limit is *UCL*.

### NRESIDUAL(rootname)

Saves noise residuals. The default rootname is *NResidual*.

### FORECASTFLAG(name)

Creates a variable that indicates whether a record contains forecast data. You can specify the variable name. The default is *ForecastIndicator*.

---

## OUTFILE subcommand

### MODELSYSTEM

Saves the model system, which is associated with reestimated model parameters, to a compressed file archive (.zip file). The model system file can be reused by this procedure. It can also be used by the TCM ANALYSIS procedure to run scenario analysis. The keyword is ignored if REESTIMATE=NO on the OPTIONS subcommand.

**DATA** Specifies the name of a file or a previously declared dataset where new variables that are specified on the SAVE subcommand are written, along with any transformations of the data (such as aggregation or imputation of missing values).

- Date/time values in the saved data are aligned to the beginning of each time interval, such as the first of the month, and represent the time interval at which the data were modeled. For example, if the observations are daily but the data are aggregated to months then date/time values in the saved data represent months.

- Enclose file specifications in quotation marks and use fully qualified paths to avoid ambiguity. You can use an asterisk (\*) to specify that the data is written to the active dataset, replacing the current active dataset.

**Related information:**

Chapter 264, "TCM ANALYSIS," on page 1931

---

## **PASSPROTECT subcommand**

The PASSPROTECT subcommand saves an external file, that was specified on the DATA keyword of the OUTFILE subcommand, as an encrypted file. An encrypted file can be opened only by providing the correct password.

### **PASSWORD**

Specifies the password that is required to open this file. Passwords are limited to 10 characters and are case-sensitive. The specified value must be enclosed in quotation marks. The keyword NONE specifies not to encrypt the file and is the default.

### **ENCRYPTEDPW**

Specifies whether the password is encrypted.

**NO** The password is not encrypted. It is treated as plain text. This option is the default.

**YES** The password is encrypted. Use ENCRYPTEDPW=YES only when the password is known to be encrypted. Passwords are always encrypted in pasted syntax.

### Creating strong passwords

- Use eight or more characters.
- Include numbers, symbols and even punctuation in your password.
- Avoid sequences of numbers or characters, such as "123" and "abc", and avoid repetition, such as "111aaa".
- Do not create passwords that use personal information such as birthdays or nicknames.
- Periodically change the password.

*Note:* Encrypted data files and output documents cannot be opened in versions of IBM SPSS Statistics prior to version 21. Encrypted syntax files cannot be opened in versions prior to version 22.

---

## Chapter 266. TCM MODEL

TCM MODEL is available in SPSS Statistics Professional Edition or the Forecasting option.

```

\*\*Default if keyword omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

Syntax for the TCM MODEL command can be generated from the dialog.

## Release History

Release 23.0

- Command introduced.

## Example

```
TCM MODEL  
  /DATASETTINGS TIMETYPE=DATETIMEVAR TIMEVAR=date INPUTINTERVAL=MONTH  
  /FIELDSGROUP  
  /FIELDS TARGETS=ARI TO UNF_ROOM_ANTS_YOY INPUTS=ARI TO UNF_ROOM_ANTS_YOY
```

## Overview

The TCM MODEL procedure builds temporal causal models. In temporal causal modeling, you specify a set of target series and a set of candidate inputs to those targets. The procedure then builds an autoregressive time series model for each target and includes only those inputs that have a causal relationship with the target. This approach differs from traditional time series modeling where you must explicitly specify the predictors for a target series. Since temporal causal modeling typically involves building models for multiple related time series, the result is referred to as a *model system*.

In the context of temporal causal modeling, the term *causal* refers to Granger causality. A time series *X* is said to “Granger cause” another time series *Y* if regressing for *Y* in terms of past values of both *X* and *Y* results in a better model for *Y* than regressing only on past values of *Y*.

## Data Structures

Temporal causal modeling supports two types of data structures.

### Column-based data

For column-based data, each time series field contains the data for a single time series. This structure is the traditional structure of time series data, as used by the Time Series Modeler.

### Multidimensional data

For multidimensional data, each time series field contains the data for multiple time series. Separate time series, within a particular field, are then identified by a set of values of categorical fields referred to as *dimension* fields.

For example, sales data for different regions and brands might be stored in a single *sales* field, so that the dimensions in this case are *region* and *brand*. Each combination of *region* and *brand* identifies a particular time series for *sales*. For example, in the following table, the records that have 'north' for *region* and 'brandX' for *brand* define a single time series.

Table 116. Multidimensional data

date	region	brand	sales
01/01/2014	north	brandX	82350
01/01/2014	north	brandY	86380
01/01/2014	south	brandX	91375
01/01/2014	south	brandY	70320
01/02/2014	north	brandX	83275
01/02/2014	north	brandY	85260
01/02/2014	south	brandX	94760
01/02/2014	south	brandY	69870

**Note:** Data that is imported from OLAP cubes, such as from IBM Cognos TM1, is represented as multidimensional data.

## Basic Specification

The basic specification is the DATASETTINGS subcommand with the TIMETYPE and TIMEVAR keywords, a FIELDSEGROUP subcommand, and a FIELDS subcommand with the TARGETS and INPUTS keywords.

- For multidimensional data, the DIMENSIONS keyword on the DATASETTINGS subcommand must be specified.
- If the active dataset has a date specification, then the DATASETTINGS subcommand is not required.
- If the observations are defined by record order, then the TIMEVAR keyword is not included. Record order means that the first record represents the first observation, the second record represents the second observation, and so on.

## Syntax Rules

- The following subcommands are global and must appear before any FIELDSEGROUP subcommand: DATASETTINGS, DATAFILTER, BUILDOPTIONS, TARGETFILTER, SERIESFILTER, FILTEREDOUTPUT, SYSTEMOUTPUT, SAVE, OUTFILE, and PASSPROTECT.
- Multiple SERIESFILTER subcommands are allowed.
- Multiple FILTEREDOUTPUT subcommands are allowed. If the same value of the INCLUDE keyword appears on multiple FILTEREDOUTPUT subcommands, then the specifications for only the last such subcommand are honored.
- Multiple FIELDSEGROUP subcommands are allowed, but at least one is required. The specified set of FIELDSEGROUP subcommands defines a single temporal causal model system.
- Multiple FIELDS subcommands can be specified for each FIELDSEGROUP subcommand.
- Global subcommands can be specified in any order.
- Each keyword can be specified only once within a subcommand.
- Empty subcommands are not allowed, with the one exception that the FIELDSEGROUP subcommand is always empty.
- Parentheses, equals signs, and slashes that are shown in the syntax chart are required.
- The command name, subcommand names, and keywords must be spelled in full.

## Operations

- The procedure honors the USE command but it also has settings for specifying the estimation period. Settings on the ESTIMATIONPERIOD keyword are applied after any case selection that is specified with the USE command.
- The procedure does not honor the PREDICT command. The TCM MODEL procedure provides an option to specify the forecast period.
- The procedure does not honor the TSET command. The TCM MODEL procedure provides options for handling missing values.
- The procedure does not honor the following commands: MODEL NAME or SAVE MODEL. The TCM MODEL procedure provides the option to save the model system.
- The TDISPLAY command does not display model systems that are saved from TCM MODEL.

## Limitations

- The SPLIT FILE setting is ignored by this procedure.
- Case weighting is ignored by this procedure.

---

## DATASETTINGS subcommand

The DATASETTINGS subcommand specifies settings that are used to prepare the data for the analysis. It includes the following settings:

- The dimension fields that define each time series for multidimensional data.
- The field, or fields, that define the observations, the time interval between observations, and the time interval for the analysis.
- The method by which data are aggregated or distributed when the time interval for the analysis differs from the time interval between the observations.
- Handling of missing values.

### DIMENSIONS

Specifies the dimension fields, if any, that identify each time series. Specify one or more field names. The keyword T0 is supported but the keyword ALL is not supported.

### MAXDIMVALUES

Specifies the maximum number of distinct values per dimension field. The default is 10000. The value must be an integer that is greater than 100.

### TIMETYPE

Specifies how the time of each observation is defined. The keyword is required unless the active dataset has a date specification, in which case it cannot be specified. Date specifications are created with the DATE command.

### DATETIMEVAR

Specifies that a field with a date, datetime, or time (duration) format defines the observations.

### ISO8601

Specifies that the observations are defined by a string variable that represents dates or times (durations). Dates are specified in the form yyyy-mm-dd. Datetimes are specified in the form yyyy-mm-dd hh:mm:ss. Times are specified in the form hh:mm:ss. Two digits are not required for month, day, hours, minutes or seconds specifications. For example, 2014-1-1 is interpreted as 2014-01-01 and 3:2:1 is interpreted as 03:02:01.

### CYCLICPERIODS

Specifies that the observations are defined by one or more integer fields that define a hierarchy of periodic levels. The field that defines the lowest level is referred to as the *period* field. Fields that define higher levels are referred to as *cycle* fields.

With this structure, you can describe series of observations that don't fit one of the standard time intervals. For example, a fiscal year with only 10 months can be described with a cycle field that represents years and a period field that represents months, where the length of one cycle is 10.

Field values for each level, except the highest, must be periodic with respect to the next highest level. Values for the highest level cannot be periodic. For example, in the case of the 10-month fiscal year, months are periodic within years and years are not periodic.

#### **NONE**

Specifies that the observations are defined by record order so that the first record represents the first observation, the second record represents the second observation, and so on. It is then assumed that the records represent observations that are equally spaced in time. The value NONE cannot be used when the DIMENSIONS keyword is specified.

#### **TIMEVAR**

Specifies the field, or fields, that define each observation. It is required when TIMETYPE=DATETIMEVAR, TIMETYPE=ISO8601, or TIMETYPE=CYCLICPERIODS.

**var** Specifies the date, datetime, or time field that defines the observations when TIMETYPE=DATETIMEVAR. It also specifies the string field that defines the observations when TIMETYPE=ISO8601. Specify a field name for var.

**var(TYPE=PERIOD [INCREMENT=integer]  
[START=integer])**

Specifies the period field when TIMETYPE=CYCLICPERIODS. Specify a field name for var.

- The optional INCREMENT keyword specifies the integer increment between successive observations. The default is 1.
- The optional START keyword specifies the starting value when there are one or more cycle fields. The value must be a positive integer. The default is 1. For example, a field with the periodic sequence 2,3,4,5 has a starting value of 2. START is ignored if there are no cycle fields.

**var(TYPE=CYCLE LEVEL=integer  
LENGTH=integer [START=integer])**

Specifies a cycle field when TIMETYPE=CYCLICPERIODS. Specify a field name for var. An arbitrary number of cycle fields can be specified.

- The LEVEL keyword is required and must specify a positive integer. The lowest level cycle field must have LEVEL=1. The next cycle field in the hierarchy must have LEVEL=2, and so on.
- The LENGTH keyword is required and specifies the length of the cycle. The length of a cycle at a particular level is the periodicity of the next lowest level. Consider the example of a 10-month fiscal year that is described by a period field for month and a first level cycle field for year. The cycle field for year has a length of 10 since the next lowest level represents months and there are 10 months in the specified fiscal year. The value of LENGTH must be a positive integer.
- The optional START keyword specifies the starting value when the cycle field is periodic. The value must be a positive integer, and the default is 1. This setting is necessary for detecting missing values. For example, if a periodic field starts from 2 but the starting value is specified as 1, then the procedure assumes that there is a missing value for the first period in each cycle of that field. START is ignored for the highest level cycle field.

#### **INPUTINTERVAL**

Specifies the interval between successive observations and any additional information needed to specify the sequence of observations. The keyword can be specified only when TIMETYPE=DATETIMEVAR or TIMETYPE=ISO8601.

**AUTODETECT**

Specifies that the interval between successive observations will be automatically determined from the data. This is the default.

**IRREGULAR**

Specifies that successive observations are not equally spaced, such as observations that represent the time at which a sales order is processed. When IRREGULAR is specified, you must specify ANALYSISINTERVAL.

**YEAR** Specifies that the interval between successive observations is one or more years. Use the INCREMENT keyword to specify the number of years between successive observations. The default is 1.

**QUARTER**

Specifies that the interval between successive observations is one quarter.

**MONTH**

Specifies that the interval between successive observations is one or more months. Use the INCREMENT keyword to specify the number of months between successive observations. The default is 1.

**WEEK** Specifies that the interval between successive observations is one week.

**DAY** Specifies that the interval between successive observations is one or more days.

- Use the WKSTART keyword to specify the start of the week. The default is SUN, which specifies Sunday.
- Use the DAYSWK keyword to specify the number of days per week. Specify an integer between 1 and 7. The default is 7.
- Use the INCREMENT keyword to specify the number of days between successive observations. The default is 1.

**HOUR**

Specifies that the interval between successive observations is one or more hours and that observations are represented as a datetime.

- Use the WKSTART keyword to specify the start of the week. The default is SUN, which specifies Sunday.
- Use the DAYSWK keyword to specify the number of days per week. Specify an integer between 1 and 7. The default is 7.
- Use the HRSDAY keyword to specify the number of hours per day. Specify an integer between 1 and 24. The default is 24.
- Use the DAYSTART keyword to specify the starting hour of the day. Specify an integer between 0 and 23. The default is 0.
- Use the INCREMENT keyword to specify the number of hours between successive observations. The default is 1.

**MINUTE**

Specifies that the interval between successive observations is one or more minutes and that observations are represented as a datetime.

- Use the WKSTART keyword to specify the start of the week. The default is SUN, which specifies Sunday.
- Use the DAYSWK keyword to specify the number of days per week. Specify an integer between 1 and 7. The default is 7.
- Use the HRSDAY keyword to specify the number of hours per day. Specify an integer between 1 and 24. The default is 24.
- Use the DAYSTART keyword to specify the starting hour of the day. Specify an integer between 0 and 23. The default is 0.

- Use the INCREMENT keyword to specify the number of minutes between successive observations. The default is 1.

## SECOND

Specifies that the interval between successive observations is one or more seconds and that observations are represented as a datetime.

- Use the WKSTART keyword to specify the start of the week. The default is SUN, which specifies Sunday.
- Use the DAYSWK keyword to specify the number of days per week. Specify an integer between 1 and 7. The default is 7.
- Use the HRSDAY keyword to specify the number of hours per day. Specify an integer between 1 and 24. The default is 24.
- Use the DAYSTART keyword to specify the starting hour of the day. Specify an integer between 0 and 23. The default is 0.
- Use the INCREMENT keyword to specify the number of seconds between successive observations. The default is 1.

## DURATION

Specifies that observations are represented by a field with a time (duration) format, as in hh:mm:ss.

- The INTERVAL keyword specifies the interval between observations and is required.
- Use the INCREMENT keyword to specify the number of hours, minutes, or seconds between observations. The default is 1.

## ANALYSISINTERVAL

Specifies the time interval for the analysis. For example, if the time interval of the observations is Days, you might choose Months for the time interval for analysis. The data are then aggregated from daily to monthly data before the model is built. You can also choose to distribute the data from a longer to a shorter time interval. For example, if the observations are quarterly then you can distribute the data from quarterly to monthly data.

- USEINPUT specifies that the time interval for analysis is the same as the interval between the observations. It is the default unless INPUTINTERVAL=IRREGULAR. If INPUTINTERVAL=IRREGULAR, ANALYSISINTERVAL must be specified and it cannot be specified as USEINPUT.
- CYCLE(LEVEL=integer) applies when TIMETYPE=CYCLICPERIODS and there are one or more cycle fields (in addition to the period field). It specifies to aggregate the data to the cycle level specified by the LEVEL keyword. The allowed values for LEVEL are 1 to the number of cycle fields.

**Note:** When TIMETYPE=CYCLICPERIODS, only CYCLE(LEVEL=integer) or USEINPUT can be specified for ANALYSISINTERVAL.

- When TIMETYPE=DATETIMEVAR or TIMETYPE=ISO8601, the following rules apply:
  - ANALYSISINTERVAL can be set to any value that is longer than, or equal to, the value of INPUTINTERVAL. For example, if INPUTINTERVAL=QUARTER then you can set ANALYSISINTERVAL to QUARTER or YEAR. The one exception is that when INPUTINTERVAL=WEEK, ANALYSISINTERVAL cannot be set to MONTH or QUARTER.
  - ANALYSISINTERVAL can be set to certain values that are shorter than the value of INPUTINTERVAL. The values of INPUTINTERVAL, followed by the allowed values of ANALYSISINTERVAL for this case, are as follows:
    - YEAR: QUARTER, MONTH
    - QUARTER: MONTH
    - MONTH: DAY
    - WEEK: DAY
    - DAY: HOUR

- HOUR or DURATION(INTERVAL=HOUR): MINUTE
- MINUTE or DURATION(INTERVAL=MINUTE): SECOND

**Note:** If INCREMENT > 1 (for INPUTINTERVAL) then ANALYSISINTERVAL cannot be shorter than INPUTINTERVAL.

- When the active dataset has a date specification, aggregation is supported but distribution is not supported. For example, if the date specification is YEAR, QUARTER then ANALYSISINTERVAL can be set to YEAR but it cannot be set to MONTH.
  - You cannot aggregate from MONTH to QUARTER for a date specification.
  - If the date specification has a cycle field, then CYCLE(LEVEL=1) can be specified for ANALYSISINTERVAL.

## GROUP

Specifies the method to use when multiple observations occur in the same time interval. For example, if INPUTINTERVAL is MONTH then multiple dates in the same month are grouped together. The specification for GROUP applies to all time series fields. You can, however, override that specification for particular fields. For example, to group values of *temperature* using the mean of the values, specify `temperature(MEAN)`. The following methods are available:

**SUM** The sum of the original values. This is the default.

**MEAN**  
The mean of the original values.

**MODE**  
The mode of the original values.

**MIN** The minimum of the original values.

**MAX** The maximum of the original values.

**Note:** Although grouping is a form of aggregation, it is done before any handling of missing values whereas formal aggregation is done after any missing values are handled. When the time interval of the observations is specified as Irregular, aggregation is done only with the grouping function.

## AGGREGATE

Specifies the method to be used when the data are aggregated. Aggregation is done when the value for ANALYSISINTERVAL is longer than the value for INPUTINTERVAL; for example, when ANALYSISINTERVAL is YEAR and INPUTINTERVAL is MONTH. The specification for AGGREGATE applies to all time series fields. You can, however, override that specification for particular fields. For example, to aggregate values of *temperature* using the mean of the values, specify `temperature(MEAN)`. The available methods are the same as for the GROUP keyword.

## DISTRIBUTE

Specifies the method to be used when data are distributed. Distribution is done when the value for ANALYSISINTERVAL is shorter than the value for INPUTINTERVAL; for example, when ANALYSISINTERVAL is QUARTER and INPUTINTERVAL is YEAR. The specification for DISTRIBUTE applies to all time series fields. You can, however, override that specification for particular fields. For example, to distribute values of *temperature* using the mean of the values, specify `temperature(MEAN)`.

## INTERPOLATE

Specifies the method to be used for interpolating missing values. The following options are available:

**LINT** Replaces missing values by using a linear interpolation. The last valid value before the missing value and the first valid value after the missing value are used for the

interpolation. If the first or last observation in the series has a missing value, then the two nearest non-missing values at the beginning or end of the series are used. This option is the default.

#### **MEAN**

Replaces missing values with the mean for the entire series.

#### **KMEAN(integer)**

Missing values are replaced by the mean of the specified number of nearest preceding and subsequent values. The default is 2.

#### **KMEDIAN(integer)**

Missing values are replaced by the median of the specified number of nearest preceding and subsequent observations. The default is 2.

#### **LTREND**

This option uses all non-missing observations in the series to fit a simple linear regression model, which is then used to impute the missing values.

#### **USERMISSING**

Specifies whether user-missing values are treated as valid values.

#### **EXCLUDE**

Specifies that user-missing values are treated as invalid. This is the default.

#### **INCLUDE**

Specifies that user-missing values are treated as valid.

#### **MAXMISSING**

Specifies the maximum percentage of missing values that are allowed for any series. Series with more missing values than the specified maximum are excluded from the analysis. The value is specified as a percentage and the default is 25.

#### **CROSSDAYHRS**

Specifies whether observations with times that cross a day boundary are aggregated to the values for the previous day. For example, for hourly observations with an eight-hour day that starts at 20:00, this setting specifies whether observations between 00:00 and 04:00 are included in the aggregated results for the previous day. **CROSSDAYHRS** only applies when **INPUTINTERVAL** is **HOUR**, **MINUTE**, or **SECOND** and **ANALYSISINTERVAL** is **DAY**.

#### **EXCLUDE**

Specifies that observations that cross a day boundary are not aggregated to the results for the previous day. This is the default.

#### **INCLUDE**

Specifies that observations that cross a day boundary are aggregated to the results for the previous day.

---

## **DATAFILTER subcommand**

The **DATAFILTER** subcommand defines filter criteria for specifying which dimension values are included in the analysis. It applies only to multidimensional data. The specified filter applies to all time series that are included in the analysis. For example, if there are dimension fields for *region* and *brand*, then you might choose to limit the analysis to particular regions but include all brands for those regions.

#### **DIMVALUES**

The **DIMVALUES** keyword specifies the filter. The form of the specification for a particular dimension field is `dimField(INCLUDE|EXCLUDE=dimValueList)`, where `dimField` is the name of the field and `dimValueList` is a list of values for that field.

- The **INCLUDE** or **EXCLUDE** keyword is required.
- **INCLUDE** specifies a list of values, from the associated dimension field, to include.

- EXCLUDE specifies a list of values, from the associated dimension field, to exclude.
- You can specify included or excluded values for one or more dimension fields. For dimension fields that are not specified on DIMVALUES, all values of the associated field are included.
- Fields that are specified on the DIMVALUES keyword do not support ALL and TO.
- String values do not need to be quoted, unless the string contains apostrophes or quotation marks. If the string contains apostrophes or single quotes, then enclose the string in double quotes. If the string contains double quotes, then enclose the string in single quotes.

---

## BUILDOPTIONS subcommand

### ESTIMATIONPERIOD

Specifies the estimation period that defines the set of observations that are used for the analysis.

- ALL** Specifies that all observations are used. This setting is the default. When ALL is specified, the estimation period starts at the time of the earliest observation and ends at the time of the latest observation across all series.

### TIMES

Specifies a range of observations by start and end time.

- If START is specified without END, then all observations from START to the last observation (across all series) are used. If END is specified without START, then all observations from the first observation (across all series) through END are used.
- The FORMAT keyword specifies the format of the values for START and END. It is required when TIMETYPE=DATETIMEVAR or TIMETYPE=ISO8601, and is ignored otherwise. Values for START and END must be quoted in this case.

### VARIABLE

Specifies to use the variable format of the field that is specified on the TIMEVAR keyword; for example, mm/dd/yyyy. This option only applies when TIMETYPE=DATETIMEVAR.

### ISO8601

Specifies that values for START and END are in the general form of yyyy-mm-dd hh:mm:ss. FORMAT=ISO8601 must be specified when TIMETYPE=ISO8601.

- Dates are specified in the form yyyy-mm-dd. Datetimes are specified in the form yyyy-mm-dd hh:mm:ss. Times are specified in the form hh:mm:ss.
- Two digits are not required for month, day, hours, minutes or seconds specifications. For example, 2014-1-1 is interpreted as 2014-01-01 and 3:2:1 is interpreted as 03:02:01.
- Values can be specified with reduced precision. For example, 2014-10 is interpreted as 2014-10-01 and 03:02 is interpreted as 03:02:00.
- For TIMETYPE=CYCLICPERIODS, START and END are lists of integers, consisting of one value for each field that is specified by the TIMEVAR keyword. The first value is the value for the highest level cycle field, followed by the next highest cycle field, and so on.

For example, the following syntax specifies the start and end time when there are two cycle levels:

```
START = 3 6 2  END = 5 1 4
```

The start of the estimation period is defined by a value of 3 for the second-level cycle, a value of 6 for the first-level cycle, and a value of 2 for the period field. The end of the estimation period is defined by a value of 5 for the second-level cycle, a value of 1 for the first-level cycle, and a value of 4 for the period field.

- For TIMETYPE=NONE, START and END consist of a single value that specifies the starting record number and the ending record number. For example, the following syntax specifies an estimation period that starts at record 1 and ends at record 60:

START = 1 END = 60

- If a date specification exists for the active dataset, then START and END are lists of integers that consist of one value for each of the components of the date specification. For example, if the date specification is YEAR and MONTH, then the lists consist of two items, one for the year and one for the month. The order of the values is from the highest level component to the lowest level component. For example, the following syntax specifies start and end time for a date specification that is defined by YEAR and MONTH:

START = 2008 1 END = 2013 12

The start of the estimation period is defined by a value of 2008 for the year and 1 for the month. The end of the estimation period is defined by a value of 2013 for the year and 12 for the month.

### **OBSERVATIONS**

Defines the estimation period as a specified number of time intervals that start at the earliest time interval or end at the latest time interval in the data, with an optional offset. In this context, the time interval refers to the time interval of the analysis.

**TYPE** TYPE=NEWEST specifies to use the most recent time intervals. TYPE=OLDEST specifies to use the earliest time intervals.

### **OFFSET**

Specifies an offset from the earliest time interval (when TYPE=OLDEST) or the most recent time interval (when TYPE=NEWEST). The value of OFFSET must be an integer greater than or equal to 0. The default is 0 and specifies to start at the earliest time interval or end at the most recent time interval.

### **NUMBER**

Specifies the number of time intervals to include. The value must be an integer that is greater than or equal to 2. The default is 1000. If the specified value exceeds the number of time intervals in the data, then all time intervals, starting from the optional offset, are included.

### **FORECASTPERIODS**

Specifies the number of time intervals to forecast beyond the end of the estimation period. The time interval in this case is the time interval of the analysis, which is specified by the ANALYSISINTERVAL keyword. The default value of FORECASTPERIODS is 0, which means that forecasts are not created.

### **CILEVEL**

Specifies the confidence level for computing confidence intervals for forecasts and parameter estimates. The value must be positive number that is greater than 0 and less than 100. The default is 95.

### **MAXINPUTS**

The MAXINPUTS keyword specifies the maximum number of inputs that can be included in the model for any target.

- The minimum value is 1 and the maximum value is 20.
- The default value, which is specified by DEFAULT, is the lesser of 5 or the total number of series.
- The model for each target always includes lagged values of itself, so setting this value to 1 specifies that the only input is the target itself.

**LAGS** Specifies the number of lag terms that are included for each time series in the system. The minimum value is 1 and the maximum value is 20. The default is AUTO, which automatically determines the number of lags from the time interval that is used for the analysis. For example, if the time interval is months (with an increment of one month) then the number of lags is 12.

## TOLERANCE

This setting controls the iterative process that is used for determining the best set of inputs for each target. You can specify any value that is greater than zero. The default is 0.001. Model tolerance is a stop criterion for predictor selection. It can affect the number of predictors that are included in the final model. But if a target can predict itself very well, other predictors may not be included in the final model. Some trial and error may be required (for example, if you have this value set to high, you can try setting it to a smaller value to see if other predictors can be included or not).

## OUTLIERTHRESH

An observation is flagged as an outlier if the probability, as calculated from the model, that it is an outlier exceeds this threshold. You can specify a value in the range 50 - 100. The default value is 95.

---

## TARGETFILTER subcommand

The TARGETFILTER subcommand specifies a set of target series for which output is displayed. The content of the output for the specified series is determined by the FILTEREDOUTPUT subcommand. You can specify particular series, for which output is displayed, from the SERIESFILTER subcommand.

## BESTFIT

Specifies to generate output for the target series that have the best-fitting models. By default, output is generated for the top 10 models according to the value of the root mean square percentage error.

- The N keyword specifies the number of models to include, as an integer. If the count exceeds the number of models, all models are shown. The default is 10.
- The PCT keyword specifies the number of models to include, as a percentage of the total number of models. The percentage value must be an integer between 1 and 100.
- The FITSTAT keyword specifies the fit statistic that is used to determine the best-fitting models. The default is RSQUARE.

## RSQUARE

Goodness-of-fit measure of a linear model, sometimes called the coefficient of determination. It is the proportion of variation in the target variable explained by the model. It ranges in value from 0 to 1. Small values indicate that the model does not fit the data well.

## RMSPE

Root Mean Square Percentage Error. A measure of how much the model-predicted values differ from the observed values of the series. It is independent of the units that are used and can therefore be used to compare series with different units.

**RMSE** Root Mean Square Error. The square root of mean square error. A measure of how much a dependent series varies from its model-predicted level, expressed in the same units as the dependent series.

**BIC** Bayesian Information Criterion. A measure for selecting and comparing models based on the -2 reduced log likelihood. Smaller values indicate better models. The BIC also "penalizes" overparameterized models (complex models with a large number of inputs, for example), but more strictly than the AIC.

**AIC** Akaike Information Criterion. A measure for selecting and comparing models based on the -2 reduced log likelihood. Smaller values indicate better models. The AIC "penalizes" overparameterized models (complex models with a large number of inputs, for example).

## ALLTARGETS

Specifies that output is generated for all target series.

## TARGETSNOINPUTS

Specifies that only target series with no inputs (other than lagged values of the target itself) are included.

---

## SERIESFILTER subcommand

The SERIESFILTER subcommand specifies particular series for which output is displayed. The content of the output for the specified series is determined by the FILTEREDOUTPUT subcommand. You can specify multiple SERIESFILTER subcommands.

### FIELDS

The FIELDS keyword is required and specifies the list of fields that contain the series that you want. The keyword T0 is supported but the keyword ALL is not supported. For multidimensional data, all series that are contained in each specified field are included by default. You can specify a subset of series by specifying particular sets of values for one or more dimension fields on the DIMVALUES keyword.

### DIMVALUES

Specifies optional lists of dimension field values that define a subset of series for the fields that are specified on the FIELDS keyword. The DIMVALUES keyword applies only to multidimensional data. The form of the specification for a particular dimension field is `dimField(INCLUDE|EXCLUDE=dimValueList)`, where `dimField` is the name of the field and `dimValueList` is a list of values for that field.

- The INCLUDE or EXCLUDE keyword is required.
- INCLUDE specifies a list of values, from the associated dimension field, to include.
- EXCLUDE specifies a list of values, from the associated dimension field, to exclude.
- You can specify included or excluded values for one or more dimension fields. For dimension fields that are not specified on DIMVALUES, all values of the associated field are included.
- Fields that are specified on the DIMVALUES keyword do not support ALL and T0.
- String values do not need to be quoted, unless the string contains apostrophes or quotation marks. If the string contains apostrophes or single quotes, then enclose the string in double quotes. If the string contains double quotes, then enclose the string in single quotes.

---

## FILTEREDOUTPUT subcommand

The FILTEREDOUTPUT subcommand controls the output that is displayed for the series that are specified on the TARGETFILTER and SERIESFILTER subcommands.

### INCLUDE

Specifies the set of series to which the current FILTEREDOUTPUT subcommand applies. You can specify up to three FILTEREDOUTPUT subcommands, one for each of the values of INCLUDE.

- TARGETS specifies that the current settings apply to the targets that are specified by the TARGETFILTER subcommand.
- SERIES specifies that the current settings apply to the series that are specified by the SERIESFILTER subcommands.
- BOTH specifies that the current settings apply to the targets that are specified by the TARGETFILTER subcommand and the series that are specified by the SERIESFILTER subcommands.

### NETWORKGRAPH

Specifies whether the Overall Model System output item is generated. The default is YES. The Overall Model System item displays a graphical representation of the causal relations between series in the model system. Tables of both model fit statistics and outliers for the displayed

targets are included as part of the output item. When this option is specified with INCLUDE=SERIES or INCLUDE=BOTH, a separate output item is created for each series that is specified on a SERIESFILTER subcommand.

- The SIGLEVEL keyword specifies the significance level threshold for hiding causal connections between series in the Overall Model System graph. A smaller significance level indicates a more significant connection. Connections with significance levels that are higher than the threshold are hidden. Specify a numeric value in the range 0-1. The default is 0.05.

## **PRINT**

Controls the display of tabular output. One or more of the following keyword values can be specified. By default, none of this tabular output is displayed.

### **MODELFIT**

Tables of model fit statistics for the target series that are selected for display. The tables contain the same information as the model fit statistics table in the Overall Model System item. The tables support all standard features for pivoting and editing tables.

### **OUTLIERS**

Tables of outliers for the target series that are selected for display. The tables contain the same information as the outliers table in the Overall Model System item. The tables support all standard features for pivoting and editing tables.

### **MODELEFFECTS**

Tables of model effects tests for the target series that are selected for display. Model effects tests include the F statistic and associated significance value for each input included in the model.

### **PARAMETERS**

Tables of model parameters for the target series that are selected for display.

### **FORECASTS**

Tables of forecasted values and confidence intervals of those forecasts for the target series that are selected for display. The FORECASTS keyword is ignored if forecasts are not requested. Forecasts are requested with the FORECASTPERIODS keyword on the BUILDOPTIONS subcommand.

**PLOT** Controls the display of chart output. One or more of the following keyword values can be specified. By default, none of this chart output is displayed.

### **SERIESPLOT**

Plots of observed and predicted values for the target series that are selected for display. When forecasts are requested, the plot also shows the forecasted values and the confidence intervals for the forecasts.

### **TOPINPUTS**

Plots of each displayed target, over time, along with the top 3 inputs for the target. The top inputs are the inputs with the lowest significance value. To accommodate different scales for the inputs and target, the y axis represents the z score for each series.

### **NRESIDUAL**

Plots of the model residuals for the target series that are selected for display.

## **IMPACTDIAGRAMS**

Specifies whether impact diagrams are generated. An impact diagram displays a graphical representation of the causal relations between a series of interest and other series that it affects or that affect it. Series that affect the series of interest are referred to as *causes*. When the IMPACTDIAGRAMS keyword is specified, impact diagrams are generated for all series that are selected for display. By default, impact diagrams are not generated.

### **EFFECTS**

Creates an impact diagram that is initialized to show the series that are affected by the series of interest. You can specify the number of levels of effects to display, as in

EFFECTS(4) for four levels of effects. The first level represents the series of interest. Each additional level shows more indirect effects of the series of interest. For example, the third level consists of the series that contain series in the second level as a direct input. Series in the third level are then indirectly affected by the series of interest since the series of interest is a direct input to the series in the second level. By default, 3 levels of effects are displayed. You can specify any number of levels up to a maximum of 99.

#### **CAUSES**

Creates an impact diagram that is initialized to show the series that affect the series of interest. You can specify the number of levels of causes to display, as in CAUSES(4) for four levels of causes. The concept of levels for causes is the same as for levels of effects. By default, 3 levels of causes are displayed. You can specify any number of levels up to a maximum of 99.

**Note:** You can interactively toggle between causes and effects in the output item that displays the impact diagram.

#### **OUTLIER\_ROOTCAUSES**

Specifies whether outlier root cause analysis is done. Outlier root cause analysis determines which series are most likely to be the cause of each outlier in a series of interest. The analysis is done for each series that is specified on a SERIESFILTER subcommand and that has outliers. By default, outlier root cause analysis is not done.

#### **LEVELS**

Specifies the number of causal levels that are searched for root causes of outliers. By default, 3 causal levels are searched. The maximum number of levels is 5. The concept of levels that is used here is the same as described for impact diagrams.

#### **DISPLAY**

- The value INTERACTIVE creates an interactive visualization that contains a table and chart of outliers and root causes of those outliers for each series of interest. The table contains a single row for each outlier. The chart is an impact diagram. Selecting a row in the table highlights the path, in the impact diagram, from the series of interest to the series that most likely causes the associated outlier.
- The value TABLE creates a table of outliers and root causes of those outliers for each series of interest. This table contains the same information as the table in the interactive display. This table supports all standard features for pivoting and editing tables.
- The value BOTH generates the interactive visualization and the separate table.

---

## **SYSTEMOUTPUT subcommand**

The SYSTEMOUTPUT subcommand controls output associated with the entire temporal causal model system.

#### **MODELFIT**

Controls the display of histograms of model fit for all models. One or more fit statistics can be specified. A single histogram that is based on RSQUARE is generated by default.

#### **RSQUARE**

Goodness-of-fit measure of a linear model, sometimes called the coefficient of determination. It is the proportion of variation in the target variable explained by the model. It ranges in value from 0 to 1. Small values indicate that the model does not fit the data well.

#### **RMSPE**

Root Mean Square Percentage Error. A measure of how much the model-predicted values differ from the observed values of the series. It is independent of the units that are used and can therefore be used to compare series with different units.

**RMSE** Root Mean Square Error. The square root of mean square error. A measure of how much a dependent series varies from its model-predicted level, expressed in the same units as the dependent series.

**BIC** Bayesian Information Criterion. A measure for selecting and comparing models based on the  $-2 \log$  likelihood. Smaller values indicate better models. The BIC also "penalizes" overparameterized models (complex models with a large number of inputs, for example), but more strictly than the AIC.

**AIC** Akaike Information Criterion. A measure for selecting and comparing models based on the  $-2 \log$  likelihood. Smaller values indicate better models. The AIC "penalizes" overparameterized models (complex models with a large number of inputs, for example).

**NONE**  
Specifies that histograms are not generated. NONE cannot be specified with any other keywords.

## TRANSFORMATIONS

Table of any transformations that were applied to the series in the model system. The possible transformations are missing value imputation, aggregation, and distribution. The default is YES, which specifies that the table is generated.

## OUTLIERPLOT

Bar chart of the number of outliers, across all targets, for each time interval in the estimation period. The default is NO, which specifies that the bar chart is not generated.

---

## SAVE subcommand

The SAVE subcommand saves new variables that represent predicted values, residuals, and confidence intervals. By default, no new variables are saved.

- Specify one or more keywords, along with optional rootnames to be used as the prefix for new variable names.
- The rootname, if specified, must conform to the rules for valid variable names.
- If the DATA keyword of the OUTFILE subcommand is specified, then the new variables are written to that location. If the DATA keyword is not specified and the new variables cannot be written to the active dataset, then they are written to an autogenerated dataset. New variables can be written to the active dataset only if the observations are defined by a date specification, or record order, and the data are not aggregated.

## TARGETS

**ALL** Specifies that new variables are created for all targets in the model system.

### FILTERED

Specifies that new variables are created just for the targets that are specified by the TARGETFILTER and SERIESFILTER subcommands. This option is the default.

## PREDICTED(rootname)

Saves model fit and forecast values. The default rootname is *Predicted*.

## CL(LCLROOT=rootname UCLROOT=rootname)

Saves upper and lower confidence limits. LCLROOT specifies the root name for the lower confidence limit and UCLROOT specifies the root name for the upper confidence limit. The default root name for the lower confidence limit is *LCL* and the default root name for the upper confidence limit is *UCL*.

## NRESIDUAL(rootname)

Saves noise residuals. The default rootname is *NResidual*.

**FORECASTFLAG(name)**

Creates a variable that indicates whether a record contains forecast data. You can specify the variable name. The default is *ForecastIndicator*.

---

**OUTFILE subcommand****MODELSYSTEM**

Saves the model system to a compressed file archive (.zip file). The model system file can be used by the Temporal Causal Model Forecasting procedure to obtain updated forecasts or to generate any of the available output. It can also be used by the Temporal Causal Model Scenarios procedure to run scenario analysis.

**DATA** Specifies the name of a file or a previously declared dataset where the data that was used for modeling, and any new variables that are specified on the SAVE subcommand, are written. The data that is used for modeling includes any aggregation or distribution that was specified for the original data, and any imputation of missing values.

- Date/time values in the saved data are aligned to the beginning of each time interval, such as the first of the month, and represent the time interval of the analysis for the model system.
  - Enclose file specifications in quotation marks and use fully qualified paths to avoid ambiguity. You can use an asterisk (\*) to specify that the data is written to the active dataset, replacing the current active dataset.
- 

**PASSPROTECT subcommand**

The PASSPROTECT subcommand saves an external file, that was specified on the DATA keyword of the OUTFILE subcommand, as an encrypted file. An encrypted file can be opened only by providing the correct password.

**PASSWORD**

Specifies the password that is required to open this file. Passwords are limited to 10 characters and are case-sensitive. The specified value must be enclosed in quotation marks. The keyword NONE specifies not to encrypt the file and is the default.

**ENCRYPTEDPW**

Specifies whether the password is encrypted.

**NO** The password is not encrypted. It is treated as plain text. This option is the default.

**YES** The password is encrypted. Use ENCRYPTEDPW=YES only when the password is known to be encrypted. Passwords are always encrypted in pasted syntax.

**Creating strong passwords**

- Use eight or more characters.
- Include numbers, symbols and even punctuation in your password.
- Avoid sequences of numbers or characters, such as "123" and "abc", and avoid repetition, such as "111aaa".
- Do not create passwords that use personal information such as birthdays or nicknames.
- Periodically change the password.

*Note:* Encrypted data files and output documents cannot be opened in versions of IBM SPSS Statistics prior to version 21. Encrypted syntax files cannot be opened in versions prior to version 22.

---

## FIELDSGROUP subcommand

The FIELDSGROUP subcommand is required and signals the start of a fields group block. A fields group block consists of one or more FIELDS subcommands. Multiple FIELDSGROUP subcommands can be specified. The set of all FIELDSGROUP subcommands defines the complete set of fields, and their roles, for the temporal causal model system.

- At least one FIELDSGROUP subcommand must be specified.
- At least one FIELDS subcommand in each fields group block must contain a TARGETS keyword.

---

## FIELDS subcommand

The FIELDS subcommand specifies targets and inputs for the current fields group block. Fields group blocks are created with the FIELDSGROUP subcommand

- All fields on the FIELDS subcommand, except those specified on the DIMVALUES keyword, must be numeric.
- Field lists that use the keyword ALL include all numeric fields in the active dataset with the following exceptions: fields specified on the TIMEVAR keyword (on the DATASETTINGS subcommand); fields created from the DATE command.
- For multidimensional data, all series that are contained in each specified field are included by default. You can specify a subset of series by specifying particular sets of values for one or more dimension fields on the DIMVALUES keyword.

### TARGETS

Specifies target fields for the current fields group block.

### INPUTS

Specifies inputs that are considered for inclusion in the model for each target in the current fields group block.

- Fields specified on the INPUTS keyword can also be specified on the TARGETS keyword.
- The model for each target automatically contains lagged values of the target itself as an input.

### FORCE

Specifies fields that are always included as inputs in the model for each target in the current fields group block. Specifications on the FORCE keyword override those on the INPUTS and EXCLUDEDINPUTS keywords in the current fields group block.

### EXCLUDEDTARGETS

Specifies fields that are excluded from the specified targets in the current fields group block. The EXCLUDEDTARGETS keyword is most useful when ALL or T0 is used on the TARGETS keyword.

### EXCLUDEDINPUTS

Specifies fields that are excluded from the specified inputs in the current fields group block. The EXCLUDEDINPUTS keyword is most useful when ALL or T0 is used on the INPUTS keyword.

### DIMVALUES

Specifies optional lists of dimension field values that define a subset of series for fields specified in all keywords on the current FIELDS subcommand. The DIMVALUES keyword applies only to multidimensional data.

- The INCLUDE or EXCLUDE keyword is required.
- INCLUDE specifies a list of values, from the associated dimension field, to include.
- EXCLUDE specifies a list of values, from the associated dimension field, to exclude.
- You can specify included or excluded values for one or more dimension fields. For dimension fields that are not specified on DIMVALUES, all values of the associated field are included.
- Fields that are specified on the DIMVALUES keyword do not support ALL and T0.

- String values do not need to be quoted, unless the string contains apostrophes or quotation marks. If the string contains apostrophes or single quotes, then enclose the string in double quotes. If the string contains double quotes, then enclose the string in single quotes.

---

## Chapter 267. TDISPLAY

```
TDISPLAY [{ALL          }]
          {model names }
          {command names}
```

```
[/TYPE={MODEL**}]
      {COMMAND}
```

\*\*Default if the subcommand or keyword is omitted.

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Example

```
TDISPLAY.
```

---

## Overview

TDISPLAY displays information about currently active models. These models are automatically generated by a number of procedures for use with the APPLY subcommand.

### Options

If models are specified on TDISPLAY, information about only those models is displayed. You can use the TYPE subcommand to control whether models are specified by model name or by the name of the procedure that generated them.

### Basic Specification

The basic specification is simply the command keyword TDISPLAY.

- By default, TDISPLAY produces a list of all currently active models. The list includes the model names, the commands that created each model, model labels (if specified), and creation dates and times.

### Syntax Rules

- To display information about a subset of active models, specify those models after TDISPLAY.
- Models can be specified by using individual model names or the names of the procedures that created them. To use procedure names, you must specify the TYPE subcommand with the keyword COMMAND.
- Model names are either the default *MOD\_n* names or the names that are assigned with MODEL NAME.
- If procedure names are specified, all models that are created by those procedures are displayed.
- Model names and procedure names cannot be mixed on the same TDISPLAY command.
- You can specify the keyword ALL after TDISPLAY to display all models that are currently active. This setting is the default.

### Operations

- Only currently active models are displayed.
- The following procedures can generate models that can be displayed with the TDISPLAY command: AREG, ARIMA, EXSMOOTH, SEASON, and SPECTRA in the Forecasting add-on module; ACF, CASEPLOT, CCF, CURVEFIT, PACF, PLOT, and TSPLIT in the Core system; and WLS and 2SLS in the Regression add-on module.

---

## TYPE Subcommand

TYPE indicates whether models are specified by model name or procedure name.

- One keyword, MODEL or COMMAND, can be specified after TYPE.
- MODEL is the default and indicates that models are specified as model names.
- COMMAND specifies that models are specified by procedure name.
- TYPE has no effect if model names or command names are not listed after TDISPLAY.
- If more than one TYPE subcommand is specified, only the last subcommand is used.
- The TYPE specification applies only to the current TDISPLAY command.

### Example

```
TDISPLAY ACF CURVEFIT  
/TYPE=COMMAND.
```

- This command displays all currently active models that were created by procedures ACF and CURVEFIT.

---

## Chapter 268. TEMPORARY

### TEMPORARY

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. See the topic “Command Order” on page 40 for more information.

---

## Overview

TEMPORARY signals the beginning of temporary transformations that are in effect only for the next procedure. With the exception of variables created or modified by the next procedure (for example, residual values saved as variables by REGRESSION), numeric or string variables created while the TEMPORARY command is in effect are temporary variables, and any modifications made to existing variables while the TEMPORARY command is in effect are also temporary. Any variables created or modified by the next procedure are permanent.

With TEMPORARY, you can perform separate analyses for subgroups in the data and then repeat the analysis for the file as a whole. You can also use TEMPORARY to transform data for one analysis but not for other subsequent analyses.

TEMPORARY can be applied to the following commands:

- Transformation commands COMPUTE, RECODE, IF, and COUNT, and the DO REPEAT utility.
- The LOOP and DO IF structures.
- Format commands PRINT FORMATS, WRITE FORMATS, and FORMATS.
- Data selection commands SELECT IF, SAMPLE, FILTER, and WEIGHT.
- Variable declarations NUMERIC, STRING, and VECTOR.
- Labeling commands VARIABLE LABELS and VALUE LABELS, and the MISSING VALUES command.
- SPLIT FILE.
- PRINT, WRITE, XSAVE.

### Basic specification

The only specification is the keyword TEMPORARY. There are no additional specifications.

### Operations

- Once TEMPORARY is specified, you cannot refer to previously existing scratch variables.
- Temporary transformations apply to the next command that reads the data. Once the data are read, the temporary transformations are no longer in effect.
- The XSAVE command leaves temporary transformations in effect. SAVE, however, reads the data and turns temporary transformations off after the file is written. (See “Examples.”)
- TEMPORARY cannot be used with SORT CASES, MATCH FILES, ADD FILES, or COMPUTE with a LAG function. If any of these commands follows TEMPORARY in the command sequence, there must be an intervening procedure or command that reads the data to first execute the TEMPORARY command.
- TEMPORARY cannot be used within the DO IF–END IF or LOOP–END LOOP structures.

If any variables have an unknown measurement level, the measurement level for those variables remains unknown after a procedure that follows a TEMPORARY command. (In the absence of the TEMPORARY command, the data pass performed by the procedure would assign default measurement levels to all variables with an unknown measurement level.)

---

## Examples

### Basic example

```
SORT CASES BY SEX.  
TEMPORARY.  
SPLIT FILE BY SEX.  
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.  
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.
```

- SPLIT FILE applies to the first FREQUENCIES procedure, which generates separate median income tables for men and women.
- SPLIT FILE is not in effect for the second FREQUENCIES procedure, which generates a single median income table that includes both men and women.

### Temporary transformations for a new variable

```
DATA LIST FILE=HUBDATA RECORDS=3  
  /1 #MOBIRTH #DABIRTH #YRBIRTH 6-11 DEPT88 19.  
COMPUTE AGE=($JDATE - YRMODA(#YRBIRTH,#MOBIRTH,#DABIRTH))/365.25.  
VARIABLE LABELS AGE 'EMPLOYEE'S AGE'  
  DEPT88 'DEPARTMENT CODE IN 1988'.
```

```
TEMPORARY.  
RECODE AGE (LO THRU 20=1)(20 THRU 25=2)(25 THRU 30=3)(30 THRU 35=4)  
  (35 THRU 40=5)(40 THRU 45=6)(45 THRU 50=7)(50 THRU 55=8)  
  (55 THRU 60=9)(60 THRU 65=10)(65 THRU HI=11).  
VARIABLE LABELS AGE 'EMPLOYEE AGE CATEGORIES'.  
VALUE LABELS AGE 1 'Up to 20' 2 '20 to 25' 3 '25 to 30' 4 '30 to 35'  
  5 '35 to 40' 6 '40 to 45' 7 '45 to 50' 8 '50 to 55'  
  9 '55 to 60' 10 '60 to 65' 11 '65 and older'.
```

```
FREQUENCIES VARIABLES=AGE.  
MEANS AGE BY DEPT88.
```

- COMPUTE creates variable *AGE* from the dates in the data.
- FREQUENCIES uses the temporary version of variable *AGE* with temporary variable and value labels.
- MEANS uses the unrecoded values of *AGE* and the permanent variable label.

### Using XSAVE with TEMPORARY

```
GET FILE='data/hub.sav'.  
TEMPORARY.  
RECODE DEPT85 TO DEPT88 (1,2=1) (3,4=2) (ELSE=9).  
VALUE LABELS DEPT85 TO DEPT88 1 'MANAGEMENT'  
  2 'OPERATIONS'  
  3 'UNKNOWN'.  
XSAVE OUTFILE='temp/hubtemp.sav'.  
CROSSTABS DEPT85 TO DEPT88 BY JOBCAT.
```

- Both the saved data file and the CROSSTABS output will reflect the temporary recoding and labeling of the department variables.
- If XSAVE is replaced with SAVE, the saved data file will reflect the temporary recoding and labeling but the CROSSTABS output will not.

---

## Chapter 269. TIME PROGRAM

TIME PROGRAM.  
[commands to compute time dependent covariates]

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. See the topic “Command Order” on page 40 for more information.

---

### Overview

TIME PROGRAM is required to define time-dependent covariates. These are covariates whose values change during the course of the study.

#### Basic Specification

The basic specification is the TIME PROGRAM command followed by one or more commands that define time-dependent covariates.

#### Syntax Rules

- TIME PROGRAM and the transformations that define the time-dependent covariate(s) must precede the command that analyzes the time-dependent covariate(s).
- A time-dependent covariate is a function of the current time, which is represented by the special variable  $T_.$
- The active dataset must not have a variable named  $T_.$  If it does, rename the variable. Otherwise, you will trigger an error.
- $T_.$  cannot be specified as a covariate. Any other variable in the TIME PROGRAM can be specified on the covariate list.
- For every time-dependent covariate, values are generated for each valid case for all uncensored times in the same stratum that occur before the observed time. If no STRATA subcommand is specified, all cases are considered to belong to one stratum.
- If any function defined by the time program results in a missing value for a case that has no missing values for any other variable used in the procedure, this causes an error.

---

### Example

```
TIME PROGRAM.  
COMPUTE Z=AGE + T_.  
  
COXREG VARIABLES = SURVIVAL WITH Z  
/STATUS SURVSTA EVENT (1).
```

- TIME PROGRAM defines the time-dependent covariate  $Z$  as the current age.  $Z$  is then specified as a covariate in COXREG.

---

## Chapter 270. TITLE

TITLE [']text[']

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Example

```
TITLE "Running Shoe Study from Runner's World Data".
```

---

## Overview

TITLE inserts a title on the top line of each page of output. The default title indicates the version of the system being used.

### Basic Specification

The only specification is the title.

### Syntax Rules

- The title can include any characters. To specify a blank title, enclose a blank in quotes (" ").
- The title can be up to 60 bytes long. Titles longer than 60 bytes are truncated.
- The quotes enclosing the title are optional; using them allows you to include apostrophes or quotation marks in the title. See the topic “String Values in Command Specifications” on page 39 for more information.
- More than one TITLE command is allowed in a single session.
- A title cannot be placed between a procedure command and BEGIN DATA–END DATA or within data records when the data are inline.

### Operations

- The title is displayed as part of the output heading, which also includes the date and page number. If HEADER=NO is specified on SET, the heading, including the title and subtitle, will not be displayed.
- Each TITLE command overrides the previous one and takes effect on the next output page.
- Only the title portion of the heading changes. The date and page number are still displayed.
- TITLE is independent of SUBTITLE, and each can be changed separately.

---

## Examples

```
TITLE My Title.  
TITLE "Fred's Title".  
TITLE 'Fred''s "Quoted" Title'.
```

- The first title doesn't need to be enclosed in quotes because it doesn't contain any quotes or apostrophes.
- The second title is enclosed in double quotes because it contains an apostrophe (single quote).
- The last title is enclosed in single quotes since it contains double quotes, and two single quotes are used to specify the apostrophe.

---

## Chapter 271. TMS BEGIN

```
TMS BEGIN
  /DESTINATION OUTFILE='file specification'
```

### Release History

#### Release 15.0

- Command introduced.

#### Release 16.0

- Added support for new string functions CHAR.CONCAT, CHAR.LENGTH, and CHAR.SUBSTR within TMS blocks.

#### Release 21.0

- Added support for comparison operators and logical operators.

### Example

```
TMS BEGIN
  /DESTINATION OUTFILE='/mydir/mytransformations.xml'.
  COMPUTE modelvar=ln(var).
TMS END.
```

---

## Overview

The TMS BEGIN command indicates the beginning of a block of transformations to be exported to a file in PMML format--specifically, PMML 3.1 with IBM SPSS Statistics extensions. The exported transformations can be merged (using TMS MERGE) with a PMML model file in order to include any transformations of the raw data required to create the variables used in the model. The merged PMML file can be used to score data with scoring functions. (For more information on scoring functions, see “Scoring expressions” on page 93.) When you score data with a model file containing transformations, the transformations will be applied to the data before scoring. The transformations are carried out as part of the internal scoring process and have no effect on the active dataset. The TMS END command is used to end the block.

From the point of view of the active dataset, transformations in a TMS BEGIN-TMS END block are no different than transformations outside a TMS block--they are pending and will be executed with the next command that reads the active dataset. Source variables used in transformation expressions in TMS blocks must exist in the active dataset. In a typical scenario, you would run TMS BEGIN-TMS END command syntax on the raw dataset used to build the associated model, assuming it contains the source variables used in any transformation expressions.

Commands within a TMS block are categorized as belonging to one of four types: exported, tolerated, invalid, and those causing an implicit TMS END.

**Exported.** These are commands that produce export to PMML. Commands in this category include the supported transformations--for example, RECODE. Many transformations are expressed with functions included on a COMPUTE command. Export to PMML is supported for a limited set of such functions. The set of commands that produce export to PMML, as well as the set of supported functions, are provided at the end of this topic.

**Tolerated.** These are commands that can be included in a TMS BEGIN-TMS END block, are executed in normal fashion, but do not produce export to PMML. Examples include NUMERIC, STRING, USE, INCLUDE, and INSERT. In the case of INCLUDE or INSERT, supported transformations from the inserted file will be exported to PMML.

**Invalid.** These are commands that cannot be processed within a TMS block and will give rise to an error. The list of invalid commands is provided at the end of this topic.

**Implicit TMS END.** These commands are executed in normal fashion but cause an implicit end to the current block, which then causes the output PMML file to be written. Transformations (in the current block) occurring after one of these commands are not exported to the output PMML file. Commands in this category include all of the statistical procedures--for example, ANOVA and REGRESSION--as well as the EXECUTE command. ADD FILES, MATCH FILES and COMPARE DATASETS belong to this category as well as any command that causes a different dataset to become active--for example, DATASET ACTIVATE, GET, and GET DATA.

## Basic Specification

The basic specification for TMS BEGIN is the command name followed by a DESTINATION subcommand that contains an OUTFILE specification.

## Syntax Rules

- The DESTINATION subcommand is required.
- An error occurs if the DESTINATION subcommand is specified more than once.
- An error occurs if the OUTFILE keyword is specified more than once.
- Equal signs (=) shown in the syntax chart are required.
- Subcommand names and keywords must be spelled in full.

## Operations

- Once a TMS BEGIN command is executed, it remains in effect until the end of the session, until explicitly ended by a TMS END command, or until a command that implicitly ends a TMS block--for example, any statistical procedure--is encountered.
- TMS commands (for example, TMS MERGE) are not allowed within a TMS block.
- TMS BEGIN verifies that the path specified for the destination file is valid. If the path is invalid, the commands in the block will be processed in the normal manner but no PMML will be exported.
- The following conditions will cause the destination file to be written: a command that causes an implicit end of the block is executed; the TMS block ends explicitly with TMS END; the current session ends before the block ends (either explicitly or implicitly). The destination file is unavailable to other commands until after it is written. TMS END has no effect if the block is ended implicitly.
- An error occurs if a transformation in the block is not supported. The command containing the invalid transformation is not executed. This type of error does not cause an implicit end to the TMS block and has no effect on when the destination file is written.
- The order of the transformations in the destination file may not be the order in which they were specified in the TMS block.
- Transformations specified in a TMS block are processed in the normal manner--that is, pending and to be executed with the next command that reads the active dataset.

## Exported Commands

The following commands produce export to PMML: ADD VALUE LABELS, COMPUTE, DO REPEAT, MISSING VALUES, RECODE, VALUE LABELS, VARIABLE LABELS, VARIABLE LEVEL.

- For COMPUTE, the target variable must be a variable that has not already been assigned a value or otherwise used in the associated TMS block. For example, the following is invalid:  
`COMPUTE var = var + 1.`
- For RECODE, all input and output keywords are supported except CONVERT. In addition, you must always recode INTO a variable that has not already been assigned a value or otherwise used in the associated TMS block. When a recoding transformation is carried out on a dataset to be scored, the results depend

on whether the target variable exists in the dataset. If the target variable already exists, cases with values (of the source variable) not mentioned in the value specifications for the recode are not changed. If the target variable does not already exist, cases with values not mentioned are assigned the system-missing value.

### Invalid Commands

The following commands are invalid inside a TMS block: AGGREGATE, BREAK, COUNT, DO IF - END IF, ELSE, ELSE IF, END CASE, END FILE, FILE TYPE - END FILE TYPE, FILTER, IF INPUT PROGRAM - END INPUT PROGRAM, KEYED DATA LIST, LEAVE, LOOP - END LOOP, N OF CASES, POINT, RECORD TYPE, REPEATING DATA, REREAD, SAMPLE, SELECT IF, VECTOR, WEIGHT, WRITE.

The following functions, operations, and system variables are supported for use with the COMPUTE command in TMS blocks. In a few cases--for example, CHAR.SUBSTR--multiple forms (differing in the number of parameters) exist, but only a single form is supported. The parameters available in the supported form are:

- + Addition
- - Subtraction
- \* Multiplication
- / Division
- \*\* Exponentiation
- & Logical AND
- | Logical OR
- ~ Logical NOT
- = Equal to
- ~= Not equal to
- < Less than
- > Greater than <= Less than or equal to
- >= Greater than or equal to
- ABS
- CDF.NORMAL
- CDFNORM
- CHAR.CONCAT
- CHAR.LENGTH
- CHAR.SUBSTR(strexpr,pos)
- CONCAT
- EXP
- IDF.NORMAL
- LG10
- LENGTH
- LN
- LOWER
- LTRIM(strexpr)
- MAX
- MEAN
- MIN
- MOD
- PDF.NORMAL

- RND
- RTRIM(strexpr)
- SD
- SQRT
- SUBSTR(strexpr,pos)
- SUM
- SYSMIS
- TRUNC
- UPCASE
- VALUE
- VARIANCE

#### Notes

- Within a TMS block it is recommended to use CHAR.CONCAT, CHAR.LENGTH, and CHAR.SUBSTR in place of CONCAT, LENGTH, and SUBSTR.
- String arguments for the MAX and MIN functions are not supported for scoring.

---

## EXAMPLES

```
TMS BEGIN
  /DESTINATION OUTFILE='/mydir/mytransformations.xml'.
  COMPUTE modelvar=ln(var).
TMS END.
```

- TMS BEGIN marks the beginning of a block of transformation commands that will be evaluated for export to PMML.
- The variable *var* is transformed with a log function to create the variable *modelvar*, which is to be used in a model. The details of this transformation will be included as PMML in the file */mydir/mytransformations.xml*.
- TMS END marks the end of the block and causes the output file to be written, but has no effect on the state of the transformations contained in the block. In the present example, the transformation to create *modelvar* is still pending after the completion of the block.

#### Tolerated Commands in a TMS Block

```
TMS BEGIN
  /DESTINATION OUTFILE='/mydir/mytransformations.xml'.
  STRING new_strvar (A1).
  RECODE strvar ('A','B','C'='A') ('D','E','F'='B') (ELSE=' ')
    INTO new_strvar.
TMS END.
```

- The STRING command is used to create a new string variable that is to be the target of a recode transformation of an existing string variable. STRING is a tolerated command so it is executed in the normal manner, without generating an error or implicitly ending the TMS block.

#### Commands that Cause an Implicit TMS END

```
TMS BEGIN
  /DESTINATION OUTFILE='/mydir/mytransformations.xml'.
  RECODE numvar1 (0=1) (1=0) (ELSE=SYSMIS) INTO new_numvar1.
  FREQUENCIES new_numvar1.
  RECODE numvar2 (1 THRU 5=1)(6 THRU 10=2)(11 THRU HI=3)(ELSE=0)
    INTO new_numvar2.
TMS END.
```

- The FREQUENCIES command causes an implicit end to the TMS block, causing the output PMML file to be written. The output file only contains the recode transformation for *numvar1*--that is, the transformations prior to the command causing the implicit TMS END.

- Although the FREQUENCIES command implicitly ends the block, the recode transformation for *numvar2* is processed in the normal manner and remains pending until the next command that reads the active dataset.
- Although we have included it in this example, the TMS END command is not needed when there is a command that implicitly ends the TMS block. In this example, execution of the TMS END command generates a warning indicating that there is no current TMS command in effect.

### Using EXECUTE in a TMS Block

```
TMS BEGIN
  /DESTINATION OUTFILE='/mydir/mytransformations.xml'.
RECODE numvar1 (0=1) (1=0) (ELSE=SYSMIS) INTO new_numvar1.
RECODE numvar2 (1 THRU 5=1)(6 THRU 10=2)(11 THRU HI=3)(ELSE=0)
  INTO new_numvar2.
EXECUTE.
```

- You can include EXECUTE in a TMS block. In its usual manner, it will cause all pending transformations to be executed. In addition, it causes an implicit end to the block which then causes the output PMML file to be written.
- In the current example, we have omitted the TMS END command since the block is implicitly ended by the EXECUTE command.

---

## DESTINATION Subcommand

The DESTINATION subcommand is required. It must include the OUTFILE keyword followed by an equals sign (=) and a file specification in quotes or a previously defined file handle defined with the FILE HANDLE command. It is recommended to include the extension *.xml* in the file specification.

---

## Chapter 272. TMS END

```
TMS END
  [/PRINT RESULTS={SUMMARY**}]
  {NONE}
```

\*\* Default if the subcommand or keyword is omitted.

### Release History

#### Release 15.0

- Command introduced.

### Example

```
TMS BEGIN
  /DESTINATION OUTFILE='/mydir/mytransformation.xml'.
COMPUTE mymodelvar=ln(var).
TMS END
  /PRINT RESULTS=NONE.
```

---

## Overview

The TMS END command is used to indicate the end of a block of transformations to be exported to a file in PMML format--specifically, PMML 3.1 with IBM SPSS Statistics extensions. The exported transformations can be merged (using TMS MERGE) with a PMML model file in order to include any transformations of the raw data required to create the variables used in the model. The merged PMML file can be used to score data with scoring functions. (For more information on scoring functions, see “Scoring expressions” on page 93.) When you score data with a model file containing transformations, the transformations will be applied to the data before scoring. The transformations are carried out as part of the internal scoring process and have no effect on the active dataset. The TMS BEGIN command is used to indicate the beginning of the block.

### Basic Specification

The basic specification for TMS END is the command name. For examples of TMS BEGIN-TMS END blocks, see the TMS BEGIN command.

### Syntax Rules

- An error occurs if the PRINT subcommand is specified more than once.
- An error occurs if the RESULTS keyword is specified more than once.
- Equal signs (=) shown in the syntax chart are required.
- Subcommand names and keywords must be spelled in full.

### Operations

- TMS END will generate a warning if there is no TMS BEGIN command in effect. This condition occurs in the obvious case that there is no prior TMS BEGIN command, but will also occur if there is a TMS BEGIN command followed by a command that implicitly ends a TMS block--for instance, any statistical procedure or the EXECUTE command--followed by TMS END.
- TMS END causes the destination file to be written, unless the associated TMS block ended implicitly (see previous bullet), thus causing the file to be written before execution of TMS END. For more information, see the Examples for the TMS BEGIN command.
- TMS END does not cause transformations in the associated TMS block to be executed. In normal fashion, they are pending and will be executed with the next command that reads the active dataset.

---

## **PRINT Subcommand**

The PRINT subcommand is optional and specifies whether or not to print a table summarizing the derived variables defined by the transformations in the block.

**SUMMARY.** *Print a summary of the derived variables.* This is the default.

**NONE.** *Do not print a summary.*

---

## Chapter 273. TMS IMPORT

```
TMS IMPORT
/INFILE TRANSFORMATIONS='filespec'
  [MODE={FORWARD** (ROLES={UPDATE**})          }]
      {LEAVE }
    {BACK(PREDICTED=fieldname
          SUFFIX={'_backtransformed'})
      {suffixname } )}
```

```
[/SAVE TRANSFORMED={YES**}]
  {NO }
[/OUTFILE SYNTAX='filespec'].
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Release History

#### Release 18

- Command introduced.

### Example

```
TMS IMPORT
/INFILE TRANSFORMATIONS='file.xml'.
```

---

## Overview

TMS IMPORT converts transformations contained in an XML file created by ADP (transformations files created by TMS BEGIN-END are not currently "reversible") into command syntax and applies the converted transformations to the active dataset or saves them to a syntax file.

### Basic Specification

The basic specification is the TMS IMPORT command and an INFILE subcommand with a transformations file specification.

### Syntax Rules

- The INFILE subcommand is required. All other subcommands are optional.
- Each subcommand can be specified only once.
- Subcommands may be used in any order.
- An error occurs if a keyword is specified more than once within a subcommand.
- Equal signs (=) shown in the syntax chart are required.
- Subcommand names and keywords must be spelled in full.

---

## Examples

```
TMS IMPORT
/INFILE TRANSFORMATIONS='file.xml'.
```

- TMS IMPORT reads the file *file.xml*, converts the transformations from XML to command syntax, and applies them to the active dataset.

### Using Backtransformations

```
TMS IMPORT
/INFILE TRANSFORMATIONS='workingDirectory/car_sales_transformations.xml'
MODE=BACK (PREDICTED=PRE_2 SUFFIX='_backtransformed').
EXECUTE.
```

- The TMS IMPORT command reads the transformations in *car\_sales\_transformations.xml* and applies the backtransformation to *PRE\_2*.
- The new field containing the backtransformed values is named *PRE\_2\_backtransformed*.
- The EXECUTE command causes the transformations to be processed. When using this as part of a longer stream of syntax, you may be able to remove the EXECUTE command to save some processing time.

---

## INFILE Subcommand

The INFILE subcommand specifies the location of the XML file containing the transformations.

TRANSFORMATIONS Keyword

The TRANSFORMATIONS keyword specifies the location of the XML file containing the transformations. Specify a filename in quotation marks. The filename must be specified in full.

The MODE keyword specifies the direction of the transformations.

**FORWARD (ROLES= UPDATE|LEAVE).** Convert the "forward" transformations from XML to command syntax. These are the transformations from the original fields into fields that are used in modeling. ROLES determines whether to update field roles based upon transformations in the file. UPDATE will set the role of any "obsolete" field to None. LEAVE will leave the roles of existing fields as they currently are. FORWARD is the default mode. See the topic Chapter 293, "VARIABLE ROLE," on page 2133 for more information. .

**BACK(PREDICTED=fieldname SUFFIX=suffixname).** Convert the backtransformation of target values into command syntax and apply to the field specified on the PREDICTED keyword. The backtransformed values are saved to a field with the name on the PREDICTED keyword and suffix on the SUFFIX keyword. *\_backtransformed* is the default suffix.

### Example

```
TMS IMPORT
  /INFILE TRANSFORMATIONS='file.xml'.
REGRESSION VARIABLES=target_transformed input_transformed
  /DEPENDENT=target_transformed
  /METHOD=ENTER input_transformed
  /SAVE=PRED(predicted) SDBETA(BETA) ICIN.
TMS IMPORT
  /INFILE TRANSFORMATIONS='file.xml' MODE=BACK(PREDICTED=predicted).
```

- The first TMS IMPORT reads the file *file.xml*, converts the transformations from XML to command syntax, and applies them to the active dataset. The fields *target\_transformed* and *input\_transformed* result.
- The REGRESSION command builds a model for *target\_transformed* using *input\_transformed*, and adds *predicted* to the active dataset, containing the predicted values.
- The second TMS IMPORT reads the file *file.xml*, converts the backtransformations from XML to command syntax, and applies them to the active dataset. The field *predicted\_backtransformed* results, and contains predicted values in the original scale of the target field.

---

## SAVE Subcommand

The SAVE subcommand adds the prepared fields to the active dataset.

**TRANSFORMED.** *Transformed data.* The transformed fields are added to the active dataset. The values are not computed immediately; instead the transformations are stored, pending execution with the next command that reads the dataset.

---

## OUTFILE Subcommand

The OUTFILE subcommand specifies the location of the file to which command syntax should be saved.

**SYNTAX=filename.** *Syntax file.* Specify a filename in quotation marks. The filename must be specified in full; no extension is supplied. It is recommended to include the extension *.sps* in the file specification.

---

## Chapter 274. TMS MERGE

```
TMS MERGE
/DESTINATION OUTFILE='file specification'
/TRANSFORMATIONS INFILE='file specification'
/MODEL INFILE='file specification'
[/PRINT RESULTS={SUMMARY**}]
{NONE}
```

\*\* Default if the subcommand or keyword is omitted.

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Release History

#### Release 15.0

- Command introduced.

### Example

```
TMS MERGE
/DESTINATION OUTFILE='/mydir/mymergedmodel.xml'
/TRANSFORMATIONS INFILE='/mydir/mytransformations.xml'
/MODEL INFILE='/mydir/mymodel.xml'
```

---

## Overview

The TMS MERGE command is used to merge a PMML file containing transformations with a PMML model file containing variables whose derivations are expressed by those transformations. The merged PMML file can be used to score data with scoring functions. (For more information on scoring functions, see “Scoring expressions” on page 93.) When you score data with a model file containing transformations, the transformations will be applied to the data before scoring. The transformations are carried out as part of the internal scoring process and have no effect on the active dataset. Transformations are exported as PMML using the TMS BEGIN and TMS END commands. See the topic Chapter 271, “TMS BEGIN,” on page 1979 for more information.

### Basic Specification

The basic specification is the command name followed by DESTINATION, TRANSFORMATIONS, and MODEL subcommands that contain file specifications.

### Syntax Rules

- Each subcommand can be specified only once.
- Subcommands may be used in any order.
- An error occurs if a keyword is specified more than once within a subcommand.
- Equal signs (=) shown in the syntax chart are required.
- Subcommand names and keywords must be spelled in full.

### Operations

- TMS MERGE has no effect on the active dataset. It relies completely on the information contained in the transformations and model files.
- TMS MERGE verifies that the paths specified for the input files and destination file are valid. The destination file is unavailable to other commands until the TMS MERGE command is ended.

- An error occurs if properties of derived variables in the transformations file do not match the properties for those same variables in the model file--for example, conflicting definitions of missing values.

#### Limitations

- TMS MERGE cannot be used to merge transformations with an ensemble model.
- TMS MERGE cannot be used to merge transformations with a model that contains splits (separate model information for each split group).

---

## TRANSFORMATIONS, MODEL, and DESTINATION Subcommands

The TRANSFORMATIONS, MODEL, and DESTINATION subcommands specify the file containing the transformations (created from a TMS BEGIN-TMS END block), the file containing the model specifications, and the destination for the merged file. All three of these subcommands are required.

- File specifications should be enclosed in quotation marks.
- The filename must be specified in full. No extension is supplied.
- It is recommended to include the extension *.xml* in the specification for the destination file.

---

## PRINT Subcommand

The PRINT subcommand is optional and specifies whether or not to print tables summarizing the variables in the merged XML file.

**SUMMARY.** *Print summary tables.* This is the default.

**NONE.** *Do not print summary tables.*

---

## Chapter 275. TREE

TREE is available in SPSS Statistics Professional Edition or the Decision Trees option.

*Note:* Square brackets used in the TREE syntax chart are required parts of the syntax and are not used to indicate optional elements. Equals signs (=) used in the syntax chart are required elements. All subcommands are optional.

```
TREE dependent_variable [level]

```

\*\* Default if subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

## Release History

### Release 13.0

- Command introduced.

### Release 18.0

- TARGETRESPONSE subcommand introduced.

## Example

```
TREE risk BY income age creditscore employment.
```

---

## Overview

The TREE procedure creates a tree-based model. It classifies cases into groups or predicts values of a dependent variable based on values of predictor variables. The procedure provides validation tools for exploratory and confirmatory classification analysis.

## Options

**Model.** You can specify the dependent (target) variable and one or more independent (predictor) variables. Optionally you can force one independent variable into the model as the first variable.

**Growing Method.** Four growing algorithms are available: CHAID (the default), Exhaustive CHAID, CRT, and QUEST. Each performs a type of recursive splitting. First, all predictors are examined to find the one that gives the best classification or prediction by splitting the sample into subgroups (nodes). The process is applied recursively, dividing the subgroups into smaller and smaller groups. It stops when one or more stopping criteria are met.

The four growing methods have different performance characteristics and features:

- CHAID chooses predictors that have the strongest interaction with the dependent variable. Predictor categories are merged if they are not significantly different with respect to the dependent variable (Kass, 1980).
- Exhaustive CHAID is a modification of CHAID that examines all possible splits for each predictor (Biggs et al., 1991).
- CRT is a family of methods that maximizes within-node homogeneity (Breiman et al., 1984).
- QUEST trees are computed rapidly, but the method is available only if the dependent variable is nominal. (Loh and Shih, 1997).

**Stopping Criteria.** You can set parameters that limit the size of the tree and control the minimum number of cases in each node.

**Validation.** You can assess how well your tree structure generalizes to a larger sample. Split-sample partitioning and cross-validation are supported. Partitioning divides your data into a training sample, from which the tree is grown, and a testing sample, on which the tree is tested. Cross-validation involves dividing the sample into a number of smaller samples. Trees are generated excluding the data from each subsample in turn. For each tree, misclassification risk is estimated using data for the subsample that was excluded in generating it. A cross-validated risk estimate is calculated as the average risk across trees.

**Output.** Default output includes a tree diagram and risk statistics. Classification accuracy is reported if the dependent variable is categorical. Optionally, you can obtain charts of gain- and profit-related measures as well as classification rules that can be used to select or score new cases. You can also save the model's predictions to the active dataset, including assigned segment (node), predicted class/value, and predicted probability.

#### Basic Specification

- The basic specification is a dependent variable and one or more independent variables.

#### Operations

- The tree is grown until one or more stopping criteria are met. The default growing method is CHAID.
- The type of model depends on the measurement level of the dependent variable. If the dependent variable is scale (continuous), a prediction model is computed. If it is categorical (nominal or ordinal), a classification model is generated.
- Measurement level determines allowable combinations of predictor values within a node. For ordinal and scale predictors, only adjacent categories/values may occur in a node. There are no restrictions on grouping of nominal categories.
- TREE honors the SET SEED value if split-sample model validation is requested.
- SPLIT FILE is ignored by the TREE procedure.
- If a WEIGHT variable is defined the weights are treated as replication weights. Fractional weights are rounded.

Note: Since measurement level can affect the results, if any variables (fields) have an unknown measurement level, an initial data pass will be performed to determine default measurement level for any variables with an unknown measurement level. For information on the criteria used to determine default measurement level, see SET SCALEMIN.

#### Syntax Rules

- The minimum specification is a dependent variable, the keyword BY and one or more independent variables.
- All subcommands are optional.
- Only a single instance of each subcommand is allowed.

- A keyword may be specified only once within a subcommand.
- Equals signs (=) shown in the syntax chart are required.
- Subcommand names and keywords must be spelled in full.
- Subcommands may be used in any order.
- SPLIT FILE is ignored by the TREE procedure.
- CHAID and Exhaustive CHAID: A categorical dependent variable may not have more than 126 categories. If the dependent variable is categorical, then the limit for a categorical predictor is also 126 categories.
- CRT: A nominal predictor may not have more than 32 categories.
- QUEST: If a predictor is nominal, then the limit for the dependent variable (which must be nominal) is 127 categories. A nominal predictor may not have more than 25 categories.

## Examples

TREE risk BY income age creditscore employment.

- A tree model is computed that estimates credit risk using an individual's income, age, credit score, and employment category as predictor variables.
- The default method, CHAID, is used to grow the tree.
- Since measurement level is not specified, it is obtained from the data dictionary for each model variable. If no measurement levels have been defined, numeric variables are treated as scale and string variables are treated as nominal.

```
TREE risk [o] BY income [o] age [s] creditscore [s] employment [n]
/METHOD TYPE=CRT
/VALIDATION TYPE=SPLITSAMPLE
/SAVE NODEID PREDVAL.
```

- A tree model is computed that estimates credit risk using an individual's income, age, credit score, and employment category as predictor variables.
- Age and credit score will be treated as scale variables, risk and income as ordinal, and employment category as nominal.
- The CRT method, which performs binary splits, is used to grow the tree.
- Split-sample validation is requested. By default, 50% of cases are assigned to the training sample. Remaining cases are used to validate the tree.
- Two variables are saved to the active dataset: node (segment) identifier and predicted value.

---

## Model Variables

The command name TREE is followed by the dependent variable, the keyword BY, and one or more independent variables.

### Dependent Variable

The dependent (target) variable must be the first specification on the TREE command.

- Only one dependent variable can be specified.
- The dependent variable cannot be the WEIGHT variable.

### Independent Variables

You can specify one or more independent (predictor) variables.

- ALL and T0 can be used in the independent variable list. ALL represents all variables in the active dataset. T0 refers to a range of variables in the active dataset.
- In general, if the independent variable list refers to the WEIGHT variable or a variable that is used elsewhere in the tree specification (e.g., dependent variable or cell weight variable), the variable is not

used as an independent variable. The exception is that scale variables used both in the independent variable list and the INTERVAL subcommand are not dropped from the independent variable list.

- Repeated instances of the same independent variable are filtered out of the list. For example, a b a c a is equivalent to a b c. Assuming that the active dataset contains variables *a*, *b*, and *c*, a ALL is also equivalent to a b c.

## Measurement Level

Optionally, a measurement level can be specified in square brackets following any model variable. The measurement level can be defined as scale ([S]), ordinal ([O]), or nominal ([N]). Categorical ([C]) is accepted as a synonym for nominal.

- If a measurement level is specified, it temporarily overrides the setting recorded in the data dictionary. If a measurement level is not specified for a variable, the dictionary setting is used.
- If a measurement level is not specified and no setting is recorded in the data dictionary, a numeric variable is treated as scale and a string variable is treated as nominal.
- If a string variable is defined as scale, a warning is issued and the variable is treated as nominal.
- A measurement level applies only to the variable that immediately precedes it in the variable list. For example, age income [S] and age T0 income [S] assign the scale level of measurement to *income* only.
- The keyword ALL followed by a measurement level specification will apply that measurement level to all independent variables.
- If a variable appears more than once in the independent variable list and the measurement level varies across instances, the measurement level specified for the last instance of the variable is used. For example, if ALL [S] z [N] is specified, *z* is treated as a nominal predictor.

## FORCE Keyword

- By default, the procedure evaluates each predictor variable for inclusion in the model. The optional FORCE keyword forces an independent variable into the model as the first split variable (the first variable used to split the root node into child nodes).
- The FORCE keyword must be followed by an equals sign (=) and a single variable.
- A measurement level may be specified in square brackets following the variable name. If the variable is also included in the independent variable list, the measurement level specified for the FORCE variable is used. If the variable has a specified measurement level in the independent list but no explicit measurement level on the FORCE specification, the defined measurement level for the variable is used.
- The variable cannot be the dependent variable or the WEIGHT variable.

### Example

```
TREE risk [o] BY income [o] age [s] creditscore [s] FORCE = gender [n].
```

- The independent variables *income*, *age*, and *creditscore* may or may not be included in the model, depending on how strongly they interact with the dependent variable *risk*.
- The independent variable *gender* will be included in the model regardless of the level of interaction with the dependent variable, and the root node will first be split into nodes for male and female before any other independent variables are considered.

---

## DEPCATEGORIES Subcommand

For categorical dependent variables, the DEPCATEGORIES subcommand controls the categories of the dependent variable included in the model and/or specifies target categories.

- By default, all valid categories are used in the analysis and user-missing values are excluded.
- There is no default target category.
- DEPCATEGORIES applies only to categorical dependent variables. If the dependent variable is scale, the subcommand is ignored and a warning is issued.

## Example

```
TREE risk [n] BY income [o] age [s] creditscore [s] employment [n]  
/DEPCATEGORIES USEVALUES=[VALID 99] TARGET=[1].
```

## USEVALUES keyword

USEVALUES controls the categories of the dependent variable included in the model.

- The keyword is followed by an equals sign (=) and a list of values enclosed in square brackets, as in: USEVALUES=[1 2 3].
- At least two values must be specified.
- Any cases with dependent variable values not included in the list are excluded from the analysis.
- Values can be string or numeric but must be consistent with the data type of the dependent variable. String and date values must be quoted. Date values must be consistent with the variable's print format.
- If the dependent variable is nominal, the list can include user-missing values. If the dependent variable is ordinal, any user-missing values in the list are excluded and a warning is issued.
- The keywords VALID and MISSING can be used to specify all valid values and all user-missing values respectively. For example, USEVALUES=[VALID MISSING] will include all cases with valid or user-missing values for the dependent variable.
- A warning is issued if a specified category does not exist in the data or in the training sample if split-sample validation is in effect. See the topic "VALIDATION Subcommand" on page 2007 for more information.

## TARGET Keyword

The TARGET keyword specifies categories of the dependent variable that are of primary interest in the analysis. For example, if you are trying to predict mortality, "death" would be defined as the target category. If you are trying to identify individuals with high or medium credit risk, you would define both "high credit risk" and "medium credit risk" as target categories.

- The keyword is followed by an equals sign (=) and a list of values enclosed in square brackets, as in: TARGET=[1].
- There is no default target category. If not specified, some classification rule options and gains-related output are not available.
- Values can be string or numeric but must be consistent with the data type of the dependent variable. String and date values must be quoted. Date values must be consistent with the variable's print format.
- If USEVALUES is also specified, the target categories must also be included (either implicitly or explicitly) in the USEVALUES list.
- If a target category is user-missing and the dependent variable is not nominal, the target category is ignored and a warning is issued.

---

## TREE Subcommand

The TREE subcommand allows you to specify the appearance of the tree or suppress it altogether. You can control its orientation, node contents, and the labeling of splits and nodes. Each keyword is followed by an equals sign (=) and the value for that keyword.

## Example

```
TREE risk BY income age creditscore  
/TREE DISPLAY=LEFTTORIGHT NODES=BOTH BRANCHSTATISTICS=NO.
```

## DISPLAY Keyword

The DISPLAY keyword controls the orientation the tree and can also be used to suppress the display of the tree. The following alternatives are available:

**TOPDOWN.** *Tree grows top down.* The root node appears at the top of the diagram. The tree grows downward. This is the default.

**LEFTTORIGHT.** *Tree grows from left to right.*

**RIGHTTOLEFT.** *Tree grows from right to left.*

**NONE.** *Tree diagram is not generated.*

**NODES** Keyword

The **NODES** keyword controls the contents of tree nodes.

**STATISTICS.** *Nodes display summary statistics.* This is the default. For a categorical dependent variable, percentages and counts are shown for each category as well as the total count and percentage. (Total percentage is the percentage of cases in the sample assigned to the node. If you specify prior probabilities, the total percentage is adjusted to account for those priors.)

For a scale dependent variable, nodes display mean, standard deviation, number of cases, and predicted value.

**CHART.** *Nodes display a summary chart.* For a categorical dependent variable, nodes display a bar chart of percentages for each category. For a scale dependent variable a histogram is shown that summarizes the distribution of the dependent variable.

**BOTH.** *Statistics and chart are shown.*

**BRANCHSTATISTICS** Keyword

The **BRANCHSTATISTICS** keyword controls whether branch (split) statistics are shown in the tree.

- For CHAID and Exhaustive CHAID, branch statistics include  $F$  value (for scale dependent variables) or chi-square value (for categorical dependent variables), as well as the significance value and degrees of freedom.
- For CRT, the improvement value is shown.
- For QUEST,  $F$ , the significance value, and degrees of freedom are shown for scale and ordinal independent variables. For nominal independent variables, chi-square, the significance value, and degrees of freedom are shown.

**YES.** *Branch statistics are displayed.* This is the default.

**NO.** *Branch statistics are not displayed.*

**NODEDEFS** Keyword

The **NODEDEFS** keyword controls whether descriptive labels are shown for each node. Node labels show the independent variable (predictor) values assigned to each node.

**YES.** *Node labels are displayed.* This is the default.

**NO.** *Node labels are not displayed.*

**SCALE** Keyword

The **SCALE** keyword controls the initial scale of the tree diagram.

**AUTO.** *Adjust the scale according to the number of nodes and levels of tree growth.* The scale is reduced automatically for large trees. This is the default.

**value.** *User-specified percentage value.* The value can be between 5 and 200, inclusive.

---

## PRINT Subcommand

The PRINT subcommand controls the display of optional tabular output. If the PRINT subcommand is specified, only the output explicitly requested will be produced. The subcommand name is followed by an equals sign (=) and one or more of the following options:

**MODELSUMMARY.** *Model summary.* The summary includes the method used, variables included in the model, and variables specified but not included in the model. Shown by default if subcommand omitted.

**IMPORTANCE.** *Predictor importance.* Ranks each independent (predictor) variable according to its importance to the model. IMPORTANCE can be specified only for the CRT method; otherwise it is ignored, and a warning is issued.

**SURROGATES.** *Surrogate predictors.* Lists surrogate predictors for each split in the tree. Each node is split based on an independent (predictor) variable; for cases in which the value for that predictor is missing, other predictors having high associations with the original predictor are used for classification. These alternative predictors are called surrogates. SURROGATES can be specified only for the CRT and QUEST methods. If surrogates are not computed, this keyword is ignored, and a warning is issued.

**CLASSIFICATION.** *Classification table.* Shows the number of cases classified correctly and incorrectly for each category of the dependent variable. A warning is issued if CLASSIFICATION is specified for a scale dependent variable. Shown by default for categorical dependent variables if subcommand omitted.

**RISK.** *Risk estimate and its standard error.* A measure of the tree's predictive accuracy. For categorical dependent variables, the risk estimate is the proportion of cases correctly classified after adjustment for prior probabilities and misclassification costs. For scale dependent variables, the risk estimate is within-node variance. Shown by default if subcommand omitted.

**CATEGORYSPEC.** *Cost, prior probability, score, and profit values used in the analysis.* This keyword is ignored if the dependent variable is a scale variable.

**TREETABLE.** *Tree model in tabular format.* Summary information for each node in the tree, including parent node number, branch statistics, independent variable value(s) for the node, mean and standard deviation for scale dependent variables or counts and percents for categorical dependent variables.

**CPS.** *Case processing summary.* Shown by default if subcommand omitted.

**NONE.** *None of the output controlled by the PRINT subcommand is generated.* An error occurs if any other PRINT keyword is specified with NONE.

---

## GAIN Subcommand

The GAIN subcommand controls the display of tables that summarize gain and index values and other measures that indicate the relative performance of nodes in the tree. You can obtain tables that summarize results by node, percentile group, or both. Each keyword is followed by an equals sign (=) and the value for that keyword.

### Example

```
TREE risk BY income age creditscore  
/GAIN SUMMARYTABLE=YES TYPE=[NODE, PTILE].
```

## SUMMARYTABLE Keyword

The SUMMARYTABLE keyword controls whether a summary table of index values is shown.

- For scale dependent variables, the table includes node number, number of cases, and mean value of the dependent variable.
- For categorical dependent variables, the table includes node number, number of cases, average profit, and ROI (return on investment) values.
- For categorical dependent variables, the summary table is not displayed unless profits have been specified on the PROFITS subcommand.

**YES.** *Display summary table.* This is the default for scale dependent variables if the subcommand is omitted or SUMMARYTABLE=NO is not included on the subcommand.

**NO.** *The summary table is not displayed.*

## CATEGORYTABLE Keyword

The CATEGORYTABLE keyword displays gain and index values for target categories of the dependent variable.

- The dependent variable must be categorical.
- Target categories must be specified on the DEPCATEGORIES subcommand.
- A separate table is generated for each target category.
- If the dependent variable is scale or no target categories are specified, the keyword is ignored and a warning is issued.

**YES.** *Display a table of gain statistics for each target category of the dependent variable.* The table includes percentage gain, response percent, and index percent (lift) by node or percentile group. This is the default.

**NO.** No category table is shown.

## TYPE Keyword

The TYPE keyword specifies the type of gain table(s) that are produced. The keyword is followed by an equals sign (=) and one or both of the following types enclosed in square brackets:

**NODE.** *Terminal nodes.* Rows of the table represent terminal nodes. This is the default.

**PTILE.** *Percentile.* Each row of the table summarizes a percentile group.

## SORT Keyword

The SORT keyword specifies how rows are sorted in all gain tables.

**DESCENDING.** *Rows are sorted in descending order of index value.* This is the default.

**ASCENDING.** *Rows are sorted in ascending order of index value.*

## INCREMENT Keyword

The INCREMENT keyword controls the width of percentile groupings for a percentile gain table (TYPE=[PTILE]).

- The default increment is 10, which gives decile intervals.

- You can specify one of the following percentage increments: 1, 2, 5, 10, 20, or 25. If a different value is specified, a warning is issued and the default increment is used.
- INCREMENT is ignored for node-by-node gain tables.

### CUMULATIVE Keyword

The CUMULATIVE keyword specifies whether node-by-node tables (TYPE=[NODE]) include cumulative statistics. It is ignored for percentile gain tables, which are always cumulative.

**YES.** *Cumulative statistics are displayed.* This is the default.

**NO.** *Cumulative statistics are not displayed.*

---

## PLOT Subcommand

The PLOT subcommand generates charts that may help you evaluate your tree model. The subcommand name is followed by an equals sign (=) and any or all of the following chart types:

**GAIN.** *Line chart of percentage gain.* The chart shows percentage gain for each target category of the dependent variable. GAIN is available only for categorical dependent variables with target categories defined on the DEPCATEGORIES subcommand.

**RESPONSE.** *Line chart of response.* The chart shows percentage of responses for each target category of the dependent variable. RESPONSE is available only for categorical dependent variables with target categories defined on the DEPCATEGORIES subcommand.

**INDEX.** *Line chart of index percent.* The chart shows index percent (lift). INDEX is available only for categorical dependent variables with target categories defined on the DEPCATEGORIES subcommand.

**MEAN.** *Line chart of mean value for scale dependent variables.* If the dependent variable is categorical, this keyword is ignored and a warning is issued.

**PROFIT.** *Line chart of average profit for categorical dependent variables.* If profits are not defined or the dependent variable is scale, this keyword is ignored and a warning is issued. See the topic "PROFITS Subcommand" on page 2013 for more information.

**ROI.** *Line chart of ROI (return on investment).* ROI is computed as the ratio of profits to expenses. If profits are not defined or the dependent variable is scale, this keyword is ignored and a warning is issued.

**IMPORTANCE.** *Bar chart of model importance by predictor.* IMPORTANCE is available for CRT models only; otherwise the keyword is ignored and a warning is issued.

### Example

```

TREE risk [o] BY income age creditscore
/METHOD TYPE=CRT
/DEPCATEGORIES TARGET=[1]
/PLOT=IMPORTANCE GAIN INDEX INCREMENT=5.

```

### INCREMENT Keyword

The INCREMENT keyword controls the width of percentile group charts.

- The keyword is followed by an equals sign (=) and one of the following values: 1, 2, 5, 10, 20, or 25. If a different value is specified a warning is issued and the default increment is used.
- INCREMENT is ignored for the predictor importance chart.

---

## RULES Subcommand

The RULES subcommand generates syntax that can be used to select or classify cases based on values of independent (predictor) variables.

- You can generate rules for all nodes, all terminal nodes, the top  $n$  terminal nodes, terminal nodes that correspond to the top  $n$  percent of cases, or nodes with index values that meet or exceed a cutoff value.
- Rules are available in three different forms: internal command syntax format, SQL, and generic (plain English pseudocode).
- You can specify an external destination file for the rules.
- Each keyword is followed by an equals sign (=) and the value for that keyword.

### Example

```
TREE risk [o] BY income age creditscore
/RULES NODES=TERMINAL SYNTAX=INTERNAL TYPE=SCORING
OUTFILE='/jobfiles/treescores.sps'.
```

### NODES Keyword

The NODES keyword specifies the scope of generated rules. Specify one of the following alternatives:

**TERMINAL.** *Generates rules for each terminal node.* This is the default.

**ALL.** *Generates rules for all nodes.* Rules are shown for all parent and terminal nodes.

For categorical dependent variables with defined target categories, the following additional alternatives are available:

**TOPN(value).** *Generates rules for the top  $n$  terminal nodes based on index values.* The number must be a positive integer, enclosed in parentheses. If the number exceeds the number of nodes in the tree, a warning is issued and rules are generated for all terminal nodes.

**TOPPCT(value).** *Generates rules for terminal nodes for the top  $n$  percent of cases based on index values.* The percent value must be a positive number greater than zero and less than 100, enclosed in parentheses.

**MININDEX(value).** *Generates rules for all terminal nodes with an index value greater than or equal to the specified value.* The value be a positive number, enclosed in parentheses.

### SYNTAX Keyword

The SYNTAX keyword specifies the syntax of generated rules. It determines the form of the selection rules in both output displayed in the Viewer and selection rules saved to an external file.

**INTERNAL.** *Command syntax language.* Rules are expressed as a set of commands that define a filter condition that can be used to select subsets of cases (this is the default) or as COMPUTE statements that can be used to score cases (with TYPE=SCORING).

**SQL.** *SQL.* Standard SQL rules are generated to select/extract records from a database or assign values to those records. The generated SQL rules do not include any table names or other data source information.

**GENERIC.** *Plain English pseudocode.* Rules are expressed as a set of logical "if...then" statements that describe the model's classifications or predictions for each node.

### TYPE Keyword

The TYPE keyword specifies the type of SQL or internal command syntax rules to generate. It is ignored if generic rules are requested.

**SCORING.** *Scoring of cases.* The rules can be used to assign the model's predictions to cases that meet node membership criteria. A separate rule is generated for each node within the scope specified on the NODES keyword. This is the default.

**SELECTION.** *Selection of cases.* The rules can be used to select cases that meet node membership criteria. For internal command syntax and SQL rules, a single rule is generated to select all cases within the scope specified on the NODES keyword.

*Note:* For internal command syntax or SQL rules with NODES=TERMINAL and NODES=ALL, TYPE=SELECTION will produce a rule that effectively selects every case included in the analysis.

#### SURROGATES Keyword

For CRT and QUEST, the SURROGATES keyword controls whether rules use surrogate predictors to classify cases that have missing predictor values. The keyword is ignored if the method is not CRT or QUEST or if generic rules are requested.

Rules that include surrogates can be quite complex. In general, if you just want to derive conceptual information about your tree, exclude surrogates. If some cases have incomplete predictor data and you want rules that mimic your tree, include surrogates.

**INCLUDE.** *Include surrogates.* Surrogate predictors are used in generated rules. This is the default.

**EXCLUDE.** *Exclude surrogates.* Rules exclude surrogate predictors.

#### LABELS Keyword

The LABELS keyword specifies whether value and variable labels are used in generic decision rules.

- By default, any defined value and variable labels are used. When labels aren't available, values and variable names are used.
- LABELS is ignored for SQL and internal command syntax rules.

**YES.** *Any defined value and variable labels are used in generic rules.* This is the default.

**NO.** *Values and variable names are used instead of labels.*

#### OUTFILE Keyword

OUTFILE writes the rules to an external text file.

- The keyword is followed by an equals sign (=) and a file specification enclosed in quotes.
- If the file specification includes a path, an error will result if the specified directory/folder location doesn't exist.
- For command syntax, the file can be used as a command syntax file in both interactive and batch modes.
- For SQL syntax, the generated SQL does not include any table names or other data source information.
- OUTFILE is ignored if NODES=NONE, and a warning is issued.

---

## SAVE Subcommand

The SAVE subcommand writes optional model variables to the active dataset.

- Specify one or more model variables.
- Optionally, you can specify new variable names in parentheses after each model variable name. The names must be unique, valid variable names.

- If new names are not specified, or if specified names are not valid variable names, unique variable names are automatically generated using the model variable name with a suffix.

**NODEID.** *Node identifier.* The terminal node to which a case is assigned. The value is the tree node number.

**PREDVAL.** *Predicted value.* The class or value predicted by the model.

**PREDPROB.** *Predicted probability.* The probability associated with the model's prediction. One variable is saved for each category of the dependent variable. If you specify an optional variable name, it is used as a root for generated variable names. PREDPROB is ignored if the dependent variable is a scale variable. Probabilities are saved only for the first 126 categories of the dependent variable when the CRT or QUEST algorithms are used.

**ASSIGNMENT.** *Sample assignment.* The variable indicates whether a case was used in the training or testing sample. Cases in the training sample have a value of 1, and cases in the testing sample have a value of 0. ASSIGNMENT is ignored if split-sample validation is not specified.

#### Example

```
TREE risk [o] BY income age creditscore
/SAVE NODEID(node_number) PREDVAL(predicted_value).
```

---

## METHOD Subcommand

The METHOD subcommand specifies the growing method and optional parameters. Each keyword is followed by an equals sign (=) and the value for that keyword.

#### Example

```
TREE risk [o] BY income age creditscore
/METHOD TYPE=CRT MAXSURROGATES=2 PRUNE=SE(0).
```

#### TYPE Keyword

TYPE specifies the growing method. For CRT and QUEST, splits are always binary. CHAID and Exhaustive CHAID allow multiway splits.

**CHAID.** *Chi-squared Automatic Interaction Detection.* At each step, CHAID chooses the independent (predictor) variable that has the strongest interaction with the dependent variable. Categories of each predictor are merged if they are not significantly different with respect to the dependent variable. This is the default method.

**EXHAUSTIVECHAID.** *Exhaustive CHAID.* A modification of CHAID that examines all possible ways of merging predictor categories.

**CRT.** *Classification and Regression Trees.* CRT splits the data into segments that are as homogeneous as possible with respect to the dependent variable.

**QUEST.** *Quick, Unbiased, Efficient Statistical Tree.* A method that is fast and avoids other methods' bias in favor of predictors with many categories. QUEST can be specified only if the dependent variable is nominal. An error occurs if the dependent variable is ordinal or scale.

#### MAXSURROGATES Keyword

CRT and QUEST can use surrogates for independent (predictor) variables. For cases in which the value for that predictor is missing, other predictors having high associations with the original predictor are

used for classification. These alternative predictors are called surrogates. The MAXSURROGATES keyword specifies the maximum number of surrogate predictors to compute.

If the growing method is CHAID or EXHAUSTIVECHAID, this keyword is ignored and a warning is issued.

**AUTO.** *The maximum is the number of independent variables minus one.* This is the default.

**value.** *User-specified value.* The value must be a non-negative integer that is less than the number of independent variables in the model. If you don't want to use surrogates in the model, specify MAXSURROGATES=0. If the value equals or exceeds the number of independent variables, the setting is ignored and a warning is issued.

#### PRUNE Keyword

For CRT and QUEST, the tree can be automatically pruned. Pruning can help avoid creating a tree that overfits the data. If you request pruning, the tree is grown until stopping criteria are met. Then it is trimmed automatically according to the specified criterion.

If the growing method is CHAID or EXHAUSTIVECHAID, PRUNE is ignored and a warning is issued.

**NONE.** The tree is not pruned. This is the default.

**SE(value).** *Prune tree using standard error criterion.* The procedure prunes down to the smallest subtree with a risk value within a specified number of standard errors of that of the subtree with the minimum risk. You can specify the number of standard errors in parentheses. The default is 1. The value must be nonnegative. To obtain the subtree with the minimum risk, specify 0.

---

## GROWTHLIMIT Subcommand

The GROWTHLIMIT subcommand specifies stopping criteria that limit the size of the tree. Each keyword is followed by an equals sign (=) and the value for that keyword.

#### Example

```
TREE risk [o] BY income age creditscore  
  /METHOD TYPE=CRT  
  /GROWTHLIMIT MAXDEPTH=4 MINCHILDSIZE=10.
```

#### MAXDEPTH Keyword

MAXDEPTH specifies the maximum number of levels of growth beneath the root node. You can change the maximum depth to adjust the size of the tree.

**AUTO.** *Three levels for CHAID and Exhaustive CHAID, five levels for CRT and QUEST.* This is the default.

**value.** *User-specified value.* The value must be a positive integer.

#### MINPARENTSIZE Keyword

MINPARENTSIZE specifies the minimum number of cases required to split a node. Nodes with fewer cases are not split. You can use this setting to avoid splitting nodes that have few cases.

- The size value must be a positive integer. The default is 100.
- MINPARENTSIZE must be greater than MINCHILDSIZE.

#### MINCHILDSIZE Keyword

MINCHILDSIZE specifies the minimum number of cases in any child node. A node will not be split if any of the resulting child nodes would have fewer cases than the specified value.

- The size value must be a positive integer. The default is 50.
- MINCHILDSIZE must be less than MINPARENTSIZE.

#### MINIMPROVEMENT Keyword

For CRT, you can use MINIMPROVEMENT to specify the minimum decrease in impurity. The CRT growing method attempts to maximize within-node homogeneity. In other words, a terminal node in which all cases have the same value for the dependent variable is a homogeneous, "pure" node. A node is not split if impurity would decrease less than the specified value.

The improvement value must be positive value. The default is 0.0001. As the value increases, the number of nodes in the tree tends to decrease.

---

## VALIDATION Subcommand

The VALIDATION subcommand allows you to assess how well your tree structure generalizes to a larger population.

- Split-sample validation and cross-validation are available.
- By default, validation is not performed.
- If you want to be able to reproduce validated results later, use SET SEED before the TREE procedure to initial the random number seed.

Each keyword in the subcommand is followed by an equals sign (=) and the value for that keyword.

#### Example

```
TREE risk [o] BY income age creditscore  
/VALIDATION TYPE=SPLITSAMPLE(25) OUTPUT=TESTSAMPLE.
```

#### TYPE Keyword

**NONE.** *The tree model is not validated.* This is the default.

**SPLITSAMPLE(percent).** *Split-sample validation.* The model is generated using a training sample and tested on a hold-out sample. The value or variable specified in parentheses determines the training sample size. Enter a percent value greater than 0 and less than 100, or a numeric variable, the values of which determine how cases are assigned to the training or testing samples: cases with a value of 1 for the variable are assigned to the training sample, and all other cases are assigned to the testing sample. The variable cannot be the dependent variable, weight variable, influence variable or a forced independent variable. See the topic "INFLUENCE Subcommand" on page 2013 for more information. *Note:* Split-sample validation should be used with caution on small data files (data files with a small number of cases). Small training sample sizes may yield poor models since there may not be enough cases in some categories to adequately grow the tree.

**CROSSVALIDATION (value).** *Crossvalidate the tree model.* The sample is divided into a number of subsamples, or **folds**. Tree models are then generated excluding the data from each subsample in turn. The first tree is based on all of the cases *except* those in the first sample fold, the second tree is based on all of the cases except those in the second sample fold, and so on. For each tree, misclassification risk is estimated by applying the tree to the subsample excluded in generating it. Specify a positive integer between 2 and 25 in parentheses. The higher the value, the fewer the number of cases excluded for each tree model. Crossvalidation produces a single, final tree model. The cross-validated risk estimate for the final tree is calculated as the average of the risks for all of the trees. CROSSVALIDATION is ignored with a warning if FORCE is also specified.

## OUTPUT Keyword

With split-sample validation, the OUTPUT keyword controls the output generated. This setting is ignored if SPLITSAMPLE is not specified.

**BOTHSAMPLES.** *Output is produced for training and test samples.* This is the default. Choose this option if you want to compare results for each partition.

**TESTSAMPLE.** *Output is produced for the test sample only.* Choose this option if you want validated results only.

---

## CHAID Subcommand

The CHAID subcommand sets parameters for a CHAID tree. Except where noted, all parameters also apply to Exhaustive CHAID. It is ignored for CRT and QUEST trees, and an warning is issued.

Each keyword in the subcommand is followed by an equals sign (=) and the value for that keyword.

### Example

```
TREE risk [o] BY income age creditscore
/METHOD TYPE=CHAID
/CHAID ALPHASPLIT=.01 INTERVALS=age income (10) creditscore (5).
```

## ALPHASPLIT Keyword

The ALPHASPLIT keyword specifies the significance level for splitting of nodes. An independent variable will not be used in the tree if significance level for the split statistic (chi-square or *F*) is less than or equal to specified value.

- Specify a value greater than zero and less than 1.
- The default value is 0.05.

## ALPHAMERGE Keyword

The ALPHAMERGE keyword specifies the significance level for merging of predictor categories. Small values tend to result in a greater degree of merging.

- Specify a value greater than zero and less than or equal to 1.
- The default value is 0.05.
- If you specify a value of 1, predictor categories are not merged.
- ALPHAMERGE is available only for the CHAID method. For Exhaustive CHAID, the keyword is ignored, and a warning is issued.

## SPLITMERGED Keyword

The SPLITMERGED keyword specifies whether predictor categories that are merged in a CHAID analysis are allowed to be resplit.

**NO.** *Merged predictor categories cannot be resplit.* This is the default.

**YES.** *Merged predictor categories can be resplit.*

## CHISQUARE Keyword

For nominal dependent variables, the CHISQUARE keyword specifies the chi-square measure used in CHAID analysis. For ordinal and scale dependent variables, the keyword is ignored and a warning is issued.

**PEARSON.** *Pearson chi-square.* This is the default.

**LR.** *Likelihood-ratio chi-square.*

#### CONVERGE Keyword

For nominal and ordinal dependent variables, the CONVERGE keyword specifies the convergence value for estimation of the CHAID model.

- Specify a value greater than zero and less than 1.
- The default value is 0.05.
- If the dependent variable is nominal or scale, this keyword is ignored, and a warning is issued.

#### MAXITERATIONS Keyword

For nominal and ordinal dependent variables, the MAXITERATIONS keyword specifies the maximum number of iterations for estimation of the CHAID model.

- Specify a positive integer value.
- The default value is 100.
- If the dependent variable is nominal or scale, this keyword is ignored, and a warning is issued.

#### ADJUST Keyword

The ADJUST keyword specifies how to adjust significance values for multiple comparisons.

**BONFERRONI.** *Significance values are adjusted using the Bonferroni method.* This is the default.

**NONE.** *Significance values are not adjusted.*

#### INTERVALS Keyword

In CHAID analysis, scale independent (predictor) variables are always banded into discrete groups (for example, 0-10, 11-20, 21-30, and so on) prior to analysis. You can use the INTERVALS keyword to control the number of discrete intervals for scale predictors.

- By default, each scale predictor is divided into 10 intervals that have approximately equal numbers of cases.
- The INTERVALS keyword is ignored if the model contains no scale independent variables.

**value.** *The specified value applies to all scale predictors.* For example: INTERVALS=5. The value must be a positive integer less than or equal to 64.

**varlist (value).** *The specified value applies to the preceding variable list only.* Specify a list of variables followed by the number of intervals in parentheses. Multiple lists can be specified. For example: INTERVALS=age income (10) creditscore (5). The value must be a positive integer less than or equal to 64.

For the varlist (value) form:

- If a variable in the list is not a scale variable and/or the variable is not specified as an independent variable, the interval specification is ignored for that variable, and a warning is issued.
- If a variable appears in more than one list, the last specification is used.
- For any scale variables not include in the list(s), the default number of intervals (10) is used.

---

## CRT Subcommand

The CRT subcommand sets parameters for the CRT method. For other tree growing methods, the subcommand is ignored, and a warning is issued.

Each keyword in the subcommand is followed by an equals sign (=) and the value for that keyword.

### Example

```
TREE risk [o] BY income age creditscore
/METHOD TYPE=CRT
/CRT IMPURITY=TWOING MINIMPROVEMENT=.001.
```

### IMPURITY Keyword

For categorical dependent variables, the IMPURITY keyword specifies the impurity measure used.

**GINI.** Gini is based on squared probabilities of membership for each category of the dependent variable. It reaches its minimum (zero) when all cases in a node fall into a single category. This is the default.

**TWOING.** Twoing groups categories of the dependent variable into the two best subclasses and computes the variance of the binary variable indicating the subclass to which each case belongs.

**ORDEREDTWOING.** A variant of twoing for ordinal dependent variables in which only adjacent classes can be combined. This method is available only for ordinal dependent variables only.

For scale dependent variables the least squared deviation (LSD) measure of impurity is used. It is computed as the within-node variance, adjusted for any frequency weights or influence values.

### MINIMPROVEMENT Keyword

MINIMPROVEMENT specifies the minimum decrease in impurity for CRT trees. A node is not split if impurity would decrease less than the specified value.

- The default value is 0.0001.
- Specify a positive value. Large improvement values tend to result in smaller trees.

---

## QUEST Subcommand

The ALPHASPLIT keyword on the QUEST subcommand sets the alpha criterion for selection of independent (predictor) variables. Specify a value greater than 0 and less than 1. The default is 0.05.

### Example

```
TREE risk [n] BY income age creditscore
/METHOD TYPE=QUEST
/QUEST ALPHASPLIT=.01.
```

---

## COSTS Subcommand

For categorical dependent variables, the COSTS subcommand allows you to specify penalties for misclassifying cases.

- Costs are used in node assignment and risk estimation for all trees.
- They also affect the tree-growing process for all trees except QUEST trees and CRT trees that use a twoing measure. To include cost information in the tree-growing process for such trees, use adjusted priors. See the topic “PRIORS Subcommand” on page 2011 for more information.
- The COST subcommand is ignored if the dependent variable is scale, and a warning is issued.

The subcommand name is followed by an equals sign (=) and one of the following alternatives:

**EQUAL.** *Misclassification costs are equal across categories of the dependent variable.* Cost is set to 1 for all possible misclassifications. This is the default.

**CUSTOM.** *User-specified costs.* Use this to specify costs for one or more combinations of actual and predicted categories. Any combination for which a cost is not specified defaults to 1.

## Custom Costs

For each combination of dependent variable categories:

- Specify the actual category, predicted category, and misclassification cost, in that order.
- The cost value must be enclosed in square brackets.
- At least one cost specification must be provided, but you don't have to specify all possible combinations. Any combination for which a cost is not specified defaults to 1.
- If multiple cost specifications are provided for a particular combination of predicted and actual categories, the last one is used.
- Costs specified for categories that do not exist in the data are ignored, and a warning is issued.
- Cost values must be non-negative.
- Category values must be consistent with the data type of the dependent variable. String and date values must be quoted. Date values must be consistent with the variable's print format.
- Correct classifications, where the predicted category and the actual category match, are always assigned a cost of zero. A warning is issued if a nonzero cost is specified for a correct classification. For example, `COSTS CUSTOM=1 1 [3]` would be ignored and the cost would be set to 0.

### Example

```
TREE risk [0] BY age income employment
/COSTS CUSTOM=3 2 [2]
3 1 [8].
```

- Assuming that the dependent variable is coded 1=*low*, 2=*medium*, and 3=*high*, the cost of misclassifying a high-risk individual as medium risk is 2.
- The cost of misclassifying a high-risk individual as low risk is 8.
- All other misclassifications, such as classifying a medium-risk individual as high risk, are assigned the default cost, 1.
- Correct classifications such as classifying a high-risk individual as high risk are always assigned a cost of 0.

---

## PRIORS Subcommand

For CRT and QUEST trees with categorical dependent variables, the PRIORS subcommand allows you to specify prior probabilities of group membership. **Prior probabilities** are estimates of the overall relative frequency for each target category of the dependent variable prior to knowing anything about the values of the independent (predictor) variables. Using prior probabilities helps correct any tree growth caused by data in the sample that is not representative of the entire population.

- If the growing method is CHAID or Exhaustive CHAID, this subcommand is ignored and a warning is issued.
- If the dependent variable is scale, this subcommand is ignored and a warning is issued.

**FROMDATA.** *Obtain priors from the training sample.* Use this setting if the distribution of groups in the training sample is representative of the population distribution. This is the default. If you have not specified a training sample using the VALIDATION subcommand, then the distribution of values in the entire data file is used.

**EQUAL.** *Equal priors across categories.* Use this if categories of the dependent variable are represented equally in the population. For example, if there are four categories, approximately 25% of the cases are in each category.

**CUSTOM.** *User-specified prior probabilities.* For each category of the dependent variable, specify the category followed by a non-negative prior probability value enclosed in square brackets.

- Prior probabilities must be specified for all values of the dependent variable included in the analysis (either all non-missing values found in the data or all values defined on the DEPCATEGORIES subcommand).
- The values must be non-negative.
- The specified category values must be consistent with the data type of the dependent variable. String and date values must be quoted. Date values must be consistent with the variable's print format.
- If you specify the same category more than once, the last one is used.
- A warning is issued if you specify a prior probability for a category that does not exist in the data or in the training sample if split-sample validation is in effect. See the topic "VALIDATION Subcommand" on page 2007 for more information.
- Prior probability values are "normalized" to relative proportions before the tree is grown.

#### Example

```
TREE risk [o] BY age income employment  
/METHOD TYPE=CRT  
/PRIORS CUSTOM= 1 [30] 2 [75] 3 [45].
```

The prior probabilities of 30, 75, and 45 are normalized to proportions of 0.2, 0.5, and 0.3, respectively.

#### ADJUST Keyword

The ADJUST keyword specifies whether prior probabilities are adjusted to take into account misclassification costs.

**NO.** *Priors are unadjusted.* This is the default.

**YES.** *Priors are adjusted to take into account misclassification costs.*

---

## SCORES Subcommand

For CHAID or Exhaustive CHAID trees with ordinal dependent variables, the SCORES subcommand allows you to specify scores that are used to scale the dependent variable. By default, scores are assigned in sorted value order: the first category is assigned a score of 1, the second category is assigned a score of 2, and so forth.

- If the growing method is CRT or QUEST, this subcommand is ignored, and a warning is issued.
- If the dependent variable is nominal or scale, this subcommand is ignored, and a warning is issued.

The subcommand name is followed by an equals sign (=) and one of the two following alternatives:

**EQUALINCREMENTS.** *Scores are ordinal ranks.* The lowest category of the dependent variable is assigned a score of 1, the next highest category is assigned a score of 2, and so on. This is the default.

**CUSTOM.** *User-specified scores.* For each category of the dependent variable, specify the category value followed by a score in square brackets.

- Scores must be numeric and unique. You cannot assign the same score to more than one category.
- Scores must be specified for all values of the dependent variable included in the analysis (either all non-missing values found in the data or all values defined on the DEPCATEGORIES subcommand).
- Category values must be consistent with the data type of the dependent variable. String and date values must be quoted. Date values must be consistent with the variable's print format.
- If you specify multiple score values for the same category value, the last one is used.

- A warning is issued if you specify a score for a category that does not exist in the data or in the training sample if split-sample validation is in effect. See the topic “VALIDATION Subcommand” on page 2007 for more information.

#### Example

```
TREE income [o] BY age employment gender region
/SCORES CUSTOM=1 [1] 2 [2.5] 3 [8].
```

- By default, the CHAID method is used to grow the tree.
- CUSTOM contains one score specification for each category of the ordinal dependent variable.
- Category 1 is assigned a score of 1; category 2 is assigned a score of 2.5; and category 3 is assigned a score of 8. In other words, scores are used to rescale income so there is a smaller gap between categories 1 and 2 than between 2 and 3.

---

## PROFITS Subcommand

For categorical dependent variables, the PROFITS subcommand allows you to assign revenue and expense values to levels of the dependent variable. Revenues and expenses are used in tables and charts that summarize expected profits and return on investment (ROI). Profit is computed as revenue minus expense.

If the dependent variable is scale, this subcommand is ignored and warning is issued.

- The subcommand name is followed by an equals sign (=), the keyword CUSTOM, and a list of dependent variable values, each followed by a pair of values, representing revenues and expenses respectively, enclosed in square brackets.
- Revenue and expense values must be numeric and must be specified for all values of the dependent variable included in the analysis (either all non-missing values found in the data or all values defined on the DEPCATEGORIES subcommand).
- Category values must be consistent with the data type of the dependent variable. String and date values must be quoted. Date values must be consistent with the variable’s print format.
- If you specify the same category value more than once, the expense and revenue values for the last one are used.
- A warning is issued if you specify a category of the dependent variable that does not exist in the data or in the training sample if split-sample validation is in effect. See the topic “VALIDATION Subcommand” on page 2007 for more information.

#### Example

```
TREE income [o] BY age employment gender region
/PROFITS CUSTOM=1 [.1 .25]
                2 [.5 .25]
                3 [15 .25].
```

- Expected revenue and expense values are defined for each income category.
- Revenues vary across groups. For group 1, the lowest income group, expected revenue is 0.10 per individual. For group 2, the middle income group, expected revenue is 0.50 per individual. For group 3, the high income group, expected revenue is 15 per individual.
- The matrix specifies a fixed expense for each group. For each group, expected expense is 0.25 per person.

---

## INFLUENCE Subcommand

The INFLUENCE subcommand defines an optional influence variable that defines how much influence a case has on the tree-growing process. Cases with lower influence values have less influence, cases with higher values have more.

- The variable must be numeric.
- The dependent variable cannot be used as the influence variable.

- The weight variable (see the WEIGHT command) cannot be used as the influence variable.
- For QUEST, this subcommand is ignored and a warning is issued.

---

## OUTFILE Subcommand

The OUTFILE subcommand writes the tree model to an XML file.

**TRAININGMODEL='filespec'**. Writes the model to the specified file. For split-sample validated trees, this is the model for the training sample.

**TESTMODEL='filespec'**. Writes the model for the test sample to the specified file. Available only with /VALIDATION TYPE=SPLITSAMPLE. Ignored for unvalidated and cross-validated models.

### Example

```
TREE income [o] BY age employment gender region  
/OUTFILE TRAININGMODEL='/myfolder/model.xml'.
```

---

## MISSING Subcommand

The MISSING subcommand controls the handling of nominal, user-missing, independent (predictor) variable values.

- Handling of ordinal and scale user-missing independent variable values varies between growing methods.
- By default, if the values of all independent variables are system- or user-missing, the case is excluded.
- Handling of nominal dependent variables is controlled by the DEPCATEGORIES subcommand.
- For the dependent variable, cases with system-missing or user-missing ordinal or scale values are always excluded.

### NOMINALMISSING Keyword

The NOMINALMISSING keyword controls the treatment of user-missing values of nominal independent (predictor) variables.

**MISSING.** Handling of user-missing values of nominal predictor variables depends on the growing method. This is the default.

**VALID.** Treat user-missing values of nominal independent variables as valid values. User-missing values of nominal independent variables are treated as ordinary values in tree growing and classification.

### Method-Dependent Rules

If some, but not all independent variable values are system- or user-missing:

- For CHAID and Exhaustive CHAID, system- and user-missing scale and ordinal independent variable values are included in the tree-growing process as a "floating" category that is allowed to merge with other categories in tree nodes. By default, nominal user-missing values are also handled in this fashion.
- For CRT and QUEST, cases with missing independent variable values are excluded from the tree-growing process but are classified using surrogate predictors, if surrogates are included in the method. By default, nominal user-missing values are also handled in this fashion.

### Weight Variables

If the analysis uses frequency weights or an influence variable, all cases with zero, negative, system-missing, or user-missing values of either variable are excluded from the analysis.

---

## TARGETRESPONSE Subcommand

The TARGETRESPONSE subcommand displays a description of the attributes of each terminal node and the percentage of cases in that node with the specified target value. The output includes a table of percentages and cumulative percentages of the target value in each terminal node and a chart of cumulative response rates.

The TARGETRESPONSE subcommand is only executed under the following conditions:

- The subcommand must be explicitly specified. There is no default setting.
- The target variable must be nominal or ordinal.
- Target values must be specified on the DEPCATEGORIES subcommand. See the topic “DEPCATEGORIES Subcommand” on page 1997 for more information.

The results are sorted in descending order of percentages. The table can be color-coded based on a specified cumulative minimum percentage, with rows at or above the minimum colored green and rows below the minimum colored red. The minimum value is also displayed as a reference line on the chart. If more than one target value is specified, a separate table and chart are displayed for each target value.

You must specify one of the following alternatives:

**RATE=NONE.** *No minimum percentage.* The table is not color-coded, and there is no reference line on the chart.

**RATE=value.** *Use the specified percentage value as the minimum.* The value must be greater than 0 and less than 100.

### Special Considerations

- The terminal node attributes displayed in the table represent a general description. They are not a substitute for precise rules. See the topic “RULES Subcommand” on page 2003 for more information.
- For the CHAID and Exhaustive CHAID methods, the attributes displayed in the table do not include any missing data conditions, and terminal nodes that represent the missing categories of a predictor are not included in the output. See the topic “MISSING Subcommand” on page 2014 for more information.
- For the CRT and QUEST methods, surrogate values are not included in the list of attribute conditions. See the topic “METHOD Subcommand” on page 2005 for more information.

---

## Chapter 276. TSAPPLY

TSAPPLY is available in SPSS Statistics Professional Edition or the Forecasting option.

*Note:* Square brackets that are shown in the TSAPPLY syntax chart are not used to indicate optional elements. Where indicated, they are required parts of syntax when a list of values is specified, but they may be omitted when a single value is specified. Equals signs (=) that are used in the syntax chart are required elements. The MODEL subcommand is required. All other subcommands are optional.

TSAPPLY

Global subcommands:

```
/MODELSUMMARY PRINT=[MODELFIT** RESIDACF RESIDPACF NONE]
                PLOT=[SRSQUARE RSQUARE RMSE MAPE MAE MAXAPE
                     MAXAE NORMBIC RESIDACF RESIDPACF]

/MODELSTATISTICS DISPLAY={YES**}
                  {NO }
                MODELFIT=[SRSQUARE** RSQUARE RMSE MAPE MAE
                          MAXAPE MAXAE NORMBIC]

/MODELDETAILS PRINT=[PARAMETERS RESIDACF RESIDPACF FORECASTS]
                PLOT=[RESIDACF RESIDPACF]

/SERIESPLOT OBSERVED FORECAST FIT FORECASTCI FITCI

/OUTPUTFILTER DISPLAY={ALLMODELS**
                     {[BESTFIT({N=integer }) WORSTFIT({N=integer })]}
                     {PCT=percent} {PCT=percent}}
                MODELFIT={SRSQUARE**
                          {RSQUARE }
                          {RMSE }
                          {MAPE }
                          {MAE }
                          {MAXAPE }
                          {MAXAE }
                          {NORMBIC }}

/SAVE PREDICTED(rootname)
      LCL(rootname)
      UCL(rootname)
      NRESIDUAL(rootname)

/AUXILIARY REESTIMATE={NO**} CILEVEL={95** } MAXACFLAGS={24** }
                  {YES } {number} {integer}
                SEASONLENGTH=integer

/MISSING USERMISSING={EXCLUDE**}
                  {INCLUDE }
```

MODEL (local subcommand):

```
/MODEL FILE=file {DROP=['ModelID' 'ModelID' ...]}
                {KEEP=['ModelID' 'ModelID' ...]}
        OUTFILE=file
        OUTPML=file
```

\*\*Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

Release History

Release 14.0

- Command introduced.

## Example

```
PREDICT THRU YEAR 2006 MONTH 6.  
TSAPPLY  
  /MODELDETAILS PRINT=FORECASTS  
  /MODEL FILE='/models/models.xml'.
```

---

## Overview

The TSAPPLY procedure loads existing time series models from an external file and applies them to data. Models are generated by using the TSMODEL procedure. You can use TSAPPLY to obtain forecasts for series for which new or revised data are available.

### Options

**Models.** By default, parameter estimates saved in the model file are used to produce forecasts. Optionally, model parameters can be reestimated. Reestimation of model parameters has no effect on the model structure. For example, an ARIMA(1,0,1) model will remain so, but the autoregressive and moving-average parameters will be reestimated by using the data in the active dataset. Outliers, if any, are always taken from the model file.

**Output.** TSAPPLY offers the same output as the TSMODEL procedure. However, autocorrelations and partial autocorrelations are available only if model parameters are reestimated.

**Saved Variables.** You can save forecasts and their confidence intervals to the active dataset. Fit values and noise residuals are available if model parameters are reestimated.

**Missing Values.** You can control whether user-missing values are treated as valid or invalid values.

### Basic Specification

- The basic specification is a MODEL subcommand that specifies a model file. By default, all models in the file are loaded.
- Default output includes a summary of the distribution of goodness of fit across loaded models and a table of stationary *R*-square, Ljung-Box *Q*, and number of outliers by model.

### Syntax Rules

- The following subcommands are global: MODELSUMMARY, MODELSTATISTICS, MODELDETAILS, SERIESPLOT, OUTPUTFILTER, SAVE, AUXILIARY, and MISSING.
- Each global subcommand is optional, may be used only once, and must appear before any MODEL subcommand.
- The MODEL subcommand must be used at least once.
- An error occurs if a keyword or attribute is specified more than once within a subcommand.
- All subcommands other than MODEL are optional.
- Subcommand names and keywords must be spelled in full.
- Equals signs (=) that are shown in the syntax chart are required.
- An error is issued if any subcommand is empty.

### Operations

- Models are applied to variables in the active dataset with the same names as the variables that are specified in the model.
- TSAPPLY honors time intervals and periodicity specified with the DATE command.
- The procedure verifies that date variables that are implied by the current date specification exist and that their values coincide with the date specification within the estimation period. If the data are filtered, values of date variables are verified within the filtered subset of data.

- If you choose to reestimate model parameters, reestimation happens within the currently active USE period. If the model has outliers, the outlier periods must be inside the effective USE period. The USE period is ignored if model parameters are not reestimated.
- The PREDICT command defines the end of the forecast period for tables, charts, and model variables that are produced by TSAPPLY.
- TSAPPLY does not honor the following commands: MODEL NAME, SAVE MODEL, and READ MODEL.
- TSAPPLY does not honor TSET. It does, however, provide options for missing-value handling, setting the width of confidence intervals, and setting the maximum number of lags displayed for autocorrelations.
- The TDISPLAY command does not display models that are saved by using TSAPPLY.

#### Limitations

- An error occurs if SPLIT FILE is in effect.
- WEIGHT is ignored with a warning.

---

## Examples

This section provides simple examples that are designed to get you started with the TSAPPLY procedure. Further examples that are specific to each subcommand are provided in the subcommand topics.

### Forecasting

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /MODELDETAILS PRINT=FORECASTS
  /MODEL FILE='/models/models.xml'.
```

- The PREDICT command is used to specify the forecast period for the TSAPPLY procedure.
- The MODELDETAILS subcommand specifies that the output includes a table containing the forecasts.
- The MODEL subcommand specifies that all models in the file */models/models.xml* will be applied to the active dataset. Models are applied to variables in the active dataset with the same names as the variables that are specified in the model.
- Forecasts are created by using the model parameters from *models.xml*, without reestimating any of those parameters. This behavior is the default behavior.

### Forecasting with Reestimated Model Parameters

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /MODELDETAILS PRINT=FORECASTS
  /AUXILIARY REESTIMATE=YES
  /MODEL FILE='/models/models.xml'
  OUTFILE='/models/models_updated.xml'.
```

- The AUXILIARY subcommand specifies that model parameters for all models in */models/models.xml* will be reestimated prior to forecasting. Model parameters are reestimated by using the data in the active dataset.
- Reestimation of model parameters has no effect on the model structure. For example, an ARIMA(1,0,1) model will remain so, but the autoregressive and moving-average parameters will be reestimated.
- The OUTFILE keyword specifies that the reestimated models will be saved to the file */models/models\_updated.xml*.

### Applying a Selected Subset of Models

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /MODELDETAILS PRINT=FORECASTS
  /MODEL FILE='/models/models.xml' KEEP=['CustomArima_1'].
```

- The KEEP keyword specifies that only the model named *CustomArima\_1* will be applied to the active dataset. All other models in */models/models.xml* will be excluded.

```
PREDICT THRU YEAR 2006 MONTH 6.  
TSAPPLY  
/MODELDETAILS PRINT=FORECASTS  
/MODEL FILE='/models/models.xml' DROP=['Expert_1' 'Expert_2'].
```

- The DROP keyword specifies that the models named *Expert\_1* and *Expert\_2* will be excluded. All other models in */models/models.xml* will be applied to the active dataset.

---

## Goodness-of-Fit Measures

The following model goodness-of-fit measures are available in TSAPPLY:

**SRSQUARE.** *Stationary R-squared.* A measure that compares the stationary part of the model to a simple mean model. This measure is preferable to ordinary R-squared when there is a trend or seasonal pattern. Stationary R-squared can be negative with a range of negative infinity to 1. Negative values mean that the model under consideration is worse than the baseline model. Positive values mean that the model under consideration is better than the baseline model.

**RSQUARE.** *R-squared.* An estimate of the proportion of the total variation in the series that is explained by the model. This measure is most useful when the series is stationary. R-squared can be negative with a range of negative infinity to 1. Negative values mean that the model under consideration is worse than the baseline model. Positive values mean that the model under consideration is better than the baseline model.

**RMSE.** *RMSE.* Root Mean Square Error. The square root of mean square error. A measure of how much a dependent series varies from its model-predicted level, expressed in the same units as the dependent series.

**MAPE.** *MAPE.* Mean Absolute Percentage Error. A measure of how much a dependent series varies from its model-predicted level. It is independent of the units used and can therefore be used to compare series with different units.

**MAE.** *MAE.* Mean absolute error. Measures how much the series varies from its model-predicted level. MAE is reported in the original series units.

**MAXAPE.** *MaxAPE.* Maximum Absolute Percentage Error. The largest forecasted error, expressed as a percentage. This measure is useful for imagining a worst-case scenario for your forecasts.

**MAXAE.** *MaxAE.* Maximum Absolute Error. The largest forecasted error, expressed in the same units as the dependent series. Like MaxAPE, it is useful for imagining the worst-case scenario for your forecasts. Maximum absolute error and maximum absolute percentage error may occur at different series points—for example, when the absolute error for a large series value is slightly larger than the absolute error for a small series value. In that case, the maximum absolute error will occur at the larger series value and the maximum absolute percentage error will occur at the smaller series value.

**NORMBIC.** *Normalized BIC.* Normalized Bayesian Information Criterion. A general measure of the overall fit of a model that attempts to account for model complexity. It is a score based upon the mean square error and includes a penalty for the number of parameters in the model and the length of the series. The penalty removes the advantage of models with more parameters, making the statistic easy to compare across different models for the same series.

---

## MODELSUMMARY Subcommand

The MODELSUMMARY subcommand controls the display of tables and charts that summarize goodness of fit, residual autocorrelations, and residual partial autocorrelations across estimated models. Each keyword is followed by an equals sign (=) and one or more of the available options enclosed in square brackets.

Example

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
/MODELDETAILS PRINT=FORECASTS
/AUXILIARY REESTIMATE=YES
/MODELSUMMARY PLOT=[SRSQUARE MAXAPE]
/MODEL FILE='/models/models.xml'.
```

- The output includes two histograms: one histogram for stationary  $R$ -squared and one histogram for the maximum absolute percentage error. Each histogram consists of results across all models.

## PRINT Keyword

The PRINT keyword controls the display of model summary tables.

**MODELFIT.** *Goodness of fit.* Table of summary statistics and percentiles for stationary  $R$ -square,  $R$ -square, root mean square error, mean absolute percentage error, mean absolute error, maximum absolute percentage error, maximum absolute error, and normalized Bayesian Information Criterion. Note that if models are not reestimated, model fit statistics are loaded from the model file. This table is displayed by default.

**RESIDACF.** *Residual autocorrelation function.* Table of summary statistics and percentiles for autocorrelations of the residuals. RESIDACF is ignored with a warning if REESTIMATE=NO.

**RESIDPACF.** *Residual partial autocorrelation function.* Table of summary statistics and percentiles for partial autocorrelations of the residuals. RESIDPACF is ignored with a warning if REESTIMATE=NO.

**NONE.** *No tables are shown.* An error occurs if NONE is used in combination with any other PRINT option.

## PLOT Keyword

The PLOT keyword controls the display of model summary charts. By default no charts are shown. (For detailed definitions of the following terms, see “Goodness-of-Fit Measures” on page 2020.)

**SRSQUARE.** *Histogram of Stationary R-Square.*

**RSQUARE.** *Histogram of R-Square.*

**RMSE.** *Histogram of Root Mean Square Error.*

**MAPE.** *Histogram of Mean Absolute Percentage Error.*

**MAE.** *Histogram of Mean Absolute Error.*

**MAXAPE.** *Histogram of Maximum Absolute Percentage Error.*

**MAXAE.** *Histogram of Maximum Absolute Error.*

**NORMBIC.** *Histogram of Normalized Bayesian Information Criterion (BIC).*

**RESIDACF.** *Boxplot of Residual Autocorrelation Function by Lag.* RESIDACF is ignored with a warning if REESTIMATE=NO.

**RESIDPACF.** *Boxplot of Residual Partial Autocorrelation Function by Lag.* RESIDPACF is ignored with a warning if REESTIMATE=NO.

---

## MODELSTATISTICS Subcommand

The MODELSTATISTICS subcommand controls display of a table listing all models along with chosen goodness-of-fit statistics. Note that if models are not reestimated, model fit statistics are loaded from the model file.

### Example

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
/MODELDETAILS PRINT=FORECASTS
/AUXILIARY REESTIMATE=YES
/MODELSTATISTICS DISPLAY=YES MODELFIT=RSQUARE
/MODEL FILE='/models/model1s.xml'.
```

- The output includes a table displaying the value of *R*-squared for each model.

### DISPLAY Keyword

The DISPLAY keyword controls whether the model statistics table is shown.

**YES.** *Model statistics table is shown.* Table of model goodness of fit, Ljung-Box Q statistic, and number of outliers by model. This setting is the default. The Q statistic measures the degree of pattern in the residuals. Large values of Q in relation to its degrees of freedom indicate that model residuals are not randomly distributed.

**NO.** *Model statistics table is not shown.*

### MODELFIT Keyword

The MODELFIT keyword controls which fit statistics are shown in the model statistics table, and this keyword is ignored if DISPLAY=NO. The keyword is followed by an equals sign (=) and one or more of the following options enclosed in square brackets. (For detailed definitions of the following terms, see “Goodness-of-Fit Measures” on page 2020.)

**SRSQUARE.** *Stationary R-square.* This setting is the default.

**RSQUARE.** *R-Square.*

**RMSE.** *Root Mean Square Error.*

**MAPE.** *Mean Absolute Percentage Error.*

**MAE.** *Mean Absolute Error.*

**MAXAPE.** *Maximum Absolute Percentage Error.*

**MAXAE.** *Maximum Absolute Error.*

**NORMBIC.** *Normalized Bayesian Information Criterion (BIC).*

---

## MODELDETAILS Subcommand

The MODELDETAILS subcommand controls the display of model parameters, model forecasts, and autocorrelations of noise residuals for individual models. Each keyword is followed by an equals sign (=) and one or more of the available options enclosed in square brackets.

### Example

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
/AUXILIARY REESTIMATE=YES
/MODELDETAILS PRINT=[PARAMETERS FORECASTS]
/MODEL FILE='/models/models.xml'.
```

- The output includes tables displaying the model parameters and forecasts for each model.

## PRINT Keyword

The PRINT keyword controls display of tables for individual models. By default, no tables are shown.

**PARAMETERS.** *Model parameter estimates.* Shows separate tables for ARIMA and exponential smoothing models. If outliers exist, parameter estimates for outliers are also displayed. Note that if models are not reestimated, parameter estimates are loaded from the model file.

**RESIDACF.** *Residual autocorrelation function.* Shows residual autocorrelations by lag. RESIDACF is ignored with a warning if REESTIMATE=NO.

**RESIDPACF.** *Residual partial autocorrelation function.* Shows residual partial autocorrelations by lag. RESIDPACF is ignored with a warning if REESTIMATE=NO.

**FORECASTS.** *Forecasts and confidence intervals.* Shows model forecasts and confidence intervals.

## PLOT Keyword

The PLOT keyword controls display of charts for individual models. By default no charts are shown. PLOT is ignored with a warning if REESTIMATE=NO.

**RESIDACF.** *Residual autocorrelation function.* Shows residual autocorrelations by lag.

**RESIDPACF.** *Residual partial autocorrelation function.* Shows residual partial autocorrelations by lag.

---

## SERIESPLOT Subcommand

The SERIESPLOT subcommand allows you to obtain plots of predicted values, observed values, and confidence intervals for each model. By default, no plots are shown. The subcommand is followed by one or more of the following keywords:

**OBSERVED.** *Displays all observed values of the dependent series.* OBSERVED is ignored with a warning if REESTIMATE=NO.

**FORECAST.** *Displays model-predicted values within the forecast period.*

**FIT.** *Displays model-predicted values within the estimation period.* FIT is ignored with a warning if REESTIMATE=NO.

**FORECASTCI.** *Displays upper and lower confidence limits within the forecast period.*

**FITCI.** *Displays upper and lower confidence limits within the estimation period.* FITCI is ignored with a warning if REESTIMATE=NO.

## Example

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
/MODELDETAILS PRINT=FORECASTS
/AUXILIARY REESTIMATE=YES
/SERIESPLOT OBSERVED FORECAST
/MODEL FILE='/models/models.xml'.
```

- The output includes plots of the model-predicted values in the forecast period, as well as all observed values, for each model.

---

## OUTPUTFILTER Subcommand

The OUTPUTFILTER subcommand controls which models are included in the model statistics table (MODELSTATISTICS subcommand), detailed model output (MODELDETAILS subcommand), and time series plots (SERIESPLOT subcommand).

- By default, all models are included in the output. OUTPUTFILTER can be used to display only the best-fitting or worst-fitting models (or both). If you request both, two sets of output are displayed.
- If model parameters are not reestimated, models are selected based on goodness-of-fit statistics that are loaded from the model file.
- OUTPUTFILTER is ignored if no output is requested on the MODELSTATISTICS, MODELDETAILS, or SERIESPLOT subcommands.
- OUTPUTFILTER has no effect on output from the MODELSUMMARY subcommand.

### Example

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
/MODELDETAILS PRINT=FORECASTS
/OUTPUTFILTER DISPLAY=[BESTFIT(N=5) WORSTFIT(PCT=10)]
/MODEL FILE='/models/model1s.xml'.
```

- The output consists of two sets of results: those results for the 5 best-fitting models and those results for models with fit values in the bottom 10%. The stationary *R*-squared value is used as the goodness-of-fit measure.

### DISPLAY Keyword

The DISPLAY keyword controls which models are included in MODELSTATISTICS, MODELDETAILS, and SERIESPLOT output.

- By default, all models are displayed (DISPLAY=ALLMODELS).
- To display only those models with extreme goodness-of-fit values, specify BESTFIT, WORSTFIT, or both, in square brackets. One or both keywords must be specified.

**ALLMODELS.** *All models are displayed.* All models that could be loaded (REESTIMATE=NO) or computed (REESTIMATE=YES) are shown. This setting is the default.

**BESTFIT.** *Models having the highest fit values are shown.* To display the models with the N highest fit values, specify BESTFIT followed by N=count in parentheses—for example, BESTFIT(N=5). The count must be a positive integer. If the count exceeds the number of estimated models, all models are shown. To display the models with fit values in the top N%, specify PCT=percent in parentheses. For example, BESTFIT(PCT=5) displays models with fit values in the top 5% among estimated models. The percentage value must be greater than zero and less than 100.

**WORSTFIT.** *Models having the lowest fit values are shown.* To display the models with the N lowest fit values, specify WORSTFIT followed by N=count in parentheses—for example, WORSTFIT(N=5). The count must be a positive integer. If the count exceeds the number of models estimated, all models are shown. To display the models with fit values in the lowest N%, specify PCT=percent in parentheses. For example, WORSTFIT(PCT=5) displays models with fit values in the bottom 5% among estimated models. The percentage value must be greater than zero and less than 100.

### MODELFIT Keyword

The MODELFIT keyword specifies the fit measure that is used to filter models. MODELFIT is ignored if DISPLAY=ALLMODELS.

Specify one of the following options. (For detailed definitions of the following terms, see “Goodness-of-Fit Measures” on page 2020.)

**SRSQUARE.** *Stationary R-Square.* This setting is the default.

**RSQUARE.** *R-Square.*

**RMSE.** *Root Mean Square Error.*

**MAPE.** *Mean Absolute Percentage Error.*

**MAE.** *Mean Absolute Error.*

**MAXAPE.** *Maximum Absolute Percentage Error.*

**MAXAE.** *Maximum Absolute Error.*

**NORMBIC.** *Normalized Bayesian Information Criterion (BIC).*

---

## SAVE Subcommand

The SAVE subcommand is used to save new variables representing predicted values, residuals, and confidence intervals to the active dataset. By default, no new variables are saved to the active dataset.

- Specify one or more keywords, each keyword followed by an optional rootname to be used as the prefix for new variable names. Enclose the root name in parentheses. Each keyword gives rise to one new variable for each dependent variable.
- The root name, if specified, must conform to the rules for valid variable names.
- If no root name is specified, TSAPPLY uses a default name.
- The full variable name is the concatenation of the root name, the name of the associated dependent variable, and a model identifier. The variable name is extended if necessary to avoid variable naming conflicts.
- The PREDICT command controls whether new cases are added to the file when new variables are saved. New cases are added if PREDICT specifies a forecast period that extends beyond the length of the dependent-variable series.
- SAVE is ignored with a warning if temporary transformations are in effect.

### Example

```
PREDICT THRU YEAR 2006 MONTH 6.  
TSAPPLY  
  /AUXILIARY REESTIMATE=YES  
  /SAVE PREDICTED(ApplyPred) NRESIDUAL  
  /MODEL FILE='/models/model1s.xml'.
```

- Two new variables are created for each of the models: one variable contains the model predictions, and the other variable contains the noise residuals.
- The root name (prefix) for the variables containing model predictions is *ApplyPred*.
- The root name for the variables containing noise residuals is *NResidual* (the default).

**PREDICTED(rootname).** *Model fit and forecast values.* The default root name is *Predicted*. If REESTIMATE=NO, only forecasts are produced.

**LCL(rootname).** *Lower confidence limits.* The default root name is *LCL*. If REESTIMATE=NO, lower confidence limits are only produced for forecasts.

**UCL(rootname).** *Upper confidence limits.* The default root name is *UCL*. If REESTIMATE=NO, upper confidence limits are only produced for forecasts.

**NRESIDUAL(rootname).** *Noise residuals.* The default rootname is *NResidual*. When transformations of the dependent variable are performed (for example, natural log), these residuals are the residuals for the transformed series. NRESIDUAL is ignored with a warning if REESTIMATE=NO.

---

## AUXILIARY Subcommand

The AUXILIARY subcommand is used to specify whether model parameters are reestimated, set the confidence interval level for forecasts, set the maximum number of lags for autocorrelation and partial autocorrelation plots and tables, and specify the season length.

### Example

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /MODELDETAILS PRINT=[PARAMETERS FORECASTS]
                PLOT=[RESIDACF RESIDPACF]
  /AUXILIARY REESTIMATE=YES MAXACFLAGS=36
  /MODEL FILE='/models/models.xml'.
```

### REESTIMATE Keyword

REESTIMATE controls whether model parameters are reestimated. If REESTIMATE=NO (the default), parameter estimates that are recorded in the model file are used to produce forecasts. If REESTIMATE=YES, forecasts reflect reestimated model parameters. Outliers, if any, are always taken from the model file.

Note that if REESTIMATE=NO, any parameter estimates or goodness-of-fit statistics that are displayed in output are loaded from the model file and reflect the data that were used when each model was developed (or last updated). And if you use the OUTPUTFILTER subcommand, models will be selected on the basis of goodness-of-fit statistics that are recorded in the model file. In addition, forecasts will not take into account historical data--for either dependent or independent variables--in the active dataset. You must set REESTIMATE=YES if you want historical data to impact the forecasts. Finally, forecasts do not take into account values of the dependent series in the forecast period--but the forecasts do take into account values of independent variables in the forecast period. If you have more current values of the dependent series and want them to be included in the forecasts, you need to reestimate, adjusting the estimation period to include these values.

### CILEVEL Keyword

The CILEVEL keyword sets the confidence level.

- Specify a positive number that is less than 100.
- The default is 95.

### MAXACFLAGS Keyword

The MAXACFLAGS keyword sets the maximum number of lags displayed in residual autocorrelation and partial autocorrelation tables and plots. MAXACFLAGS is ignored if REESTIMATE=NO.

- Specify a positive integer.
- The default is 24.

### SEASONLENGTH Keyword

The SEASONLENGTH keyword specifies the length of the seasonal period (the number of observations in one period or season) for the data.

- To adjust the season length, specify a positive integer.
- If SEASONLENGTH is not specified, the periodicity that is specified by using the DATE command defines the season length.

- Note that SEASONLENGTH is used to override the date specification for the active dataset to make it consistent with the date specification from the model file. An error occurs if these two specifications are not consistent.

---

## MISSING Subcommand

The MISSING subcommand controls the handling of user-missing values.

- By default, user-missing values are treated as missing (invalid) data.
- System-missing values are always treated as invalid.
- Cases with missing values of a dependent variable that occur within the estimation period are included in the model. The specific handling of the missing value depends on the estimation method.
- For ARIMA models, a warning is issued if a predictor has any missing values within the estimation period. Any models involving the predictor are not reestimated.
- If any predictor has missing values within the forecast period, the procedure issues a warning and forecasts as far as it can.

### Example

```
PREDICT THRU YEAR 2006 MONTH 6.  
TSAPPLY  
  /MODELDETAILS PRINT=FORECASTS  
  /AUXILIARY REESTIMATE=YES  
  /MISSING USERMISSING=INCLUDE  
  /MODEL FILE='/models/models.xml'.
```

### USERMISSING Keyword

The USERMISSING keyword controls the treatment of user-missing values and is required.

**EXCLUDE.** *Exclude user-missing values.* User-missing values are treated as missing. This setting is the default.

**INCLUDE.** *Include user-missing values.* User-missing values are treated as valid data.

---

## MODEL Subcommand

The MODEL subcommand is required and specifies an external file, referred to as a model file, containing models that are developed by using TSMODEL. A model file specifies lag structure, parameters, outliers, and variables for each model.

- TSAPPLY assumes that the variables that are specified in the model file exist in the active dataset.
- You can use multiple MODEL subcommands to apply two or more sets of models to your data. Each MODEL subcommand is used to load models from a different model file. For example, one model file might contain models for series that represent unit sales, and another model file might contain models for series that represent revenue.

### FILE Keyword

The FILE keyword is used to specify an external file containing models, and the keyword is required.

- A warning is issued if a model variable that is specified in the file does not exist in the active dataset or is not numeric. Models that refer to the variable are ignored.
- A warning is issued if a model specifies a variable transformation (square root or natural log) and one or more model variables to be transformed contain values that are invalid for the specified transformation—for example, negative values. Any such models will not be applied.
- An error occurs if the date interval or cycle length that is specified in the file is inconsistent with the date specification for the active dataset. The SEASONLENGTH keyword on the AUXILIARY subcommand can be used to override the date specification for the active dataset.

- An error occurs if the file cannot be read or is invalid.
- An error occurs if two or more MODEL subcommands specify the same file.
- When multiple MODEL subcommands are used, a warning occurs if the same model ID occurs in more than one model file. The first model with that ID is loaded. The check for duplicate model IDs takes place after DROP and KEEP are applied to each model file.
- A warning is issued, and forecasts are not available for a model, if REESTIMATE=NO and the model's forecast period is inconsistent with the current USE or PREDICT interval. Specifically, forecasts are not available if model forecasts would start before the beginning of the USE period or after the end of the PREDICT interval.

#### DROP Keyword

The DROP keyword is used to exclude models.

- Specify one or more quoted model identifiers, enclosed in square brackets—for example, ['Model\_1' 'Model\_2']. All other models in the file are loaded and applied to the data.
- Redundant items in the DROP list are ignored.
- An error occurs if all models are dropped.
- Model identifiers that do not exist in the file are ignored.

#### KEEP Keyword

The KEEP keyword specifies models to be applied.

- Specify one or more quoted model identifiers, enclosed in square brackets—for example, ['Model\_1' 'Model\_2']. All other models in the file are excluded.
- Redundant items in the KEEP list are ignored.
- Model identifiers that do not exist in the file are ignored.
- DROP and KEEP are mutually exclusive. An error occurs if both are specified.

#### OUTFILE and OUTPMML Keywords

The OUTFILE and OUTPMML keywords are used to save updated models

- OUTFILE saves an XML file that can be used with other IBM SPSS applications.
- OUTPMML saves a PMML-compliant XML file that can be used with PMML-compliant applications, including IBM SPSS applications.
- Models are written to an XML file. Each model is assigned a unique name and a description that includes the name of the dependent variable and the model type.
- The filename must be specified in full. No extension is supplied.
- If two or more MODEL subcommands (within a single invocation of TSMODEL) specify the same external file, all models that are created by those MODEL subcommands are saved to that file.
- OUTFILE and OUTPMML are ignored with a warning if SPLIT FILE is in effect.

---

## Chapter 277. TSET

```
TSET
[PRINT={DEFAULT**}] [/NEWVAR={CURRENT**}] [/MXAUTO={16**}]
  {BRIEF }           {NONE }           {lags}
  {DETAILED }        {ALL }
[/MXCROSS={7** } ] [/MXNEWVARS={60**}] [/MXPREDICT={60**}]
  {lags}             {n }              {n }
[/MISSING={EXCLUDE**}] [/CIN={95** } ] [/TOLER={0.0001**}]
  {INCLUDE }         {value }         {value }
[/CONVERGE={0.001**}] [/ACFSE={IND**}]
  {value }          {MA }
[/PERIOD=n]  [/ID=varname]
[/ {CONSTANT**}]
  {NOCONSTANT}
[/DEFAULT]
```

\*\*Default if the subcommand is omitted.

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Example

```
TSET PERIOD 6 NEWVAR NONE MXAUTO 25.
```

---

## Overview

TSET sets global parameters to be used by procedures that analyze time series and sequence variables. To display the current settings of these parameters, use the TSHOW command.

### Basic Specification

The basic specification is at least one subcommand.

### Subcommand Order

- Subcommands can be specified in any order.

### Syntax Rules

- The slash between subcommands is optional.
- You can specify DEFAULT on any subcommand to restore the default setting for that subcommand.
- Subcommand DEFAULT restores all TSET subcommands to their defaults.

### Operations

- TSET takes effect immediately.
- Only the settings specified are affected. All others remain at their previous settings or the default.
- Subcommands on other procedures that perform the same function as subcommands on TSET override the TSET specifications for those procedures.
- Procedures that are affected by TSET specifications are CURVEFIT, CASEPLOT, NPLOT, and TSPLIT.

---

## DEFAULT Subcommand

DEFAULT resets all TSET settings back to their defaults. There are no additional specifications on DEFAULT.

---

## ID Subcommand

ID specifies a variable whose values are used to label observations in plots.

- The only specification on ID is the name of a variable in the active dataset.
- If ID is not specified, the *DATE\_* variable is used to label observations.
- If ID is specified within the procedure, it overrides the TSET specification for that procedure.

---

## MISSING Subcommand

MISSING controls the treatment of user-missing values.

- The specification on MISSING is keyword INCLUDE or EXCLUDE. The default is EXCLUDE.
- INCLUDE indicates that observations with user-missing values should be treated as valid values and included in analyses.
- EXCLUDE indicates that observations with user-missing values should be excluded from analyses.

---

## MXNEWVARS Subcommand

MXNEWVARS indicates the maximum number of new variables that can be generated by a procedure.

- The specification on MXNEWVARS indicates the maximum and can be any positive integer.
- The default maximum number is 60 new variables per procedure.

---

## MXPREDICT Subcommand

MXPREDICT indicates the maximum number of new cases that can be added to the active dataset per procedure when the PREDICT command is used.

- The specification on MXPREDICT can be any positive integer.
- The default maximum number of new cases is 60 per procedure.

---

## NEWVAR Subcommand

NEWVAR controls the creation of new variables in the active dataset.

- The specification on NEWVAR can be CURRENT, NONE, or ALL. The default is CURRENT.
- CURRENT specifies to save new variables and replace any existing variables of the same name.
- ALL specifies to save new variables without replacing existing ones.
- NONE specifies that no new variables are saved.

---

## PERIOD Subcommand

PERIOD indicates the size of the period to be used for seasonal differencing.

- The specification on PERIOD indicates how many observations are in one season or period and can be any positive integer.
- There is no default for the PERIOD subcommand.
- The specification on TSET PERIOD overrides the periodicity of DATE variables.
- If a period is specified within an individual procedure, it overrides the TSET PERIOD specification for that procedure.

---

## PRINT Subcommand

PRINT controls how much output is produced.

- The specification on PRINT can be BRIEF, DETAILED, or DEFAULT. The amount of output produced by DEFAULT is generally between the amount produced by BRIEF and DETAILED.

- For procedures with multiple iterations, BRIEF generally means that final statistics are displayed with no iteration history. DEFAULT provides a one-line summary at each iteration in addition to the final statistics. DETAILED provides a complete summary of each iteration (where necessary) plus the final statistics.
- For some procedures, the DEFAULT and DETAILED output is the same. For many of the simpler procedures, BRIEF, DEFAULT, and DETAILED are all the same.

---

## Chapter 278. TSHOW

TSHOW

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

---

### Overview

TSHOW displays a list of all the current specifications on the TSET, USE, PREDICT, and DATE commands.

#### Basic Specification

The command keyword TSHOW is the only specification.

#### Operations

- TSHOW is executed immediately.
- TSHOW lists every current specification for the TSET, USE, PREDICT, and DATE commands, as well as the default settings.

---

### Example

TSHOW.

- The TSHOW command produces a list of the current settings on the TSET, USE, PREDICT, and DATE commands.

---

## Chapter 279. TSMODEL

TSMODEL is available in SPSS Statistics Professional Edition or the Forecasting option.

*Note:* Square brackets that are shown in the TSMODEL syntax chart are not used to indicate optional elements. Where indicated, they are required parts of syntax when a list of values is specified, but they may be omitted when a single value is specified. Equals signs (=) that are used in the syntax chart are required elements. The MODEL subcommand is required. All other subcommands are optional.

TSMODEL

Global subcommands:

```
/MODEL SUMMARY PRINT=[MODELFIT** RESIDACF RESIDPACF NONE]
                PLOT=[SRSQUARE RSQUARE RMSE MAPE MAE MAXAPE
                     MAXAE NORMBIC RESIDACF RESIDPACF]

/MODEL STATISTICS DISPLAY={YES**}
                   {NO }
                MODELFIT=[SRSQUARE** RSQUARE RMSE MAPE MAE
                          MAXAPE MAXAE NORMBIC]

/MODEL DETAILS PRINT=[PARAMETERS RESIDACF RESIDPACF FORECASTS]
                PLOT=[RESIDACF RESIDPACF]

/SERIES PLOT OBSERVED FORECAST FIT FORECASTCI FITCI

/OUTPUT FILTER DISPLAY={ALLMODELS**
                      {[BESTFIT({N=integer }) WORSTFIT({N=integer })]}
                      {PCT=percent} {PCT=percent}}
                MODELFIT={SRSQUARE**
                          {RSQUARE }
                          {RMSE }
                          {MAPE }
                          {MAE }
                          {MAXAPE }
                          {MAXAE }
                          {NORMBIC }}

/SAVE PREDICTED(rootname)
      LCL(rootname)
      UCL(rootname)

                                             {TRANSIENT
                                             {SEASONALADDITIVE}
                                             {LOCALTREND

```

\*\*Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

## Release History

### Release 14.0

- Command introduced.

## Example

```

TSMODEL
  /MODEL DEPENDENT=sku1 TO sku10.

```

---

## Overview

The TSMODEL procedure estimates exponential smoothing, univariate Autoregressive Integrated Moving Average (ARIMA), and multivariate ARIMA (or transfer function models) models for time series, and the procedure produces forecasts. The procedure includes an Expert Modeler that attempts to identify and estimate an appropriate ARIMA or exponential smoothing model for each dependent-variable series. Alternatively, you can specify a custom ARIMA or exponential smoothing model.

## Options

**Automatic Model Identification.** The Expert Modeler can identify an appropriate seasonal or nonseasonal ARIMA or exponential smoothing model for each dependent-variable series. If predictor variables are specified, the Expert Modeler selects, for inclusion in ARIMA models, those variables that have a statistically significant relationship with the dependent series. Model variables are transformed where appropriate by using differencing and/or a square root or natural log transformation. You can limit the set of candidate models to ARIMA models only or exponential smoothing models only.

**Custom Models.** You can specify a custom exponential smoothing or ARIMA model for one or more series. Seven exponential smoothing methods are available: simple, simple seasonal, Holt's linear trend, Brown's linear trend, damped trend, Winters' additive, and Winters' multiplicative. For ARIMA models, you can specify seasonal and nonseasonal autoregressive and moving average orders, differencing, as well as transfer functions for predictor variables. For exponential smoothing and ARIMA models, you can request that model variables be transformed prior to model estimation.

**Outliers.** If you use the Expert Modeler or specify a custom ARIMA model, TSMODEL can detect and model outlier time points automatically. The following outlier types can be identified: additive, additive patch, innovational, level shift, transient, seasonal additive, and local trend. Alternatively, if you request a custom ARIMA model, you can specify that one or more time points be modeled as outliers.

**Output.** Available output includes plots and tables that summarize the distribution of model goodness of fit, residual autocorrelations, and residual partial autocorrelations across models. In addition, you can obtain a table of model goodness of fit, Ljung-Box Q, and number of outliers by model. You can also obtain details for each model, including parameter estimates, forecasts, as well as autocorrelation and partial autocorrelation functions. Output can be restricted to the best-fitting or worst-fitting models based on goodness-of fit-values.

**Saved Variables.** You can save fit and forecast values to the active dataset as well as confidence intervals and noise residuals.

**Missing Values.** You can control whether user-missing values are treated as valid or invalid values.

#### Basic Specification

- The basic specification is a MODEL subcommand that specifies one or more dependent-variable series.
- By default, TSMODEL uses the Expert Modeler to identify and estimate the best ARIMA or exponential smoothing model for each series.
- Default output includes a summary of the distribution of goodness of fit across estimated models and a table of stationary *R*-square, Ljung-Box Q, and number of outliers by model.

#### Syntax Rules

- The following subcommands are global and apply to all models specified in a single instance of the TSMODEL command: MODELSUMMARY, MODELSTATISTICS, MODELDETAILS, SERIESPLOT, OUTPUTFILTER, SAVE, AUXILIARY, and MISSING.
- Each global subcommand is optional, may be used only once, and must appear before any MODEL subcommand.
- Models are specified in blocks. The MODEL subcommand indicates the start of a block. The MODEL subcommand must be used at least once.
- The following subcommands apply to the preceding MODEL subcommand and constitute--along with a MODEL subcommand--a MODEL block: EXPERTMODELER, EXSMOOTH, ARIMA, TRANSFERFUNCTION, AUTOOUTLIER, and OUTLIER. An error occurs if any of these subcommands precedes the first MODEL subcommand.
- The EXPERTMODELER, EXSMOOTH, and ARIMA subcommands are used within a MODEL block to specify the estimation method. If none of these subcommands is specified, the implicit default is EXPERTMODELER. An error occurs if more than one of these subcommands is specified within a MODEL block.
- AUTOOUTLIER may be used only once within a MODEL block.

- TRANSFERFUNCTION and OUTLIER may be used more than once within a MODEL block.
- Each keyword may be specified only once within a subcommand.
- Empty subcommands are not allowed; all subcommands must be specified with options.
- All subcommands other than MODEL are optional.
- Subcommand names and keywords must be spelled in full.
- Subcommands can be specified in any order, with the exception that global subcommands must precede the first MODEL subcommand.
- Equals signs (=) that are shown in the syntax chart are required.

### Operations

- TSMODEL honors time intervals and periodicity specified with the DATE command.
- The procedure verifies that date variables that are implied by the current date specification exist and that their values coincide with the date specification within the estimation period. If SPLIT FILE is in effect, the check is done for each split. A split is skipped and a warning is issued if verification fails for that split. If the verification fails when SPLIT FILE is not in effect, an error occurs and processing terminates. If the data are filtered, values of date variables are verified within the filtered subset of data.
- The procedure honors the estimation (historical) period that is defined with the USE command. However, depending on available data, the actual use period may vary by dependent variable. For a given dependent variable, the estimation period is the period left after eliminating contiguous missing values of the dependent variable at the beginning and end of the USE period.
- If SPLIT FILE is in effect, and a split has fewer cases than implied by the USE period, a warning is issued and all available cases are used. If there are no cases in the USE period, the split is skipped altogether with a warning.
- The PREDICT command defines the end of the forecast period for tables, charts, and model variables that are produced by TSMODEL. The forecast period always starts after the end of the estimation (USE) period. Like the estimation period, the forecast period can vary by model, depending on available data. If a PREDICT specification ends on or before the effective end of the USE period, the forecast period is empty.
- The procedure does not honor the following commands: MODEL NAME or SAVE MODEL. Options for naming and saving models are provided with the TSMODEL procedure.
- The procedure does not honor TSET. The TSMODEL procedure provides options for handling missing values, setting the width of confidence intervals, setting the maximum number of lags displayed for autocorrelations, and setting season length.
- The TDISPLAY command does not display models that are saved by using TSMODEL.

### Limitations

- WEIGHT is ignored with a warning.

---

## Examples

This section provides simple examples that are designed to get you started with using the Expert Modeler, producing forecasts, saving results to the active dataset, and saving your model for later use. Further examples that are specific to each subcommand are provided in the subcommand topics.

### Using the Expert Modeler

```
TSMODEL
  /MODEL DEPENDENT=sku1 TO sku10.
```

- The Expert Modeler is used to find the best-fitting exponential smoothing or ARIMA model for each of the dependent series *sku1* thru *sku10*.

- The procedure invokes the Expert Modeler because the MODEL subcommand is not followed by one of the model type subcommands (i.e., EXSMOOTH or ARIMA). The absence of a model type subcommand is equivalent to specifying /EXPERTMODELER TYPE=[ARIMA EXSMOOTH] TRYSEASONAL=YES.

### Obtaining Model Forecasts

```
PREDICT THRU YEAR 2006 MONTH 6.
TSMODEL
/SERIESPLOT FORECAST
/MODELDETAILS PRINT=FORECASTS
/MODEL DEPENDENT=revenue.
```

- The PREDICT command is used to specify the forecast period for the TSMODEL procedure.
- The SERIESPLOT subcommand specifies that the output contains a plot of the predicted values within the forecast period.
- The MODELDETAILS subcommand specifies that the output includes a table containing the predicted values within the forecast period.

### Saving Models to an External File

```
TSMODEL
/MODEL DEPENDENT=sku1 TO sku50 OUTFILE='/models/models_sku1TOsku50.xml'.
```

- The OUTFILE keyword specifies that each of the resulting models is to be saved to the file */models/models\_sku1TOsku50.xml*.
- The saved models can be used to produce new forecasts with the TSAPPLY command when new data are available. See the topic Chapter 276, “TSAPPLY,” on page 2017 for more information.

### Saving Model Predictions, Residuals, and Confidence Intervals as New Variables

```
TSMODEL
/SAVE PREDICTED LCL UCL NRESIDUAL
/MODEL DEPENDENT=revenue.
```

- The SAVE subcommand specifies that new variables containing the model predictions, noise residuals, and confidence intervals are saved to the active dataset.

### Specifying Multiple Model Types

```
TSMODEL
/MODEL DEPENDENT=sku1 TO sku10 INDEPENDENT=adspending
/EXPERTMODELER TYPE=[ARIMA]
/MODEL DEPENDENT=sku11 TO sku15
/EXSMOOTH TYPE=WINTERSMULTIPLICATIVE.
```

- The first MODEL block specifies that the Expert Modeler is used to find the best-fitting ARIMA model for each of the dependent series *sku1* thru *sku10*, using the predictor variable *adspending*.
- The second MODEL block specifies that the Winters' multiplicative method is used to model each of the dependent series *sku11* thru *sku15*.
- In this example, different model types were used for different dependent variables. You can also specify multiple model types for the same dependent variable, thereby obtaining multiple models for the variable.

---

## Goodness-of-Fit Measures

The following model goodness-of-fit measures are available in TSMODEL:

**SRSQUARE.** *Stationary R-squared.* A measure that compares the stationary part of the model to a simple mean model. This measure is preferable to ordinary R-squared when there is a trend or seasonal pattern. Stationary R-squared can be negative with a range of negative infinity to 1. Negative values mean that the model under consideration is worse than the baseline model. Positive values mean that the model under consideration is better than the baseline model.

**RSQUARE.** *R-squared.* An estimate of the proportion of the total variation in the series that is explained by the model. This measure is most useful when the series is stationary. R-squared can be negative with a

range of negative infinity to 1. Negative values mean that the model under consideration is worse than the baseline model. Positive values mean that the model under consideration is better than the baseline model.

**RMSE.** *RMSE.* Root Mean Square Error. The square root of mean square error. A measure of how much a dependent series varies from its model-predicted level, expressed in the same units as the dependent series.

**MAPE.** *MAPE.* Mean Absolute Percentage Error. A measure of how much a dependent series varies from its model-predicted level. It is independent of the units used and can therefore be used to compare series with different units.

**MAE.** *MAE.* Mean absolute error. Measures how much the series varies from its model-predicted level. MAE is reported in the original series units.

**MAXAPE.** *MaxAPE.* Maximum Absolute Percentage Error. The largest forecasted error, expressed as a percentage. This measure is useful for imagining a worst-case scenario for your forecasts.

**MAXAE.** *MaxAE.* Maximum Absolute Error. The largest forecasted error, expressed in the same units as the dependent series. Like MaxAPE, it is useful for imagining the worst-case scenario for your forecasts. Maximum absolute error and maximum absolute percentage error may occur at different series points—for example, when the absolute error for a large series value is slightly larger than the absolute error for a small series value. In that case, the maximum absolute error will occur at the larger series value and the maximum absolute percentage error will occur at the smaller series value.

**NORMBIC.** *Normalized BIC.* Normalized Bayesian Information Criterion. A general measure of the overall fit of a model that attempts to account for model complexity. It is a score based upon the mean square error and includes a penalty for the number of parameters in the model and the length of the series. The penalty removes the advantage of models with more parameters, making the statistic easy to compare across different models for the same series.

---

## MODELSUMMARY Subcommand

The MODELSUMMARY subcommand controls the display of tables and charts that summarize goodness of fit, residual autocorrelations, and residual partial autocorrelations across estimated models. Each keyword is followed by an equals sign (=) and one or more of the available options enclosed in square brackets.

### Example

```
TSMODEL  
  /MODELSUMMARY PLOT=[SRSQUARE MAXAPE]  
  /MODEL DEPENDENT=sku1 TO sku100.
```

- The output includes two histograms: one histogram for stationary R-squared and one histogram for the maximum absolute percentage error. Each histogram consists of results across all models (one model for each dependent variable).

### PRINT Keyword

The PRINT keyword controls the display of model summary tables.

**MODELFIT.** *Goodness of fit.* Table of summary statistics and percentiles for stationary R-square, R-square, root mean square error, mean absolute percentage error, mean absolute error, maximum absolute percentage error, maximum absolute error, and normalized Bayesian Information Criterion.

**RESIDACF.** *Residual autocorrelation function.* Table of summary statistics and percentiles for autocorrelations of the residuals.

**RESIDPACF.** *Residual partial autocorrelation function.* Table of summary statistics and percentiles for partial autocorrelations of the residuals.

**NONE.** *No tables are shown.* An error occurs if NONE is used in combination with any other PRINT option.

PLOT Keyword

The PLOT keyword controls the display of model summary charts. By default, no charts are shown. (For detailed definitions of the following terms, see “Goodness-of-Fit Measures” on page 2039.)

**SRSQUARE.** *Histogram of Stationary R-Square.*

**RSQUARE.** *Histogram of R-Square.*

**RMSE.** *Histogram of Root Mean Square Error.*

**MAPE.** *Histogram of Mean Absolute Percentage Error.*

**MAE.** *Histogram of Mean Absolute Error.*

**MAXAPE.** *Histogram of Maximum Absolute Percentage Error.*

**MAXAE.** *Histogram of Maximum Absolute Error.*

**NORMBIC.** *Histogram of Normalized Bayesian Information Criterion (BIC).*

**RESIDACF.** *Boxplot of Residual Autocorrelation Function by Lag.*

**RESIDPACF.** *Boxplot of Residual Partial Autocorrelation Function by Lag.*

---

## MODELSTATISTICS Subcommand

The MODELSTATISTICS subcommand controls display of a table that lists all models, along with chosen goodness-of-fit statistics.

Example

```
TSMODEL
  /MODELSTATISTICS DISPLAY=YES MODELFIT=[RSQUARE]
  /MODEL DEPENDENT=sku1 TO sku25.
```

- The output includes a table displaying the value of R-squared for each model.

DISPLAY Keyword

The DISPLAY keyword controls whether the model statistics table is shown.

**YES.** *Model statistics table is shown.* Table of model goodness of fit, Ljung-Box Q statistic, and number of outliers detected by model. This setting is the default. The Q statistic measures the degree of pattern in the residuals. Large values of Q in relation to its degrees of freedom indicate that model residuals are not randomly distributed.

**NO.** *Model statistics table is not shown.*

MODELFIT Keyword

The MODELFIT keyword controls which fit statistics are shown in the model statistics table, and the keyword is ignored if DISPLAY=N0. The keyword is followed by an equals sign (=) and one or more of the following options enclosed in square brackets. (For detailed definitions of the following terms, see “Goodness-of-Fit Measures” on page 2039.)

**SRSQUARE.** *Stationary R -Square.* This setting is the default.

**RSQUARE.** *R-Square.*

**RMSE.** *Root Mean Square Error.*

**MAPE.** *Mean Absolute Percentage Error.*

**MAE.** *Mean Absolute Error.*

**MAXAPE.** *Maximum Absolute Percentage Error.*

**MAXAE.** *Maximum Absolute Error.*

**NORMBIC.** *Normalized Bayesian Information Criterion (BIC).*

---

## MODELDETAILS Subcommand

The MODELDETAILS subcommand controls the display of model parameters, model forecasts, and autocorrelations of noise residuals for individual models. Each keyword is followed by an equals sign (=) and one or more of the available options enclosed in square brackets.

### Example

```
TSMODEL  
  /MODELDETAILS PRINT=[PARAMETERS FORECASTS]  
  /MODEL DEPENDENT=sku1 TO sku50.
```

- The output includes tables displaying the model parameters and forecasts for each model (one model for each dependent variable).

### PRINT Keyword

The PRINT keyword controls display of tables for individual models. By default, no tables are shown.

**PARAMETERS.** *Model parameter estimates.* Shows separate tables for ARIMA and exponential smoothing models. If outliers exist, parameter estimates for outliers are also displayed.

**RESIDACF.** *Residual autocorrelation function.* Shows residual autocorrelations by lag.

**RESIDPACF.** *Residual partial autocorrelation function.* Shows residual partial autocorrelations by lag.

**FORECASTS.** *Forecasts and confidence intervals.* Shows model forecasts and confidence intervals.

### PLOT Keyword

The PLOT keyword controls display of charts for individual models. By default, no charts are shown.

**RESIDACF.** *Residual autocorrelation function.* Shows residual autocorrelations by lag.

**RESIDPACF.** *Residual partial autocorrelation function.* Shows residual partial autocorrelations by lag.

---

## SERIESPLOT Subcommand

The SERIESPLOT subcommand allows you to obtain plots of predicted values, observed values, and confidence intervals for each estimated model. By default, no plots are shown. The subcommand is followed by one or more of the following keywords:

**OBSERVED.** *Displays all observed values of the dependent series.*

**FORECAST.** *Displays model-predicted values within the forecast period.*

**FIT.** *Displays model-predicted values within the estimation period.*

**FORECASTCI.** *Displays upper and lower confidence limits within the forecast period.*

**FITCI.** *Displays upper and lower confidence limits within the estimation period.*

### Example

```
TSMODEL
/SERIESPLOT OBSERVED FORECAST
/MODEL DEPENDENT=sku1 TO sku5
/MODEL DEPENDENT=revenue INDEPENDENT=adspending.
```

- The plot includes the model-predicted values in the forecast period as well as all observed values for each of the dependent series.

---

## OUTPUTFILTER Subcommand

The OUTPUTFILTER subcommand controls which models are included in the model statistics table (MODELSTATISTICS subcommand), detailed model output (MODELDETAILS subcommand), and time series plots (SERIESPLOT subcommand).

- By default, all models are included in the output. OUTPUTFILTER can be used to display only the best-fitting or worst-fitting models (or both). If you request both, two sets of output are displayed.
- OUTPUTFILTER is ignored if no output is requested on the MODELSTATISTICS, MODELDETAILS, or SERIESPLOT subcommands.
- OUTPUTFILTER has no effect on output from the MODELSUMMARY subcommand.

### Example

```
TSMODEL
/MODELSTATISTICS DISPLAY=YES MODELFIT=[SRSQUARE MAXAPE NORMBIC]
/OUTPUTFILTER DISPLAY=[BESTFIT(N=5) WORSTFIT(PCT=10)]
/MODEL DEPENDENT=sku1 TO sku200.
```

- The output consists of two sets of results: those results for the 5 best-fitting models and those results for models with fit values in the bottom 10%. The stationary R-squared value is used as the goodness-of-fit measure.

### DISPLAY Keyword

The DISPLAY keyword controls which models are included in MODELSTATISTICS, MODELDETAILS, and SERIESPLOT output.

- By default, all models are displayed (DISPLAY=ALLMODELS).
- To display only those models with extreme goodness-of-fit values, specify BESTFIT, WORSTFIT, or both, in square brackets. One or both keywords must be specified.

**ALLMODELS.** *All models are displayed.* All models that could be computed are shown. This setting is the default.

**BESTFIT.** *Models having the highest fit values are shown.* To display the models with the N highest fit values, specify BESTFIT followed by N=count in parentheses—for example, BESTFIT(N=5). The count must be a positive integer. If the count exceeds the number of estimated models, all models are shown. To display the models with fit values in the top N%, specify PCT=percent in parentheses. For example, BESTFIT(PCT=5) displays models with fit values in the top 5% among estimated models. The percentage value must be greater than zero and less than 100.

**WORSTFIT.** *Models having the lowest fit values are shown.* To display the models with the N lowest fit values, specify WORSTFIT followed by N=count in parentheses—for example, WORSTFIT(N=5). The count must be a positive integer. If the count exceeds the number of estimated models, all models are shown. To display the models with fit values in the lowest N%, specify PCT=percent in parentheses. For example, WORSTFIT(PCT=5) displays models with fit values in the bottom 5% among estimated models. The percentage value must be greater than zero and less than 100.

#### MODELFIT Keyword

The MODELFIT keyword specifies the fit measure that is used to filter models. MODELFIT is ignored if DISPLAY=ALLMODELS.

Specify one of the following options. (For detailed definitions of the following terms, see “Goodness-of-Fit Measures” on page 2039.)

**SRSQUARE.** *Stationary R-Square.* This setting is the default.

**RSQUARE.** *R-Square.*

**RMSE.** *Root Mean Square Error.*

**MAPE.** *Mean Absolute Percentage Error.*

**MAE.** *Mean Absolute Error.*

**MAXAPE.** *Maximum Absolute Percentage Error.*

**MAXAE.** *Maximum Absolute Error.*

**NORMBIC.** *Normalized Bayesian Information Criterion (BIC).*

---

## SAVE Subcommand

The SAVE subcommand is used to save new variables representing predicted values, residuals, and confidence intervals to the active dataset. By default, no new variables are saved to the active dataset.

- Specify one or more keywords, each keyword followed by an optional rootname to be used as the prefix for new variable names. Enclose the rootname in parentheses. Each keyword gives rise to one new variable for each dependent variable.
- The rootname, if specified, must conform to the rules for valid variable names.
- If no rootname is specified, TSMODEL uses a default name.
- The full variable name is the concatenation of the rootname, the name of the associated dependent variable, and a model identifier. The variable name is extended if necessary to avoid variable naming conflicts.
- The PREDICT command controls whether new cases are added to the file when new variables are saved. New cases are added if PREDICT specifies a forecast period that extends beyond the length of the dependent-variable series.
- SAVE is ignored with a warning if temporary transformations are in effect.

## Example

```
TSMODEL
/SAVE PREDICTED(Pred) NRESIDUAL
/MODEL DEPENDENT=sku1 TO sku10.
```

- Two new variables are created for each of the dependent variables *sku1* thru *sku10*: one variable contains the model predictions, and the other variable contains the noise residuals.
- The rootname (prefix) for the variables containing model predictions is *Pred*.
- The rootname for the variables containing noise residuals is *NResidual* (the default).

**PREDICTED(rootname).** *Model fit and forecast values.* The default rootname is *Predicted*.

**LCL(rootname).** *Lower confidence limits.* The default rootname is *LCL*.

**UCL(rootname).** *Upper confidence limits.* The default rootname is *UCL*.

**NRESIDUAL(rootname).** *Noise residuals.* The default rootname is *NResidual*. When transformations of the dependent variable are performed (for example, natural log), these residuals are the residuals for the transformed series.

---

## AUXILIARY Subcommand

The AUXILIARY subcommand is used to set the confidence interval level for forecasts, set the maximum number of lags for autocorrelation and partial autocorrelation plots and tables, and set the season length.

### Example

```
TSMODEL
/MODELDETAILS PLOT=[RESIDACF RESIDPACF]
/AUXILIARY MAXACFLAGS=36 SEASONLENGTH=6
/MODEL DEPENDENT=sku1 TO sku20.
```

### CILEVEL Keyword

The CILEVEL keyword sets the confidence level.

- Specify a positive number that is less than 100.
- The default is 95.

### MAXACFLAGS Keyword

The MAXACFLAGS keyword sets the maximum number of lags displayed in residual autocorrelation and partial autocorrelation tables and plots.

- Specify a positive integer.
- The default is 24.

### SEASONLENGTH Keyword

The SEASONLENGTH keyword is used to specify the length of the seasonal period (the number of observations in one period or season).

- The season length must be a positive integer.
- If SEASONLENGTH is not specified, the periodicity that is specified by using the DATE command defines the season length.
- If the Expert Modeler is used, a warning occurs and the season length is treated as 1 for any splits for which there are gaps in the data. If a custom model is specified, a warning is issued and the model is not estimated for any such splits.
- For custom ARIMA or exponential smoothing models, SEASONLENGTH is ignored if the specified model has no seasonal component.

---

## MISSING Subcommand

The MISSING subcommand controls the handling of user-missing values.

- By default, user-missing values are treated as missing (invalid) data.
- System-missing values are always treated as invalid.
- Cases with missing values of a dependent variable that occur within the estimation period are included in the model. The specific handling of the missing value depends on the estimation method.
- A warning is issued if a predictor has missing values within the estimation period. For the Expert Modeler, models involving the predictor are estimated without the predictor. For custom ARIMA, models involving the predictor are not estimated.
- If any predictor has missing values within the forecast period, the procedure issues a warning and forecasts as far as it can.

### Example

```
TSMODEL
/MISSING USERMISSING=INCLUDE
/MODEL DEPENDENT=revenue INDEPENDENT=adspending.
```

### USERMISSING Keyword

The USERMISSING keyword controls the treatment of user-missing values and is required.

**EXCLUDE.** *Exclude user-missing values.* User-missing values are treated as missing. This setting is the default.

**INCLUDE.** *Include user-missing values.* User-missing values are treated as valid data.

---

## MODEL Subcommand

The MODEL subcommand is required and is used to signal the start of a model specification, as well as to specify model variable(s).

- All variables must be numeric. Any string variables are filtered out, with a warning.
- Variables that define split-file groups are filtered out of all variable lists, with a warning.
- ALL and T0 can be used in dependent and independent variable lists. ALL represents all variables in the active dataset. T0 refers to a range of variables in the active dataset.

*Note:* Specification of the model type is optional and is accomplished by including an EXPERTMODELER, EXSMOOTH, or ARIMA subcommand following the MODEL subcommand. If the model type is not specified, the best-fitting ARIMA or exponential smoothing model will automatically be selected by the Expert Modeler, which is equivalent to specifying /EXPERTMODELER TYPE=[ARIMA EXSMOOTH]. If you are unsure of which type of model to choose, or you want Expert Modeler to choose for you, use the MODEL subcommand without a model type subcommand.

### Example

```
TSMODEL
/MODEL DEPENDENT=store1 T0 store100
      INDEPENDENT=adspending
      OUTFILE='models/stores.xml'
      PREFIX='Expert'.
```

- DEPENDENT specifies that variables *store1* thru *store100* are to be modeled. The keyword T0 refers to the order of the variables in the active dataset.
- The INDEPENDENT keyword specifies that the variable *adspending* is to be considered as a predictor variable.
- OUTFILE specifies that the resulting models are to be stored in the file */models/stores.xml*.

- PREFIX specifies that the models will be named *Expert\_1* (the model for *store1*), *Expert\_2* (the model for *store2*), etc.
- The absence of a model type subcommand (EXPERTMODELER, ARIMA, or EXSMOOTH) means that the Expert Modeler will be used to find the best-fitting exponential smoothing or ARIMA model.

#### DEPENDENT Keyword

The DEPENDENT keyword is used to specify one or more dependent variables and is required.

- At least one dependent variable must be specified.
- Repeated instances of the same variable are filtered out of the list.
- A separate model is generated for each dependent variable in each MODEL block. Identical dependent variables in separate MODEL blocks generate separate models.

#### INDEPENDENT Keyword

The INDEPENDENT keyword is used to specify one or more optional independent variables.

- Order of variables within the independent variable list matters when the Expert Modeler is used. The Expert Modeler drops nonsignificant independent variables one at a time, starting with the last variable in the list.
- In the case of custom ARIMA models, all independent variables are included in the model.
- Repeated instances of an independent variable are filtered out of the list. For example, a b a c a is equivalent to a b c. Assuming that the active dataset contains variables *a*, *b*, and *c*, ALL is also equivalent to a b c.
- An independent variable that also appears in the dependent variable list is treated solely as a dependent variable and is excluded from consideration as an independent variable for the model involving that particular dependent variable. For example, if you specify DEPENDENT=a b and INDEPENDENT=a c, then *c* is the only independent variable when modeling *a*, but *a* and *c* are both used as independent variables when modeling *b*.

#### Events

- Event variables are special independent variables that are used to model effects of occurrences such as a flood, strike, or introduction of a new product line. Any abrupt shift in the level of the dependent series can be modeled by using event variables.
- To designate an independent variable as an event variable, specify [E] following the name of the variable. For example, INDEPENDENT=strike [E] indicates that the variable *strike* is an event variable.
- When the Expert Modeler is used, event variables enter the model with linear terms only (as opposed to transfer functions). Thus, event designation can save processing time and guard against overfitting when using the Expert Modeler.
- Custom ARIMA models ignore event designation.
- For event variables, the presence of an effect is indicated by cases with a value of 1. Cases with values other than 1 are treated as indicating no effect.
- The effect of an event can last a single time period or several periods. If the effect lasts several periods, the corresponding event variable should contain a series of consecutive 1s.
- Event designation applies only to the variable that immediately precedes the designation in the independent variable list. For example, x1 x2 x3 [E] and x1 T0 x3 [E] designate x3 (only) as an event variable. If event designation follows ALL, it applies to all independent variables.
- If a variable appears more than once in the independent variable list, the event specification for the last instance of the variable is honored. For example, if ALL x1 [E] is specified, x1 is treated as an event variable; if ALL [E] x1 is specified, x1 is treated as an ordinary predictor.

#### OUTFILE and OUTPMML Keywords

The OUTFILE and OUTPMML keywords are used to save models to an external file. Saved models can be used to obtain updated forecasts, based on more current data, using the TSAPPLY command. See the topic Chapter 276, “TSAPPLY,” on page 2017 for more information.

- OUTFILE saves an XML file that can be used with other IBM SPSS applications.
- OUTPMML saves a PMML-compliant XML file that can be used with PMML-compliant applications, including IBM SPSS applications.
- Models are written to an XML file. Each model is assigned a unique name and a description that includes the name of the dependent variable and the model type.
- The filename must be specified in full. No extension is supplied.
- If two or more MODEL subcommands (within a single invocation of TSMODEL) specify the same external file, all models that are created by those MODEL subcommands are saved to that file.
- OUTFILE and OUTPMML are ignored with a warning if SPLIT FILE is in effect.

#### PREFIX Keyword

Models are assigned unique names consisting of a customizable prefix, along with an integer suffix. The PREFIX keyword is used to specify a custom prefix.

- Custom prefixes must be specified in quotes—for example, PREFIX='ExpertArima'. The default prefix is 'Model'.
- Integer suffixes are unique across the set of models that have the same prefix; for example, *Model\_1*, *Model\_2*. Models with different prefixes, however, can have the same integer suffix—for example, *CustomArima\_1*, *ExpertArima\_1*.

---

## EXPERTMODELER Subcommand

The EXPERTMODELER subcommand controls options for automatic model identification that is performed by the Expert Modeler.

#### Example

```
TSMODEL
  /MODEL DEPENDENT=store1 TO store100
        INDEPENDENT=adspending
  /EXPERTMODELER TYPE=[ARIMA].
```

- The keyword ARIMA specifies that the Expert Modeler is to limit the model search to the best-fitting ARIMA model.

#### TYPE Keyword

The TYPE keyword is required and is used to specify the model types that are evaluated: ARIMA, exponential smoothing, or both.

- By default, both ARIMA and exponential smoothing models are considered.
- Either ARIMA, EXSMOOTH, or both must be specified in square brackets.
- An error occurs if you specify the EXSMOOTH keyword by itself and the model contains independent variables.

The keyword is followed by an equals sign (=) and one or both of the following options enclosed in square brackets:

**ARIMA.** *ARIMA models are considered.*

**EXSMOOTH.** *Exponential smoothing models are considered.*

#### TRYSEASONAL Keyword

The TRYSEASONAL keyword specifies whether seasonal models are considered by the Expert Modeler.

- TRYSEASONAL is ignored if the data are nonperiodic (that is, season length is 1).

**YES.** *The Expert Modeler considers seasonal models.* This setting is the default.

**NO.** *The Expert Modeler does not consider seasonal models.* Only nonseasonal models are considered.

---

## EXSMOOTH Subcommand

The EXSMOOTH subcommand controls options for custom exponential smoothing models.

- Using EXSMOOTH generates an error if independent variables are defined.
- For seasonal models (SIMPLESEASONAL, WINTERSADDITIVE, and WINTERSMULTIPLICATIVE), an error is generated if the season length has not been defined via the DATE command or the SEASONLENGTH keyword.

### Example

```
TSMODEL
/AUXILIARY SEASONLENGTH=12
/MODEL DEPENDENT=store1 TO store100
/EXSMOOTH TYPE=WINTERSMULTIPLICATIVE.
```

### TYPE Keyword

The TYPE keyword is required and is used to specify the type of exponential smoothing model. There is no default method.

**SIMPLE.** *Simple exponential smoothing model.* This model is appropriate for series in which there is no trend or seasonality. Its only smoothing parameter is level. Simple exponential smoothing is most similar to an ARIMA model with zero orders of autoregression, one order of differencing, one order of moving average, and no constant.

**SIMPLESEASONAL.** *Simple seasonal exponential smoothing model.* This model is appropriate for series with no trend and a seasonal effect that is constant over time. Its smoothing parameters are level and season. Simple seasonal exponential smoothing is most similar to an ARIMA model with zero orders of autoregression, one order of differencing, one order of seasonal differencing, and orders 1,  $p$ , and  $p + 1$  of moving average, where  $p$  is the number of periods in a seasonal interval (for monthly data,  $p = 12$ ).

**HOLT.** *Holt's method.* This model is appropriate for series in which there is a linear trend and no seasonality. Its smoothing parameters are level and trend, which are not constrained by each other's values. Holt's model is more general than Brown's model but may take longer to compute for large series. Holt's exponential smoothing is most similar to an ARIMA model with zero orders of autoregression, two orders of differencing, and two orders of moving average.

**BROWN.** *Brown's method.* This model is appropriate for series in which there is a linear trend and no seasonality. Its smoothing parameters are level and trend, which are assumed to be equal. Brown's model is therefore a special case of Holt's model. Brown's exponential smoothing is most similar to an ARIMA model with zero orders of autoregression, two orders of differencing, and two orders of moving average, with the coefficient for the second order of moving average equal to the square of one-half of the coefficient for the first order.

**DAMPEDTREND.** *Damped trend method.* This model is appropriate for series with a linear trend that is dying out and with no seasonality. Its smoothing parameters are level, trend, and damping trend. Damped exponential smoothing is most similar to an ARIMA model with 1 order of autoregression, 1 order of differencing, and 2 orders of moving average.

**WINTERSADDITIVE.** *Winters' additive method.* This model is appropriate for series with a linear trend and a seasonal effect that does not depend on the level of the series. Its smoothing parameters are level, trend, and season. Winters' additive exponential smoothing is most similar to an ARIMA model with zero orders of autoregression, one order of differencing, one order of seasonal differencing, and  $p + 1$  orders of moving average, where  $p$  is the number of periods in a seasonal interval (for monthly data,  $p = 12$ ).

**WINTERSMULTIPLICATIVE.** *Winters' multiplicative method.* This model is appropriate for series with a linear trend and a seasonal effect that depends on the level of the series. Its smoothing parameters are level, trend, and season. Winters' multiplicative exponential smoothing is not similar to any ARIMA model.

#### TRANSFORM Keyword

The TRANSFORM keyword specifies a transformation that is performed on each dependent variable before it is modeled. By default, dependent variables are not transformed.

**NONE.** *Dependent variable series are not transformed.* This setting is the default.

**SQRT.** *A square root transformation is performed.*

**LN.** *A natural log transformation is performed.*

---

## ARIMA Subcommand

The ARIMA subcommand controls options for custom ARIMA models. The model must contain at least one parameter. An error occurs if the model has no autoregressive component, moving average component, outlier, or constant term, unless independent variables are selected.

#### Example: Basic Custom Seasonal ARIMA Model

```
TSMODEL
/AUXILIARY SEASONLENGTH=12
/MODEL DEPENDENT=passengers
/ARIMA AR=[0] ARSEASONAL=[0] MA=[1] MASEASONAL=[1]
      DIFF=1 DIFFSEASONAL=1 TRANSFORM=LN.
```

- A custom ARIMA(0,1,1)(0,1,1) model is specified, including a natural log transformation of the dependent variable. The seasonal length is 12.

#### Example: Including Specific Lags in a Custom ARIMA Model

```
TSMODEL
/MODEL DEPENDENT=revenue
/ARIMA AR=0 MA=[1 3].
```

- A moving average model is specified. Moving average lags of orders 1 and 3 are included.

#### AR Keyword

The AR keyword specifies the nonseasonal autoregressive order of the model and is required.

- You can specify a single value or a list of values in square brackets. All values must be nonnegative integers.
- If you specify a single value, square brackets are optional. The specified lag will be included in the model.
- If you specify a list of positive integer values--for example, [1 3]--the specified lags are included in the model. Duplicate lags are ignored.

#### ARSEASONAL Keyword

The ARSEASONAL keyword specifies the seasonal autoregressive order of the model.

- You can specify a single value or a list of values in square brackets. All values must be nonnegative integers. The default order is zero.
  - If you specify a single value, square brackets are optional. The specified lag will be included in the model.
  - If you specify a list of positive integer values--for example, [1 3]--the specified lags are included in the model. Duplicate lags are ignored.
- An error occurs if ARSEASONAL specifies a nonzero value and the season length has not been defined via the DATE command or the SEASONLENGTH keyword.

#### MA Keyword

The MA keyword specifies the nonseasonal moving average order of the model and is required.

- You can specify a single value or a list of values in square brackets. All values must be nonnegative integers.
- If you specify a single value, square brackets are optional. The specified lag will be included in the model.
- If you specify a list of positive integer values--for example, [1 3]--the specified lags are included in the model. Duplicate lags are ignored.

#### MASEASONAL Keyword

The MASEASONAL keyword specifies the seasonal moving average order of the model.

- You can specify a single value or a list of values in square brackets. All values must be nonnegative integers. The default order is zero.
  - If you specify a single value, square brackets are optional. The specified lag will be included in the model.
  - If you specify a list of positive integer values--for example, [1 3]--the specified lags are included in the model. Duplicate lags are ignored.
- An error occurs if MASEASONAL specifies a nonzero value and the season length has not been defined via the DATE command or the SEASONLENGTH keyword.

#### CONSTANT Keyword

The CONSTANT keyword controls whether the model for each dependent variable includes a constant term.

**YES.** *The model includes a constant term. This setting is the default.*

**NO.** *No constant term is included in the model.*

#### TRANSFORM Keyword

The TRANSFORM keyword specifies a transformation that is performed on each dependent variable before it is modeled. By default, the variables are not transformed.

**NONE.** *Dependent-variable series are not transformed. This setting is the default.*

**SQRT.** *A square root transformation is performed.*

**LN.** *A natural log transformation is performed.*

#### DIFF Keyword

The DIFF keyword specifies the order of nonseasonal differencing.

- The order of nonseasonal differencing must be a nonnegative integer. The default order is zero.

#### DIFFSEASONAL Keyword

The DIFFSEASONAL keyword specifies the order of seasonal differencing.

- The order of seasonal differencing must be a nonnegative integer. The default order is zero.
- An error occurs if DIFFSEASONAL specifies a nonzero value and the season length has not been defined via the DATE command or the SEASONLENGTH keyword.

---

## TRANSFERFUNCTION Subcommand

The TRANSFERFUNCTION subcommand specifies a transfer function and transformations for predictor variables in an ARIMA model.

- By default, for each predictor in an ARIMA model, the numerator and denominator orders of the transfer function (both seasonal and nonseasonal) are set to zero. The predictors are neither transformed nor differenced by default.
- The TRANSFERFUNCTION subcommand may be used more than once in a MODEL block to specify different transfer functions and/or transformations for different independent variables.
- If there are multiple TRANSFERFUNCTION subcommands that refer to the same predictor variable within a MODEL block, the last set of specifications is honored for that variable.
- The TRANSFERFUNCTION subcommand is ignored if the EXPERTMODELER or EXSMOOTH subcommand is used.

#### Example

```
TSMODEL
  /MODEL DEPENDENT=revenue INDEPENDENT=adspending
  /ARIMA AR=[1] MA=[0]
  /TRANSFERFUNCTION VARIABLES=adspending NUM=[1] DENOM=[1].
```

- A custom ARIMA(1,0,0) model is specified and includes the independent variable *adspending*.
- The TRANSFERFUNCTION subcommand specifies that *adspending* is to be modeled with numerator and denominator lags of order 1.

#### VARIABLES Keyword

The VARIABLES keyword is used to specify a list of predictors.

- Repeated instances of the same variable are filtered out of the list.
- Variables that have not been specified as independent (with the INDEPENDENT keyword) in the preceding MODEL subcommand are ignored.
- Use ALL to specify all independent variables. This setting is the default.

#### NUM Keyword

The NUM keyword specifies the numerator order of the transfer function for nonseasonal models.

- You can specify a single value or a list of values in square brackets. All values must be nonnegative integers. The default order is zero.
- The model always includes an implicit zero, even if not specified via the NUM keyword.
- If you specify a single value, square brackets are optional. The specified lag will be included in the model.
- If you specify a list of positive integer values--for example, [1 3]--the specified lags are included in the model. Duplicate lags are ignored.

#### NUMSEASONAL Keyword

The NUMSEASONAL keyword specifies the numerator order of the transfer function for seasonal models.

- You can specify a single value or a list of values in square brackets. All values must be nonnegative integers. The default order is zero.
  - If you specify a single value, square brackets are optional. The specified lag will be included in the model.
  - If you specify a list of positive integer values--for example, [1 3]--the specified lags are included in the model. Duplicate lags are ignored.
- An error occurs if NUMSEASONAL specifies a nonzero value and the season length has not been defined via the DATE command or the SEASONLENGTH keyword.

#### DENOM Keyword

The DENOM keyword specifies the denominator order of the transfer function for nonseasonal models.

- You can specify a single value or a list of values in square brackets. All values must be nonnegative integers. The default order is zero.
- If you specify a single value, square brackets are optional. The specified lag will be included in the model.
- If you specify a list of positive integer values--for example, [1 3]--the specified lags are included in the model. Duplicate lags are ignored.

#### DENOMSEASONAL Keyword

The DENOMSEASONAL keyword specifies the denominator order of the transfer function for seasonal models.

- You can specify a single value or a list of values in square brackets. All values must be nonnegative integers. The default order is zero.
  - If you specify a single value, square brackets are optional. The specified lag will be included in the model.
  - If you specify a list of positive integer values--for example, [1 3]--the specified lags are included in the model. Duplicate lags are ignored.
- An error occurs if DENOMSEASONAL specifies a nonzero value and the season length has not been defined via the DATE command or the SEASONLENGTH keyword.

#### TRANSFORM Keyword

The TRANSFORM keyword specifies a transformation that is performed on all predictor variables. By default, predictor variables are not transformed.

**NONE.** *Predictor variables are not transformed.* This setting is the default.

**SQRT.** *A square root transformation is performed.*

**LN.** *A natural log transformation is performed.*

#### DIFF Keyword

The DIFF keyword specifies the order of nonseasonal differencing for predictor variables.

- The order of nonseasonal differencing must be a nonnegative integer. The default order is zero.

#### DIFFSEASONAL Keyword

The DIFFSEASONAL keyword specifies the order of seasonal differencing for predictor variables.

- The order of seasonal differencing must be a nonnegative integer. The default order is zero.
- DIFFSEASONAL generates an error if the season length has not been defined via the DATE command or the SEASONLENGTH keyword.

## DELAY Keyword

The DELAY keyword specifies the delay order for predictor variables.

- The delay order must be a nonnegative integer. The default order is zero.

---

## AUTOOUTLIER Subcommand

The AUTOOUTLIER subcommand specifies whether outlier time points are identified automatically.

- By default, outliers are not identified.
- If identified, outliers are not discarded but are incorporated in the model.
- The AUTOOUTLIER subcommand is ignored with a warning if it is part of a MODEL block that contains an EXSMOOTH subcommand.

### Example

```
TSMODEL
/MODELDETAILS PRINT=PARAMETERS
/MODEL DEPENDENT=revenue
/EXPERTMODELER TYPE=[ARIMA]
/AUTOOUTLIER DETECT=ON.
```

## DETECT Keyword

The DETECT keyword controls whether automatic outlier detection is performed.

**OFF.** *Outliers are not identified.* This setting is the default.

**ON.** *Outliers are identified.* ON is ignored with a warning if the model type is EXSMOOTH.

## TYPE Keyword

The optional TYPE keyword specifies the types of outliers that are identified when DETECT=ON. TYPE is ignored if DETECT=OFF.

- Additive and level shift outliers are identified by default.
- The specification of outlier types overrides the default. That is, if you specify a list of outlier types, additive and level shift outliers are not included unless explicitly requested.

The keyword is followed by an equals sign (=) and one or more of the following options enclosed in square brackets:

**ADDITIVE.** *Additive.* An outlier that affects a single observation. For example, a data coding error might be identified as an additive outlier. Default if DETECT=ON.

**LEVELSHIFT.** *Level shift.* An outlier that shifts all observations by a constant, starting at a particular series point. A level shift could result from a change in policy. Default if DETECT=ON.

**INNOVATIONAL.** *Innovational.* An outlier that acts as an addition to the noise term at a particular series point. For stationary series, an innovational outlier affects several observations. For nonstationary series, it may affect every observation starting at a particular series point.

**TRANSIENT.** *Transient.* An outlier whose impact decays exponentially to 0.

**SEASONALADDITIVE.** *Seasonal additive.* An outlier that affects a particular observation and all subsequent observations separated from it by one or more seasonal periods. All such observations are affected equally. A seasonal additive outlier might occur if, beginning in a certain year, sales are higher every January. The keyword generates an error if the season length has not been defined via the DATE command or the SEASONLENGTH keyword.

**LOCALTREND.** *Local trend.* An outlier that starts a local trend at a particular series point.

**ADDITIVEPATCH.** *Additive patch.* A group of two or more consecutive additive outliers. Selecting this outlier type results in the detection of individual additive outliers in addition to groups of them.

---

## OUTLIER Subcommand

The OUTLIER subcommand specifies outlier time points to be included in an ARIMA model.

- By default, no time points are modeled as outliers.
- For each outlier, you must specify its time point (location) and type.
- Multiple OUTLIER subcommands can be used to define two or more outliers for an ARIMA model. Duplicate specifications (same location and type) are ignored and a warning is issued.
- A warning occurs and the OUTLIER subcommand is ignored if the subcommand is part of a MODEL block that contains an EXPERTMODELER or EXSMOOTH subcommand.
- If the AUTOOUTLIER and OUTLIER subcommands are both included in a MODEL block containing an ARIMA subcommand, a warning is issued and the OUTLIER specification takes precedence.

### Example

```
TSMODEL
/MODELDETAILS PRINT=PARAMETERS
/MODEL DEPENDENT=revenue
/ARIMA AR=[1] MA=[1]
/OUTLIER LOCATION=[YEAR 2000 MONTH 8] TYPE=LOCALTREND.
```

- A custom ARIMA(1,0,1) model is specified with an outlier of type Local Trend for August, 2000.

### LOCATION Keyword

The LOCATION keyword specifies the time point to be treated as an outlier and is required.

- Specify a date in square brackets. If the data are undated, you must specify a case number. Otherwise, specify the outlier location using date keywords and values. For example, LOCATION=[YEAR 2000 MONTH 8] specifies that August, 2000 be treated as an outlier. The following date keywords may be used: CYCLE, YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, SECOND, and OBS. Every keyword in the IBM SPSS Statistics date specification must appear in LOCATION. Only keywords that correspond to system date variables may be used, and no date keyword may be used more than once. See the topic Chapter 73, "DATE," on page 575 for more information.
- A warning is issued if you specify an outlier location that is outside the estimation period or corresponds to a gap in the data. Any such models are ignored.

### TYPE Keyword

The TYPE keyword specifies the type of outlier and is required. Specify one of the following types:

**ADDITIVE.** *Additive.* An outlier that affects a single observation. For example, a data coding error might be identified as an additive outlier.

**LEVELSHIFT.** *Level shift.* An outlier that shifts all observations by a constant, starting at a particular series point. A level shift could result from a change in policy.

**INNOVATIONAL.** *Innovational.* An outlier that acts as an addition to the noise term at a particular series point. For stationary series, an innovational outlier affects several observations. For nonstationary series, it may affect every observation starting at a particular series point.

**TRANSIENT.** *Transient.* An outlier whose impact decays exponentially to 0.

**SEASONALADDITIVE.** *Seasonal additive.* An outlier that affects a particular observation and all subsequent observations separated from it by one or more seasonal periods. All such observations are affected equally. A seasonal additive outlier might occur if, beginning in a certain year, sales are higher every January. The keyword generates an error if the season length has not been defined via the DATE command or the SEASONLENGTH keyword.

**LOCALTREND.** *Local trend.* An outlier that starts a local trend at a particular series point.

---

## Chapter 280. TSPLIT

TSPLIT VARIABLES= variable names

```
[/DIFF={1}]
      {n}

[/SDIFF={1}]
      {n}

[/PERIOD=n]

[/{NOLOG**}]
      {LN }

[/ID=varname]

[/MARK={varname} ]
      {date }

[/SPLIT {UNIFORM**}]
      {SCALE }

[/APPLY [= 'mode1 name']]
```

For plots with one variable:

```
[/FORMAT=[{NOFILL**}] [{NOREFERENCE**}]]
      {BOTTOM } {REFERENCE[(value)]}
```

For plots with multiple variables:

```
[/FORMAT={NOJOIN**}]
      {JOIN }
      {HILO }
```

\*\*Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

Release History

Release 14.0

- For plots with one variable, REFERENCE keyword modified to allow specification of a value.

Example

```
TSPLIT VARIABLES = TICKETS.
```

---

## Overview

TSPLIT produces a plot of one or more time series or sequence variables. You can request natural log and differencing transformations to produce plots of transformed variables. Several plot formats are available.

Options

**Modifying the Variables.** You can request a natural log transformation of the variables using the LN subcommand and seasonal and nonseasonal differencing to any degree using the SDIFF and DIFF subcommands. With seasonal differencing, you can also specify the periodicity on the PERIOD subcommand.

**Plot Format.** With the FORMAT subcommand, you can fill in the space on one side of the plotted values on plots with one variable. You can also plot a reference line indicating the variable mean. For plots with two or more variables, you can specify whether you want to join the values for each observation with a

vertical line. With the ID subcommand, you can label the horizontal axis with the values of a specified variable. You can mark the onset of an intervention variable on the plot with the MARK subcommand.

**Split-File Processing.** You can control how data that have been divided into subgroups by a SPLIT FILE command should be plotted using the SPLIT subcommand.

#### Subcommand Order

- Subcommands can be specified in any order.

#### Syntax Rules

- VARIABLES can be specified only once.
- Other subcommands can be specified more than once, but only the last specification of each one is executed.

#### Operations

- Subcommand specifications apply to all variables named on the TSPLIT command.
- If the LN subcommand is specified, any differencing requested on that TSPLIT command is done on the log-transformed variables.
- Split-file information is displayed as part of the subtitle, and transformation information is displayed as part of the footnote.

#### Limitations

- Maximum of one VARIABLES subcommand. There is no limit on the number of variables named on the list.

---

## Basic Specification

The basic specification is one or more variable names.

- If the DATE command has been specified, the horizontal axis is labeled with the *DATE\_* variable at periodic intervals. Otherwise, sequence numbers are used. The vertical axis is labeled with the value scale of the plotted variable(s).

The following figure shows a default plot with DATE YEAR 1995 MONTH.

Figure 98. `TSPLLOT VARIABLES=SHARE`

## Example

```
TSPLLOT VARIABLES = TICKETS
/LN
/DIFF
/SDIFF
/PERIOD=12
/FORMAT=REFERENCE
/MARK=Y 55 M 6.
```

- This command produces a plot of *TICKETS* after a natural log transformation, differencing, and seasonal differencing have been applied.
- LN transforms the data using the natural logarithm (base  $e$ ) of *TICKETS*.
- DIFF differences the logged variable once.
- SDIFF and PERIOD apply one degree of seasonal differencing with a period of 12.
- FORMAT=REFERENCE adds a reference line representing the variable mean.
- MARK provides a marker on the plot at June 1955. The marker is displayed as a vertical reference line.

## VARIABLES Subcommand

VARIABLES specifies the names of the variables to be plotted and is the only required subcommand.

## DIFF Subcommand

DIFF specifies the degree of differencing used to convert a nonstationary variable to a stationary one with a constant mean and variance before plotting.

- You can specify any positive integer on DIFF.
- If DIFF is specified without a value, the default is 1.
- The number of values plotted decreases by 1 for each degree of differencing.

## Example

```
TSPLLOT VARIABLES = TICKETS  
/DIFF=2.
```

- In this example, *TICKETS* is differenced twice before plotting.

---

## SDIFF Subcommand

If the variable exhibits a seasonal or periodic pattern, you can use the *SDIFF* subcommand to seasonally difference the variable before plotting.

- The specification on *SDIFF* indicates the degree of seasonal differencing and can be any positive integer.
- If *SDIFF* is specified without a value, the degree of seasonal differencing defaults to 1.
- The number of seasons plotted decreases by 1 for each degree of seasonal differencing.
- The length of the period used by *SDIFF* is specified on the *PERIOD* subcommand. If the *PERIOD* subcommand is not specified, the periodicity established on the *TSET* or *DATE* command is used (see the *PERIOD* subcommand).

---

## PERIOD Subcommand

*PERIOD* indicates the length of the period to be used by the *SDIFF* subcommand.

- The specification on *PERIOD* indicates how many observations are in one period or season and can be any positive integer.
- If *PERIOD* is not specified, the periodicity established on *TSET PERIOD* is in effect. If *TSET PERIOD* is not specified, the periodicity established on the *DATE* command is used. If periodicity was not established anywhere, the *SDIFF* subcommand will not be executed.

## Example

```
TSPLLOT VARIABLES = TICKETS  
/SDIFF=1  
/PERIOD=12.
```

- This command applies one degree of seasonal differencing with 12 observations per season to *TICKETS* before plotting.

---

## LN and NOLOG Subcommands

*LN* transforms the data using the natural logarithm (base *e*) of the variable and is used to remove varying amplitude over time. *NOLOG* indicates that the data should not be log transformed. *NOLOG* is the default.

- If you specify *LN* on *TSPLLOT*, any differencing requested on that command will be done on the log-transformed variables.
- There are no additional specifications on *LN* or *NOLOG*.
- Only the last *LN* or *NOLOG* subcommand on a *TSPLLOT* command is executed.
- If a natural log transformation is requested, any value less than or equal to zero is set to system-missing.
- *NOLOG* is generally used with an *APPLY* subcommand to turn off a previous *LN* specification.

## Example

```
TSPLLOT VARIABLES = TICKETS  
/LN.
```

- In this example, *TICKETS* is transformed using the natural logarithm before plotting.

---

## ID Subcommand

*ID* names a variable whose values will be used as labels for the horizontal axis.

- The only specification on ID is a variable name. If you have a variable named *ID* in your active dataset, the equals sign (=) after the subcommand is required.
- If the ID subcommand is not used and TSET ID has not been specified, the axis is labeled with the *DATE\_* variable created by the DATE command. If the DATE command has not been specified, the observation number is used as the label.

#### Example

```
TSPLLOT VARIABLES = VARA
      /ID=VARB.
```

- In this example, the values of *VARB* will be used to label the horizontal axis of *VARA* at periodic intervals.

---

## FORMAT Subcommand

FORMAT controls the plot format.

- The specification on FORMAT is one of the keywords listed below.
- Keywords *NOFILL*, *BOTTOM*, *REFERENCE*, and *NOREFERENCE* apply to plots with one variable. *NOFILL* and *BOTTOM* are alternatives that indicate how the plot is filled. *NOREFERENCE* and *REFERENCE* are alternatives that specify whether a reference line is displayed.
- Keywords *JOIN*, *NOJOIN*, and *HIL0* apply to plots with multiple variables and are alternatives. *NOJOIN* is the default. Only one keyword can be specified on a FORMAT subcommand for plots with multiple variables.

The following formats are available for plots with one variable:

**NOFILL.** *Plot only the values for the variable with no fill.* NOFILL produces a plot with no fill above or below the plotted values. This is the default format when one variable is specified.

**BOTTOM.** *Plot the values for the variable and fill in the area below the curve.* If the plotted variable has missing or negative values, BOTTOM is ignored and the default NOFILL is used instead.

**NOREFERENCE.** *Do not plot a reference line.* This is the default when one variable is specified.

**REFERENCE(value)** . *Plot a reference line at the specified value or at the variable mean if no value is specified.* A fill chart is displayed as an area chart with a reference line and a non-fill chart is displayed as a line chart with a reference line.

Figure 99. *FORMAT=BOTTOM*

Figure 100. *FORMAT=REFERENCE*

The following formats are available for plots with multiple variables:

**NOJOIN.** Plot the values of each variable named. Different colors or line patterns are used for multiple variables. Multiple occurrences of the same value for a single observation are plotted using a dollar sign (\$). This is the default format for plots with multiple variables.

**JOIN.** Plot the values of each variable and join the values for each observation. Values are plotted as described for NOJOIN, and the values for each observation are joined together by a line.

**HILO.** Plot the highest and lowest values across variables for each observation and join the two values together. The high and low values are plotted as a horizontal bar and are joined with a line. If more than three variables are specified, HILO is ignored and the default NOJOIN is used.

Figure 101. *FORMAT=HILO*

## MARK Subcommand

MARK indicates the onset of an intervention variable.

- The onset date is indicated by a vertical reference line.
- The specification on MARK can be either a variable name or an onset date if the *DATE\_* variable exists.
- If a variable is named, the plot indicates where the values of that variable change.
- A date specification follows the same format as the DATE command; that is, a keyword followed by a value. For example, the specification for June 1955 is Y 1955 M 6 (or Y 55 M 6 if only the last two digits of the year are used on DATE).

The following figure shows a plot with January 2001 marked as the onset date.

Figure 102. MARK=Y 2001 M 1

---

## SPLIT Subcommand

SPLIT specifies how to plot data that have been divided into subgroups by a SPLIT FILE command. The default is UNIFORM.

**UNIFORM.** *Scale uniformly.* The vertical axis is scaled according to the values of the entire dataset.

**SCALE.** *Scale individually.* The vertical axis is scaled according to the values of each individual subgroup.

- If FORMAT=REFERENCE is specified when SPLIT=SCALE, the reference line is placed at the mean of the subgroup. If FORMAT=REFERENCE is specified when SPLIT=UNIFORM, the reference line is placed at the overall mean.

### Example

```
SPLIT FILE BY REGION.
TSPLIT VARIABLES = TICKETS / SPLIT=SCALE.
```

- In this example, the data have been split into subgroups by *REGION*. The plots produced with the SCALE subcommand have vertical axes that are individually scaled according to the values of each particular region.

---

## APPLY Subcommand

APPLY allows you to produce a plot using previously defined specifications without having to repeat the TSPLIT subcommands.

- The only specification on APPLY is the name of a previous model enclosed in quotes. If a model name is not specified, the specifications from the previous TSPLIT command are used.
- To change one or more specifications of the plot, specify the subcommands of only those portions you want to change after the subcommand APPLY.

- If no variables are specified, the variables that were specified for the original plot are used.
- To plot different variables, enter new variable names before or after the APPLY subcommand.

### Example

```
TSPLLOT VARIABLES = TICKETS
/LN
/DIFF=1
/SDIFF=1
/PERIOD=12.
TSPLLOT VARIABLES = ROUNDTRP
/APPLY.
TSPLLOT APPLY
/NOLOG.
```

- The first command produces a plot of *TICKETS* after a natural log transformation, differencing, and seasonal differencing have been applied.
- The second command plots the values for *ROUNDTRP* using the same subcommands specified for *TICKETS*.
- The third command produces another plot of *ROUNDTRP* but this time without a log transformation. *ROUNDTRP* is still differenced once and seasonally differenced with a periodicity of 12.

---

## Chapter 281. T-TEST

T-TEST is available in the Statistics Base Edition.

One-sample tests:

```
T-TEST TESTVAL n /VARIABLE=varlist
```

Independent-samples tests:

```
T-TEST GROUPS=varname ({1,2** }) /VARIABLES=varlist
                        {value }
                        {value,value}
```

Paired-samples tests:

```
T-TEST PAIRS=varlist [WITH varlist [(PAIRED)]] [/varlist ...]
```

All types of tests:

```
[/MISSING={ANALYSIS**} [INCLUDE]]
                {LISTWISE }
[/CRITERIA=CI({0.95**})
                {value }]
```

\*\*Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

Examples

```
T-TEST GROUPS=WORLD(1,3) /VARIABLES=NTCPRI NTCSAL NTCPUR.
```

```
T-TEST PAIRS=TEACHER CONSTRUC MANAGER.
```

---

## Overview

T-TEST compares sample means by calculating Student’s  $t$  and displays the two-tailed probability of the difference between the means. Statistics are available for one-sample (tested against a specified value), independent samples (different groups of cases), or paired samples (different variables). Other procedures that compare group means are ANOVA, ONEWAY, UNIANOVA, GLM, and MANOVA (GLM and MANOVA are available in SPSS Statistics Standard Edition or the Advanced Statistics Option).

Options

**Statistics.** There are no optional statistics. All statistics available are displayed by default.

Basic Specification

The basic specification depends on whether you want a one-sample test, an independent-samples test or a paired-samples test. For all types of tests, T-TEST displays Student’s  $t$ , degrees of freedom, and two-tailed probabilities, as well as the mean, standard deviation, standard error, and count for each group or variable.

- To request a one-sample test, use the TESTVAL and VARIABLES subcommands. The output includes a One-Sample Statistics table showing univariate statistics and a One-Sample Test table showing the test value, the difference between the sample mean and the test value, and the two-tailed probability level.
- To request an independent-samples test, use the GROUPS and VARIABLES subcommands. The output includes a Group Statistics table showing summary statistics by group for each dependent variable and

an Independent-Samples Test table showing both pooled- and separate-variance estimates, along with the  $F$  value used to test homogeneity of variance and its probability. The two-tailed probability is displayed for the  $t$  value.

- To request a paired-samples test, use the `PAIRS` subcommand. The output includes a Paired Statistics table showing univariate statistics by pairs, a Paired Samples Correlations table showing correlation coefficients and two-tailed probability level for a test of the coefficient for each pair, and a Paired Samples Test table showing the paired differences between the means and two-tailed probability levels for a test of the differences.

### Subcommand Order

Subcommands can be named in any order.

### Operations

- If a variable specified on `GROUPS` is a long string, only the short-string portion is used to identify groups in the analysis.
- Probability levels are two-tailed. To obtain the one-tailed probability, divide the two-tailed probability by 2.

### Limitations

- Maximum of one `TESTVAL` and one `VARIABLES` subcommand per one-sample  $t$  test.
- Maximum of one `GROUPS` and one `VARIABLES` subcommand per independent-samples  $t$  test.

---

## Examples

### One-Sample Test

```
T-TEST  
  /TESTVAL=322  
  /VARIABLES=brake  
  /CRITERIA=CIN (.90).
```

- The procedure compares the mean of *brake* with the test value 322.
- `CRITERIA` requests a 90% confidence interval for the mean difference.

### Independent-Samples Test, using specific values

```
T-TEST GROUPS=insert(0 1)  
  /MISSING=ANALYSIS  
  /VARIABLES=dollars  
  /CRITERIA=CIN(.95).
```

- The procedure compares the means of the two groups defined by values 0 and 1 of *insert* for variable *dollars*.
- All other options are set to their default values.

### Paired-Samples Test

```
T-TEST PAIRS=TEACHER CONSTRUC MANAGER.
```

- This paired-samples  $t$  test compares the means of *TEACHER* with *CONSTRUC*, *TEACHER* with *MANAGER*, and *CONSTRUC* with *MANAGER*.

---

## VARIABLES Subcommand

`VARIABLES` specifies the dependent variables to be tested in a one-sample or an independent-samples  $t$  test.

- `VARIABLES` can specify multiple variables, all of which must be numeric.
- When specified along with `TESTVAL`, the mean of all cases for each variable is compared with the specified value.

- When specified along with `GROUPS`, the means of two groups of cases defined by the `GROUPS` subcommand are compared.
- If both `TESTVAL` and `GROUPS` are specified, a one-sample test and an independent-samples test are performed on each variable.

## TESTVAL Subcommand

`TESTVAL` specifies the value with which a sample mean is compared.

- Only one `TESTVAL` subcommand is allowed.
- Only one value can be specified on the `TESTVAL` subcommand.

## GROUPS Subcommand

`GROUPS` specifies a variable used to group cases for independent-samples  $t$  tests.

- `GROUPS` can specify only one variable, which can be numeric or string.

Any one of three methods can be used to define the two groups for the variable specified on `GROUPS`:

- Specify a single value in parentheses to group all cases with a value equal to or greater than the specified value into one group and the remaining cases into the other group.
- Specify two values in parentheses to include cases with the first value in one group and cases with the second value in the other group. Cases with other values are excluded.
- If no values are specified on `GROUP`, `T-TEST` uses 1 and 2 as default values for numeric variables. There is no default for string variables.

## PAIRS Subcommand

`PAIRS` requests paired-samples  $t$  tests.

- The minimum specification for a paired-samples test is `PAIRS` with an analysis list. Only numeric variables can be specified on the analysis list. The minimum analysis list is two variables.
- If keyword `WITH` is not specified, each variable in the list is compared with every other variable on the list.
- If keyword `WITH` is specified, every variable to the left of `WITH` is compared with every variable to the right of `WITH`. `WITH` can be used with `PAIRED` to obtain special pairing.
- To specify multiple analysis lists, use multiple `PAIRS` subcommands, each separated by a slash. Keyword `PAIRS` is required only for the first analysis list; a slash can be used to separate each additional analysis list.

**(PAIRED).** *Special pairing for paired-samples test.* `PAIRED` must be enclosed in parentheses and must be used with keyword `WITH`. When `PAIRED` is specified, the first variable before `WITH` is compared with the first variable after `WITH`, the second variable before `WITH` is compared with the second variable after `WITH`, and so forth. The same number of variables should be specified before and after `WITH`; unmatched variables are ignored and a warning message is issued. `PAIRED` generates an error message if keyword `WITH` is not specified on `PAIRS`.

### Example

```
T-TEST PAIRS=TEACHER CONSTRUC MANAGER.
T-TEST PAIRS=TEACHER MANAGER WITH CONSTRUC ENGINEER.
T-TEST PAIRS=TEACHER MANAGER WITH CONSTRUC ENGINEER (PAIRED).
```

- The first `T-TEST` compares `TEACHER` with `CONSTRUC`, `TEACHER` with `MANAGER`, and `CONSTRUC` with `MANAGER`.
- The second `T-TEST` compares `TEACHER` with `CONSTRUC`, `TEACHER` with `ENGINEER`, `MANAGER` with `CONSTRUC`, and `MANAGER` with `ENGINEER`. `TEACHER` is not compared with `MANAGER`, and `CONSTRUC` is not compared with `ENGINEER`.

- The third T-TEST compares *TEACHER* with *CONSTRUC* and *MANAGER* with *ENGINEER*.
- 

## **CRITERIA Subcommand**

CRITERIA resets the value of the confidence interval. Keyword CI is required. You can specify a value between 0 and 1 in the parentheses. The default is 0.95.

---

## **MISSING Subcommand**

MISSING controls the treatment of missing values. The default is ANALYSIS.

- ANALYSIS and LISTWISE are alternatives; however, each can be specified with INCLUDE.

**ANALYSIS.** *Delete cases with missing values on an analysis-by-analysis or pair-by-pair basis.* For independent-samples tests, cases with missing values for either the grouping variable or the dependent variable are excluded from the analysis of that dependent variable. For paired-samples tests, a case with a missing value for either of the variables in a given pair is excluded from the analysis of that pair. This is the default.

**LISTWISE.** *Exclude cases with missing values listwise.* A case with a missing value for any variable specified on either GROUPS or VARIABLES is excluded from any independent-samples test. A case with a missing value for any variable specified on PAIRS is excluded from any paired-samples test.

**INCLUDE.** *Include user-missing values.* User-missing values are treated as valid values.

---

## Chapter 282. TWOSTEP CLUSTER

TWOSTEP CLUSTER is available in the Statistics Base Edition.

TWOSTEP CLUSTER

```
[/CATEGORICAL VARIABLES = varlist]
[/CONTINUOUS VARIABLES = varlist]
[/CRITERIA [INITHRESHOLD({0** })] [MXBRANCH({8**})]
           {value}                {n }
           [MXLEVEL({3**})] ]
[/DISTANCE {EUCLIDEAN }
           {LIKELIHOOD**}]
[/HANDLENOISE {0**}
              {n } ]
[/INFILE FILE = filename]
[/MEMALLOCATE {64**}
              {n } ]
[/MISSING {EXCLUDE**}
          {INCLUDE } ]
[/NOSTANDARDIZE [VARIABLES = varlist]]
[/NUMCLUSTERS {AUTO** {15**} [{AIC }]}
              {n } {BIC**}
              {FIXED = n } ]
[/OUTFILE [MODEL = 'file'] [STATE = 'file']]
[/PRINT [IC] [COUNT] [SUMMARY]]
[/VIEWMODEL [DISPLAY = {YES**}
               {NO } ]
            [EVALUATIONFIELDS = varlist]]
[/SAVE CLUSTER [VARIABLE = varname]]
```

\*\*Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Example

```
TWOSTEP CLUSTER
  /CONTINUOUS VARIABLES = INCOME
  /CATEGORICAL VARIABLES = GENDER RACE
  /PRINT SUMMARY.
```

---

## Overview

TWOSTEP CLUSTER groups observations into clusters based on a nearness criterion. The procedure uses a hierarchical agglomerative clustering procedure in which individual cases are successively combined to form clusters whose centers are far apart. This algorithm is designed to cluster large numbers of cases. It passes the data once to find the cluster centers and again to assign cluster memberships. In addition to the benefit of few data passes, the procedure allows the user to set the amount of memory used by the clustering algorithm.

### Basic Features

**Cluster Features (CF) Tree.** TWOSTEP CLUSTER clusters observations by building a data structure called the **CF tree**, which contains the cluster centers. The CF tree is grown during the first stage of clustering and values are added to its leaves if they are close to the cluster center of a particular leaf.

**Distance Measure.** Two types of distance measures are offered—the traditional Euclidean distance and the likelihood distance. The former is available when no categorical variables are specified. The latter is especially useful when categorical variables are used. The likelihood function is computed using the normal density for continuous variables and the multinomial probability mass function for categorical variables. All variables are treated as independent.

**Tuning the Algorithm.** You can control the values of algorithm-tuning parameters with the CRITERIA subcommand.

**Noise Handling.** The clustering algorithm can optionally retain any outliers that do not fit in the CF tree. If possible, these values will be placed in the CF tree after it is completed. Otherwise, TWOSTEP CLUSTER will discard them after preclustering.

**Missing Values.** TWOSTEP CLUSTER will delete listwise any records with missing fields.

**Numclusters.** This subcommand specifies the number of clusters into which the data will be partitioned. The user may tell TWOSTEP CLUSTER to automatically select the number of clusters.

**Optional Output.** You can specify output to an XML file with the OUTFILE subcommand. The cluster membership for each case used can be saved to the active dataset with the SAVE subcommand.

**Weights.** TWOSTEP CLUSTER ignores specification on the WEIGHT command.

#### Basic Specification

- The minimum specification is a list of variables, either categorical or continuous, to be clustered and at least one of the following subcommands: OUTFILE, PRINT, or SAVE.
- The number of clusters may be specified with the NUMCLUSTERS subcommand.
- Unless the NOSTANDARDIZE subcommand is given, TWOSTEP CLUSTER will standardize all continuous variables.
- If DISTANCE is Euclidean, TWOSTEP CLUSTER will accept only continuous variables.

#### Subcommand Order

- The subcommands can be specified in any order.

#### Syntax Rules

- Minimum syntax: a variable must be specified.
- Empty subcommands are silently ignored.
- Variables listed in the CONTINUOUS subcommand must be numeric.
- If a subcommand is issued more than once, TWOSTEP CLUSTER will ignore all but the last issue.

---

## Variable List

The variable lists specify those variables to be clustered. The first variable list specifies only continuous variables, and the second list specifies only categorical variables (that is, the two lists are disjoint).

---

## CATEGORICAL Subcommand

The CATEGORICAL subcommand specifies a list of categorical variables.

#### Example

```
TWOSTEP CLUSTER
/CATEGORICAL VARIABLES = RACE GENDER CITIZEN
/PRINT SUMMARY COUNT.
```

This tells TWOSTEP CLUSTER to cluster the categorical variables *RACE*, *GENDER*, and *CITIZEN*. Summary statistics by cluster and cluster frequencies are output in tables.

---

## CONTINUOUS Subcommand

The CONTINUOUS subcommand specifies a list of scale variables.

### Example

```
TWOSTEP CLUSTER
/CATEGORICAL VARIABLES = RACE GENDER CITIZEN
/CONTINUOUS VARIABLES = INCOME
/PRINT SUMMARY COUNT.
```

This tells TWOSTEP CLUSTER to cluster the categorical variables *RACE*, *GENDER*, and *CITIZEN*, and the numeric variable *INCOME*. Summary statistics by cluster and cluster frequencies are output in tables.

---

## CRITERIA Subcommand

The CRITERIA subcommand specifies the following settings for the clustering algorithm:

**INITTHRESHOLD.** *The initial threshold used to grow the CF tree.* The default is 0. If inserting a specific case into a leaf of the CF tree would yield tightness less than the threshold, the leaf is not split. If the tightness exceeds the threshold, the leaf is split.

**MXBRANCH.** *The maximum number of child nodes that a leaf node can have.* The default is 8.

**MXLEVEL.** *The maximum number of levels that the CF tree can have.* The default is 3.

---

## DISTANCE Subcommand

The distance subcommand determines how distances will be computed between clusters.

**EUCLIDEAN.** *Use the Euclidean distance to compute distances between clusters.* You may select Euclidean distance if all variables are continuous. TWOSTEP CLUSTER will return a syntax error if you specify Euclidean distance with non-numeric variables.

**LIKELIHOOD.** *Use the minus log-likelihood to compute distances between clusters.* This is the default. The likelihood function is computed assuming all variables are independent. Continuous variables are assumed to be normally distributed, and categorical variables are assumed to be multinomially distributed.

---

## HANDLENOISE Subcommand

The HANDLENOISE subcommand tells TWOSTEP CLUSTER to treat outliers specially during clustering. During growth of the CF tree, this subcommand is relevant only if the CF tree fills. The CF tree is full if it cannot accept any more cases in a leaf node and no leaf node can be split. The default value of HANDLENOISE is 0, equivalent to no noise handling.

- If the CF tree fills and HANDLENOISE is greater than 0, the CF tree will be regrown after placing any data in sparse leaves into their own noise leaf. A leaf is considered sparse if the ratio of the number of cases in the sparse leaf to the number of cases in the largest leaf is less than HANDLENOISE. After the tree is grown, the outliers will be placed in the CF tree, if possible. If not, the outliers are discarded for the second phase of clustering.

- If the CF tree fills and HANDLENOISE is equal to 0, the threshold will be increased and CF tree regrown with all cases. After final clustering, values that cannot be assigned to a cluster are labeled outliers. The outlier cluster is given an identification number of -1. The outlier cluster is not included in the count of the number of clusters; that is, if you specify  $n$  clusters and noise handling, TWOSTEP CLUSTER will output  $n$  clusters and one noise cluster.

### Example

```
TWOSTEP CLUSTER
/CATEGORICAL VARIABLES = RACE GENDER CITIZEN
/CONTINUOUS VARIABLES = INCOME
/HANDLENOISE 25
/PRINT SUMMARY COUNT.
```

This tells TWOSTEP CLUSTER to cluster the categorical variables *RACE*, *GENDER* and *CITIZEN*, and the numeric variable *INCOME*. If the CF tree fills, a noise leaf is constructed from cases whose leaves contain fewer than 25 percent of the cases contained by the largest leaf. The CF tree is then regrown, ignoring the noise leaf. After the tree is regrown, cases from the noise leaf are checked to see if they fit any of the leaves in the new tree. Any cases that still do not fit are discarded as outliers. Summary statistics by cluster and cluster frequencies are output in tables.

---

## INFILE Subcommand

The INFILE subcommand causes TWOSTEP CLUSTER to update a cluster model whose CF Tree has been saved as an XML file with the OUTFILE subcommand and STATE keyword. The model will be updated with the data in the active file. The user must supply variable names in the active file in the order they are stored in the XML file. TWOSTEP CLUSTER will update the cluster model in memory only, leaving unaltered the XML file.

- If the INFILE subcommand is given, TWOSTEP CLUSTER will ignore the CRITERIA, DISTANCE, HANDLENOISE and MEMALLOCATE subcommands, if given.

---

## MEMALLOCATE Subcommand

The MEMALLOCATE subcommand specifies the maximum amount of memory in megabytes (MB) that the cluster algorithm should use. If the procedure exceeds this maximum, it will use the disk to store information that will not fit in memory.

- The minimum value that you can specify is 4. If this subcommand is not specified, the default value is 64 MB.
- Consult your system administrator for the largest value you can specify on your system.

---

## MISSING Subcommand

The MISSING subcommand specifies how to handle cases with user-missing values.

- If this subcommand is not specified, the default is EXCLUDE.
- TWOSTEP CLUSTER deletes any case with a system-missing value.
- Keywords EXCLUDE and INCLUDE are mutually exclusive. Only one of them can be specified.

**EXCLUDE.** *Exclude both user-missing and system-missing values.* This is the default.

**INCLUDE.** *User-missing values are treated as valid.* System-missing values cannot be included in the analysis.

---

## NOSTANDARDIZE Subcommand

The NOSTANDARDIZE subcommand will prevent TWOSTEP CLUSTER from standardizing the continuous variables specified with the VARIABLES keyword. If this subcommand is not specified, or given without a variable list, TWOSTEP CLUSTER will standardize all continuous variables by subtracting the mean and dividing by the standard deviation.

---

## NUMCLUSTERS Subcommand

The NUMCLUSTERS subcommand specifies the number of clusters into which the data will be partitioned.

**AUTO.** *Automatic selection of the number of clusters.* Under AUTO, you may specify a maximum number of possible clusters. TWOSTEP CLUSTER will search for the best number of clusters between 1 and the maximum using the criterion that you specify. The criterion for deciding the number of clusters can be either the Bayesian Information Criterion (BIC) or Akaike Information Criterion (AIC). TWOSTEP CLUSTER will find at least one cluster if the AUTO keyword is given.

**FIXED.** *User-specified number of clusters.* Specify a positive integer.

### Examples

```
TWOSTEP CLUSTER
/CONTINUOUS VARIABLES = INCOME
/CATEGORICAL VARIABLES = GENDER RACE
/NUMCLUSTERS AUTO 10 AIC
/PRINT SUMMARY COUNT.
```

TWOSTEP CLUSTER uses the variables RACE, GENDER and INCOME for clustering. Specifications on the NUMCLUSTERS subcommand will instruct the procedure to automatically search for the number of clusters using the Akaike Information Criterion and require the answer to lie between 1 and 10.

```
TWOSTEP CLUSTER
/CONTINUOUS VARIABLES = INCOME
/CATEGORICAL VARIABLES = RACE GENDER
/NUMCLUSTERS FIXED 7
/PRINT SUMMARY COUNT.
```

Here the procedure will find exactly seven clusters.

---

## OUTFILE Subcommand

The OUTFILE subcommand directs TWOSTEP CLUSTER to write its output to the specified filename as XML.

**MODEL.** *Save the final model output.*

**STATE.** *Save the CF tree.* Use the STATE keyword if you want to update the model later.

You must supply a valid filename on your operating system. We recommend specifying the full path of the filename.

---

## PRINT Subcommand

The PRINT subcommand causes TWOSTEP CLUSTER to print tables related to each cluster.

**IC.** *Information criterion.* Prints the chosen information criterion (AIC or BIC) for different numbers of clusters. If this keyword is specified when the AUTO keyword is not used with the NUMCLUSTERS subcommand, TWOSTEP CLUSTER will skip this keyword and issue a warning. TWOSTEP CLUSTER will ignore this keyword if AUTO 1 is specified in the NUMCLUSTERS subcommand.

**SUMMARY.** *Descriptive statistics by cluster.* This option prints two tables describing the variables in each cluster. In one table, means and standard deviations are reported for continuous variables. The other table reports frequencies of categorical variables. All values are separated by cluster.

**COUNT.** *Cluster frequencies.* This option prints a table containing a list of clusters and how many observations are in each cluster.

---

## VIEWMODEL Subcommand

The VIEWMODEL subcommand controls options for display of model-related output, including tables and charts. Tables in the model view include a model summary and cluster-by-features grid. Graphical output in the model view includes a cluster quality chart, cluster sizes, variable importance, cluster comparison grid, and cell information.

### DISPLAY Keyword

The DISPLAY keyword specifies whether to display the model view in the output.

**YES.** *Display the model view.* This is the default.

**NO.** *Do not display the model view.*

### EVALUATIONFIELDS Keyword

The EVALUATIONFIELDS keyword calculates cluster data for variables that were not used in cluster creation. Evaluation fields can be displayed along with the input features in the model viewer by selecting them in the Display subdialog. The EVALUATIONFIELDS keyword is optional and its varlist can include fields (variables) in the dataset that are not used to create the cluster. Fields that are used to create clusters will be ignored. Fields with missing values are ignored.

```
TWOSTEP CLUSTER
  /CATEGORICAL VARIABLES=var1 var2 var3
  /CONTINUOUS VARIABLES=var4 var5
  /VIEWMODEL DISPLAY=YES EVALUATIONFIELDS=var1 var2 var8 var9
```

- The procedure creates a cluster model using *var1*, *var2*, *var3* as categorical variables and *var4* and *var5* as continuous variables, and produces a model viewer with *var8* and *var9* available as evaluation fields.

---

## SAVE Subcommand

The SAVE subcommand allows you to save cluster output to the active dataset.

**CLUSTER.** *Save the cluster identification.* The cluster number for each case is saved. You can specify a variable name using the VARIABLE keyword, otherwise, it is saved to *TSC\_n*, where *n* is a positive integer indicating the ordinal of the SAVE operation completed by this procedure in a given session. If you specify a variable name with the VARIABLE keyword, it cannot be a variable that already exists; it must be a new, unique variable name.

---

## Chapter 283. UNIANOVA

UNIANOVA is available in Statistics Base Edition.

```
UNIANOVA dependent var [BY factor list [WITH covariate list]]

[/RANDOM=factor factor...]

[/REGWT=varname]

[/METHOD=SSTYPE({1 })]
                {2 }
                {3**}
                {4 }

[/INTERCEPT=[INCLUDE**] [EXCLUDE]]

[/MISSING=[INCLUDE] [EXCLUDE**]]

[/CRITERIA=[EPS({1E-8**})] [ALPHA({0.05**})]
           {a }           {a } ]

[/PRINT = [DESCRIPTIVE] [HOMOGENEITY] [PARAMETER] [ETASQ]

          [COMPARE ADJ(LSD) (BONFERRONI) (SIDAK)]

[/ROBUST={HC0 }]]
          {HC1 }
          {HC2 }
```

```

      {HC3**}
      {HC4 }

[/SAVE=[tempvar [(name)]] [tempvar [(name)]]...]

[/OUTFILE=[COVB ('savfile'|'dataset')]
           [CORB ('savfile'|'dataset')]
           [HCCOVB ('savfile'|'dataset')]
           [EFFECT('savfile'|'dataset')] [DESIGN('savfile'|'dataset')]]

[/MBPDESIGN=[effect effect...]]

[/BPDESIGN=[effect effect...]]

[/FDESIGN=[effect effect...]]

[/DESIGN={ [INTERCEPT... ]
           { [effect effect... ] }

```

\*\* Default if the subcommand or keyword is omitted.

Temporary variables (tempvar) are:

PRED, WPRED, RESID, WRESID, DRESID, ZRESID, SRESID, WPREP, COOK, LEVER

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

## Release History

### Release 17.0

- POSTHOC subcommand: T2, T3, GH, and C keywords are not valid when multiple factors in the model.

### Release 25.0

- TYPE, ERRORBAR, MEANREFERENCE, and YAXIS keywords added to PLOT subcommand.
- ROBUST subcommand added.
- HCCOVB keyword added to OUTFILE subcommand. Any combination of COVB, CORB, and HCCOVB keywords can now be specified on OUTFILE.
- MBP, BP, F, and WHITE keywords added to PRINT subcommand.
- MBPDESIGN, BPDESIGN, and FDESIGN subcommands added.

## Example

```

UNIANOVA YIELD BY SEED FERT
  /DESIGN.

```

---

## Overview

This section describes the use of UNIANOVA for univariate analyses. The UNIANOVA procedure provides regression analysis and analysis of variance for one dependent variable by one or more factors and/or variables.

### Options

**Design Specification.** You can specify which terms to include in the design on the DESIGN subcommand. This allows you to estimate a model other than the default full factorial model, incorporate factor-by-covariate interactions or covariate-by-covariate interactions, and indicate nesting of effects.

**Contrast Types.** You can specify contrasts other than the default deviation contrasts on the CONTRAST subcommand.

**Optional Output.** You can choose from a wide variety of optional output on the PRINT subcommand. Output appropriate to univariate designs includes descriptive statistics for each cell, parameter estimates, Levene's test for equality of variance across cells, tests for heteroskedasticity, partial eta-squared for each effect and each parameter estimate, the general estimable function matrix, and a contrast coefficients table (**L'** matrix). The OUTFILE subcommand allows you to write out the covariance or correlation matrix, the design matrix, or the statistics from the between-subjects ANOVA table into a separate data file.

Using the EMMEANS subcommand, you can request tables of estimated marginal means of the dependent variable and their standard deviations. The SAVE subcommand allows you to save predicted values and residuals in weighted or unweighted and standardized or unstandardized forms. You can specify different means comparison tests for comparing all possible pairs of cell means using the POSTHOC subcommand. In addition, you can specify your own hypothesis tests by specifying an **L** matrix and a **K** matrix to test the univariate hypothesis  $\mathbf{LB} = \mathbf{K}$ .

You can display robust or heteroskedasticity-consistent (HC) standard errors by using the ROBUST subcommand, and you can write the robust covariance matrix estimates to a new file or dataset. You can also display a second set of output for custom hypothesis tests, with results based on the specified robust covariance matrix estimator.

#### Basic Specification

- The basic specification is a variable list identifying the dependent variable, the factors (if any), and the covariates (if any).
- By default, UNIANOVA uses a model that includes the intercept term, the covariate (if any), and the full factorial model, which includes all main effects and all possible interactions among factors. The intercept term is excluded if it is excluded in the model by specifying the keyword EXCLUDE on the INTERCEPT subcommand. Sums of squares are calculated and hypothesis tests are performed using type-specific estimable functions. Parameters are estimated using the normal equation and a generalized inverse of the SSCP matrix.

#### Subcommand Order

- The variable list must be specified first.
- Subcommands can be used in any order.

#### Syntax Rules

- For many analyses, the UNIANOVA variable list and the DESIGN subcommand are the only specifications needed.
- If you do not enter a DESIGN subcommand, UNIANOVA will use a full factorial model, with main effects of covariates, if any.
- At least one dependent variable must be specified, and at least one of the following must be specified: INTERCEPT, a factor, or a covariate. The design contains the intercept by default.
- If more than one DESIGN subcommand is specified, only the last one is in effect.
- Dependent variables and covariates must be numeric, but factors can be numeric or string variables.
- If a string variable is specified as a factor, only the first eight characters of each value are used in distinguishing among values.
- If more than one MISSING subcommand is specified, only the last one is in effect.
- If more than one ROBUST subcommand is specified, only the last one is in effect.
- The following words are reserved as keywords or internal commands in the UNIANOVA procedure:

INTERCEPT, BY, WITH, ALL, OVERALL, WITHIN

Variable names that duplicate these words should be changed before you run UNIANOVA.

#### Limitations

- Any number of factors can be specified, but if the number of factors plus the number of split variables exceeds 18, the Descriptive Statistics table is not printed even when you request it.
- Memory requirements depend primarily on the number of cells in the design. For the default full factorial model, this equals the product of the number of levels or categories in each factor.

---

## Example

```
UNIANOVA YIELD BY SEED FERT WITH RAINFALL
/PRINT=DESCRIPTIVE PARAMETER
/DESIGN.
```

- *YIELD* is the dependent variable; *SEED* and *FERT* are factors; *RAINFALL* is a covariate.
- The PRINT subcommand requests the descriptive statistics for the dependent variable for each cell and the parameter estimates, in addition to the default tables Between-Subjects Factors and Univariate Tests.
- The DESIGN subcommand requests the default design, a full factorial model with a covariate. This subcommand could have been omitted or could have been specified in full as

```
/DESIGN = INTERCEPT RAINFALL, SEED, FERT, SEED BY FERT.
```

---

## UNIANOVA Variable List

The variable list specifies the dependent variable, the factors, and the covariates in the model.

- The dependent variable must be the first specification on UNIANOVA.
- The names of the factors follow the dependent variable. Use the keyword BY to separate the factors from the dependent variable.
- Enter the covariates, if any, following the factors. Use the keyword WITH to separate covariates from factors (if any) and the dependent variable.

### Example

```
UNIANOVA DEPENDNT BY FACTOR1 FACTOR2, FACTOR3.
```

- In this example, three factors are specified.
- A default full factorial model is used for the analysis.

### Example

```
UNIANOVA Y BY A WITH X
/DESIGN.
```

- In this example, the DESIGN subcommand requests the default design, which includes the intercept term, the covariate X, and the factor A.

---

## RANDOM Subcommand

RANDOM allows you to specify which effects in your design are random. When the RANDOM subcommand is used, a table of expected mean squares for all effects in the design is displayed, and an appropriate error term for testing each effect is calculated and used automatically.

- Random always implies a univariate mixed-model analysis.
- If you specify an effect on RANDOM, higher-order effects containing the specified effect (excluding any effects containing covariates) are automatically treated as random effects.
- The keyword INTERCEPT and effects containing covariates are not allowed on this subcommand.
- When the RANDOM subcommand is used, the appropriate error terms for the hypothesis testing of all effects in the model are automatically computed and used.
- More than one RANDOM subcommand is allowed. The specifications are accumulated.

### Example

```
UNIANOVA DEP BY A B
  /RANDOM = B
  /DESIGN = A,B, A*B.
```

- In the example, effects  $B$  and  $A*B$  are considered as random effects. Notice that if only effect  $B$  is specified in the `RANDOM` subcommand,  $A*B$  is automatically considered as a random effect.
- The hypothesis testing for each effect ( $A$ ,  $B$ , and  $A*B$ ) in the design will be carried out using the appropriate error term, which is calculated automatically.

---

## REGWGT Subcommand

The only specification on `REGWGT` is the name of the variable containing the weights to be used in estimating a weighted least-squares model.

- Specify a numeric weight variable name following the `REGWGT` subcommand. Only observations with positive values in the weight variable will be used in the analysis.
- If more than one `REGWGT` subcommand is specified, only the last one is in effect.

### Example

```
UNIANOVA OUTCOME BY TREATMNT
  /REGWGT WT.
```

- The procedure performs a weighted least-squares analysis. The variable `WT` is used as the weight variable.

---

## METHOD Subcommand

`METHOD` controls the computational aspects of the `UNIANOVA` analysis. You can specify one of four different methods for partitioning the sums of squares. If more than one `METHOD` subcommand is specified, only the last one is in effect.

**SSTYPE(1).** *Type I sum-of-squares method.* The Type I sum-of-squares method is also known as the hierarchical decomposition of the sum-of-squares method. Each term is adjusted only for the terms that precede it on the `DESIGN` subcommand. Under a balanced design, it is an orthogonal decomposition, and the sums of squares in the model add up to the total sum of squares.

**SSTYPE(2).** *Type II sum-of-squares method.* This method calculates the sum of squares of an effect in the model adjusted for all other “appropriate” effects. An appropriate effect is one that corresponds to all effects that do not contain the effect being examined.

For any two effects  $F1$  and  $F2$  in the model,  $F1$  is said to be **contained** in  $F2$  under the following three conditions: 1) both effects  $F1$  and  $F2$  have the same covariate, if any, 2)  $F2$  consists of more factors than  $F1$ , and 3) all factors in  $F1$  also appear in  $F2$ . The intercept effect is treated as contained in all of the pure factor effects. However, it is not contained in any effect involving a covariate. No effect is contained in the intercept effect. Thus, for any one effect  $F$  of interest, all other effects in the model can be classified as in one of the following two groups: the effects that do not contain  $F$  or the effects that contain  $F$ . If the model is a main-effects design (that is, only main effects are in the model), the Type II sum-of-squares method is equivalent to the regression approach sums of squares. This means that each main effect is adjusted for every other term in the model.

**SSTYPE(3).** *Type III sum-of-squares method.* This is the default. This method calculates the sum of squares of an effect  $F$  in the design as the sum of squares adjusted for any other effects that do not contain it, and *orthogonal* to any effects (if any) that contain it. The Type III sums of squares have one major advantage—they are invariant with respect to the cell frequencies as long as the general form of estimability remains constant. Hence, this type of sums of squares is often used for an unbalanced model with no missing cells. In a factorial design with no missing cells, this method is equivalent to the Yates’ weighted squares of means technique, and it also coincides with the overparameterized  $\Sigma$ -restricted model.

**SSTYPE(4).** *Type IV sum-of-squares method.* This method is designed for a situation in which there are missing cells. For any effect *F* in the design, if *F* is not contained in any other effect, then Type IV = Type III = Type II. When *F* is contained in other effects, then Type IV distributes the contrasts being made among the parameters in *F* to all higher-level effects equitably.

#### Example

```
UNIANOVA DEP BY A B C
/METHOD=SSTYPE(3)
/DESIGN=A, B, C.
```

- The design is a main-effects model.
- The METHOD subcommand requests that the model be fitted with Type III sums of squares.

---

## INTERCEPT Subcommand

INTERCEPT controls whether an intercept term is included in the model. If more than one INTERCEPT subcommand is specified, only the last one is in effect.

**INCLUDE.** *Include the intercept term.* The intercept (constant) term is included in the model. This is the default.

**EXCLUDE.** *Exclude the intercept term.* The intercept term is excluded from the model. Specification of the keyword INTERCEPT on the DESIGN subcommand overrides INTERCEPT = EXCLUDE.

---

## MISSING Subcommand

By default, cases with missing values for any of the variables on the UNIANOVA variable list are excluded from the analysis. The MISSING subcommand allows you to include cases with user-missing values.

- If MISSING is not specified, the default is EXCLUDE.
- Pairwise deletion of missing data is not available in UNIANOVA.
- Keywords INCLUDE and EXCLUDE are mutually exclusive.
- If more than one MISSING subcommand is specified, only the last one is in effect.

**EXCLUDE.** *Exclude both user-missing and system-missing values.* This is the default when MISSING is not specified.

**INCLUDE.** *User-missing values are treated as valid.* System-missing values cannot be included in the analysis.

---

## CRITERIA Subcommand

CRITERIA controls the statistical criteria used to build the models.

- More than one CRITERIA subcommand is allowed. The specifications are accumulated. Conflicts across CRITERIA subcommands are resolved using the conflicting specification given on the last CRITERIA subcommand.
- The keyword must be followed by a positive number in parentheses.

**EPS(n).** *The tolerance level in redundancy detection.* This value is used for redundancy checking in the design matrix. The default value is 1E-8.

**ALPHA(n).** *The alpha level.* This keyword has two functions. First, it gives the alpha level at which the power is calculated for the *F* test. Once the noncentrality parameter for the alternative hypothesis is estimated from the data, then the power is the probability that the test statistic is greater than the critical value under the alternative hypothesis. The second function of alpha is to specify the level of the confidence interval. If the alpha level specified is *n*, the value (1-*n*)×100 indicates the level of confidence

for all individual and simultaneous confidence intervals generated for the specified model. The value of  $n$  must be between 0 and 1, exclusive. The default value of alpha is 0.05. This means that the default power calculation is at the 0.05 level, and the default level of the confidence intervals is 95%, since  $(1-0.05)\times 100=95$ .

---

## PRINT Subcommand

PRINT controls the display of optional output.

- Some PRINT output applies to the entire UNIANOVA procedure and is displayed only once.
- Additional output can be obtained on the EMMEANS, PLOT, and SAVE subcommands.
- Some optional output may greatly increase the processing time. Request only the output you want to see.
- If no PRINT command is specified, default output for a univariate analysis includes a factor information table and a Univariate Tests table (ANOVA) for all effects in the model.
- If more than one PRINT subcommand is specified, only the last one is in effect.

The following keywords are available for UNIANOVA univariate analyses.

**DESCRIPTIVES.** *Basic information about each cell in the design.* Observed means, standard deviations, and counts for the dependent variable in all cells. The cells are constructed from the highest-order crossing of the factors. If the number of factors plus the number of split variables exceeds 18, the Descriptive Statistics table is not printed.

**HOMOGENEITY.** *Tests of homogeneity of variance.* Levene's test for equality of variances for the dependent variable across all level combinations of the factors. If there are no factors, this keyword is not valid.

**PARAMETER.** *Parameter estimates.* Parameter estimates, standard errors,  $t$  tests, and confidence intervals for each test.

**OPOWER.** *Observed power.* The observed power for each test.

**LOF.** *Lack of fit.* Lack of fit test that allows you to determine if the current model adequately accounts for the relationship between the response variable and the predictors.

**ETASQ.** *Partial eta-squared ( $\eta^2$ ).* This value is an overestimate of the actual effect size in an  $F$  test.

**GEF.** *General estimable function table.* This table shows the general form of the estimable functions.

**TEST(LMATRIX).** *Set of contrast coefficients (L) matrices.* The transpose of the **L** matrix (**L'**) is displayed. This set always includes one matrix displaying the estimable function for each effect appearing or implied in the DESIGN subcommand. Also, any **L** matrices generated by the LMATRIX or CONTRAST subcommands are displayed. TEST(ESTIMABLE) can be used in place of TEST(LMATRIX).

**MBP.** *Modified Breusch-Pagan test for heteroskedasticity.* Tests the null hypothesis that the variance of the errors does not depend on the values of the independent variables. You can use the MBPDESIGN subcommand to specify the model on which the test is based. If the MBP keyword is specified without MBPDESIGN, then the model consists of a constant term, a term that is linear in the predicted values, a term that is quadratic in the predicted values, and an error term. For a multivariate model, tests are displayed for each dependent variable.

**BP.** *Breusch-Pagan test for heteroskedasticity.* Tests the null hypothesis that the variance of the errors does not depend on the values of the independent variables. You can use the BPDESIGN subcommand to specify the model on which the test is based. If the BP keyword is specified without BPDESIGN, then the model

consists of a constant term, a term that is linear in the predicted values, a term that is quadratic in the predicted values, and an error term. For a multivariate model, tests are displayed for each dependent variable.

**F. *F test for heteroskedasticity.*** Tests the null hypothesis that the variance of the errors does not depend on the values of the independent variables. You can use the FDESIGN subcommand to specify the model on which the test is based. If the F keyword is specified without FDESIGN, then the model consists of a constant term, a term that is linear in the predicted values, a term that is quadratic in the predicted values, and an error term. For a multivariate model, tests are displayed for each dependent variable.

**WHITE. *White's test for heteroskedasticity.*** Tests the null hypothesis that the variance of the errors does not depend on the values of the independent variables. For a multivariate model, tests are displayed for each dependent variable.

## Example

```
UNIANOVA DEP BY A B WITH COV
  /PRINT=DESCRIPTIVE, TEST(LMATRIX), PARAMETER
  /DESIGN.
```

- Because the design in the DESIGN subcommand is set as blank, the default design is used. In this case, the design includes the intercept term, the covariate *COV*, and the full factorial terms of *A* and *B*, which are *A*, *B*, and *A\*B*.
- For each combination of levels of *A* and *B*, the descriptive statistics of *DEP* are displayed.
- The set of **L** matrices that generates the sums of squares for testing each effect in the design is displayed.
- The parameter estimates, their standard errors, *t* tests, confidence intervals, and the observed power for each test are displayed.

---

## PLOT Subcommand

PL0T provides a variety of plots useful in checking the assumptions needed in the analysis. The PL0T subcommand can be specified more than once. All of the plots requested on each PL0T subcommand are produced.

Use the following keywords on the PL0T subcommand to request plots:

### SPREADLEVEL

Spread-versus-level plots. Plots of observed cell means versus standard deviations, and versus variances.

### RESIDUALS

Observed by predicted by standardized residuals plot. A plot is produced for each dependent variable. In a univariate analysis, a plot is produced for the single dependent variable.

### PROFILE

Plot of dependent variable means for one-way, two-way, or three-way crossed factors. The PROFILE keyword must be followed by parentheses containing a list of one or more factor combinations. All factors specified (either individual or crossed) must be made up of only valid factors on the factor list. Factor combinations on the PROFILE keyword may use an asterisk (\*) or the keyword BY to specify crossed factors. A factor cannot occur in a single factor combination more than once.

- The order of factors in a factor combination is important, and there is no restriction on the order of factors. If a single factor is specified after the PROFILE keyword, a line plot of estimated means at each level of the factor is produced. If a two-way crossed factor combination is specified, the output includes a multiple-line plot of estimated means at each level of the first specified factor, with a separate line drawn for each level of the second specified factor. If a three-way crossed factor combination is specified, the output includes

multiple-line plots of estimated means at each level of the first specified factor, with separate lines for each level of the second factor, and separate plots for each level of the third factor.

- The PROFILE keyword may be followed by the WITH keyword and a parenthesized list of covariates and values. Plots are produced with the values of the covariates fixed at the specified values. The keyword MEAN causes the covariate to be fixed at its observed mean value.

**TYPE=LINE | BAR**

Type of plot for profile plots. The default type is LINE.

**ERRORBAR=NO | CI | SE (value)**

Include error bars in the profile plot. The default setting is NO.

**CI** Error bars display the confidence interval. The confidence interval is determined by the ALPHA value on the CRITERIA subcommand. The confidence interval is 1-alpha. For example, if the ALPHA value is 0.05, the confidence interval is 95%.

**SE (value)**

Error bars display standard errors. The default value is 2. The value must be a positive number.

Example

```
UNIANOVA DEP BY A B
/PLOT = SPREADLEVEL PROFILE(A A*B A*B*C) WITH(X=1.0)
/DESIGN.
```

Assume each of the factors *A*, *B*, and *C* has three levels.

- Spread-versus-level plots are produced showing observed cell means versus standard deviations and observed cell means versus variances.
- Five profile plots are produced. For factor *A*, a line plot of estimated means at each level of *A* is produced (one plot). For the two-way crossed factor combination *A\*B*, a multiple-line plot of estimated means at each level of *A*, with a separate line for each level of *B*, is produced (one plot). For the three-way crossed factor combination *A\*B\*C*, a multiple-line plot of estimated means at each level of *A*, with a separate line for each level of *B*, is produced for each of the three levels of *C* (three plots). Plots are produced with the value of the covariate *X* fixed at 1.0.

---

## TEST Subcommand

The TEST subcommand allows you to test a hypothesis term against a specified error term.

- TEST is valid only for univariate analyses. Multiple TEST subcommands are allowed, each executed independently.
- You must specify both the hypothesis term and the error term. There is no default.
- The hypothesis term is specified before the keyword VS. It must be a valid effect specified or implied on the DESIGN subcommand.
- The error term is specified after the keyword VS. You can specify either a linear combination or a value. The linear combination of effects takes the general form: coefficient\*effect +/- coefficient\*effect . . . .
- All effects in the linear combination must be specified or implied on the DESIGN subcommand. Effects specified or implied on DESIGN but not listed after VS are assumed to have a coefficient of 0.
- Duplicate effects are allowed. UNIANOVA adds coefficients associated with the same effect before performing the test. For example, the linear combination 5\*A-0.9\*B-A will be combined to 4\*A-0.9B.
- A coefficient can be specified as a fraction with a positive denominator—for example, 1/3 or -1/3, but 1/-3 is invalid.
- If you specify a value for the error term, you must specify the degrees of freedom after the keyword DF. The degrees of freedom must be a positive real number. DF and the degrees of freedom are optional for a linear combination.

## Example

```
UNIANOVA DEP BY A B
  /TEST = A VS B + A*B
  /DESIGN = A, B, A*B.
```

- $A$  is tested against the pooled effect of  $B + A*B$ .

---

## LMATRIX Subcommand

The LMATRIX subcommand allows you to customize your hypotheses tests by specifying the **L** matrix (contrast coefficients matrix) in the general form of the linear hypothesis  $\mathbf{LB} = \mathbf{K}$ , where  $\mathbf{K} = \mathbf{0}$  if it is not specified on the KMATRIX subcommand. The vector **B** is the parameter vector in the linear model.

- The basic format for the LMATRIX subcommand is an optional label in quotation marks, an effect name or the keyword ALL, and a list of real numbers. There can be multiple effect names (or the keyword ALL) and number lists.
- The optional label is a string with a maximum length of 255 characters. Only one label can be specified.
- Only valid effects appearing or implied on the DESIGN subcommand can be specified on the LMATRIX subcommand.
- The length of the list of real numbers must be equal to the number of parameters (including the redundant ones) corresponding to that effect. For example, if the effect  $A*B$  takes up six columns in the design matrix, then the list after  $A*B$  must contain exactly six numbers.
- A number can be specified as a fraction with a positive denominator—for example,  $1/3$  or  $-1/3$ , but  $1/-3$  is invalid.
- A semicolon (;) indicates the end of a row in the **L** matrix.
- When ALL is specified, the length of the list that follows ALL is equal to the total number of parameters (including the redundant ones) in the model.
- Effects appearing or implied on the DESIGN subcommand must be explicitly specified here.
- If LMATRIX is specified along with the ROBUST subcommand, then contrast estimates and tests are calculated with the robust covariance matrix, in addition to the tests that use the standard (or model-based) covariance matrix.
- Multiple LMATRIX subcommands are allowed. Each is treated independently.

## Example

```
UNIANOVA DEP BY A B
  /LMATRIX = "B1 vs B2 at A1"
    B 1 -1 0 A*B 1 -1 0 0 0 0 0 0 0
  /LMATRIX = "Effect A"
    A 1 0 -1
    A*B 1/3 1/3 1/3
        0 0 0
        -1/3 -1/3 -1/3;
    A 0 1 -1
    A*B 0 0 0
        1/3 1/3 1/3
        -1/3 -1/3 -1/3
  /LMATRIX = "B1 vs B2 at A2"
    ALL 0
        0 0 0
        1 -1 0
        0 0 0 1 -1 0 0 0 0
  /DESIGN = A, B, A*B.
```

Assume that factors  $A$  and  $B$  each have three levels. There are three LMATRIX subcommands; each is treated independently.

- **B1 versus B2 at A1.** In the first LMATRIX subcommand, the difference is tested between levels 1 and 2 of effect  $B$  when effect  $A$  is fixed at level 1. Since there are three levels each in effects  $A$  and  $B$ , the interaction effect  $A*B$  takes up nine columns in the design matrix.
- **Effect A.** In the second LMATRIX subcommand, effect  $A$  is tested. Since there are three levels in effect  $A$ , at most two independent contrasts can be formed; thus, there are two rows in the **L** matrix, which are

separated by a semicolon (;). The first row tests the difference between levels 1 and 3 of effect *A*, while the second row tests the difference between levels 2 and 3 of effect *A*.

- **B1 versus B2 at A2.** In the last LMATRIX subcommand, the keyword ALL is used. The first 0 corresponds to the intercept effect; the next three zeros correspond to effect *A*.

---

## KMATRIX Subcommand

The KMATRIX subcommand allows you to customize your hypothesis tests by specifying the **K** matrix (contrast results matrix) in the general form of the linear hypothesis  $\mathbf{LB} = \mathbf{K}$ . The vector **B** is the parameter vector in the linear model.

- The default **K** matrix is a zero matrix; that is,  $\mathbf{LB} = \mathbf{0}$  is assumed.
- For the KMATRIX subcommand to be valid, at least one of the following subcommands must be specified: the LMATRIX subcommand or the INTERCEPT = INCLUDE subcommand.
- If KMATRIX is specified but LMATRIX is not specified, the LMATRIX is assumed to take the row vector corresponding to the intercept in the estimable function, provided the subcommand INTERCEPT = INCLUDE is specified. In this case, the **K** matrix can be only a scalar matrix.
- If KMATRIX and LMATRIX are specified, then the number of rows in the requested **K** and **L** matrices must be equal. If there are multiple LMATRIX subcommands, then all requested **L** matrices must have the same number of rows, and **K** must have the same number of rows as these **L** matrices.
- A semicolon (;) can be used to indicate the end of a row in the **K** matrix.
- If more than one KMATRIX subcommand is specified, only the last one is in effect.

### Example

```
UNIANOVA DEP BY A B
  /LMATRIX = "Effect A"
            A 1 0 -1; A 1 -1 0
  /LMATRIX = "Effect B"
            B 1 0 -1; B 1 -1 0
  /KMATRIX = 0; 0
  /DESIGN = A B.
```

In this example, assume that factors *A* and *B* each have three levels.

- There are two LMATRIX subcommands; both have two rows.
- The first LMATRIX subcommand tests whether the effect of *A* is 0, while the second LMATRIX subcommand tests whether the effect of *B* is 0.
- The KMATRIX subcommand specifies that the **K** matrix also has two rows, each with value 0.

---

## CONTRAST Subcommand

CONTRAST specifies the type of contrast desired among the levels of a factor. For a factor with *k* levels or values, the contrast type determines the meaning of its *k*-1 degrees of freedom.

- Specify the factor name in parentheses following the subcommand CONTRAST.
- You can specify only one factor per CONTRAST subcommand, but you can enter multiple CONTRAST subcommands.
- After closing the parentheses, enter an equals sign followed by one of the contrast keywords.
- This subcommand creates an **L** matrix such that the columns corresponding to the factor match the contrast given. The other columns are adjusted so that the **L** matrix is estimable.

The following contrast types are available:

**DEVIATION.** *Deviations from the grand mean.* This is the default for factors. Each level of the factor except one is compared to the grand mean. One category (by default, the last) must be omitted so that the

effects will be independent of one another. To omit a category other than the last, specify the number of the omitted category (which is not necessarily the same as its value) in parentheses after the keyword **DEVIATION**. For example:

```
UNIANOVA Y BY B
/CONTRAST(B)=DEVIATION(1).
```

Suppose factor *B* has three levels, with values 2, 4, and 6. The specified contrast omits the first category, in which *B* has the value 2. Deviation contrasts are not orthogonal.

**POLYNOMIAL**. *Polynomial contrasts*. This is the default for within-subjects factors. The first degree of freedom contains the linear effect across the levels of the factor, the second contains the quadratic effect, and so on. In a balanced design, polynomial contrasts are orthogonal. By default, the levels are assumed to be equally spaced; you can specify unequal spacing by entering a metric consisting of one integer for each level of the factor in parentheses after the keyword **POLYNOMIAL**. (All metrics specified cannot be equal; thus, (1, 1, . . . 1) is not valid.) For example:

```
UNIANOVA RESPONSE BY STIMULUS
/CONTRAST(STIMULUS) = POLYNOMIAL(1,2,4)
```

Suppose that factor *STIMULUS* has three levels. The specified contrast indicates that the three levels of *STIMULUS* are actually in the proportion 1:2:4. The default metric is always (1, 2, . . . *k*), where *k* levels are involved. Only the relative differences between the terms of the metric matter; (1, 2, 4) is the same metric as (2, 3, 5) or (20, 30, 50) because, in each instance, the difference between the second and third numbers is twice the difference between the first and second.

**DIFFERENCE**. *Difference or reverse Helmert contrasts*. Each level of the factor except the first is compared to the mean of the previous levels. In a balanced design, difference contrasts are orthogonal.

**HELMERT**. *Helmert contrasts*. Each level of the factor except the last is compared to the mean of subsequent levels. In a balanced design, Helmert contrasts are orthogonal.

**SIMPLE**. *Each level of the factor except the last is compared to the last level*. To use a category other than the last as the omitted reference category, specify its number (which is not necessarily the same as its value) in parentheses following the keyword **SIMPLE**. For example:

```
UNIANOVA Y BY B
/CONTRAST(B)=SIMPLE(1).
```

Suppose that factor *B* has three levels with values 2, 4, and 6. The specified contrast compares the other levels to the first level of *B*, in which *B* has the value 2. Simple contrasts are not orthogonal.

**REPEATED**. *Comparison of adjacent levels*. Each level of the factor except the first is compared to the previous level. Repeated contrasts are not orthogonal.

**SPECIAL**. *A user-defined contrast*. Values specified after this keyword are stored in a matrix in column major order.

**Orthogonal contrasts** are particularly useful. In a balanced design, contrasts are orthogonal if the sum of the coefficients in each contrast row is 0 and if, for any pair of contrast rows, the products of corresponding coefficients sum to 0. **DIFFERENCE**, **HELMERT**, and **POLYNOMIAL** contrasts always meet these criteria in balanced designs.

#### Example

```
UNIANOVA DEP BY FAC
/CONTRAST(FAC)=DIFFERENCE
/DESIGN.
```

- Suppose that the factor *FAC* has five categories and therefore four degrees of freedom.
- **CONTRAST** requests **DIFFERENCE** contrasts, which compare each level (except the first) with the mean of the previous levels.

## POSTHOC Subcommand

POSTHOC allows you to produce multiple comparisons between means of a factor. These comparisons are usually not planned at the beginning of the study but are suggested by the data in the course of study.

- Post hoc tests are computed for the dependent variable. The alpha value used in the tests can be specified by using the keyword ALPHA on the CRITERIA subcommand. The default alpha value is 0.05. The confidence level for any confidence interval constructed is  $(1-\alpha) \times 100$ . The default confidence level is 95.
- Only factors appearing in the factor list are valid in this subcommand. Individual factors can be specified.
- You can specify one or more effects to be tested. Only fixed main effects appearing or implied on the DESIGN subcommand are valid test effects.
- Optionally, you can specify an effect defining the error term following the keyword VS after the test specification. The error effect can be any single effect in the design that is not the intercept or a main effect named on a POSTHOC subcommand.
- A variety of multiple comparison tests are available. Some tests are designed for detecting homogeneity subsets among the groups of means, some are designed for pairwise comparisons among all means, and some can be used for both purposes.
- For tests that are used for detecting homogeneity subsets of means, non-empty group means are sorted in ascending order. Means that are not significantly different are included together to form a homogeneity subset. The significance for each homogeneity subset of means is displayed. In a case where the numbers of valid cases are not equal in all groups, for most post hoc tests, the harmonic mean of the group sizes is used as the sample size in the calculation. For QREGW or FREGW, individual sample sizes are used.
- For tests that are used for pairwise comparisons, the display includes the difference between each pair of compared means, the confidence interval for the difference, and the significance. The sample sizes of the two groups being compared are used in the calculation.
- Output for tests specified on the POSTHOC subcommand are available according to their statistical purposes. The following table illustrates the statistical purpose of the post hoc tests:

Table 117. Post hoc comparisons

Keyword	Homogeneity Subsets Detection	Pairwise Comparison and Confidence Interval
LSD		Yes
SIDAK		Yes
BONFERRONI		Yes
GH		Yes
T2		Yes
T3		Yes
C		Yes
DUNNETT		Yes <sup>†</sup>
DUNNETTL		Yes*
DUNNETTR		Yes*
SNK	Yes	
BTUKEY	Yes	
DUNCAN	Yes	
QREGW	Yes	
FREGW	Yes	
WALLER	Yes <sup>†</sup>	

Table 117. Post hoc comparisons (continued)

Keyword	Homogeneity Subsets Detection	Pairwise Comparison and Confidence Interval
TUKEY	Yes	Yes
SCHEFFE	Yes	Yes
GT2	Yes	Yes
GABRIEL	Yes	Yes

\* Only CIs for differences between test group means and control group means are given.

† No significance for Waller test is given.

- Tests that are designed for homogeneity subset detection display the detected homogeneity subsets and their corresponding significances.
- Tests that are designed for both homogeneity subset detection and pairwise comparison display both kinds of output.
- For the DUNNETT, DUNNETTL, and DUNNETTR keywords, only individual factors can be specified.
- The default reference category for DUNNETT, DUNNETTL, and DUNNETTR is the last category. An integer greater than 0 within parentheses can be used to specify a different reference category. For example, POSTHOC = A (DUNNETT(2)) requests a DUNNETT test for factor *A*, using the second level of *A* as the reference category.
- The keywords DUNCAN, DUNNETT, DUNNETTL, and DUNNETTR must be spelled out in full; using the first three characters alone is not sufficient.
- If the REGWT subcommand is specified, weighted means are used in performing post hoc tests.
- Multiple POSTHOC subcommands are allowed. Each specification is executed independently so that you can test different effects against different error terms.

**SNK.** *Student-Newman-Keuls procedure based on the Studentized range test.*

**TUKEY.** *Tukey's honestly significant difference.* This test uses the Studentized range statistic to make all pairwise comparisons between groups.

**BTUKEY.** *Tukey's b.* Multiple comparison procedure based on the average of Studentized range tests.

**DUNCAN.** *Duncan's multiple comparison procedure based on the Studentized range test.*

**SCHEFFE.** *Scheffé's multiple comparison t test.*

**DUNNETT(refcat).** *Dunnnett's two-tailed t test.* Each level of the factor is compared to a reference category. A reference category can be specified in parentheses. The default reference category is the last category. This keyword must be spelled out in full.

**DUNNETTL(refcat).** *Dunnnett's one-tailed t test.* This test indicates whether the mean at any level (except the reference category) of the factor is *smaller* than that of the reference category. A reference category can be specified in parentheses. The default reference category is the last category. This keyword must be spelled out in full.

**DUNNETTR(refcat).** *Dunnnett's one-tailed t test.* This test indicates whether the mean at any level (except the reference category) of the factor is *larger* than that of the reference category. A reference category can be specified in parentheses. The default reference category is the last category. This keyword must be spelled out in full.

**BONFERRONI.** *Bonferroni t test.* This test is based on Student's *t* statistic and adjusts the observed significance level for the fact that multiple comparisons are made.

**LSD.** *Least significant difference t test.* Equivalent to multiple  $t$  tests between all pairs of groups. This test does not control the overall probability of rejecting the hypotheses that some pairs of means are different, while in fact they are equal.

**SIDAK.** *Sidak t test.* This test provides tighter bounds than the Bonferroni test.

**GT2.** *Hochberg's GT2.* Pairwise comparisons test based on the Studentized maximum modulus test. Unless the cell sizes are extremely unbalanced, this test is fairly robust even for unequal variances.

**GABRIEL.** *Gabriel's pairwise comparisons test based on the Studentized maximum modulus test.*

**FREGW.** *Ryan-Einot-Gabriel-Welsch's multiple stepdown procedure based on an F test.*

**QREGW.** *Ryan-Einot-Gabriel-Welsch's multiple stepdown procedure based on the Studentized range test.*

**T2.** *Tamhane's T2.* Tamhane's pairwise comparisons test based on a  $t$  test. This test can be applied in situations where the variances are unequal. This test is invalid when there are multiple factors in the model, and the keyword is ignored with a warning in such cases.

**T3.** *Dunnett's T3.* Pairwise comparisons test based on the Studentized maximum modulus. This test is appropriate when the variances are unequal. This test is invalid when there are multiple factors in the model, and the keyword is ignored with a warning in such cases.

**GH.** *Games and Howell's pairwise comparisons test based on the Studentized range test.* This test can be applied in situations where the variances are unequal. This test is invalid when there are multiple factors in the model, and the keyword is ignored with a warning in such cases.

**C.** *Dunnett's C.* Pairwise comparisons based on the weighted average of Studentized ranges. This test can be applied in situations where the variances are unequal. This test is invalid when there are multiple factors in the model, and the keyword is ignored with a warning in such cases.

**WALLER(kratio).** *Waller-Duncan t test.* This test uses a Bayesian approach. It is restricted to cases with equal sample sizes. For cases with unequal sample sizes, the harmonic mean of the sample size is used. The  $k$ -ratio is the Type 1/Type 2 error seriousness ratio. The default value is 100. You can specify an integer greater than 1 within parentheses.

---

## EMMEANS Subcommand

EMMEANS displays estimated marginal means of the dependent variable in the cells (with covariates held at their overall mean value) and their standard errors for the specified factors. Note that these are predicted, not observed, means. The estimated marginal means are calculated using a modified definition by Searle, Speed, and Milliken (1980).

- TABLES, followed by an option in parentheses, is required. COMPARE is optional; if specified, it must follow TABLES.
- Multiple EMMEANS subcommands are allowed. Each is treated independently.
- If identical EMMEANS subcommands are specified, only the last identical subcommand is in effect. EMMEANS subcommands that are redundant but not identical (for example, crossed factor combinations such as  $A*B$  and  $B*A$ ) are all processed.

**TABLES(option).** *Table specification.* Valid options are the keyword OVERALL, factors appearing on the factor list, and crossed factors constructed of factors on the factor list. Crossed factors can be specified using an asterisk (\*) or the keyword BY. All factors in a crossed factor specification must be unique.

- If OVERALL is specified, the estimated marginal means of the dependent variable are displayed, collapsing over factors.

- If a factor, or a crossing of factors, is specified on the TABLES keyword, UNIANOVA collapses over any other factors before computing the estimated marginal means for the dependent variable.
- The TABLES keyword may be followed by the WITH keyword and a parenthesized list of covariates and values. Tables are produced with the values of the covariates fixed at the specified values. The keyword MEAN causes the covariate to be fixed at its observed mean value.

**COMPARE(factor) ADJ(method).** *Main- or simple-main-effects omnibus tests and pairwise comparisons of the dependent variable.* This option gives the mean difference, standard error, significance, and confidence interval for each pair of levels for the effect specified in the TABLES command, as well as an omnibus test for that effect. If only one factor is specified on TABLES, COMPARE can be specified by itself; otherwise, the factor specification is required. In this case, levels of the specified factor are compared with each other for each level of the other factors in the interaction.

- The optional ADJ keyword allows you to apply an adjustment to the confidence intervals and significance values to account for multiple comparisons. Methods available are LSD (no adjustment), BONFERRONI, or SIDAK.
- If OVERALL is specified on TABLES, COMPARE is invalid.

### Example

```
UNIANOVA DEP BY A B
  /EMMEANS = TABLES(A*B) WITH(X=1.0) COMPARE(A) ADJ(LSD)
  /DESIGN.
```

- The output of this analysis includes a pairwise comparisons table for the dependent variable *DEP*.
- Assume that *A* has three levels and *B* has two levels. The first level of *A* is compared with the second and third levels, the second level with the first and third levels, and the third level with the first and second levels, with the value of the covariate *X* fixed at 1.0. The pairwise comparison is repeated for the two levels of *B*.

---

## ROBUST Subcommand

ROBUST displays a table of parameter estimates, along with robust or heteroskedasticity-consistent (HC) standard errors; and *t* statistics, significance values, and confidence intervals that use the robust standard errors.

- ROBUST enables specification of the HCCOVB keyword on the OUTFILE subcommand, saving the robust covariance matrix estimates to a new file or dataset.
- ROBUST displays a second set of output for any custom hypothesis tests that are specified on LMATRIX subcommands, with results based on the specified robust covariance matrix estimator.

Five different methods are available for the robust covariance matrix estimation. You can specify only one method. If more than one ROBUST subcommand is specified, then the last subcommand is in effect.

- HC0** Based on the original asymptotic or large sample robust, empirical, or "sandwich" estimator of the covariance matrix of the parameter estimates. The middle part of the sandwich contains squared OLS (ordinary least squares) or squared weighted WLS (weighted least squares) residuals.
- HC1** A finite-sample modification of HC0, multiplying it by  $N/(N-p)$ , where *N* is the sample size and *p* is the number of non-redundant parameters in the model.
- HC2** A modification of HC0 that involves dividing the squared residual by  $1-h$ , where *h* is the leverage for the case.
- HC3** A modification of HC0 that approximates a jackknife estimator. Squared residuals are divided by the square of  $1-h$ . This method is the default if ROBUST is specified without specifying a method.
- HC4** A modification of HC0 that divides the squared residuals by  $1-h$  to a power that varies according to *h*, *N*, and *p*, with an upper limit of 4.

---

## SAVE Subcommand

Use SAVE to add one or more residual or fit values to the active dataset.

- Specify one or more temporary variables, each followed by an optional new name in parentheses.
- WPRED and WRESID can be saved only if REGWGT has been specified.
- Specifying a temporary variable on this subcommand results in a variable being added to the active data file for each dependent variable.
- You can specify variable names for the temporary variables. These names must be unique, valid variable names.
- If new names are not specified, UNIANOVA generates a rootname using a shortened form of the temporary variable name with a suffix.
- If more than one SAVE subcommand is specified, only the last one is in effect.

**PRED.** *Unstandardized predicted values.*

**WPRED.** *Weighted unstandardized predicted values.* Available only if REGWGT has been specified.

**RESID.** *Unstandardized residuals.*

**WRESID.** *Weighted unstandardized residuals.* Available only if REGWGT has been specified.

**DRESID.** *Deleted residuals.*

**ZRESID.** *Standardized residuals.*

**SRESID.** *Studentized residuals.*

**SEPREP.** *Standard errors of predicted value.*

**COOK.** *Cook's distances.*

**LEVER.** *Uncentered leverage values.*

---

## OUTFILE Subcommand

The OUTFILE subcommand writes IBM SPSS Statistics data files that can be used in other procedures.

- You must specify a keyword on OUTFILE. There is no default.
- You must specify a quoted file specification or a previously declared dataset name (DATASET DECLARE command), enclosed in quotes. The asterisk (\*) is not allowed.
- If you specify more than one keyword, a different file specification is required for each.
- If more than one OUTFILE subcommand is specified, only the last one is in effect.
- For COVB or CORB, the output will contain, in addition to the covariance or correlation matrix, four rows for each dependent variable: a row of parameter estimates, a row of standard errors of the parameter estimates, a row of residual degrees of freedom, and a row of significance values for the *t* statistics corresponding to the parameter estimates. All statistics are displayed separately by split. For HCCOVB, the covariance matrix is calculated with a robust estimator, the row of standard errors displays the robust standard errors, and the significance values reflect the robust errors.

**COVB ('savfile'|'dataset').** *Writes the parameter covariance matrix.*

**CORB ('savfile'|'dataset').** *Writes the parameter correlation matrix.*

**HCCOVB ('savfile'|'dataset').** Writes the parameter covariance matrix, calculated with a robust estimator. HCCOVB is valid only if the ROBUST subcommand is specified.

**EFFECT ('savfile'|'dataset').** Writes the statistics from the between-subjects ANOVA table.

**DESIGN ('savfile'|'dataset').** Writes the design matrix. The number of rows equals the number of cases, and the number of columns equals the number of parameters. The variable names are *DES\_1*, *DES\_2*, ..., *DES\_p*, where *p* is the number of the parameters.

---

## MBPDESIGN, BPDESIGN, and FDESIGN Subcommands

MBPDESIGN, BPDESIGN, and FDESIGN specify the auxiliary regression model that is used to test for heteroskedasticity. MBPDESIGN specifies the model for the Modified Breusch-Pagan test. BPDESIGN specifies the model for the Breusch-Pagan test. FDESIGN specifies the model for the F test.

**Note:** MBPDESIGN, BPDESIGN, and FDESIGN are necessary only when you don't want to use the default model for the associated test. The default model consists of a constant term, a term that is linear in the predicted values, a term that is quadratic in the predicted values, and an error term. The default model is requested with the MBP, BP, or F keyword on the PRINT subcommand.

- Specify a list of terms to be included in the model, and separate the terms by spaces or commas. The model that is used to test for heteroskedasticity always includes an intercept term, so specifying INTERCEPT has no effect.
- If MBPDESIGN, BPDESIGN, or FDESIGN is specified by itself (without any explicit terms), then the model that is specified by the DESIGN subcommand is used. An intercept term is included if the specified model does not contain one.
- To include a term for the main effect of a factor, enter the name of the factor.
- To include a term for an interaction between factors, use the keyword BY or the asterisk (\*) to join the factors that are involved in the interaction. For example,  $A*B$  means a two-way interaction effect of *A* and *B*, where *A* and *B* are factors.  $A*A$  is not allowed because factors inside an interaction effect must be distinct.
- To include a term for nesting one effect within another effect, use the keyword WITHIN or use a pair of parentheses. For example,  $A(B)$  means that *A* is nested within *B*. The expression  $A(B)$  is equivalent to the expression *A WITHIN B*. When more than one pair of parentheses is present, each pair of parentheses must be enclosed or nested within another pair of parentheses. Thus,  $A(B)(C)$  is not valid.
- Multiple nesting is allowed. For example,  $A(B(C))$  means that *B* is nested within *C* and *A* is nested within  $B(C)$ .
- Interactions between nested effects are not valid. For example, neither  $A(C)*B(C)$  nor  $A(C)*B(D)$  is valid.
- To include a covariate term in the design, enter the name of the covariate.
- Covariates can be connected—but not nested—through the \* operator to form another covariate effect. Therefore, interactions among covariates such as  $X1*X1$  and  $X1*X2$  are valid but not  $X1(X2)$ .
- Factor and covariate effects can be connected only by the \* operator. Suppose *A* and *B* are factors and  $X1$  and  $X2$  are covariates. Examples of valid factor-by-covariate interaction effects are  $A*X1$ ,  $A*B*X1$ ,  $X1*A(B)$ ,  $A*X1*X1$ , and  $B*X1*X2$ .
- If more than one MBPDESIGN, BPDESIGN, or FDESIGN subcommand is specified, only the last subcommand is in effect.

---

## DESIGN Subcommand

DESIGN specifies the effects included in a specific model. The cells in a design are defined by all of the possible combinations of levels of the factors in that design. The number of cells equals the product of the number of levels of all the factors. A design is *balanced* if each cell contains the same number of cases. UNIANOVA can analyze both balanced and unbalanced designs.

- Specify a list of terms to be included in the model, separated by spaces or commas.

- The default design, if the DESIGN subcommand is omitted or is specified by itself, is a design consisting of the following terms in order: the intercept term (if INTERCEPT=INCLUDE is specified), next the covariates given in the covariate list, and then the full factorial model defined by all factors on the factor list and excluding the intercept.
- To include a term for the main effect of a factor, enter the name of the factor on the DESIGN subcommand.
- To include the intercept term in the design, use the keyword INTERCEPT on the DESIGN subcommand. If INTERCEPT is specified on the DESIGN subcommand, the subcommand INTERCEPT=EXCLUDE is overridden.
- To include a term for an interaction between factors, use the keyword BY or the asterisk (\*) to join the factors involved in the interaction. For example,  $A*B$  means a two-way interaction effect of  $A$  and  $B$ , where  $A$  and  $B$  are factors.  $A*A$  is not allowed because factors inside an interaction effect must be distinct.
- To include a term for nesting one effect within another, use the keyword WITHIN or a pair of parentheses on the DESIGN subcommand. For example,  $A(B)$  means that  $A$  is nested within  $B$ . The expression  $A(B)$  is equivalent to the expression  $A$  WITHIN  $B$ . When more than one pair of parentheses is present, each pair of parentheses must be enclosed or nested within another pair of parentheses. Thus,  $A(B)(C)$  is not valid.
- Multiple nesting is allowed. For example,  $A(B(C))$  means that  $B$  is nested within  $C$ , and  $A$  is nested within  $B(C)$ .
- Interactions between nested effects are not valid. For example, neither  $A(C)*B(C)$  nor  $A(C)*B(D)$  is valid.
- To include a covariate term in the design, enter the name of the covariate on the DESIGN subcommand.
- Covariates can be connected, but not nested, through the \* operator to form another covariate effect. Therefore, interactions among covariates such as  $X1*X1$  and  $X1*X2$  are valid, but not  $X1(X2)$ . Using covariate effects such as  $X1*X1$ ,  $X1*X1*X1$ ,  $X1*X2$ , and  $X1*X1*X2*X2$  makes fitting a polynomial regression model easy in UNIANOVA.
- Factor and covariate effects can be connected only by the \* operator. Suppose  $A$  and  $B$  are factors, and  $X1$  and  $X2$  are covariates. Examples of valid factor-by-covariate interaction effects are  $A*X1$ ,  $A*B*X1$ ,  $X1*A(B)$ ,  $A*X1*X1$ , and  $B*X1*X2$ .
- If more than one DESIGN subcommand is specified, only the last one is in effect.

### Example

```
UNIANOVA Y BY A B C WITH X
/DESIGN A B(A) X*A.
```

- In this example, the design consists of a main effect  $A$ , a nested effect  $B$  within  $A$ , and an interaction effect of a covariate  $X$  with a factor  $A$ .

---

## Chapter 284. UPDATE

```
UPDATE FILE={master file} [PASSWORD='password']
        {*}
[/RENAME=(old varnames=new varnames)...]
[/IN=varname]
/FILE={transaction file1} [PASSWORD='password']
        {*}
[/FILE=transaction file2 [PASSWORD='password'] ]
/By key variables
[/MAP]
[/KEEP={ALL** } ] [/DROP=varlist]
        {varlist}
```

\*\*Default if the subcommand is omitted.

### Release History

#### Release 22.0

- PASSWORD keyword introduced on the FILE subcommand.

### Example

```
UPDATE FILE='/data/maillist.sav'
/FILE='/data/newlist.sav'
/By=ID.
```

---

## Overview

UPDATE replaces values in a master file with updated values recorded in one or more files called transaction files. Cases in the master file and transaction file are matched according to a key variable.

The master file and the transaction files must be IBM SPSS Statistics data files or datasets available in the current session, including the active dataset. UPDATE replaces values and creates a new active dataset, which replaces the original active dataset.

UPDATE is designed to update values of existing variables for existing cases. Use MATCH FILES to add new variables to a data file and ADD FILES to add new cases.

### Options

**Variable Selection.** You can specify which variables from each input file are included in the new active dataset using the DROP and KEEP subcommands.

**Variable Names.** You can rename variables in each input file before combining the files using the RENAME subcommand. This permits you to combine variables that are the same but whose names differ in different input files, or to separate variables that are different but have the same name.

**Variable Flag.** You can create a variable that indicates whether a case came from a particular input file using IN. You can use the FIRST or LAST subcommand to create a variable that flags the first or last case of a group of cases with the same value for the key variable.

**Variable Map.** You can request a map showing all variables in the new active dataset, their order, and the input files from which they came using the MAP subcommand.

## Basic Specification

The basic specification is two or more FILE subcommands and a BY subcommand.

- The first FILE subcommand must specify the master file. All other FILE subcommands identify the transaction files.
- BY specifies the key variables.
- All files must be sorted in ascending order by the key variables.
- By default, all variables from all input files are included in the new active dataset.

## Subcommand Order

- The master file must be specified first.
- RENAME and IN must immediately follow the FILE subcommand to which they apply.
- BY must follow the FILE subcommands and any associated RENAME and IN subcommands.
- MAP, DROP, and KEEP must be specified after all FILE and RENAME subcommands.

## Syntax Rules

- BY can be specified only once. However, multiple variables can be specified on BY. All files must be sorted in ascending order by the key variables named on BY.
- The master file cannot contain duplicate values for the key variables.
- RENAME can be repeated after each FILE subcommand and applies only to variables in the file named on the immediately preceding FILE subcommand.
- MAP can be repeated as often as needed.

## Operations

- UPDATE reads all input files named on FILE and builds a new active dataset. The new active dataset is built when the data are read by one of the procedure commands or the EXECUTE, SAVE, or SORT CASES command.
  - If the current active dataset is included and is specified with an asterisk (FILE=\*), the new merged dataset replaces the active dataset. If that dataset is a named dataset, the merged dataset retains that name. If the current active dataset is not included or is specified by name (for example, FILE=Dataset1), a new unnamed, merged dataset is created, and it becomes the active dataset. For information on naming datasets, see Chapter 72, “DATASET NAME,” on page 571.
- The new active dataset contains complete dictionary information from the input files, including variable names, labels, print and write formats, and missing-value indicators. The new active dataset also contains the documents from each input file, unless the DROP DOCUMENTS command is used.
- UPDATE copies all variables in order from the master file, then all variables in order from the first transaction file, then all variables in order from the second transaction file, and so on.
- Cases are updated when they are matched on the BY variable(s). If the master and transaction files contain common variables for matched cases, the values for those variables are taken from the transaction file, provided that the values are not missing or blanks. Missing or blank values in the transaction files are not used to update values in the master file.
- When UPDATE encounters duplicate keys within a transaction file, it applies each transaction sequentially to that case to produce one case per key value in the resulting file. If more than one transaction file is specified, the value for a variable comes from the last transaction file with a nonmissing value for that variable.
- Variables that are in the transaction files but not in the master file are added to the master file. Cases that do not contain those variables are assigned the system-missing value (for numerics) or blanks (for strings).
- Cases that are in the transaction files but not in the master file are added to the master file and are interleaved according to their values for the key variables.

- If the active dataset is named as an input file, any N and SAMPLE commands that have been specified are applied to the active dataset before files are combined.
- The TEMPORARY command cannot be in effect if the active dataset is used as an input file.

#### Limitations

- A maximum of one BY subcommand. However, BY can specify multiple variables.

---

## Examples

### Basic Example

```
UPDATE FILE='/data/mailist.sav'
      /FILE='/data/newlist.sav'
      /BY=ID.
```

- *mailist.sav* is specified as the master file. *newlist.sav* is the transaction file. *ID* is the key variable.
- Both *mailist.sav* and *newlist.sav* must be sorted in ascending order of *ID*.
- If *newlist.sav* has cases or nonmissing variables that are not in *mailist.sav*, the new cases or variables are added to the resulting file.

### Using Multiple Key Variables

```
SORT CASES BY LOCATN DEPT.
UPDATE FILE='/data/master.sav' /FILE=* /BY LOCATN DEPT
      /KEEP AVGHOUR AVGRAISE LOCATN DEPT SEX HOURLY RAISE /MAP.
SAVE OUTFILE='/data/personnel.sav'.
```

- SORT CASES sorts the active dataset in ascending order of the variables to be named as key variables on UPDATE.
- UPDATE specifies *master.sav* as the master file and the sorted active dataset as the transaction file. The file *master.sav* must also be sorted by *LOCATN* and *DEPT*.
- BY specifies the key variables *LOCATN* and *DEPT*.
- KEEP specifies the subset and order of variables to be retained in the resulting file.
- MAP provides a list of the variables in the resulting file and the two input files.
- SAVE saves the resulting file as a data file in IBM SPSS Statistics format.

---

## FILE Subcommand

FILE identifies each input file. At least two FILE subcommands are required on UPDATE: one specifies the master file and the other a transaction file. A separate FILE subcommand must be used to specify each transaction file.

- The first FILE subcommand must specify the master file.
- An asterisk on FILE refers to the active dataset.
- The files must be IBM SPSS Statistics data files or datasets available in the current session. File specifications should be enclosed in quotes.
- All files must be sorted in ascending order according to the variables specified on BY.
- The master file cannot contain duplicate values for the key variables. However, transaction files can and often do contain cases with duplicate keys (see "Operations") .

### PASSWORD Keyword

The PASSWORD keyword specifies the password required to open an encrypted IBM SPSS Statistics data file. The specified value must be enclosed in quotation marks and can be provided as encrypted or as plain text. Encrypted passwords are created when pasting command syntax from the Save Data As dialog. The PASSWORD keyword is ignored if the file is not encrypted.

## Text Data Files

You can update data from text data files -- or from any data format that IBM SPSS Statistics can read -- using defined datasets.

### Example

```
DATA LIST FILE='/data/update.txt'  
  ID 1-3 NAME 5-17 (A) ADDRESS 19-28 (A) ZIP 30-34.  
SORT CASES BY ID.  
DATASET NAME updatefile.  
GET FILE='/maillist.sav'.  
SORT CASES BY ID.  
DATASET NAME=masterfile.  
UPDATE FILE='masterfile'  
  /RENAME=(STREET=ADDRESS)  
  /FILE='updatefile'  
  /BY=ID /MAP.
```

---

## BY Subcommand

BY specifies one or more identification, or key, variables that are used to match cases between files.

- BY must follow the FILE subcommands and any associated RENAME and IN subcommands.
- BY specifies the names of one or more key variables. The key variables must exist in all input files and have the same names in all of the files. The key variables can be string variables (long strings are allowed).
- All input files must be sorted in ascending order of the key variables. If necessary, use SORT CASES before UPDATE.
- Missing values for key variables are handled like any other values.
- The key variables in the master file must identify unique cases. If duplicate cases are found, the program issues an error and UPDATE is not executed. The system-missing value is treated as one single value.

---

## RENAME Subcommand

RENAME renames variables on the input files *before* they are processed by UPDATE. RENAME must follow the FILE subcommand that contains the variables to be renamed.

- RENAME applies only to the immediately preceding FILE subcommand. To rename variables from more than one input file, specify a RENAME subcommand after each FILE subcommand.
- Specifications for RENAME consist of a left parenthesis, a list of old variable names, an equals sign, a list of new variable names, and a right parenthesis. The two variable lists must name or imply the same number of variables. If only one variable is renamed, the parentheses are optional.
- More than one rename specification can be specified on a single RENAME subcommand, each enclosed in parentheses.
- The T0 keyword can be used to refer to consecutive variables in the file and to generate new variable names.
- RENAME takes effect immediately. Any KEEP and DROP subcommands entered prior to a RENAME must use the old names, while KEEP and DROP subcommands entered after a RENAME must use the new names.
- All specifications within a single set of parentheses take effect simultaneously. For example, the specification RENAME (A,B = B,A) swaps the names of the two variables.
- Variables cannot be renamed to scratch variables.

### Example

```
UPDATE FILE='/data/master.sav' /FILE=CLIENTS  
  /RENAME=(TEL_NO, ID_NO = PHONE, ID)  
  /BY ID.
```

- UPDATE updates the master phone list by using current information from the file *CLIENTS*.

- Two variables on *CLIENTS* are renamed prior to the match. *TEL\_NO* is renamed *PHONE* to match the name used for phone numbers in the master file. *ID\_NO* is renamed *ID* so that it will have the same name as the identification variable in the master file and can be used on the *BY* subcommand.
- The old variable names are listed before the equals sign, and the new variable names are listed in the same order after the equals sign. The parentheses are required.
- The *BY* subcommand matches cases according to client ID numbers.

---

## DROP and KEEP Subcommands

*DROP* and *KEEP* are used to include a subset of variables in the resulting file. *DROP* specifies a set of variables to exclude, and *KEEP* specifies a set of variables to retain.

- *DROP* and *KEEP* do not affect the input files on disk.
- *DROP* and *KEEP* must follow all *FILE* and *RENAME* subcommands.
- *DROP* and *KEEP* must specify one or more variables. If *RENAME* is used to rename variables, specify the new names on *DROP* and *KEEP*.
- *DROP* cannot be used with variables created by the *IN* subcommand.
- The keyword *ALL* can be specified on *KEEP*. *ALL* must be the last specification on *KEEP*, and it refers to all variables not previously named on *KEEP*.
- *KEEP* can be used to change the order of variables in the resulting file. With *KEEP*, variables are kept in the order in which they are listed on the subcommand. If a variable is named more than once on *KEEP*, only the first mention of the variable is in effect; all subsequent references to that variable name are ignored.
- Multiple *DROP* and *KEEP* subcommands are allowed. Specifying a variable that is not in the active dataset or that has been dropped because of a previous *DROP* or *KEEP* subcommand results in an error and the *UPDATE* command is not executed.

### Example

```
UPDATE FILE='data/maillist.sav' /FILE='data/newlist.sav' /RENAME=(STREET=ADDRESS)
  /BY ID /KEEP=NAME ADDRESS CITY STATE ZIP ID.
```

- *KEEP* specifies the variables to keep in the result file. The variables are stored in the order specified on *KEEP*.

---

## IN Subcommand

*IN* creates a new variable in the resulting file that indicates whether a case came from the input file named on the preceding *FILE* subcommand. *IN* applies only to the file specified on the immediately preceding *FILE* subcommand.

- *IN* has only one specification, the name of the flag variable.
- The variable created by *IN* has the value 1 for every case that came from the associated input file and the value 0 if the case came from a different input file.
- Variables created by *IN* are automatically attached to the end of the resulting file and cannot be dropped.

### Example

```
UPDATE FILE=WEEK10 /FILE=WEEK11 /IN=INWEEK11 /BY=EMPID.
```

- *IN* creates the variable *INWEEK11*, which has the value 1 for all cases in the resulting file that came from the input file *WEEK11* and the value 0 for those cases that were not in file *WEEK11*.

---

## MAP Subcommand

MAP produces a list of the variables in the new active dataset and the file or files from which they came. Variables are listed in the order in which they appear in the resulting file. MAP has no specifications and must be placed after all FILE, RENAME, and IN subcommands.

- Multiple MAP subcommands can be used. Each MAP shows the current status of the active dataset and reflects only the subcommands that precede the MAP subcommand.
- To obtain a map of the resulting file in its final state, specify MAP last.
- If a variable is renamed, its original and new names are listed. Variables created by IN are not included in the map, since they are automatically attached to the end of the file and cannot be dropped.

---

## Chapter 285. USE

```
USE [{start date      }][THRU [{end date      }]]
    {start case number} {end case number}
    {FIRST             } {LAST             }

    [ALL]

    /PERMANENT
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Example

```
USE Y 1960.
```

---

## Overview

USE designates a range of observations to be used with time series procedures. Cases outside the defined range are filtered but not deleted from the active dataset unless the /PERMANENT subcommand is specified.

### Basic Specification

The basic specification is either the start of the range, the end of the range, or both. You can also simply specify the keyword THRU or ALL.

- The default start is the first observation in the file, and the default end is the last observation.
- The keyword THRU is required if the end of the range is specified.
- The keyword ALL defines a USE range starting with the first observation and ending with the last observation in the series. It can be specified to restore processing to the entire series.
- The keyword THRU by itself is the same as specifying the keyword ALL.

### Operations

- USE is ignored by the utility procedures CREATE and RMV. These procedures process all of the available data.
- The DATE command turns off all existing USE and PREDICT specifications.
- FILTER and USE are mutually exclusive. USE automatically turns off any previous FILTER command, and FILTER automatically turns off any previous USE command.
- The SORT command automatically turns off any previous USE command specification.
- USE remains in effect in a session until it is changed by another USE command or until a new DATE, FILTER, or SORT command is issued.

### Limitations

- A maximum of one range (one start and/or one end) can be specified.

---

## Syntax Rules

- The start and end can be specified as either DATE specifications or case (observation) numbers.
- DATE specifications and case numbers cannot be mixed on a USE command.
- Any observation within the file can be used as the start or end as long as the starting observation comes before the end observation.

## DATE Specifications

- A DATE specification consists of DATE keywords and values (see DATE). These specifications must correspond to existing DATE variables.
- If more than one DATE variable exists, the highest-order one must be used in the specification.
- Values on the keyword YEAR must have the same format (two or four digits) as the YEAR specifications on the DATE command.

## Case Specifications

- The case number specification is the sequence number of the case (observation) as it is read by the program.

## Keywords FIRST and LAST

- The start can also be specified with the keyword FIRST, and the end, with the keyword LAST. These keywords designate the first and last cases in the file, respectively.
- The keywords FIRST and LAST can be used along with either DATE or case specifications.

---

## PERMANENT Subcommand

The PERMANENT subcommand deletes cases outside the defined range from the active dataset.

---

## Examples

USE ALL.

- This command includes all observations in the file in the USE range.
- This specification is the same as USE THRU or USE FIRST THRU LAST.

USE Y 1960.

- This command selects observations starting with a YEAR\_ value of 1960 through the last observation in the file. It is equivalent to USE Y 1960 THRU LAST.

USE THRU D 5.

- This command selects all cases from the first case in the file to the last one with a DAY\_ value of 5. It is equivalent to USE FIRST THRU D 5.

USE THRU 5.

- This command selects cases starting with the first case and ending with the fifth case.

USE Y 1955 M 6 THRU Y 1960 M 6.

- This selects cases from June, 1955, through June, 1960.

USE W 16 D 3 THRU W 48 D 3.

- This example selects cases from day 3 of week 16 through day 3 of week 48.

USE CYCLE 2 OBS 4 THRU CYCLE 2 OBS 17.

- This example selects observations 4 through 17 of the second cycle.

---

## Chapter 286. VALIDATEDATA

VALIDATEDATA is available in Statistics Base Edition.

```
VALIDATEDATA    [VARIABLES=varlist]
                [ID=varlist]
                [CROSSVARRULES=rulelist]
[/VARCHHECKS   [STATUS={ON**}]
                {OFF }
                [PCTMISSING={70** }
                {number }
                [PCTEQUAL={95** }
                {number }
                [PCTUNEQUAL={90** }
                {number }
                [CV={0.001**}]
                {number }
                [STDDEV={0** }]]
[/IDCHECKS     [INCOMPLETE**] [DUPLICATE**] [NONE]
[/CASECHECKS   [REPORTEMPTY={YES**}] [SCOPE={ANALYSISVARS}]
                {NO } {ALLVARS }
[/RULESUMMARIES [BYVARIABLE**] [BYRULE] [NONE]
[/CASEREPORT   DISPLAY={YES**}
                {NO }
                [MINVIOLATIONS={1** }
                {integer}
                [CASELIMIT={FIRSTN({500** } )}]
                {integer}
                {NONE }
[/SAVE         [EMPTYCASE[(varname)]]
                [INCOMPLETEID[(varname)]]
                [DUPLICATEID[(varname)]]
                [RULEVIOLATIONS[(varname)]]]
```

\*\* Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Release History

#### Release 14.0

- Command introduced.

### Example

```
VALIDATEDATA VARIABLES=ALL.
```

---

## Overview

The VALIDATEDATA procedure identifies suspicious and invalid cases, variables, and data values in the active dataset.

The procedure can summarize two types of validation rules. Single-variable rules consist of a fixed set of checks that are applied to individual data values, such as range checks. Cross-variable rules are user-specified rules that typically examine combinations of data values for two or more variables.

### Options

**Analysis Variables.** The procedure can identify variables that have a high proportion of missing values as well as variables that are constant (or nearly so). You can set the maximum acceptable percentage of missing values as well as thresholds for considering categorical and scale variables as constants.

**Case Identifiers.** The procedure can identify incomplete and duplicate case identifiers. A single variable or a combination of variables can be treated as the identifier for a case.

**Cases.** The procedure can identify empty cases. A case can be regarded as empty if all analysis variables are blank or missing or all non-ID variables are blank or missing.

**Single-Variable Rules.** Single-variable validation rules can be summarized by variable and rule. Single-variable rules are defined using the DATAFILE ATTRIBUTE command and are linked to analysis variables using the VARIABLE ATTRIBUTE command.

**Cross-Variable Rules.** The procedure can summarize violations of cross-variable validation rules. Cross-variable rules are defined using the DATAFILE ATTRIBUTE command.

**Saved Variables.** You can save variables that identify suspicious cases and values in the active dataset.

#### Basic Specification

- The minimum specification is a list of analysis variables, case identifier variables, or cross-variable rules.
- By default, if you specify analysis variables, the procedure reports all analysis variables that have a high proportion of missing values, as well as analysis variables that are constant or nearly so. If single-variable validation rules are defined for analysis variables, the procedure reports rule violations for each variable.
- By default, if case identifier variables are specified, the procedure reports all incomplete and duplicate case identifiers.
- If you specify cross-variable rules, the procedure reports the total number of cases that violated each rule.
- If you specify single-variable or cross-variable rules, a casewise report is shown that lists the first 500 cases that violated at least one validation rule.
- Empty cases are identified by default.

#### Syntax Rules

- Each subcommand is global and can be used only once.
- Subcommands can be used in any order.
- An error occurs if a keyword or attribute is specified more than once within a subcommand.
- Equals signs and slashes shown in the syntax chart are required.
- Subcommand names and keywords must be spelled out in full.
- Empty subcommands generate a procedure error.

#### Operations

- The procedure honors SPLIT FILE specifications. Split variables are filtered out of all variable lists.
- The procedure treats user- and system-missing values as missing values.
- An error occurs if no procedure output is requested.

Note: Since measurement level can affect the results, if any variables (fields) have an unknown measurement level, an initial data pass will be performed to determine default measurement level for any variables with an unknown measurement level. For information on the criteria used to determine default measurement level, see SET SCALEMIN.

#### Limitations

- The weight variable, if specified, is ignored with a warning.

#### Validation Rules

- VALIDATEDATA ignores invalid rules and links with a warning.
- If an analysis variable is linked to multiple rules, VALIDATEDATA applies the rules independently; it does not check for conflicts or redundancies among the constituent rules.
- A rule outcome variable must be associated with each rule that indicates which cases violated the rule. Outcome variables are created outside the VALIDATEDATA procedure and should be coded such that 1 indicates an invalid value or combination of values and 0 indicates a valid value.
- An error occurs if the same outcome variable is referenced by two or more rules.
- Values of all outcome variables are assumed to be current with respect to the active dataset.

---

## Examples

### Default Analysis Variable Validation

```
VALIDATEDATA VARIABLES=ALL.
```

- The only specification is a list of analysis variables (all variables in the active dataset).
- The procedure reports all variables with a high proportion of missing values, as well as variables that are constant or nearly so.
- In addition, empty cases are identified.

### Default Case Identifier Variable Validation

```
VALIDATEDATA ID=Firstname Lastname.
```

- Two case identifier variables are specified.
- By default, the procedure reports cases having incomplete or duplicate case identifiers. The combination of *Firstname* and *Lastname* values is treated as a case identifier.
- In addition, empty cases are identified.

### Non-Default Analysis and Case Identifier Variable Validation

```
VALIDATEDATA VARIABLES=Satis1 Satis2 Satis3
              ID=Firstname Lastname
/VARCHECKS STATUS=ON PCTMISSING=30
/IDCHECKS DUPLICATE
/SAVE EMPTYCASE.
```

- Three ordinal satisfaction variables (*Satis1*, *Satis2*, *Satis3*) are specified as analysis variables.
- ID specifies two case identifier variables, *Firstname* and *Lastname*.
- VARCHECKS reports analysis variables with more than 30% missing values. By default, the procedure also reports categorical analysis variables if more than 95% of their cases fall into a single category.
- IDCHECKS reports cases that have duplicate case identifiers and turns off the default check for incomplete case identifiers.
- Empty cases are identified by default.
- SAVE saves a variable to the active dataset that indicates which cases are empty.

### Using Single-Variable Validation Rules

```
DATAFILE ATTRIBUTE
  ATTRIBUTE=$VD.SRule[1] ("Label='Likert 1 to 5','+
                        "Description='Likert 5-point scale','+
                        "Type='Numeric','+
                        "Domain='Range','+
                        "FlagUserMissing='No','+
                        "FlagSystemMissing='No','+
                        "FlagBlank='No','+
                        "Minimum='1','+
                        "Maximum='5','+
                        "FlagNoninteger='Yes']").

COMPUTE Likert1to5_Satis_=NOT(Satis LE 5 AND Satis GE 1 AND
                             Satis=TRUNC(Satis)).

VARIABLE ATTRIBUTE
  VARIABLES= Likert1to5_Satis_
  ATTRIBUTE=$VD.RuleOutcomeVar("Yes").
```

```
VARIABLE ATTRIBUTE
  VARIABLES=Satis
  ATTRIBUTE=$VD.SRuleRef[1] ("Rule='$VD.SRule[1]',"+
    "OutcomeVar='Likert1to5_Satis_']").
```

```
VALIDATEDATA VARIABLES=Satis
/CASEREPORT DISPLAY=YES CASELIMIT=NONE
/SAVE RULEVIOLATIONS.
```

- DATAFILE ATTRIBUTE defines a single-variable validation rule named *\$VD.SRule[1]*. The rule flags any value that is not an integer within the range 1 to 5.
- The first VARIABLE ATTRIBUTE command links the rule to the variable *Satis*. It also references an outcome variable where 1 indicates an invalid value for the variable *Satis*.
- COMPUTE creates the rule outcome variable.
- The second VARIABLE ATTRIBUTE command marks *Likert1to5\_Satis\_* as an outcome variable in the data dictionary.
- VALIDATEDATA specifies *Satis* as an analysis variable. In addition to performing default checks for constants, variables with a large proportion of missing values, and empty cases, the procedure summarizes violations of single-variable validation rules defined for *Satis*.
- CASEREPORT reports all cases having a rule violation.
- SAVE saves a variable to the active dataset that indicates the total number of validation rule violations per case.

### Using Cross-Variable Validation Rules

```
DATAFILE ATTRIBUTE
  ATTRIBUTE=$VD.CRule[1] ("Label='Pregnant Male',"+
    "Expression='Sex ='Male'' AND Pregnant ''Yes''","+
    "OutcomeVar='PregnantMale_']").
```

```
COMPUTE PregnantMale_ = Sex ='Male' AND Pregnant = 'Yes'.
```

```
VARIABLE ATTRIBUTE
  VARIABLES=PregnantMale_
  ATTRIBUTE=$VD.RuleOutcomeVar("Yes").
```

```
VALIDATEDATA CROSSVARRULES=$VD.CRule[1]
/CASECHECKS REPORTEEMPTY=NO.
```

- DATAFILE ATTRIBUTE defines the cross-variable rule *\$VD.CRule[1]*.
- COMPUTE creates the outcome variable *PregnantMale\_* referenced by the cross-variable rule. For *PregnantMale\_*, values of 1 identify cases containing males coded as being pregnant.
- VARIABLE ATTRIBUTE marks *PregnantMale\_* as an outcome variable in the data dictionary.
- VALIDATEDATA specifies *\$VD.CRule[1]* as a cross-variable rule to be summarized. The procedure reports the total number of pregnant males in the active dataset.
- CASECHECKS turns off the default check for empty cases.
- By default, the first 500 cases that violated at least one validation rule are listed.

---

## Variable Lists

You must specify VARIABLES, ID, or CROSSVARRULES.

### VARIABLES Keyword

The VARIABLES list specifies analysis variables to be validated.

- Specify one or more analysis variables. ALL and T0 can be used to refer to all variables or a range of variables, respectively.
- Repeated instances of the same variable are filtered out of the list.
- Rule outcome variables are filtered out of the list.

### ID Keyword

The ID list specifies case ID variables to be validated. ID variables are also used to label casewise output.

- Specify one or more variables. If two or more ID variables are specified, the combination of their values is treated as a case identifier.
- Repeated instances of the same variable are filtered out of the list.
- Rule outcome variables are filtered out of the list.

### CROSSVARRULES Keyword

The CROSSVARRULES keyword specifies cross-variable rules to be summarized.

- Specify one or more cross-variable rules of the form *\$VD.CRule[n]*, where *n* is a positive integer. Alternatively, you can provide a list of integers, where 1 means *\$VD.CRule[1]*, 2 means *\$VD.CRule[2]*, etc.
- The list accepts the keyword ALL, which signifies all cross-variable rules recorded in the data dictionary.
- Repeated instances of the same rule are filtered out of the list.
- A warning occurs if a specified rule does not exist. The rule is ignored.

---

## VARCHECKS Subcommand

The VARCHHECKS subcommand specifies checks to be performed on analysis variables. The subcommand is ignored if no analysis variables are defined.

**STATUS.** *Perform variable checks.* By default, variable checks are performed. To turn off variable checks, specify STATUS=NO; any other VARCHHECKS keywords are then ignored.

**PCTMISSING.** *Maximum percentage of missing values.* Reports analysis variables with a percentage of missing values greater than the specified value. The specified value must be a positive number less than or equal to 100. The default value is 70.

**PCTEQUAL.** *Maximum percentage of cases representing a single category.* Reports categorical analysis variables with a percentage of cases representing a single nonmissing category greater than the specified value. The specified value must be a positive number less than or equal to 100. The default value is 95. The percentage is based on cases with nonmissing values of the variable. PCTEQUAL is ignored if no categorical analysis variables are specified.

**PCTUNEQUAL.** *Percentage of categories containing only one case in a categorical variable.* If the percentage of an analysis variable's categories containing only one case is greater than the specified value, the variable is reported. The specified value must be a positive number less than or equal to 100. The default value is 90. PCTUNEQUAL is ignored if no categorical analysis variables are specified.

**CV.** *Minimum absolute coefficient of variation.* A variable's coefficient of variation is defined as its standard deviation divided by its mean. If the absolute value of the coefficient of variation is less than the specified value, the variable is reported. This setting applies only to continuous predictors and only if the mean is non-zero. The specified value must be a non-negative number. Specifying 0 turns off the coefficient of variation check. The default value is 0.001. CV is ignored if no scale analysis variables are specified.

**STDDEV.** *Minimum standard deviation.* Reports variables whose standard deviation is less than the specified value. This setting applies only to scale analysis variables. The specified value must be a non-negative number. The default value is 0, which, in effect, turns off the standard deviation check. STDDEV is ignored if no scale analysis variables are specified.

---

## IDCHECKS Subcommand

The IDCHECKS subcommand specifies checks to be performed on case identifiers. The subcommand is ignored if no ID variables are specified.

**INCOMPLETE.** *Incomplete case identifiers.* Reports cases with incomplete case identifiers. For a particular case, an identifier is considered incomplete if the value of any ID variable is blank or missing. Default.

**DUPLICATE.** *Duplicate case identifiers.* Reports cases with duplicate case identifiers. Incomplete identifiers are excluded from the set of possible duplicates. Default.

**NONE .** *Case identifiers are not validated.*

---

## CASECHECKS Subcommand

The CASECHECKS subcommand specifies checks to be performed on cases in the active dataset.

REPORTEMPTY Keyword

Empty cases are identified by default. To turn off the check for empty cases, specify REPORTEMPTY=NO.

SCOPE Keyword

The SCOPE keyword controls which variables are considered when the procedure determines whether a case is empty. SCOPE is ignored if REPORTEMPTY=NO.

**ANALYSISVARS.** *Procedure considers analysis variables only.* A case is considered empty if values of all analysis variables are blank or missing. This is the default if analysis variables are specified. ANALYSISVARS is ignored if no analysis variables are specified.

**ALLVARS.** *Procedure considers all variables.* A case is regarded as empty if all variables in the active dataset are blank or missing. This is the default if no analysis variables are specified. ID variables, split file variables, and rule outcome variables are always disregarded when determining whether a case is empty.

---

## RULESUMMARIES Subcommand

The RULESUMMARIES subcommand is used to summarize violations of single-variable validation rules.

- By default, single-variable rule violations are summarized by analysis variable.
- Cross-variable validation rules are always summarized by rule.
- RULESUMMARIES generates a warning if summaries are requested but single-variable validation rules are not defined for at least one analysis variable.

**BYVARIABLE.** *Summarize by variable.* For each analysis variable, shows all single-variable validation rules that were violated and the number of values that violated each rule. Also reports the total number of single-variable rule violations for each variable. This is the default.

**BYRULE .** *Summarize by rule.* For each single-variable validation rule, reports variables that violated the rule and the number of invalid values per variable. Also reports the total number of values that violated each rule across variables.

**NONE .** *No summaries are produced for single-variable rules.* An error occurs if NONE is specified along with any other RULESUMMARIES keyword.

---

## CASEREPORT Subcommand

The CASEREPORT subcommand is used to obtain a report that lists validation rule violations for individual cases.

- The case report includes violations of single-variable and cross-variable rules.
- CASEREPORT is ignored if no single-variable or cross-variable rules are applied.

### DISPLAY Keyword

- The case report is shown by default. To turn off the report, specify DISPLAY=NO.
- If you specify a case identifier, it is used to label cases in the report. Cases are also identified by case number.

### MINVIOLATIONS Keyword

- MINVIOLATIONS specifies the minimum number of rule violations required for a case to be included in the report. Specify a positive integer.
- The default is 1 violation.
- MINVIOLATIONS is ignored if DISPLAY=NO.

### CASELIMIT Keyword

- The CASELIMIT keyword specifies the maximum number of cases included in the case report. By default the maximum is 500.
- To change the maximum number of cases in the report, specify FIRSTN followed by a positive integer in parentheses.
- NONE turns off the case limit. All cases that meet the MINVIOLATIONS threshold are reported.
- CASELIMIT is ignored if DISPLAY=NO.

---

## SAVE Subcommand

The SAVE subcommand specifies optional variables to save. Specify one or more keywords, each followed by an optional variable name.

- The name, if specified, must be enclosed in parentheses—for example, EMPTYCASE(Empty)—and must be a valid variable name.
- If you do not specify a variable name, the procedure uses a default name.
- If the default name is used and it conflicts with that of an existing variable, a suffix is added to make the name unique.
- If you specify a name and it conflicts with that of an existing variable, an error occurs.

**EMPTYCASE.** *Empty case indicator.* Empty cases are assigned the value 1. All other cases are coded 0. The default rootname is *EmptyCase*. Values of EMPTYCASE reflect the scope specified via the CASECHECKS subcommand.

**INCOMPLETEID.** *Incomplete ID indicator.* Cases with empty or incomplete case identifiers are assigned a value 1. All other cases are coded 0. The default rootname is *IncompleteID*.

**DUPLICATEID.** *Duplicate ID group.* Cases that have the same case identifier (other than cases with incomplete identifiers) are assigned the same group number. Cases with unique or incomplete identifiers are coded 0. The default rootname is *DuplicateIDGroup*.

**RULEVIOLATIONS .** *Total count of single-variable and cross-variable validation rule violations.* The default rootname is *ValidationRuleViolations*. Ignored if no single-variable or cross-variable validation rules are applied.

---

## Defining Validation Rules

### Single-Variable Validation Rules

To use a single-variable validation rule with the VALIDATEDATA procedure requires:

1. A rule definition (using the DATAFILE ATTRIBUTE command).

#### Defining a Single-Variable Validation Rule

Single-variable validation rules are attributes of the data file and are generally defined according to the following syntax diagram:

```
DATAFILE ATTRIBUTE
  ATTRIBUTE=$VD.SRule[n] ("Label='value', "+
    "Description='value', "+
    "Type={Numeric}', "+
    {String }
    {Date }
    "Format='dateformat' "+
    "Domain={Range}', "+
    {List }
    "FlagUserMissing='{Yes}' "+
    {No }
    "FlagSystemMissing='{Yes}' "+
    {No }
    "FlagBlank='{Yes}' "+
    {No }

  -- when Domain='Range' --
    "Minimum='value', "+
    "Maximum='value', "+
    "FlagUnlabeled='{Yes}' "+
    {No }
    "FlagNoninteger='{Yes}' "+
    {No }

  -- when Domain='List' --
    "List='value1' 'value2' ... 'valuen' "+
    "CaseSensitive='{Yes}' "+
    {No }
  ").
```

- Single-variable rule attribute names must be of the form `$VD.SRule[n]`, where *n* is a positive integer.
- Each rule specification includes a comma-separated list of properties that define the rule. Except where noted in the following table, each property is required. The order in which properties appear does not matter. Unrecognized rule properties are ignored. If the same property appears more than once in a rule specification, the value for the last one is honored.

*Label*. The label is text that uniquely identifies the rule among single-variable and cross-variable rules. It cannot be the null string. Leading and trailing blanks are trimmed for the purpose of determining the uniqueness of the label.

*Description*. Any text (optional).

*Type*. This is the type of variable to which the rule can be applied. Select from Numeric, String, and Date. It is used by VALIDATEDATA to ensure that the rule is internally consistent and appropriate for the variable to which it is applied.

*Format*. This allows you to select the date format for rules that can be applied to date variables. Specify any IBM SPSS Statistics date or time format. See the topic “Date and Time Formats” on page 57 for more information. This property is not required if *Type* is not *Date*.

*FlagUserMissing*. Controls whether user-missing values are flagged as invalid. Specify *Yes* or *No*.

*FlagSystemMissing*. Controls whether system-missing values are flagged as invalid. This does not apply to string rule types. Specify *Yes* or *No*.

*FlagBlank*. Controls whether blank—that is, completely empty—string values are flagged as invalid. This does not apply to non-string rule types. Specify *Yes* or *No*.

*Domain*. You can specify the valid values either as a *Range* or a *List* of values. “Range” properties are ignored if `Domain='List'`, and “List” properties are ignored if `Domain='Range'`.

*Minimum*. This property is optional\*\*. Its value must be consistent with the rule type and format and be less than or equal to *Maximum*. The value is ignored if null. It cannot have a noninteger value if *FlagNoninteger*='Yes'.

*Maximum*. This property is optional\*\*. Its value must be consistent with the rule type and format and be greater than or equal to *Minimum*. The value is ignored if null. It cannot have a non-integer value if *FlagNoninteger*='Yes'.

*FlagUnlabeled*. Controls whether unlabeled values are flagged as invalid. Specify *Yes* or *No*.

*FlagNoninteger*. Controls whether non-integer values are flagged as invalid. Specify *Yes* or *No*.

*List*. Specify one or more values consistent with the rule type and format. Null strings are ignored. Each item in the list must be quoted.

*CaseSensitive*. Controls whether case matters when string data values are checked against the list of acceptable values. Specify *Yes* or *No*.

\*\* Range properties are optional if *Domain*='Range'. However, if *Domain*='Range' and *FlagUserMissing*, *FlagSystemMissing*, and *FlagBlank* are all set to *No*, then *Minimum* or *Maximum* must be specified or *FlagUnlabeled* or *FlagNoninteger* must be *Yes*. Otherwise, no values would be validated when the rule is applied.

## 2. A rule outcome variable (using COMPUTE and VARIABLE ATTRIBUTE).

### Creating a Rule Outcome Variable

Rule outcome variables are generated to validate values of variables and are generally defined according to the following syntax diagram:

```
COMPUTE outcomevar1=expression for analysisvar1.  
COMPUTE outcomevar2=...
```

```
VARIABLE ATTRIBUTE  
VARIABLES=outcomevarlist  
ATTRIBUTE=$VD.RuleOutcomeVar("Yes").
```

- The COMPUTE expression for each outcome variable should generate the value 1 for invalid cases of a variable, according to the associated single-variable rule definition.
- The rule outcome variable is marked as such using the VARIABLE ATTRIBUTE command. Rule outcome variable attribute names must be *\$VD.RuleOutcomeVar* with the property *Yes*.

## 3. A link between the analysis and outcome variable (using VARIABLE ATTRIBUTE).

### Linking Analysis and Outcome Variables

Single-variable rule links are attributes of the analysis variables and are generally defined according to the following syntax diagram:

```
VARIABLE ATTRIBUTE  
VARIABLES=analysisvar1  
ATTRIBUTE=$VD.SRuleRef[n] ("Rule='$VD.SRule[n]', "+  
"OutcomeVar='outcomevar1'")  
/VARIABLES=analysisvar2...
```

- Single-variable rule link attribute names must be of the form *\$VD.SRuleRef[n]*, where *n* is a positive integer.
- The *Rule* and *OutcomeVar* properties are required. The order in which they appear does not matter. Unrecognized rule properties are ignored. If the same property appears more than once in a rule specification, the value for the last one is honored.

*Rule*. An existing single-variable validation rule whose *Type* property is consistent with that of the variable to which it is linked. String rules can be applied to string variables.

*Outcomevar*. A rule outcome variable associated with the analysis variable.

## Cross-Variable Validation Rules

To use a cross-variable validation rule with the VALIDATEDATA procedure requires:

1. A rule definition (using the DATAFILE ATTRIBUTE command).

## Creating a Rule Definition

Cross-variable validation rules are attributes of the data file and are generally defined according to the following syntax diagram:

```
DATAFILE ATTRIBUTE
ATTRIBUTE=$VD.CRule[1] ("Label='value',"
                        "Expression='value'."
                        "OutcomeVar='outcomevar'").
```

Cross-variable rule attribute names must be of the form *\$VD.CRule[n]*, where *n* is a positive integer.

- Each rule specification includes a list of properties that define the rule. Each property is required. The order in which properties appear does not matter. Unrecognized rule properties are ignored. If the same property appears more than once in a rule specification, the value for the last one is honored.

*Label.* The label is text that uniquely identifies the rule among single-variable and cross-variable rules. It cannot be the null string. Leading and trailing blanks are trimmed for the purpose of determining the uniqueness of the label.

*Expression.* The expression must be valid command syntax for the right side of a COMPUTE statement. Any variables used in the expression must exist in the data file.

*OutcomeVar.* A rule outcome variable associated with the cross-variable rule.

2. A rule outcome variable (using COMPUTE and VARIABLE ATTRIBUTE).

## Creating a Rule Outcome Variable

```
COMPUTE outcomevar = expression.
```

```
VARIABLE ATTRIBUTE
VARIABLES=outcomevar
ATTRIBUTE=$VD.RuleOutcomeVar("Yes").
```

- The COMPUTE expression for each outcome variable should generate the value 1 for invalid cases. It should be equivalent to the *Expression* in the cross-variable rule definition.
- The rule outcome variable is marked as such using the VARIABLE ATTRIBUTE command. Rule outcome variable attribute names must be *\$VD.RuleOutcomeVar* with the property *Yes*.

---

## Chapter 287. VALUE LABELS

```
VALUE LABELS varlist value 'label' value 'label'... [/varlist...]  
[/datevarlist 'value' 'label'...]
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Release History

#### Release 14.0

- The maximum length of a value label is extended to 120 bytes (previous limit was 60 bytes).

#### Release 16.0

- Limitation preventing assignment of missing values to strings with a defined width greater than eight bytes removed.

### Example

```
VALUE LABELS JOBGRADE 'P' 'Parttime Employee' 'C' 'Customer Support'.
```

---

## Overview

VALUE LABELS deletes all existing value labels for the specified variable(s) and assigns new value labels. ADD VALUE LABELS can be used to add new labels or alter labels for specified values without deleting other existing labels.

## Basic Specification

The basic specification is a variable name and the individual values with their assigned labels.

## Syntax Rules

- Labels can be assigned to any previously defined variables.
- It is not necessary to enter value labels for all values for a variable.
- Each value label must be enclosed in quotes. For string variables, the values themselves must also be enclosed in quotes.
- For date format variables (for example, DATE, ADATE), values expressed in date formats must be enclosed in quotes, and values must be expressed in the same date format as the defined date format for the variable.
- Value labels can contain any characters, including blanks. To enter an apostrophe as part of a label, enclose the label in double quotes or enter two apostrophes (two single quotes). See the topic “String Values in Command Specifications” on page 39 for more information.
- Each value label can be up to 120 bytes long.
- The same labels can be assigned to the values of different variables by specifying a list of variable names. For string variables, the variables specified must be of equal length.
- Multiple sets of variable names and value labels can be specified on one VALUE LABELS command as long as the sets are separated by slashes.
- To continue a label from one command line to the next, specify a plus (+) sign before the continuation of the label. Each string segment of the label must be enclosed in quotes. To insert a blank between the strings, the blank must be included in the label specification.

- To control line wrapping of labels in pivot tables and charts, insert \n as part of the label wherever you want a line break. The \n is not displayed in output; it is interpreted as a line-break character. (Note: Labels will *always* wrap wherever \n appears in the defined label even if there is enough space to display the label without wrapping.)

## Operations

- Unlike most transformations, VALUE LABELS takes effect as soon as it is encountered in the command sequence. Thus, special attention should be paid to its position among commands. See the topic “Command Order” on page 40 for more information.
- VALUE LABELS deletes all previously assigned value labels for the specified variables.
- The value labels assigned are stored in the dictionary of the working file and are automatically displayed on the output from many procedures.
- If a specified value is longer than the format of the variable, the program will be unable to read the full value and may not be able to assign the value label correctly.
- If the value specified for a string variable is shorter than the format of the variable, the value specification is right-padded without warning.

---

## Examples

### Assigning Value Labels to Multiple Variables

```
VALUE LABELS V1 TO V3 1 'Officials & Managers'
              6 'Service Workers'
              /V4 'N' 'New Employee'.
```

- Labels are assigned to the values 1 and 6 for the variables between and including *V1* and *V3* in the active dataset.
- Following the required slash, a label for the value *N* of *V4* is specified. *N* is a string value and must be enclosed in quotes.
- If labels exist for the values 1 and 6 on *V1* to *V3* and the value *N* on *V4*, they are changed in the dictionary of the working file. If labels do not exist for these values, new labels are added to the dictionary.
- Existing labels for values other than 1 and 6 on *V1* to *V3* and the value *N* on *V4* are deleted.

### Combining Strings to Construct Value Labels

```
VALUE LABELS OFFICE88 1 "EMPLOYEE'S OFFICE ASSIGNMENT PRIOR"
              + " TO 1988".
```

- The label for *OFFICE88* is created by combining two strings with the plus sign. The blank between *PRIOR* and *TO* must be included in the first or second string to be included in the label.

### Value Labels for String Variables

```
VALUE LABELS=STATE REGION 'U' "UNKNOWN".
```

- The label *UNKNOWN* is assigned to the value *U* for both *STATE* and *REGION*.
- *STATE* and *REGION* must be string variables of equal length. If *STATE* and *REGION* have unequal lengths, a separate specification must be made for each, as in

```
VALUE LABELS STATE 'U' "UNKNOWN" / REGION 'U' "UNKNOWN".
```

### Using Value Labels with DATA LIST

```
DATA LIST / CITY 1-8(A) STATE 10-12(A).
VALUE LABELS STATE 'TEX' "TEXAS" 'TEN' "TENNESSEE"
              'MIN' "MINNESOTA".
```

```
BEGIN DATA
AUSTIN TEX
MEMPHIS TEN
ST. PAUL MIN
END DATA.
FREQUENCIES VARIABLES=STATE.
```

- The DATA LIST command defines two variables. *CITY* is eight characters wide and *STATE* is three characters. The values are included between the BEGIN DATA and END DATA commands.
- The VALUE LABELS command assigns labels to three values of variable *STATE*. Each value and each label is specified in quotes.
- The format for the variable *STATE* must be at least three characters wide because the specified values, *TEX*, *TEN*, and *MIN*, are three characters. If the format for *STATE* were two characters, the program would issue a warning. This would occur even though the values named on VALUE LABELS and the values after BEGIN DATA agree.

### Forcing Value Labels to Wrap

```
VALUE LABELS myvar 1 "A long value label \n that always wraps".
FREQUENCIES myvar.
```

**A Fairly Long Label That Always Wraps**

	Frequency	Percent	Valid Percent	Cumulative Percent
Valid A long value label that always wraps	1	100.0	100.0	100.0

Figure 103. Using \n to wrap value labels

---

## Chapter 288. VARCOMP

VARCOMP is available in SPSS Statistics Standard Edition or the Advanced Statistics Option.

VARCOMP dependent variable BY factor list [WITH covariate list]

```
/RANDOM = factor [factor ...]

[/METHOD = {MINQUE({1})**}]
           {0}
           {ML      }
           {REML    }
           {SSTYPE({3}) }
           {1}

[/INTERCEPT = {INCLUDE**}]
               {EXCLUDE  }

[/MISSING = {EXCLUDE**}]
           {INCLUDE  }

[/REGWGT = varname]

[/CRITERIA = [CONVERGE({1.0E-8**})] [EPS({1.0E-8**})] [ITERATE({50**})]]
            {n      }      {n      }      {n      }

[/PRINT = [EMS] [HISTORY({1**})] [SS]]
         {n      }

[/OUTFILE = [VAREST] [{COVB}] ('savfile'|'dataset') ]
            {CORB}

[/DESIGN = {[INTERCEPT] [effect effect ...]]]
```

\*\* Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Example

```
VARCOMP Y1 BY B C WITH X1 X2
/RANDOM = C.
```

---

## Overview

The VARCOMP procedure estimates variance components for mixed models. Following the general linear model approach, VARCOMP uses indicator variable coding to construct a design matrix and then uses one of the four available methods to estimate the contribution of each random effect to the variance of the dependent variable.

### Options

**Regression Weights.** You can use the REGWGT subcommand to specify regression weights for the model.

**Estimation Methods.** You can use the METHOD subcommand to use one of the four methods that are available for estimating variance components.

**Tuning the Algorithm.** You can control the values of algorithm-tuning parameters with the CRITERIA subcommand.

**Optional Output.** You can request additional output using the PRINT subcommand.

**Saving the Results.** You can save the variance component estimates and their asymptotic covariance matrix (if produced) to an external data file.

### Basic Specification

The basic specification is one dependent variable and one or more factor variables (that define the crosstabulation) and one or more factor variables on the RANDOM subcommand (to classify factors into either fixed or random factors). By default, VARCOMP uses the minimum norm quadratic unbiased estimator with unit prior weights to estimate variance components. Default output includes a factor-level information table and a variance component estimates table.

### Subcommand Order

- The variable specification must come first.
- Other subcommands can be specified in any order.

### Syntax Rules

- Only one dependent variable can be specified.
- At least one factor must be specified after BY.
- At least one factor must be specified on the RANDOM subcommand.

---

## Example

```
VARCOMP
  amtspent BY storeid  shopfor usecoup
  /RANDOM = storeid
  /METHOD = SSTYPE (3)
  /PRINT = SS
  /PRINT = EMS
  /DESIGN = shopfor usecoup shopfor*usecoup storeid
  /INTERCEPT = INCLUDE .
```

- The procedure fits a model to *amtspent* using *storeid*, *shopfor*, and *usecoup* as factors.
- RANDOM identifies *storeid* as a random effect.
- METHOD specifies ANOVA estimation using Type III sums of squares.
- PRINT requests tabular display of the sums of squares and expected mean squares.
- DESIGN indicates that the model fit is a factorial model for the fixed effects, plus a main-effects term for the random effect. The intercept is included.

---

## Variable List

The variable list specifies the dependent variable and the factors in the model.

- The dependent variable must be the first specification on VARCOMP.
- The factors follow the dependent variable and are separated from it by the keyword BY.
- The covariates, if any, follow the factors and are separated from the dependent variable and the factors by the keyword WITH.
- The dependent variable and the covariates must be numeric, but the factor variables can be either numeric or string.

---

## RANDOM Subcommand

The RANDOM subcommand allows you to specify random factors.

- You must specify at least one RANDOM subcommand with one random factor.
- You can specify multiple random factors on a RANDOM subcommand. You can also use multiple RANDOM subcommands. Specifications are accumulative.

- Only factors that are listed after the keyword BY in the variable list are allowed on the RANDOM subcommand.
- If you specify a factor on RANDOM, all effects containing the factor are automatically declared as random effects.

#### Example

```
VARCOM Y BY DRUG SUBJECT
/RANDOM = SUBJECT
/DESIGN = DRUG DRUG*SUBJECT.
```

- This example specifies a mixed model where *DRUG* is the fixed factor and *SUBJECT* is a random factor.
- The default method MINQUE(1) is used to estimate the contribution of the random effect DRUG\*SUBJECT to the variance of the dependent variable.

---

## METHOD Subcommand

The METHOD subcommand offers four different methods for estimating the variances of the random effects. If more than one METHOD subcommand is specified, only the last subcommand is in effect. If the subcommand is not specified, the default method MINQUE(1) is used. METHOD cannot be specified without a keyword.

**MINQUE(n).** *Minimum norm quadratic unbiased estimator.* This method is the default method. When  $n = 0$ , zero weight is assigned to the random effects and unit weight is assigned to the residual term. When  $n = 1$ , unit weight is assigned to both the random effects and the residual term. By default,  $n = 1$ .

**ML.** *Maximum likelihood method.* Parameters of the fixed effects and variances of the random effects are estimated simultaneously. However, only the variances are reported.

**REML.** *Restricted maximum likelihood method.* Variances of the random effects are estimated based on residuals of the model after adjusting for the fixed effects.

**SSTYPE(n).** *ANOVA method.* The ANOVA method equates the expected mean squares of the random effects to their observed mean squares. Their variances are then estimated by solving a system of linear equations. The expected mean squares are computed based on the chosen type of sum of squares. Two types are available in VARCOMP: Type I ( $n = 1$ ) and Type III ( $n = 3$ ). Type III is the default option for this method.

---

## INTERCEPT Subcommand

The INTERCEPT subcommand controls whether an intercept term is included in the model. If more than one INTERCEPT subcommand is specified, only the last subcommand is in effect.

**INCLUDE.** *Include the intercept term.* The intercept (constant) term is included in the model. This setting is the default when INTERCEPT is not specified.

**EXCLUDE.** *Exclude the intercept term.* The intercept (constant) term is excluded from the model. EXCLUDE is ignored if you specify the keyword INTERCEPT on the DESIGN subcommand.

---

## MISSING Subcommand

By default, cases with missing values for any of the variables on the VARCOMP variable list are excluded from the analyses. The MISSING subcommand allows you to include cases with user-missing values.

- Pairwise deletion of missing data is not available in VARCOMP.
- If more than one MISSING subcommand is specified, only the last subcommand is in effect.

**EXCLUDE.** *Exclude both user-missing and system-missing values.* This setting is the default when MISSING is not specified.

**INCLUDE.** *Treat user-missing values as valid.* System-missing values cannot be included in the analysis.

---

## REGWGT Subcommand

REGWGT specifies the weight variable. Values of this variable are used as regression weights in a weighted least squares model.

- Specify one numeric variable name on the REGWGT subcommand.
- Cases with nonpositive values in the regression weight variable are excluded from the analyses.
- If more than one variable is specified on the same REGWGT subcommand, only the last variable is in effect.
- If more than one REGWGT subcommand is specified, only the last subcommand is in effect.

---

## CRITERIA Subcommand

The CRITERIA subcommand specifies numerical tolerance for checking singularity and offers control of the iterative algorithm that is used for ML or REML estimation.

- Multiple CRITERIA subcommands are allowed.
- The last specified value for any keyword takes effect. If no value is specified, the default is used.

**EPS(n).** *Epsilon value that is used as tolerance in checking singularity.* The value for  $n$  must be a positive value. The default is 1.0E-8.

**CONVERGE(n).** *Convergence criterion.* Convergence is assumed if the relative change in the objective function is less than the specified value. The value for  $n$  must be a positive value. The default is 1.0E-8. This process is available only if you specify ML or REML on the METHOD subcommand.

**ITERATE(n).** *Maximum number of iterations.* The value for  $n$  must be a positive integer. The default is 50. This process is available only if you specify ML or REML on the METHOD subcommand.

---

## PRINT Subcommand

The PRINT subcommand controls the display of optional output. If PRINT is not specified, the default output includes a factor information table and a variance component estimates table.

- For the maximum likelihood (ML) and restricted maximum likelihood (REML) methods, an asymptotic covariance matrix of the variance estimates table is also displayed.
- If more than one PRINT subcommand is specified, the specifications are accumulated. However, if you specify the keyword HISTORY more than once but with different values for  $n$ , the last specification is in effect.

**EMS.** *Expected mean squares.* This output shows expected mean squares of all of the effects. This process is available only if you specify SSTYPE(n) on the METHOD subcommand.

**HISTORY(n).** *Iteration history.* The table contains the objective function value and variance component estimates at every  $n$  iteration. The value for  $n$  must be a positive integer. The default is 1. The last iteration is always printed if HISTORY is specified on PRINT. This process is available only if you specify ML or REML on the METHOD subcommand.

**SS.** *Sums of squares.* The table contains sums of squares, degrees of freedom, and mean squares for each source of variation. This process is available only if you specify SSTYPE(n) on the METHOD subcommand.

---

## OUTFILE Subcommand

The OUTFILE subcommand writes the variance component estimates to a data file or a previously declared dataset (DATASET DECLARE command) that can be used in other procedures. For the ML and REML methods, OUTFILE can also write the asymptotic covariance or correlation matrix. If more than one OUTFILE subcommand is specified, the last specification is in effect.

- OUTFILE writes to an external data file or previously declared dataset. You must specify a quoted file specification or dataset name in parentheses.
- COVB and CORB are available only if you specify ML or REML on the METHOD subcommand.
- COVB and CORB are mutually exclusive; only one of them can be specified on an OUTFILE subcommand.

**VAREST.** *Variance component estimates.* A variable will be created to contain the estimates, and another variable will be created to hold the labels of the variance components.

**COVB.** *Covariance matrix.* This matrix is the asymptotic covariance matrix of the variance component estimates. One variable is created for each variance component.

**CORB.** *Correlation matrix.* This matrix is the asymptotic correlation matrix of the variance component estimates. One variable is created for each variance component.

**('savfile'|'dataset').** *Output file specification or previously declared dataset name.* Specify a quoted file specification or dataset name, enclosed in parentheses. The variance component estimates and the asymptotic covariance or correlation matrix (if requested) are written to the same file.

---

## DESIGN Subcommand

The DESIGN subcommand specifies the effects in a model. DESIGN can be specified anywhere after the variable list. If more than one DESIGN subcommand is specified, only the last subcommand is in effect.

- Specify a list of effect terms to be included in the design. Each term must be separated from the next term by a comma or a space. Valid specifications include the keyword INTERCEPT, factors, covariates, and interaction or nested terms.
- The factors and covariates must have been specified on the variable list.
- If a factor is specified on the RANDOM subcommand, all effects that include that factor are random effects.
- If the DESIGN subcommand is omitted or specified without any term, the default design is generated. The default design includes the intercept term (if INTERCEPT=EXCLUDE is not specified), the covariates (if any) in the order in which they are specified on the variable list, the main factorial effects, and all orders of factor-by-factor interaction.

**INTERCEPT.** *Include the intercept term.* Specifying INTERCEPT on DESIGN explicitly includes the intercept term, regardless of the specification on the INTERCEPT subcommand.

**BY.** *Interaction.* You can also use the asterisk (\*). Interaction terms can be formed among factors, among covariates, and between factors and covariates.

- Factors inside an interaction effect must be distinct. For factors  $A$ ,  $B$ , and  $C$ , expressions like  $A*C*A$  or  $A*A$  are invalid.
- Covariates inside an interaction effect do not have to be distinct. For covariate  $X$ ,  $X*X$  is the product of  $X$  and itself. This is equivalent to a covariate whose values are the square of the values of  $X$ .

**WITHIN.** *Nesting.* You can also use a pair of parentheses. Factors and covariates can be nested within factors, but no effects can be nested within covariates. Suppose that  $A$  and  $B$  are factors and  $X$  and  $Y$  are covariates. Both  $A(B)$  and  $X(B)$  are valid, but  $X(Y)$  is not valid.

- Factors inside a nested effect must be distinct. Expressions like  $A(A)$  are invalid.

- Multiple-level nesting is supported. For example,  $A(B(C))$  or  $A \text{ WITHIN } B \text{ WITHIN } C$  means that factor  $B$  is nested within factor  $C$ , and factor  $A$  is nested within  $B(C)$ . The expression  $A(B)(C)$  is invalid.
- Nesting within an interaction effect is valid. For example,  $A(B*C)$  means that factor  $A$  is nested within  $B*C$  while  $X(A*B)$  means that covariate  $X$  is nested within  $A*B$ .
- Interactions among nested effects are allowed. For example,  $A*B(C)$  means interaction between  $A$  and  $B$  within levels of  $C$ .  $X*Y(A)$  means the product of  $X$  and  $Y$  nested within levels of  $C$ . The expression  $A(C)*B(C)$  is invalid.

### Example

```
VARCOM Y BY DRUG SUBJECT WITH X
/RANDOM = SUBJECT
/DESIGN = DRUG SUBJECT DRUG*SUBJECT X*SUBJECT.
```

- The `DESIGN` subcommand specifies two main effects and two interaction terms.
- All effects that involve the factor `SUBJECT` are assumed to be random.

---

## Chapter 289. VARIABLE ALIGNMENT

```
VARIABLE ALIGNMENT varlist ({LEFT }) ... [/varlist...]  
                          {CENTER}  
                          {RIGHT }
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Example

```
VARIABLE ALIGNMENT sales95 sales96 (LEFT)  
/id gender (RIGHT).
```

---

## Overview

VARIABLE ALIGNMENT specifies the alignment of data values in the Data Editor. It has no effect on the format of the variables or the display of the variables or values in other windows or printed results.

### Basic Specification

The basic specification is a variable name and the keyword LEFT, RIGHT, or CENTER in parentheses.

---

## Chapter 290. VARIABLE ATTRIBUTE

```
VARIABLE ATTRIBUTE
  VARIABLES=varlist
  ATTRIBUTE=name('value') name('value')...
              arrayname[1]('value') arrayname[2]('value')...
  DELETE=name name...
              arrayname[n] arrayname...
/VARIABLES...
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Release History

#### Release 14.0

- Command introduced.

### Example

```
VARIABLE ATTRIBUTE VARIABLES=Age Gender Region
  ATTRIBUTE=DemographicVars ('1').
```

---

## Overview

VARIABLE ATTRIBUTE provides you with the ability to define your own variable attributes and assign attribute values to variables in the active dataset. For example, you could create a variable attribute that identifies the type of response for survey questions (e.g., single selection, multiple selection, fill-in-the-blank) or the formulas used for computed variables.

- User-defined variable attributes are saved with the data file in the data dictionary.
- The VARIABLE ATTRIBUTE command takes effect immediately, updating the data dictionary without requiring a data pass.
- You can display a list of data file and variable attributes with DISPLAY ATTRIBUTES. See the topic Chapter 79, “DISPLAY,” on page 631 for more information.

### Basic Specification

The basic specification is:

- The VARIABLES subcommand followed by an equals sign (=) and a list of valid variables.
- The ATTRIBUTE keyword followed by an equals sign (=) and one or more attribute names that follow variable naming rules, with each attribute name followed by a quoted attribute value enclosed in parentheses.

or

- The DELETE keyword followed by an equals sign (=) and a list of defined attribute names or attribute arrays.

### Syntax Rules

- The VARIABLES subcommand is required.
- All subcommands and keywords (VARIABLES, ATTRIBUTE, DELETE) must be followed by an equals sign (=).
- Each ATTRIBUTE keyword must be followed by a name that follows variable naming rules and a single, quoted attribute value enclosed in parentheses. See the topic “Variable Names” on page 46 for more information.

- Attribute names that begin with @ cannot be displayed in Variable View of the Data Editor and are not displayed by DISPLAY DICTIONARY or DISPLAY ATTRIBUTES. They can only be displayed with DISPLAY @ATTRIBUTES.
- Attribute names that begin with a dollar sign (\$) are reserved for internal IBM SPSS Statistics use.
- All attribute values must be quoted (single or double quotes), even if the values are numbers.
- Attribute values can be up to 32,767 bytes in length.

## Attribute Arrays

If you append an integer enclosed in square brackets to the end of an attribute name, the attribute is interpreted as an array of attributes. For example,

```
VARIABLE ATTRIBUTE VARIABLES=Age
  ATTRIBUTE=MyAttribute[99]('not quite 100').
```

will create 99 attributes--*MyAttribute[01]* through *MyAttribute[99]*--and will assign the value "not quite 100" to the last one.

- Array subscripts (the value enclosed in square brackets) must be integers greater than 0. (Array subscript numbering starts with 1, not 0.)
- If the root name of an attribute array is the same as an existing attribute name for any variables specified on the VARIABLES subcommand, the attribute array replaces the existing attribute for those variables (and vice versa). If no value is assigned to the first element in the array (subscript [1]), the original attribute value is used for that element value.

With the DELETE keyword, the following rules apply to attribute arrays:

- If you specify DELETE followed by an array rootname and no value in square brackets, all attributes in the array are deleted.
- If you specify DELETE with an array name followed by an integer value in square brackets, the specified array element is deleted and the integer values for all subsequent attributes in the array (in numeric order) are changed to reflect the new order of array elements.

---

## Example

```
VARIABLE ATTRIBUTE
  VARIABLES=Age Income1 Income2 Income3
  ATTRIBUTE=AnswerFormat('Fill-in')
  /VARIABLES=Gender OwnHome MortgageType
  ATTRIBUTE=AnswerFormat('Single select')
  /VARIABLES=AvgIncome
  ATTRIBUTE=AnswerFormat('Computed value')
  /VARIABLES=AvgIncome
  ATTRIBUTE=Formula('mean(Income1, Income2, Income3)')
  /VARIABLES=AvgIncome
  ATTRIBUTE=DerivedFrom[1]('Income1')
  DerivedFrom[2]('Income2')
  DerivedFrom[3]('Income3').
DISPLAY ATTRIBUTES.
```

- The variables *Age*, *Income1*, *Income2*, and *Income3* are assigned the variable attribute *AnswerFormat* with a value of *Fill-in*.
- The variables *Gender*, *OwnHome*, and *MortgageType* are assigned the variable attribute *AnswerFormat* with a value of *Single select*.
- The variable *AvgIncome* is assigned the variable attribute *AnswerFormat* with a value of *Computed value*.
- The variable *AvgIncome* is assigned the variable attribute *Formula*, with a value the describes the formula used to calculate the value of this variable.
- The variable *AvgIncome* is assigned the variable attribute array *DerivedFrom*, and each array value identifies one of the variables used to calculate the value of *AvgIncome*.
- DISPLAY ATTRIBUTES lists the variable attributes for each variable in the active dataset.

Variable Attributes

Variable	Attribute	Value
Age	AnswerFormat	Fill-in
Gender	AnswerFormat	Single select
Income1	AnswerFormat	Fill-in
Income2	AnswerFormat	Fill-in
Income3	AnswerFormat	Fill-in
OwnHome	AnswerFormat	Single select
MortgageType	AnswerFormat	Single select
AvgIncome	AnswerFormat	Computed value
	DerivedFrom[1]	Income1
	DerivedFrom[2]	Income2
	DerivedFrom[3]	Income3
	Formula	mean(Income1 , Income2, Income3)

Figure 104. Variable attributes

---

## Chapter 291. VARIABLE LABELS

VARIABLE LABELS varname 'label' [/varname...]

### Example

```
VARIABLE LABELS YRHIRED 'YEAR OF FIRST HIRING'.
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

---

## Overview

VARIABLE LABELS assigns descriptive labels to variables in the active dataset.

### Basic Specification

The basic specification is a variable name and the associated label in quotes.

### Syntax Rules

- Labels can be added to any previously defined variable. It is not necessary to enter labels for all variables in the active dataset.
- Each variable label must be enclosed in quotes.
- Variable labels can contain any characters, including blanks. To enter an apostrophe as part of a label, enclose the label in double quotes or enter a two apostrophes (two single quotes). See the topic “String Values in Command Specifications” on page 39 for more information.
- Each variable label can be up to 255 bytes long, although some procedures print fewer than the 255 bytes. All statistical procedures display at least 40 bytes.
- Multiple variables can be assigned labels on a single VARIABLE LABELS command. Only one label can be assigned to each variable, and each label can apply to only one variable.
- To continue a label from one command line to the next, specify a plus (+) sign before the continuation of the label. Each string segment of the label must be enclosed in quotes. To insert a blank between the strings, the blank must be included in the label specification.
- To control line wrapping of labels in pivot tables and charts, insert \n as part of the label wherever you want a line break. The \n is not displayed in output; it is interpreted as a line-break character. (*Note:* Labels will *always* wrap wherever \n appears in the defined label, even if there is enough space to display the label without wrapping.)

## Operations

- Unlike most transformations, `VARIABLE LABELS` takes effect as soon as it is encountered in the command sequence. Thus, special attention should be paid to its position among commands. See the topic “Command Order” on page 40 for more information.
- Variable labels are automatically displayed in the output from many procedures and are stored in the dictionary of the active dataset.
- `VARIABLE LABELS` can be used for variables that have no previously assigned variable labels. If a variable has a previously assigned variable label, the new label replaces the old label.

---

## Examples

### Assigning Variable Labels to Multiple Variables

```
VARIABLE LABELS YRHIRED 'YEAR OF FIRST HIRING'  
DEPT88 'DEPARTMENT OF EMPLOYMENT IN 1988'  
SALARY88 'YEARLY SALARY IN 1988'  
JOB CAT 'JOB CATEGORIES'.
```

- Variable labels are assigned to the variables `YRHIRED`, `DEPT88`, `SALARY88`, and `JOB CAT`.

### Combining Strings to Construct Variable Labels

```
VARIABLE LABELS OLDSAL "EMPLOYEE'S GROSS SALARY PRIOR"  
+ " TO 1988".
```

- The label for `OLDSAL` is created by combining two strings with the plus sign. The blank between `PRIOR` and `TO` must be included in the first or second string to be included in the label.

### Forcing Variable Labels to Wrap

```
VARIABLE LABELS myvar "A Fairly Long Label \n That Always Wraps".  
FREQUENCIES myvar.
```

**A Fairly Long Label  
That Always Wraps**

	Frequency	Percent	Valid Percent	Cumulative Percent
Valid	1.00	1	100.0	100.0

Figure 105. Using `\n` to wrap variable labels

---

## Chapter 292. VARIABLE LEVEL

```
VARIABLE LEVEL varlist ({SCALE }) ... [/varlist...]  
                        {ORDINAL}  
                        {NOMINAL}
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Example

```
VARIABLE LEVEL sales95 sales96 (SCALE)  
/region division (NOMINAL)  
/expense (ORDINAL).
```

---

## Overview

VARIABLE LEVEL specifies the level of measurement for variables.

### Basic Specification

The basic specification is a variable name, followed by a measurement level enclosed in parentheses. The measurement level can be:

**NOMINAL.** A variable can be treated as nominal when its values represent categories with no intrinsic ranking; for example, the department of the company in which an employee works. Examples of nominal variables include region, zip code, or religious affiliation.

**ORDINAL.** A variable can be treated as ordinal when its values represent categories with some intrinsic ranking; for example, levels of service satisfaction from highly dissatisfied to highly satisfied. Examples of ordinal variables include attitude scores representing degree of satisfaction or confidence and preference rating scores.

**SCALE.** A variable can be treated as scale when its values represent ordered categories with a meaningful metric, so that distance comparisons between values are appropriate. Examples of scale variables include age in years and income in thousands of dollars.

---

## Chapter 293. VARIABLE ROLE

```
VARIABLE ROLE  
  [/INPUT varlist]  
  [/TARGET varlist]  
  [/BOTH varlist]  
  [/NONE varlist]  
  [/PARTITION varlist]  
  [/SPLIT varlist]
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Release History

#### Release 18.0

- Command introduced.

### Example

```
VARIABLE ROLE  
  /INPUT Age Income Gender Education Debt  
  /TARGET Credit_rating /NONE Customer_ID.
```

---

## Overview

Some dialogs support predefined roles that can be used to pre-select variables for analysis. When you open one of these dialogs, variables that meet the role requirements will be automatically displayed in the destination list(s). Available role subcommands are:

**Input.** The variable will be used as an input (e.g., predictor, independent variable).

**Target.** The variable will be used as an output or target (e.g., dependent variable).

**Both.** The variable will be used as both input and output.

**None.** The variable has no role assignment.

**Partition.** The variable will be used to partition the data into separate samples for training, testing, and validation.

**Split.** Included for round-trip compatibility with IBM SPSS Modeler. Variables with this role are *not* used as split-file variables in IBM SPSS Statistics.

- By default, all variables are assigned the *Input* role. This includes data from external file formats and data files from versions of IBM SPSS Statistics prior to version 18.
- Role assignment only affects dialogs that support role assignment. It has no effect on command syntax.

### Basic Specification

The basis specification is the command name, at least one subcommand, and at least one variable specified on that subcommand.

### Syntax Rules

- At least one subcommand must be specified.
- Only a single instance of each subcommand is allowed.
- Each subcommand must be preceded by a forward slash.

- Each subcommand must specify at least one variable.
- The command name and subcommand names must be spelled in full.
- Keyword ALL can be used to specify all variables in the active dataset, and keyword T0 can be used to specify a list of variables (in file order).

#### Operations

- If a variable is specified more than once, the last role assignment is used.
- This command takes effect immediately. It does not read the active dataset or execute pending transformations.

#### Example

```
VARIABLE ROLE  
  /INPUT Age Income Gender Education Debt  
  /TARGET Credit_rating /NONE Customer_ID.
```

---

## Chapter 294. VARIABLE WIDTH

VARIABLE WIDTH varlist (n) ... [/varlist...]

### Example

```
VARIABLE WIDTH sales95 sales96 (10)
  /id gender (2).
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

---

### Overview

VARIABLE WIDTH specifies the column width for the display of variables in the Data Editor. It has no effect on the format of the variable or the display of the variable or values in other windows or printed results.

#### Basic Specification

The basic specification is a variable name and a positive integer in parentheses for the column width. Column width for proportional fonts is based on average character width. Depending on the characters used in the value, more or fewer characters may be displayed in the specified width.

---

## Chapter 295. VARSTOCASES

### VARSTOCASES

```
/MAKE new variable ["label"] [FROM] varlist [/MAKE ...]

[/INDEX = {new variable ["label"]}
           {new variable ["label"] (make variable name)
           {new variable ["label"] (n) new variable ["label"] (n) ...}}]

[/ID = new variable ["label"]]

[/NULL = {DROP**}
         {KEEP  }

[/COUNT=new variable ["label"]]

[/KEEP={ALL** } ] [/DROP=varlist]
  {varlist}
```

\*\*Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Example

```
VARSTOCASES /MAKE newvar FROM var1 TO var4.
```

---

## Overview

A **variable** contains information that you want to analyze, such as a measurement or a test score. A **case** is an observation, such as an individual or an institution. In a simple data structure, each variable is a single **column** in your data. So if you are measuring test scores, for example, all test score values would appear in only one column. In a simple data structure, each case is a single **row** in your data. So if you were measuring scores for all students in a class, there would be a row for each student.

VARSTOCASES restructures **complex** data structures (in which information about a variable is stored in more than one column) into a data file in which those measurements are organized into separate rows of a single column. It replaces the active dataset.

You can use VARSTOCASES to restructure data files in which repeated measurements of a single case were recorded in one row into a new data file in which each measurement for a case appears in a new row.

### Options

**Creating New Variables.** You can create an **identification** variable that identifies the row in the original data file that was used to create a group of new rows, a **count** variable that contains the number of new rows generated by a row in the original data, and one or more **index** variables that identify the original variable from which the new row was created.

**Variable Selection.** You can use the DROP and KEEP subcommands to specify which variables from the original data file are included in the new data file.

### Basic Specification

The basic specification is one or more MAKE subcommands, each of which specifies a list of variables to be combined into a single variable in which each value is displayed on a separate row.

### Subcommand Order

Subcommands can be specified in any order.

### Syntax Rules

- The MAKE subcommand is required and can be specified as many times as needed.
- The rest of the subcommands can be specified only once.

### Operations

- **Row order.** New rows are created in the order in which the variables are specified on the FROM list.
- **Propagated variables.** Variables that are not named on the MAKE or DROP subcommands are kept in the new data file. Their values are propagated for each new row.
- **Split file processing.** The SPLIT FILE command does not affect the results of VARSTOCASES. If split file processing is in effect, it will remain in effect in the new data file unless a variable that is used to split the file is named on the MAKE or DROP subcommands.
- **Weighted files.** The WEIGHT command does not affect the results of VARSTOCASES. If original data are weighted, the new data will be weighted unless the variable that is used to split the file is named on the MAKE or DROP subcommands.
- **Selected cases.** The FILTER and USE commands do not affect the results of VARSTOCASES. It processes all cases.

### Limitations

The TEMPORARY command cannot be in effect when VARSTOCASES is executed.

---

## Example

The following is the LIST output for a data file where repeated measurements for the same case are stored in variables on a single row:

caseid	var1	var2	var3	var4
001	.00	.05	5.00	3.00
002	7.00	1.00	5.00	4.00
003	6.00	3.00	6.00	2.00

The command:

```
VARSTOCASES  
/MAKE newvar FROM var1 TO var4.
```

creates a new variable, *newvar*, using the values of *var1* through *var4*. The LIST output for the new active dataset is as follows:

caseid	newvar
001	.00
001	.05
001	5.00
001	3.00
002	7.00
002	1.00
002	5.00
002	4.00
003	6.00
003	3.00
003	6.00
003	2.00

The values for the new variable *newvar* are the values from *var1* through *var4* from the original data. There are now four rows for each case—one row for each variable that was named on the FROM list.

---

## MAKE Subcommand

The MAKE subcommand names, and optionally labels, the new variable to be created from the variables on the FROM list.

- One new variable is required on each MAKE subcommand. It must have a unique name.
- The label for the new variable is optional and, if specified, must be enclosed in quotes.
- The new variable will have the values of the variables listed on the FROM list. For each case in the original data, one new row will be created for each variable on the FROM list.
- All of the variables on the FROM list are required to be of the same type. For example, they must all be numeric or they must all be string.
- The dictionary information for the new variable (for example, value labels and format) is taken from the first variable in the FROM list. If string variables of different lengths are specified, the longest length is used.
- Rows are created in the order in which variables appear on the FROM list.
- Variables that appear on the FROM list will not appear in the new data file.
- Variables that are kept in the new data file and not named on the FROM list will have their values propagated for each new row.
- When multiple MAKE subcommands are used, a variable may not appear on more than one FROM list.
- A variable may be listed more than once on a FROM list. Its values are repeated.
- When multiple MAKE subcommands are used, the FROM lists must all contain the same number of variables (variables that are listed more than once must be included in the count).

---

## ID Subcommand

The ID subcommand creates a new variable that identifies the permanent case sequence number (*\$casenum*) of the original row that was used to create the new rows. Use the ID subcommand when the original data file does not contain a variable that identifies cases.

- One new variable is named on the ID subcommand. It must have a unique name.
- The label for the new variable is optional and, if specified, must be enclosed in quotes.
- The format of the new variable is F8.0.

---

## INDEX Subcommand

In the original data file, a case appears on a single row. In the new data file, that case will appear on multiple rows. The INDEX subcommand creates a new variable that sequentially identifies a group of new rows based on the original variables from which it was created.

- You can choose among three types of indices—a simple numeric index, an index that lists the variables on a FROM list, or multiple numeric indices.
- New variable(s) are named on the INDEX subcommand. A new variable must have a unique name.
- The label for the new variable is optional and, if specified, must be enclosed in quotes.

### Simple Numeric Index

A simple numeric index numbers the rows sequentially within a new group.

- The basic specification is `/INDEX=ivar`, where *ivar* is a name for the new index variable.
- The new index variable starts with 1 and increments each time a FROM variable is encountered in a row in the original file. After the last FROM variable is encountered, the index restarts at 1.
- Gaps in the index sequence can occur if null data are dropped.

Example

```
VARSTOCASES
  /MAKE newvar FROM var1 TO var4
  /INDEX=ivar.
```

caseid	ivar	newvar
001	1	.00
001	2	.05
001	3	5.00
001	4	3.00
002	1	7.00
002	2	1.00
002	3	5.00
002	4	4.00
003	1	6.00
003	2	3.00
003	3	6.00
003	4	2.00

## Variable Name Index

A variable name index works like the simple numeric index, except that it lists the name of the original FROM variable instead of a sequential number.

- The basic specification is `/INDEX=ivar (make variable name)`, where *ivar* is the name for the new index variable and *make variable name* is the name of a variable on the MAKE subcommand from which the index is to be constructed.
- The new index variable is a string that lists the name of the FROM variable from which the new row was created.

### Example

```
VARSTOCASES
  /MAKE newvar FROM var1 TO var4
  /INDEX=ivar (newvar).
```

caseid	ivar	newvar
001	VAR1	.00
001	VAR2	.05
001	VAR3	5.00
001	VAR4	3.00
002	VAR1	7.00
002	VAR2	1.00
002	VAR3	5.00
002	VAR4	4.00
003	VAR1	6.00
003	VAR2	3.00
003	VAR3	6.00
003	VAR4	2.00

## Multiple Numeric Indices

Multiple numeric indices are used to identify groups of new rows that share a particular combination of factors. You can create multiple numeric indices if the original variables are ordered so that levels of a given factor are grouped together.

- The basic specification is `/INDEX=ivar(n) ivar(n) ...`, where *ivar* is the name of the new index for a factor and *n* is the number of factor levels represented in the variable group for which the index is being constructed.
- The last index specified varies the fastest.

### Example

	B1	B2
A1	.00	.05
A2	5.00	3.00

- Data were collected for a designed experiment with two levels of factor A and two levels of factor B. The table shows the data for the first case.

caseid	v_a1b1	v_a1b2	v_a2b1	v_a2b2
001	.00	.05	5.00	3.00

- The original data file is structured so that each case has one variable for each combination of factors. Note that factor B varies fastest.

```
VARSTOCASES
  /MAKE newvar FROM v_a1b1 TO v_a2b2
  /INDEX=a(2) b(2).
```

caseid	a	b	newvar
001	1	1	.00
001	1	2	.05
001	2	1	5.00
001	2	2	3.00

- The command restructures the data file and creates two indices, *A* and *B*.

## NULL Subcommand

The NULL subcommand checks each potential new row for **null** values. A null value is a system-missing or blank value. By default, VARSTOCASES does not add a new row that contains null values for all variables created by MAKE subcommands. You can change the default null-value treatment with the NULL subcommand.

**DROP.** *Do not include a new row when all MAKE variables are null.* A potential new row with null values for all of the variables created by MAKE subcommands is excluded from the new data file. This is the default. With this option, you may want to create a count variable to keep track of new rows because cases in the original data file are not guaranteed to appear in the new data file.

**KEEP.** *Include a new row when all MAKE variables are null.* A potential new row with null values for all of the variables created by the MAKE subcommand is included in the new data. With this option, you may not need a count variable to keep track of cases because each row in the original data will result in a consistent number of rows in the new data file.

## COUNT Subcommand

When there are no null data, VARSTOCASES generates *n* new rows for each row in the original data file, where *n* is the number of variables on the FROM list(s). When the original data file contains null values and you drop them, it is possible to generate a different number of rows for a given subject in the original data file. The COUNT subcommand creates a new variable that contains the number of new rows generated by the original subject.

- One new variable is named on the COUNT subcommand. It must have a unique name.
- The label for the new variable is optional and, if specified, must be enclosed in quotes.
- The format of the new variable is F4.0.

## DROP and KEEP Subcommands

The DROP and KEEP subcommands are used to include only a subset of variables in the new active dataset. The DROP subcommand specifies a set of variables to exclude and the KEEP subcommand specifies a set of variables to retain. Variables not specified on the KEEP subcommand are dropped.

- DROP and KEEP cannot be used with variables that appear on a FROM list.
- DROP and KEEP are mutually exclusive. Only one DROP or one KEEP subcommand can be used on the VARSTOCASES command.
- KEEP affects the order of variables in the new data file. The order of the variables kept in the new data file is the order in which they are named on the KEEP subcommand.

### Example

```
VARSTOCASES
  /MAKE newvar FROM var1 to var4
  /DROP caseid.
```

- *Caseid* is dropped from the new data file. The new data file contains one variable, *newvar*.

---

## Chapter 296. VECTOR

```
VECTOR {vector name=varname TO varname} [/vector name...]  
       {vector name(n [format])      }
```

### Example

```
VECTOR V=V1 TO V6.
```

---

## Overview

VECTOR associates a vector name with a set of existing variables or defines a vector of new variables. A vector is a set of variables that can be referred to using an index. The vector can refer to either string or numeric variables, and the variables can be permanent or temporary.

For each variable in the reference list, VECTOR generates an element. Element names are formed by adding a subscript in parentheses to the end of the vector name. For example, if the vector *AGES* has three elements, the element names are *AGES(1)*, *AGES(2)*, and *AGES(3)*. Although the VECTOR command has other uses within the transformation language, it is most often used with LOOP structures because the indexing variable on LOOP can be used to refer to successive vector elements.

### Options

**File Structures.** VECTOR can be used with the END CASE command to restructure data files. You can build a single case from several cases or, conversely, you can build several cases from a single case (see the examples for the END CASE command ).

**Short-Form Vectors.** VECTOR can be used to create a list of new variables and the vector that refers to them simultaneously. VECTOR in the short form can be used to establish the dictionary order of a group of variables before they are defined on a DATA LIST command (see "VECTOR: Short Form" ).

### Basic Specification

- The basic specification is VECTOR, a vector name, a required equals sign, and the list of variables that the vector refers to. The TO keyword must be used to specify the variable list, and it defines a variable list based on file order.
- For the short form of VECTOR, the basic specification is VECTOR, an alphabetical prefix, and, in parentheses, the number of variables to be created.

### Syntax Rules

- Multiple vectors can be created on the same command by using a slash to separate each set of specifications.
- Variables specified on VECTOR must already be defined unless the short form of VECTOR is used to create variables (see "VECTOR: Short Form" ).
- The TO convention must be used to specify the variable list. Thus, variables specified must be consecutive and must be from the same dictionary, permanent or scratch.
- A single vector must comprise all numeric variables or all string variables. The string variables must have the same length.
- A scalar (a variable named on NUMERIC), a function, and a vector can all have the same name, for example *MINI*. The scalar can be identified by the lack of a left parenthesis following the name. Where a vector has the same name as a function (or the abbreviation of a function), the vector name takes precedence (see the example on name conflicts in "VECTOR: Short Form" ).
- Vector element names must always be specified with a subscript in parentheses.

## Operations

- VECTOR takes effect as soon as it is encountered in the command sequence, unlike most transformations, which do not take effect until the data are read. Thus, special attention should be paid to its position among commands. See the topic “Command Order” on page 40 for more information.
- VECTOR is in effect only until the first procedure that follows it. The vector must be redeclared to be reused.

## Limitations

- A vector element is an *expression* and can be used wherever an expression can be used in transformation commands. It can also be the *target* of an assignment in a COMPUTE or IF command. It cannot be used in other transformation commands where a variable name is required. Specifically, vector elements cannot be used instead of variable names in RECODE, COUNT, XSAVE, DO REPEAT, or other transformation commands that require variable names but not expressions.
- Vectors cannot be used in procedure commands (for example, statistical or charting procedures).
- Vector names (for the whole vector rather than elements) cannot be used anywhere but in the VECTOR command itself.

---

## Examples

### Example

```
DATA LIST FREE /height age weight.
BEGIN DATA
1 2 3
END DATA.
VECTOR x=height TO weight.
VECTOR y=age TO weight.
VECTOR z=age TO height.
```

- The list of variables specified with TO defines a list of variables in file order.
- Vector *x* contains the variables *height*, *age*, and *weight*.
- Vector *y* contains the variables *age* and *weight*.
- The last VECTOR command generates an error because *height* comes before *age* in file order.

### Example

\* Replace a case's missing values with the mean of all nonmissing values for that case.

```
DATA LIST FREE /V1 V2 V3 V4 V5 V6 V7 V8.
MISSING VALUES V1 TO V8 (99).
COMPUTE MEANSUB=MEAN(V1 TO V8).
```

```
VECTOR V=V1 TO V8.
LOOP #I=1 TO 8.
+ DO IF MISSING (V(#I)).
+ COMPUTE V(#I)=MEANSUB.
+ END IF.
END LOOP.
```

```
BEGIN DATA
1 99 2 3 5 6 7 8
2 3 4 5 6 7 8 9
2 3 5 5 6 7 8 99
END DATA.
LIST.
```

- The first COMPUTE command calculates the variable *MEANSUB* as the mean of all nonmissing values for each case.
- VECTOR defines the vector *V* with the original variables as its elements.
- For each case, the loop is executed once for each variable. The COMPUTE command within the loop is executed only when the variable has a missing value for that case. COMPUTE replaces the missing value with the value of *MEANSUB*.

- For the first case, the missing value for the variable *V2* is changed to the value of *MEANSUB* for that case. The missing value for the variable *V8* for the third case is changed to the value of *MEANSUB* for that case.

For additional examples of VECTOR, see the examples for the END CASE command and the IF command .

---

## VECTOR: Short Form

VECTOR can be used to create a list of new variables and the vector that refers to them simultaneously. The short form of VECTOR specifies a prefix of alphanumeric characters followed, in parentheses, by the length of the vector (the number of variables to be created).

- The new variable names must not conflict with existing variables. If the prefix starts with the # character, the new variables are created according to the rules for scratch variables.
- More than one vector of the same length can be created by naming two or more prefixes before the length specification.
- By default, variables created with VECTOR receive F8.2 formats. Alternative formats for the variables can be specified by including a format specification with the length specification within the parentheses. The format and length can be specified in either order and must be separated by at least one space or comma. If multiple vectors are created, the assigned format applies to all of them unless you specify otherwise.

### Creating a Vector from a Set of New Scratch Variables

```
VECTOR #WORK(10).
```

- The program creates the vector #WORK, which refers to 10 scratch variables: #WORK1, #WORK2, and so on, through #WORK10. Thus, the element #WORK(5) of the vector is the variable #WORK5.

### Creating Multiple Vectors of the Same Length

```
VECTOR X,Y(5).
```

- VECTOR creates the vectors X and Y, which refer to the new variables X1 through X5 and Y1 through Y5, respectively.

### Specifying the Format of Vector Variables

```
VECTOR X(6,A5).
```

- VECTOR assigns an A5 format to the variables X1 through X6.

### Creating Multiple Vectors of Different Lengths and Formats

```
VECTOR X,Y(A5,6) Z(3,F2).
```

- VECTOR assigns A5 formats to the variables X1 to X6 and Y1 to Y6, and F2 formats to the variables Z1 to Z3. It doesn't matter whether the format or the length is specified first within the parentheses.

### Predetermining Variable Order Using the Short Form of VECTOR

```
INPUT PROGRAM.
VECTOR X Y (4,F8.2).
DATA LIST / X4 Y4 X3 Y3 X2 Y2 X1 Y1 1-8.
END INPUT PROGRAM.
```

```
PRINT /X1 TO X4 Y1 TO Y4.
BEGIN DATA
49382716
49382716
49382716
END DATA.
```

- The short form of VECTOR is used to establish the dictionary order of a group of variables before they are defined on a DATA LIST command. To predetermine variable order, both VECTOR and DATA LIST must be enclosed within the INPUT PROGRAM and END INPUT PROGRAM commands.
- The order of the variables in the active dataset will be X1, X2, X3, and X4, and Y1, Y2, Y3, and Y4, even though they are defined in a different order on DATA LIST.

- The program reads the variables with the F1 format specified on DATA LIST. It writes the variables with the output format assigned on VECTOR (F8.2).
- Another method for predetermining variable order is to use NUMERIC (or STRING if the variables are string variables) before the DATA LIST command (see the example on variable order for the NUMERIC command). The advantage of using NUMERIC or STRING is that you can assign mnemonic names to the variables.

### Name Conflicts in Vector Assignments

```
INPUT PROGRAM.
NUMERIC MIN MINI_A MINI_B MINIM(F2).
COMPUTE MINI_A = MINI(2). /*MINI is function MINIMUM.
VECTOR MINI(3,F2).
DO REPEAT I = 1 TO 3.
+ COMPUTE MINI(I) = -I.
END REPEAT.
COMPUTE MIN = MIN(1). /*The second MIN is function MINIMUM.
COMPUTE MINI_B = MINI(2). /*MINI now references vector MINI
COMPUTE MINIM = MINIM(3). /*The second MINIM is function MINIMUM.
END CASE.
END FILE.
END INPUT PROGRAM.
```

- In this example, there are potential name conflicts between the scalars (the variables named on NUMERIC), the vectors (named on VECTOR), and the statistical function MINIMUM.
- A name that is not followed by a left parenthesis is treated as a scalar.
- When a name followed by a left parenthesis may refer to a vector element or a function, precedence is given to the vector.

---

## VECTOR outside a Loop Structure

VECTOR is most commonly associated with the loop structure, since the index variable for LOOP can be used as the subscript. However, the subscript can come from elsewhere, including from the data.

### Example

\* Create a single case for each of students 1, 2, and 3.

```
DATA LIST /STUDENT 1 SCORE 3-4 TESTNUM 6.
BEGIN DATA
1 10 1
1 20 2
1 30 3
1 40 4
2 15 2
2 25 3
3 40 1
3 55 3
3 60 4
END DATA.

VECTOR RESULT(4).
COMPUTE RESULT(TESTNUM)=SCORE.

AGGREGATE OUTFILE=*/BREAK=STUDENT
/RESULT1 TO RESULT4=MAX(RESULT1 TO RESULT4).

PRINT FORMATS RESULT1 TO RESULT4 (F2.0).
PRINT /STUDENT RESULT1 TO RESULT4.
EXECUTE.
```

- Data are scores on tests recorded in separate cases along with a student identification number and a test number. In this example, there are four possible tests for three students. Not all students took every test.
- The vector *RESULT* creates the variables *RESULT1* through *RESULT4*.
- For each case, *COMPUTE* assigns the *SCORE* value to one of the four vector variables, depending on the value of *TESTNUM*. The other three vector variables for each case keep the system-missing value they were initialized to.

- Aggregating by the variable *STUDENT* creates new cases, as shown by the output from the PRINT command. The MAX function in AGGREGATE returns the maximum value across cases with the same value for *STUDENT*. If a student has taken a particular test, the one valid value is returned as the value for the variable *RESULT1*, *RESULT2*, *RESULT3*, or *RESULT4*.

```
1 10 20 30 40
2 . 15 25 .
3 40 . 55 60
```

Figure 106. PRINT output after aggregating

---

## Chapter 297. VERIFY

VERIFY [VARIABLES=series name]

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Example

VERIFY.

---

## Overview

VERIFY produces a report on the status of the most current DATE, USE, and PREDICT specifications. The report lists the first and last observations in the active dataset, the current USE and PREDICT ranges, and any anomalies in the DATE variables. The number of missing values and the values of the first and last observations in the file and in the USE and PREDICT ranges can also be displayed for a specified series.

VERIFY should be used before a time series procedure whenever there is a possibility that DATE variables or USE and PREDICT ranges have been invalidated. In particular, the active dataset should be verified after you have modified the file structure with commands such as SELECT IF, SORT CASES, and AGGREGATE.

### Options

If a series is specified after VERIFY, the values of the first and last observations in the file and in the USE and PREDICT periods are reported for that series. In addition, the number of observations in the active dataset that have missing values for that series is displayed. This can be useful for determining the USE ranges that do not include any missing values.

### Basic Specification

The basic specification is the command keyword VERIFY.

- VERIFY displays the first and last observations in the active dataset and in the USE and PREDICT ranges. This information is presented by case number and by the values of the DATE variables.
- For DATE variables, VERIFY reports the number of missing or invalid values. In addition, DATE variables that are not properly nested within the next higher-level DATE variable, that have start or end values other than those expected at the beginning or end of a cycle, or that increment by more than the expected increment are flagged with an asterisk next to the problem. An explanation of the problem is given.

### Operations

- VERIFY reports on cases remaining after any preceding SELECT IF commands.
- The USE and PREDICT ranges are defined by the last USE and PREDICT commands specified before the VERIFY command. If USE and PREDICT have not been specified, the USE range is the entire series, and the PREDICT range does not exist.

### Limitations

- A maximum of 1 VARIABLES subcommand. Only one series can be specified on VARIABLES.

---

## VARIABLES Subcommand

VARIABLES names a series to include in the report and is optional. The actual keyword VARIABLES can be omitted.

- The series named on *VARIABLES* must be numeric. The *DATE\_* series is non-numeric and cannot be specified.
  - Only one *VARIABLES* subcommand can be specified, and it can name only one series.
- 

## Examples

*VERIFY*.

- This command produces a report on the status of the most recent *DATE*, *USE*, and *PREDICT* specifications, as well as the first and last valid cases in the file.

*VERIFY VARIABLE=STOCK*.

- In addition to the default *VERIFY* information, this command displays information on the series *STOCK*, including the values of the first and last cases and how many values in that series are missing.

---

## Chapter 298. WEIGHT

```
WEIGHT {BY varname}
       {OFF }
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Example

```
WEIGHT BY V1.
```

---

## Overview

WEIGHT gives cases different weights (by simulated replication) for statistical analysis. WEIGHT can be used to weight a sample up to population size for reporting purposes or to replicate an example from a table or other aggregated data. With WEIGHT, you can arithmetically alter the sample size or its distribution.

To apply weights resulting from your sampling design, see SPSS Statistics Premium Edition or the Complex Samples option.

### Basic Specification

The basic specification is keyword BY followed by the name of the weight variable. Cases are weighted according to the values of the specified variable.

### Syntax Rules

- Only one numeric variable can be specified. The variable can be a precoded weighting variable, or it can be computed with the transformation language.
- WEIGHT cannot be placed within a FILE TYPE–END FILE TYPE or INPUT PROGRAM–END INPUT PROGRAM structure. It can be placed nearly anywhere following these commands in a transformation program. See the topic Chapter 304, “Commands and Program States,” on page 2187 for more information.

### Operations

- Unlike most transformations, WEIGHT takes effect as soon as it is encountered in the command sequence. Thus, special attention should be paid to its position among commands. See the topic “Command Order” on page 40 for more information.
- Weighting is permanent during a session unless it is preceded by a TEMPORARY command, changed by another WEIGHT command, or turned off with the WEIGHT OFF specification.
- Each WEIGHT command overrides the previous one.
- WEIGHT uses the value of the specified variable to arithmetically replicate cases for subsequent procedures. Cases are not physically replicated.
- Weight values do not need to be integer, and some procedures, such as FREQUENCIES, CROSSTABS, and CTABLES, will use fractional values on the WEIGHT variable. However, most procedures treat the WEIGHT variable as a replication weight and will simply round fractional weights to the nearest integer. Some procedures ignore the WEIGHT variable completely, and this limitation is noted in the procedure-specific documentation. Procedures in the Complex Samples add-on module can use inverse sampling weights specified on the CSPLAN command.
- Cases with missing or nonpositive values for the weighting variable are treated as having a weight of 0 and are thus invisible to statistical procedures. They are not used in calculations even where unweighted counts are specified. These cases do remain in the file, however, and are included in case listings and saved when the file is saved.
- A file saved when weighting is in effect maintains the weighting.

- If the weighted number of cases exceeds the sample size, tests of significance are inflated; if it is smaller, they are deflated.
- 

## Examples

```
WEIGHT BY V1.  
FREQ VAR=V2.
```

- The frequency counts for the values of variable *V2* will be weighted by the values of variable *V1*.

```
COMPUTE WVAR=1.  
IF (GROUP EQ 1) WVAR=.5.  
WEIGHT BY WVAR.
```

- Variable *WVAR* is initialized to 1 with the `COMPUTE` command. The `IF` command changes the value of *WVAR* to 0.5 for cases where *GROUP* equals 1.
- Subsequent procedures will use a case base in which cases from group 1 count only half as much as other cases.

---

## Chapter 299. WLS

WLS is available in SPSS Statistics Standard Edition or the Regression Option.

WLS VARIABLES= dependent varname WITH independent varnames

```
[/SOURCE=varname]
[/DELTA=[{1.0**          }]]
          {value list    }
          {value TO value BY value}
[/WEIGHT=varname]
[/ {CONSTANT**}
 {NOCONSTANT}]
[/PRINT={BEST}]
          {ALL }
[/SAVE = WEIGHT]
[/APPLY[='model name']]
```

\*\*Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

### Example

```
WLS VARIABLES = VARY WITH VARX VARZ
/SOURCE=VARZ
/DELTA=2.
```

---

## Overview

WLS (weighted least squares) estimates regression models with different weights for different cases. Weighted least squares should be used when errors from an ordinary regression are heteroscedastic—that is, when the size of the residual is a function of the magnitude of some variable, termed the **source**.

The WLS model is a simple regression model in which the residual variance is a function of the source variable, up to some power transform indicated by a delta value. For fuller regression results, save the weights produced by WLS and specify that weight variable on the REGWGT subcommand in REGRESSION.

### Options

**Calculated and Specified Weights.** WLS can calculate the weights based on a source variable and delta values (subcommands SOURCE and DELTA), or it can apply existing weights contained in a series (subcommand WEIGHT). If weights are calculated, each weight value is calculated as the source series value raised to the negative delta value.

**New Variables.** You can change NEWVAR settings on the TSET command prior to WLS to evaluate the regression coefficients and log-likelihood function without saving the weight variable, or save the new values to replace the values saved earlier, or save the new values without erasing values saved earlier (see the TSET command). You can also use the SAVE subcommand on WLS to override the NONE or the default CURRENT settings on NEWVAR for the current procedure.

**Statistical Output.** You can change the PRINT setting on the TSET command prior to WLS to display regression coefficients or the list of log-likelihood functions at each delta value, or to limit the output to only the regression statistics for the delta value at which the log-likelihood function is maximized (see the

TSET command). You can also use the PRINT subcommand to override the PRINT setting on the TSET command for the current procedure and obtain regression coefficients at each value of delta in addition to the default output.

### Basic Specification

- The basic specification is the VARIABLES subcommand specifying one dependent variable, the keyword WITH, and one or more independent variables. Weights are calculated using the first independent variable as the source variable and a default delta value of 1.
- The default output for calculated weights displays the log-likelihood function for each value of delta. For the value of delta at which the log-likelihood function is maximized, the displayed summary regression statistics include  $R$ ,  $R^2$ , adjusted  $R^2$ , standard errors, analysis of variance, and  $t$  tests of the individual coefficients. A variable named *WGT#1* containing the calculated weights is automatically created, labeled, and added to the active dataset.

### Syntax Rules

- VARIABLES can be specified only once.
- DELTA can be specified more than once. Each specification will be executed.
- If other subcommands are specified more than once, only the last specification of each one is executed.
- You can specify either SOURCE and DELTA, or just the WEIGHT subcommand. You cannot specify all three, and you cannot specify WEIGHT with SOURCE or with DELTA.

### Subcommand Order

- Subcommands can be specified in any order.

### Operations

- If neither the WEIGHT subcommand nor the SOURCE and DELTA subcommands are specified, a warning is issued and weights are calculated using the default source and delta value.
- Only one *WGT#1* variable is created per procedure. If more than one delta value is specified, the weights used when the log-likelihood function is maximized are the ones saved as *WGT#1*.
- *WGT#1* is not created when the WEIGHT subcommand is used.
- The WEIGHT command specifies case replication weights, which are *not* the same as the weights used in weighted least squares. If the WEIGHT command and WLS WEIGHT subcommand are both specified, both types of weights are incorporated in WLS.
- WLS uses listwise deletion of missing values. Whenever one variable is missing a value for a particular observation, that observation will not be included in any computations.

### Limitations

- Maximum one VARIABLES subcommand.
- Maximum one dependent variable on the VARIABLES subcommand. There is no limit on the number of independent variables.
- Maximum 150 values specified on the DELTA subcommand.

---

## Example

```
WLS cost WITH sqft inorout yrexp
/SOURCE sqft
/POWER 0 TO 5 BY 0.5
/CONSTANT
/SAVE WEIGHT
/PRINT BEST.
```

- This command specifies a weighted least-squares regression in which *cost* is the dependent variable and *sqft*, *inorout*, and *yrexp* are the independent variables.
- The SOURCE subcommand identifies *sqft* as the source of heteroscedasticity.

- The POWER subcommand specifies that several equations will be fit, one for each value from 0 to 5, incrementing by 0.5. Weights will be calculated using *sqft*.
- The SAVE subcommand requests that the weights that maximize the log-likelihood function be saved to the active dataset.
- All other options are set to their default values.

---

## VARIABLES Subcommand

VARIABLES specifies the variable list and is the only required subcommand.

---

## SOURCE Subcommand

SOURCE is used in conjunction with the DELTA subcommand to compute weights. SOURCE names the variable that is the source of heteroscedasticity.

- The only specification on SOURCE is the name of a variable to be used as the source of heteroscedasticity.
- Only one source variable can be specified.
- If neither SOURCE nor WEIGHT is specified, the first independent variable specified on the VARIABLES subcommand is assumed to be the source variable.

---

## DELTA Subcommand

DELTA, alias POWER, is used in conjunction with the SOURCE subcommand to compute weights. DELTA specifies the values to use in computing weights. The weights are equal to  $1/(\text{SOURCE raised to the DELTA power})$ .

- The specification on DELTA is a list of possible delta values and/or value grids.
- Multiple values and grids can be specified on one DELTA subcommand.
- Delta values can be any value in the range of  $-6.5$  to  $+7.5$ . Values below this range are assigned the minimum ( $-6.5$ ), and values above are assigned the maximum ( $7.5$ ).
- A grid is specified by naming the starting value, the keyword T0, an ending value, the keyword BY, and an increment value. Alternatively, the keyword BY and the increment value can be specified after the starting value.
- More than one DELTA subcommand can be specified; each subcommand will be executed.
- If DELTA is not specified, the delta value defaults to 1.0.

### Example

```
WLS VARIABLES = X1 WITH Y1 Z1
/SOURCE=Z1
/DELTA=0.5.
```

- In this example, weights are calculated using the source variable *Z1* and a delta value of 0.5. Thus, the weights are  $1/(\text{SQRT}(Z1))$ .

### Example

```
WLS VARIABLES = SHARES WITH PRICE
/DELTA=0.5 TO 2.5 BY 0.5.
```

- In this example, several regression equations will be fit, one for each value of delta.
- Weights are calculated using the source variable *PRICE* (the default).
- The delta values start at 0.5 and go up to 2.5, incrementing by 0.5. This specification is equivalent to 0.5 BY 0.5 TO 2.5.
- The weights that maximize the log-likelihood function will be saved as variable *WGT#1*.

---

## WEIGHT Subcommand

WEIGHT specifies the variable containing the weights to be used in weighting the cases. WEIGHT is an alternative to computing the weights using the SOURCE and DELTA subcommands. If a variable containing weights is specified, the output includes the regression coefficients, log-likelihood function, and summary regression statistics such as  $R$ ,  $R^2$ , adjusted  $R^2$ , standard errors, analysis of variance, and  $t$  tests of the coefficients. Since no new weights are computed, no new variable is created.

- The only specification on WEIGHT is the name of the variable containing the weights. Typically, *WGT* variables from previous WLS procedures are used.
- Only one variable can be specified.

### Example

```
WLS VARIABLES = SHARES WITH PRICE  
  /WEIGHT=WGT_1.
```

- This WLS command uses the weights contained in variable *WGT\_1* to weight cases.

---

## CONSTANT and NOCONSTANT Subcommands

Specify CONSTANT or NOCONSTANT to indicate whether a constant term should be estimated in the regression equation. The specification of either subcommand overrides the CONSTANT setting on the TSET command for the current procedure.

- CONSTANT is the default and specifies that the constant term is used as an instrument.
- NOCONSTANT eliminates the constant term.

---

## SAVE Subcommand

SAVE saves the weight variable generated during the current session to the end of the active dataset. The default name *WGT\_n* will be generated, where  $n$  increments to make the variable name unique. The only specification on SAVE is WEIGHT. The specification overrides the NONE or the default CURRENT setting on NEWVAR for the current procedure.

---

## PRINT Subcommand

PRINT can be used to override the PRINT setting on the TSET command for the current procedure. Two keywords are available.

**BEST.** *Display coefficients for the best weight only.* This is the default.

**ALL.** *Display coefficients for all weights.*

---

## APPLY Subcommand

- The APPLY subcommand allows you to use a previously defined WLS model without having to repeat the specifications.
- The only specification on APPLY is the name of a previous model in quotes. If a model name is not specified, the model specified on the previous WLS command is used.
- To change one or more model specifications, specify the subcommands of only those portions you want to change after the APPLY subcommand.
- If no variables are specified on the command, the variables that were originally specified with the model being reapplied are used.

### Example

```
WLS VARIABLES = X1 WITH Y1
/SOURCE=Y1
/DELTA=1.5.
WLS APPLY
/DELTA=2.
```

- The first command produces a weighted least-squares regression of *X1*, with *Y1* as the source variable and delta equal to 1.5.
- The second command uses the same variable and source but changes the delta value to 2.

### Example

```
WLS VARIABLES = X1 WITH Y1 Z1
/SOURCE=Z1
/DELTA=1 TO 3 BY 0.5
WLS APPLY
/WEIGHT=WGT#1.
```

- The first command regresses *X1* on *Y1* and *Z1*, using *Z1* as the source variable. The delta values range from 1 to 3, incrementing by 0.5.
- The second command again regresses *X1* on *Y1* and *Z1*, but this time applies the values of *WGT#1* as the weights.

---

## Chapter 300. WRITE

```
WRITE [OUTFILE='file']
      [ENCODING='encoding'] [BOM={YES}]
                                {NO }
      [RECORDS={1}] [{NOTABLE}]
                    {n}   {TABLE }

/{1  } varlist [{col location [(format)]}] [varlist...]
{rec #}      {(format list)   }
              {*               }
```

```
[/{2  }...]
{rec #}
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. See the topic “Command Order” on page 40 for more information.

### Release History

#### Release 16.0

- ENCODING subcommand added for Unicode support.

#### Release 22.0

- BOM keyword added.

### Example

```
WRITE OUTFILE="/data/personnel.txt" / MOHIRED YRHIRED DEPT SALARY NAME.
EXECUTE.
```

---

## Overview

WRITE writes files in a machine-readable format that can be used by other software applications. When used for this purpose, the OUTFILE subcommand is required. If OUTFILE is not specified, the output from WRITE that can be displayed is included with the output from your session in a format similar to that used by the PRINT command.

### Options

**Formats.** You can specify formats for the variables.

**Strings.** You can include strings within the variable specifications. The strings can be used to label values or to add extra space between values.

**Multiple Lines per Case.** You can write variables on more than one line for each case. See the RECORDS subcommand.

**Output File.** You can direct the output to a specified file using the OUTFILE subcommand.

**Summary Table.** You can display a table that summarizes the variable formats with the TABLE subcommand.

### Subcommand Order

Subcommands can be specified in any order. However, all subcommands must be used before the slash that precedes the first variable list.

## Basic Specification

The basic specification is a slash followed by a variable list. The values for all of the variables specified on the list are included with the rest of the output from your session.

### Syntax Rules

- A slash must precede the variable specifications. The first slash begins the definition of the first (and possibly only) line per case of the WRITE output.
- Specified variables must already exist, but they can be numeric, string, scratch, temporary, or system variables. Subscripted variable names, such as *X(1)* for the first element in vector *X* cannot be used.
- Keyword ALL can be used to write the values of all user-defined variables in the active dataset.

### Operations

- WRITE is executed once for each case constructed from the data file.
- Values are written to the file as the data are read.
- WRITE is a transformation and will not be executed unless it is followed by a procedure or the EXECUTE command.
- When writing to an external file with the OUTFILE subcommand, line/record width can be up to 2.1 billion bytes. When writing to the Viewer, however (when there is no OUTFILE subcommand), if a line width exceeds the line width defined by SET WIDTH, an error results and the WRITE command is not executed. The maximum line width you can specify with SET WIDTH is 255 bytes.
- There are no carriage control characters in the output file generated by WRITE.
- User-missing values are written just like valid values. System-missing values are represented by blanks.
- If you are writing a file to be used on another system, you should take into account that some data types cannot be read by all computers.
- If long records are less convenient than short records with multiple records per case, you can write out a case identifier and insert a string as a record identification number. The receiving system can then check for missing record numbers (see for an example).

---

## Examples

### Writing a Specific Set of Variables

```
WRITE OUTFILE="/data/personnel.txt" / MOHIRED YRHIRED DEPT SALARY NAME.  
FREQUENCIES VARIABLES=DEPT.
```

- WRITE writes values for each variable on the variable list to file *personnel.txt*. The FREQUENCIES procedure reads the data and causes WRITE to be executed.
- All variables are written with their dictionary formats.

### Writing All Variables

```
WRITE OUTFILE="/data/personnel.txt" /ALL.  
EXECUTE.
```

- WRITE writes values for all user-defined variables in the active dataset to file *personnel.txt*. The EXECUTE command executes WRITE.

---

## Formats

By default, WRITE uses the dictionary write formats. You can specify formats for some or all variables specified on WRITE. For a string variable, the specified format must have the same width as that of the dictionary format.

- Format specifications can be either column-style or FORTRAN-like (see DATA LIST). The column location specified with column-style formats or implied with FORTRAN-like formats refers to the column in which the variable will be written.

- A format specification following a list of variables applies to all the variables in the list. Use an asterisk to prevent the specified format from applying to variables preceding the asterisk. The specification of column locations implies a default print format, and that format will apply to all previous variables if no asterisk is used.
- All available formats can be specified on WRITE. Note that hex and binary formats use different widths. For example, the AHEX format must have a width twice that of the corresponding A format. For more information on specifying formats and on the formats available, see DATA LIST and .
- Format specifications are in effect only for the WRITE command. They do not change the dictionary write formats.
- To specify a blank between variables in the output, use a string (see ), specify blank columns in the format, or use an X or T format element in the WRITE specifications (see DATA LIST for information on X and T).

### Example

```
WRITE OUTFILE='/data/personnel.txt' / TENURE (F2.0) ' ' MOHIRED YRHIRED DEPT *
      SALARY85 TO SALARY88 (4(DOLLAR8,1X)) NAME.
EXECUTE.
```

- Format F2.0 is specified for *TENURE*. A blank between quotes is specified as a string after *TENURE* to separate values of *TENURE* from those of *MOHIRED*.
- *MOHIRED*, *YRHIRED*, and *DEPT* are written with default formats because the asterisk prevents them from receiving the DOLLAR8 format specified for *SALARY85* to *SALARY88*. The 1X format element is specified with DOLLAR8 to add one blank after each value of *SALARY85* to *SALARY88*.
- *NAME* uses the default dictionary format.

---

## Strings

You can specify strings within the variable list. Strings must be enclosed in quotes.

- If a format is specified for a variable list, the application of the format is interrupted by a specified string. Thus, the string has the same effect within a variable list as an asterisk.

### Example

```
WRITE OUTFILE='/data/personnel.txt'
      /EMPLOYID '1' MOHIRED YRHIRED SEX AGE JOBCAT NAME
      /EMPLOYID '2' DEPT86 TO DEPT88 SALARY86 TO SALARY88.
EXECUTE.
```

- Strings are used to assign the constant 1 to record 1 of each case, and 2 to record 2 to provide record identifiers in addition to the case identifier *EMPLOYID*.

---

## RECORDS Subcommand

RECORDS indicates the total number of lines written per case. The number specified on RECORDS is informational only. The actual specification that causes variables to be written on a new line is a slash within the variable specifications. Each new line is requested by another slash.

- RECORDS must be specified before the slash that precedes the start of the variable specifications.
- The only specification on RECORDS is an integer to indicate the number of records for the output. If the number does not agree with the actual number of records indicated by slashes, the program issues a warning and ignores the specification on RECORDS.
- Specifications for each line of output must begin with a slash. An integer can follow the slash, indicating the line on which values are to be written. The integer is informational only. It cannot be used to rearrange the order of records in the output. If the integer does not agree with the actual record number indicated by the number of slashes in the variable specifications, the integer is ignored.
- A slash that is not followed by a variable list generates a blank line in the output.

### Examples

```
WRITE OUTFILE='/data/personnel.txt' RECORDS=2
  /EMPLOYID NAME DEPT
  /EMPLOYID TENURE SALARY.
EXECUTE.
```

- WRITE writes the values of an individual's name and department on one line, tenure and salary on the next line, and the employee identification number on both lines.

```
WRITE OUTFILE='/data/personnel.txt' RECORDS=2
  /1 EMPLOYID NAME DEPT
  /2 EMPLOYID TENURE SALARY.
EXECUTE.
```

- This command is equivalent to the command in the preceding example.

```
WRITE OUTFILE='/data/personnel.txt' / EMPLOYID NAME DEPT / EMPLOYID TENURE SALARY.
EXECUTE.
```

- This command is equivalent to the commands in both preceding examples.

---

## OUTFILE Subcommand

OUTFILE specifies the target file for the output from the WRITE command. By default, the output is included with the rest of the output from the session.

- OUTFILE must be specified before the slash that precedes the start of the variable specifications.

### Example

```
WRITE OUTFILE='/data/writeout.txt'
  /1 EMPLOYID DEPT SALARY /2 NAME.
EXECUTE.
```

- OUTFILE specifies *writeout.txt* as the file that receives the WRITE output.

---

## ENCODING Subcommand

ENCODING specifies the encoding format of the file. The keyword is followed by an equals sign and a quoted encoding specification.

- In Unicode mode, the default is UTF8. For more information, see SET command, UNICODE subcommand.
- In code page mode, the default is the current locale setting. For more information, see SET command, LOCALE subcommand.
- The quoted encoding value can be: Locale (the current locale setting), UTF8, UTF16, UTF16BE (big endian), UTF16LE (little endian), a numeric Windows code page value (for example, '1252'), or an IANA code page value (for example, 'iso8859-1' or cp1252).
- If there is no OUTFILE subcommand, the ENCODING subcommand is ignored.

## BOM Keyword

By default, files encoded in any of the UTF formats include a byte order mark (BOM). Some applications cannot interpret the byte order mark. You can use the BOM keyword to suppress the byte order mark.

### BOM=YES

Include the byte order mark in UTF files. This option is the default.

### BOM=NO

No not include the byte order mark in UTF files.

---

## TABLE Subcommand

TABLE requests a table showing how the variable information is formatted. NOTABLE is the default.

- TABLE must be specified before the slash that precedes the start of the variable specifications.

### Example

```
WRITE OUTFILE='/data/personnel.txt' TABLE  
  /1 EMPLOYID DEPT SALARY /2 NAME.  
EXECUTE.
```

- TABLE requests a summary table describing the WRITE specifications.

---

## Chapter 301. WRITE FORMATS

WRITE FORMATS varlist (format) [varlist...]

This command takes effect immediately. It does not read the active dataset or execute pending transformations. See the topic “Command Order” on page 40 for more information.

### Example

```
WRITE FORMATS SALARY (DOLLAR8)
              / HOURLY (DOLLAR7.2)
              / RAISE BONUS (PCT2).
```

---

## Overview

WRITE FORMATS changes variable write formats. Write formats are output formats and control the form in which values are written by the WRITE command.

WRITE FORMATS changes only write formats. To change print formats, use the PRINT FORMATS command. To change both the print and write formats with a single specification, use the FORMATS command. For information on assigning input formats during data definition, see DATA LIST. For detailed information on available formats and specifications, see “Variable Types and Formats” on page 50.

### Basic Specification

The basic specification is a variable list followed by the new format specification in parentheses. All specified variables receive the new format.

### Syntax Rules

- You can specify more than one variable or variable list, followed by a format in parentheses. Only one format can be specified after each variable list. For clarity, each set of specifications can be separated by a slash.
- You can use keyword T0 to refer to consecutive variables in the active dataset.
- The specified width of a format must include enough positions to accommodate any punctuation characters such as decimal points, commas, dollar signs, or date and time delimiters. (This differs from assigning an *input* format on DATA LIST, where the program automatically expands the input format to accommodate punctuation characters in output.)
- Custom currency formats (CCw, CCw.d) must first be defined on the SET command before they can be used on WRITE FORMATS.
- For string variables, you can only use WRITE FORMATS to switch between A and AHX formats. WRITE FORMATS cannot be used to change the length of string variables. To change the length of a string variable, use the ALTER TYPE command.

### Operations

- Unlike most transformations, WRITE FORMATS takes effect as soon as it is encountered in the command sequence. Special attention should be paid to its position among commands. See the topic “Command Order” on page 40 for more information.
- Variables not specified on WRITE FORMATS retain their current formats in the active dataset. To see the current formats, use the DISPLAY command.
- The new write formats are changed only in the active dataset and are in effect for the duration of the session or until changed again with a WRITE FORMATS or FORMATS command. Write formats in the original data file (if one exists) are not changed, unless the file is resaved with the SAVE or XSAVE command.

- New numeric variables created with transformation commands are assigned default print and write formats of F8.2 (or the format specified on the `FORMAT` subcommand of `SET`). The `WRITE FORMATS` command can be used to change the new variable's write formats.
- New string variables created with transformation commands are assigned the format specified on the `STRING` command that declares the variable. `WRITE FORMATS` cannot be used to change the format of a new string variable.
- Date and time formats are effective only with the `LIST` and `TABLES` procedures and the `PRINT` and `WRITE` transformation commands. All other procedures use `F` format regardless of the date and time formats specified. See the topic "Date and Time Formats" on page 57 for more information.
- If a numeric data value exceeds its width specification, the program attempts to write some value nevertheless. First the program rounds decimal values, then removes punctuation characters, then tries scientific notation, and finally, if there is still not enough space, produces asterisks indicating that a value is present but cannot be written in the assigned width.

---

## Examples

### Specifying Write Formats for Multiple Variables

```
WRITE FORMATS SALARY (DOLLAR8)
              / HOURLY (DOLLAR7.2)
              / RAISE BONUS (PCT2).
```

- The write format for `SALARY` is changed to `DOLLAR` with eight positions, including the dollar sign and comma when appropriate. An eight-digit number would require a `DOLLAR11` format specification: eight characters for the digits, two characters for commas, and one character for the dollar sign.
- The write format for `HOURLY` is changed to `DOLLAR` with seven positions, including the dollar sign, decimal point, and two decimal places.
- The write format for both `RAISE` and `BONUS` is changed to `PCT` with two positions: one for the percentage and one for the percent sign.

### Changing the Default Format of a New Variable

```
COMPUTE V3=V1 + V2.
WRITE FORMATS V3 (F3.1).
```

- `COMPUTE` creates the new numeric variable `V3`. By default, `V3` is assigned an `F8.2` format.
- `WRITE FORMATS` changes the write format for `V3` to `F3.1`.

### Working With Custom Currency Formats

```
SET CCA='- /-.Df1 ..-'.
WRITE FORMATS COST (CCA14.2).
```

- `SET` defines a European currency format for the custom currency format type `CCA`.
- `WRITE FORMATS` assigns the write format `CCA` to variable `COST`. See the `SET` command for more information on custom currency formats.

---

## Chapter 302. XGRAPH

XGRAPH is available in the Statistics Base Edition.

XGRAPH is available only on systems with high-resolution graphics capabilities.

*Note:* Square brackets used in the XGRAPH syntax chart are required parts of the syntax and are not used to indicate optional elements. Any equals signs (=) displayed in the syntax chart are required. All subcommands except the chart expression in the first line are optional.

```
XGRAPH CHART=yvars BY xvars BY zvars

/BIN START={AUTO**} SIZE={AUTO** }
      {x } {WIDTH (x)}
      {COUNT (n)}

/DISPLAY DOT={ASYMMETRIC**}
             {SYMMETRIC }
             {FLAT }

/DISTRIBUTION TYPE=NORMAL

/COORDINATE SPLIT={NO**}
                 {YES }

/ERRORBAR {CI { (95) }
           { (n) }
           {STDDEV { (2) }
           { (n) }
           {SE { (2) }
           { (n) }

/MISSING USE={LISTWISE** } REPORT={NO**}
            {VARIABLEWISE} {YES }

/PANEL COLVAR=varlist COLOP={CROSS**} ROWVAR=varlist ROWOP={CROSS**}
      {NEST } {NEST }

/TEMPLATE FILE='filespec'

/TITLES TITLE='line' 'line2' SUBTITLE='line1'
        FOOTNOTE='line1' 'line2'
```

\*\* Default if the subcommand is omitted.

yvars defines the *y* dimension and has the general form:

```
{varname [function] [data_element_type] + ... } > {varname {[COLOR] }
                                                    {[PATTERN]}
                                                    {1 {[COLOR] }
                                                    {[PATTERN]}}
```

xvars and zvars define the *x* and *z* dimensions and have the general form:

```
{varname {[c]} } > varname {[COLOR] }
      {[s]} { [PATTERN]}
{$CASENUM [LABEL=varname] }
{1 }
```

The + operator blends the *y*-axis to accommodate all the *y*-axis variables. It is used when separate variables are displayed on the same axis. The number 1 is a placeholder for the variables on the axis. The > operator stacks data elements on the *y*-axis and clusters data elements on the *x*-axis and *z*-axis. [c] or [s] indicates whether the variable should be treated as categorical or scale. \$CASENUM is used when individual cases are displayed on the same axis.

Summary functions available for yvars: VALUE, COUNT, PCT, CUPCT, CUFREQ, MINIMUM, MAXIMUM, VALIDN, SUM, CSUM, MEAN, STDDEV, VARIANCE, MEDIAN, GMEDIAN, MODE, PTILE(x), GPTILE(x), PLT(x), PGT(x), NLT(x), NGT(x), PIN(x1,x2), and NIN(x1,x2).

Data element types available for yvars: BAR, HISTOBAR, and POINT.

This command reads the active dataset and causes execution of any pending commands. See the topic “Command Order” on page 40 for more information.

## Release History

### Release 13.0

- Command introduced.

## Example

```
XGRAPH CHART=([COUNT] [BAR]) BY jobcat [c] BY gender [c].
```

---

## Overview

XGRAPH generates a high-resolution chart by computing statistics from variables in the active dataset and constructing the chart according to your specification. The chart can be a 3-D bar chart, population pyramid, or dot plot. The chart is displayed where high-resolution display is available and can be edited with the Chart Editor and saved in an Output file.

*Note:* Although you can create other charts with XGRAPH, these are not currently supported.

## Basic Specification

The basic specification is the command name followed by a chart expression. The chart expression must identify one or more variables and a data element for the chart.

## Syntax Rules

- The chart expression is required and must appear first. It can optionally be preceded by CHART=. If CHART is used, the = must be present. All other subcommands are optional.
- After the chart expression, subcommands can appear in any order.
- Only a single instance of each subcommand is allowed.
- Subcommand names and keywords must be spelled in full.
- Required square brackets cannot be merged for different types of specifications. For example, when a summary function and a data element are adjacent, they cannot be merged. That is, [VALUE] [BAR] cannot be written as [VALUE BAR].

## Limitations

- XGRAPH does not produce charts with more than 1,000,000 data values.
- When a weight is in effect and the ERRORBAR subcommand is used on a chart that displays medians, counts, or percentages, the case weights must be integers.

---

## CHART Expression

The **chart expression** defines the data and the role of that data in the chart. It also specifies the data element type and any clustering and stacking. For clustered and stacked charts, the chart expression specifies whether color or patterns are used to distinguish the clustered and stacked groups. For charts of individual cases (that is, when \$CASENUM defines a categorical axis), the chart expression can also specify a label variable.

- The CHART keyword is optional. If it is used, it must be followed by an equals sign (=).
- The order within the chart expression matters. The yvars (the y dimension) must be first, followed by xvars and then zvars.

- The final BY variable is used as the splitter variable in a population pyramid when the COORDINATE subcommand specifies SPLIT.
- There is a limit to the number of stack and cluster specifications. There can be two clusters, or one stack and one cluster.

## Functions

Functions must be enclosed in square brackets.

*Value function:*

The VALUE function yields the value of the specified *y*-axis variable for each case. It always produces one data element for each case.

*Aggregation functions:*

Two groups of aggregation functions are available: count functions and summary functions.

*Count functions:*

**COUNT.** *Frequency of cases in each category.*

**PCT.** *Frequency of cases in each category expressed as a percentage of the whole.*

**CUPCT.** *Cumulative percentage sorted by category value.*

**CUFREQ.** *Cumulative frequency sorted by category value.*

- Count functions yield the count or percentage of valid cases within categories determined by the xvars and the zvars, as in:

```
XGRAPH ([PCT] [BAR]) BY jobcat [c] BY gender [c].
```

- Count functions do not operate on a variable.
- Count functions do not have any arguments.

*Summary functions:*

**MINIMUM.** *Minimum value of the variable.*

**MAXIMUM.** *Maximum value of the variable.*

**VALIDN.** *Number of cases for which the variable has a nonmissing value.*

**SUM.** *Sum of the values of the variable.*

**CUSUM.** *Sum of the summary variable accumulated across values of the category variable.*

**MEAN.** *Mean.*

**STDDEV.** *Standard deviation.*

**VARIANCE.** *Variance.*

**MEDIAN.** *Median.*

**GMEDIAN.** *Group median.*

**MODE.** *Mode.*

**PTILE(x).** *Xth percentile value of the variable. X must be greater than 0 and less than 100.*

**PLT(x).** *Percentage of cases for which the value of the variable is less than x.*

**PGT(x).** *Percentage of cases for which the value of the variable is greater than x.*

**NLT(x).** *Number of cases for which the value of the variable is less than x.*

**NGT(x).** *Number of cases for which the value of the variable is greater than x.*

**PIN(x1,x2) .** *Percentage of cases for which the value of the variable is greater than or equal to x1 and less than or equal to x2. x1 cannot exceed x2.*

**NIN(x1,x2) .** *Number of cases for which the value of the variable is greater than or equal to x1 and less than or equal to x2. x1 cannot exceed x2.*

- Summary functions operate on summary variables (variables that record continuous values, like age or expenses). To use a summary function, specify the name of one or more variables before the name of the function and the data element type, both of which are in square brackets, as in:

XGRAPH (salary [SUM] [BAR]) BY jobcat[c] BY gender[c].

- You can specify a list of variables on which the function operates, as in:

XGRAPH ((salary + salbegin) [SUM] [BAR]) BY jobcat[c] BY gender[c].

This syntax is equivalent to:

XGRAPH (salary [SUM] [BAR] + salbegin [SUM] [BAR]) BY jobcat[c] BY gender[c].

## Data Element Types

The data element type is a basic description of how the data are represented on the chart.

**BAR.** *Draws a bar data element. Bars show the results of a summary function. Used for 3-D bar charts and population pyramids that show the distribution of a categorical variable.*

**HISTOBAR.** *Draws a histogram data element. Histogram data elements show the counts in a range of cases. A range of cases is called a bin. Used for population pyramids.*

**POINT.** *Draws a point marker. A point marker shows a case with a specific x-axis value. Used for dot plots.*

## Measurement Level

The chart expression allows the user to specify a measurement level for BY variables. If measurement level is not specified, the following occurs:

- In a chart of BAR elements, xvars and zvars are treated as categorical.
- In a chart of HISTOBAR elements, xvars is treated as scale. zvars is treated as categorical, because the COORDINATE subcommand and SPLIT keyword are always used.
- In charts of POINT elements, the measurement level is obtained from the IBM SPSS Statistics data dictionary for each variable. If no measurement levels have been defined, numeric variables are treated as scale and string variables are treated as categorical.

[c]. *Specifies that the variable is treated as a categorical variable.*

[s]. *Specifies that the variable is treated as a scale variable.*

## Variable Placeholder

When summaries of separate variables are used to define a categorical axis, clustering, or stacking, 1 must be used as a variable placeholder.

1. *Uses the separate variables specified in `yvars` as categories on the axis, cluster categories, or stack categories. Must be defined as an integer (no decimal places).*

### Examples

```
XGRAPH CHART=((salary + salbegin) [MEAN] [BAR]) BY 1 BY gender[c].
```

- Separate variables appear on the *y*-axis.

```
XGRAPH CHART=((salary + salbegin) [MEAN] [BAR]) BY gender[c] BY 1.
```

- Separate variables appear on the *z*-axis.

## Case Numbers

Whenever the VALUE function is used, one categorical axis consists of cases, which are identified by a sequential number.

**\$CASENUM.** *Uses the sequential numbering of selected cases as the categories on the axis. This is not the actual case number.*

### Example

```
XGRAPH CHART=(salary [VALUE]) BY gender[c] BY $CASENUM.
```

## Blending, Clustering, and Stacking

Blending on an axis is indicated by +. This is used when separate variables are displayed on the same axis.

Clustering and stacking are indicated by >. On the *x*- or *z*-axis, this indicates clustering. On the *y*-axis, this indicates stacking. Stacking is allowed with one clustering variable; or two clustering variables are allowed, one on the *x*-axis and one on the *z*-axis.

+ *Scales the axis to accommodate all of the variables on that dimension.*

> *Stacks groups on the *y*-axis, and clusters groups on the *x*- and *z*-axes.*

### Stacking Example

```
XGRAPH CHART=(salary [MEAN] [BAR]) > educ BY jobcat[c] by gender[c].
```

### Clustering Example

```
XGRAPH CHART=(salary [MEAN] [BAR]) BY jobcat[c] > educ by gender[c].
```

When you use clustering or stacking, you can specify how the clusters and stacks are differentiated in the chart.

**[COLOR].** *Uses color to differentiate the clusters or stacks.*

**[PATTERN].** *Uses pattern to differentiate the clusters or stacks.*

**[COLOR]** and **[PATTERN]** follow these rules:

- The actual colors and patterns are specified in the Options. You can access these by choosing **Options** from the Edit menu. Then click the **Charts** tab.
- **[COLOR]** and **[PATTERN]** follow the stacking or clustering variable in the chart expression.

- If the specification is omitted, color is used to differentiate the clusters or stacks. The color cycle starts over for each dimension.
- If neither [COLOR] nor [PATTERN] is specified, XGRAPH uses the Style Cycle Preference specified by the Options.
- If [COLOR] or [PATTERN] is specified for both dimensions, these specifications are honored. The color or pattern cycle starts over for each dimension.
- If [COLOR] or [PATTERN] is specified for only one dimension, the specification is honored, and the other dimension uses the other specification.

#### Example

```
XGRAPH CHART=(salary [MEAN] [BAR]) BY jobcat[c] > educ[PATTERN]
by gender[c].
```

## Labels

On categorical charts of individual cases, you can specify a labeling variable by using [LABEL=varname] in the chart expression. [LABEL=varname] follows \$CASENUM in the chart expression.

[LABEL=varname]. *The variable whose values are used as the tick labels instead of the case number.*

#### Example

```
XGRAPH CHART=(salary [VALUE] [BAR]) BY $CASENUM[LABEL=gender]
> jobcat BY educ.
```

---

## BIN Subcommand

For population pyramids, the BIN subcommand controls the starting point and size of the bins. The bins are the bars in the chart and represent a group of data values. For example, if there are four bins in a chart and the values range from 0-100, the bin width is 25. Therefore, all points with values of 0-24 would be in the first bin, those with values of 25-49 would be in the second bin, and so on. Each keyword is followed by an equals sign (=) and the value for that keyword.

#### Example

```
XGRAPH CHART=( [HISTOBAR] ) BY age[s] BY gender[c]
/COORDINATE SPLIT=YES
/BIN START=30 SIZE=WIDTH(5).
```

- The first bin begins at age 30.
- Each bin includes cases with *age* values that span 5 years.
- So the first bin contains the cases with ages 30-34, the second bin contains the cases with ages 35-39, and so on.

## START Keyword

The START keyword specifies the starting value of the first bin in the chart.

**AUTO.** *Adjust the starting value of the first bin according to the data values.* The starting value is set so the first bin includes the lowest data value and the bin boundaries are at good values. This is the default.

**value.** *User-specified starting value.* The value can be set lower than the lowest data value so the first bin includes values that are not in the dataset. For example, if the lowest value in the dataset is 6, the starting value can be set to 0 so the values of 0–5 are included in the first bin.

*Note:* If the variable being binned is a date, the starting value must be a data literal in quotes and in the date format specified for the variable in the IBM SPSS Statistics data dictionary (for example, 'January 1, 2001').

## SIZE Keyword

The SIZE keyword specifies the width of the bins. The width can be determined by an exact value or by the number of bins (fewer bins result in wider bins).

**AUTO.** *Adjust bin width according to the data values.* The size is set so the bins are neither too few nor too narrow. This is the default.

**WIDTH (value).** *User-specified value for the bin width.* Note: If the variable being binned is a date, the width must be specified in quotes and in the duration format ddd hh:mm (for example, '30 12:00' for bin widths of 30 days and 12 hours). The hh:mm portion of the duration format is optional.

**COUNT (value).** *User-specified value for the number of bins.*

---

## DISPLAY Subcommand

DISPLAY controls how the data elements are displayed. Currently this subcommand applies to dot plots.

### DOT Keyword

The DOT keyword controls the display of points in a dot plot.

**ASYMMETRIC.** *Stack the points on the x-axis.* This is the default.

**SYMMETRIC.** *Arrange the points symmetrically across a central horizontal line in the chart.* In other words, the point stacks are vertically centered.

**FLAT.** *Do not stack the points.*

---

## DISTRIBUTION Subcommand

The DISTRIBUTION subcommand adds distribution curves to the chart. This subcommand applies to population pyramids.

Example

```
XGRAPH CHART=([HISTOBAR]) BY age[s] BY gender[c]  
/DISTRIBUTION TYPE=NORMAL  
/COORDINATE SPLIT=YES.
```

### TYPE Keyword

The TYPE keyword specifies the type of distribution to draw on the chart. The keyword is followed by an equals sign (=) and the value for that keyword.

**NORMAL.** *Display a normal curve on the chart.* The normal curve uses the data mean and standard deviation as parameters. This is the default.

---

## COORDINATE Subcommand

The COORDINATE subcommand specifies the coordinate system for the chart. Currently this subcommand is used to create population pyramids.

### SPLIT Keyword

The SPLIT keyword specifies whether zvars (the variable after the last BY in the chart expression) is used to split the chart and create a population pyramid. The keyword is followed by an equals sign (=) and the value for that keyword.

*Note:* The SPLIT keyword is not the same as the PANEL subcommand. The keyword splits the chart before it is paneled.

**NO.** *Do not split the chart. This is the default.*

**YES.** *Split the chart and create a population pyramid.*

---

## ERRORBAR Subcommand

The ERRORBAR subcommand adds error bars to the chart. Error bars indicate the variability of the summary statistic being displayed. The length of the error bar on either side of the summary statistic represents a confidence interval or a specified number of standard errors or standard deviations. Currently, XGRAPH supports error bars for COUNT and population pyramids.

The keywords are not followed by an equals sign (=). They are followed by a value in parentheses.

Example

```
XGRAPH CHART=([COUNT] [BAR]) BY agecat[c] BY gender[c]
/COORDINATE SPLIT=YES
/ERRORBAR CI(95).
```

### CI Keyword

**(value).** *The percentage of the confidence interval to use as the length of the error bars.*

### STDDEV Keyword

**(value).** *A multiplier indicating the number of standard deviations to use as the length of the error bars.*

### SE Keyword

**(value).** *A multiplier indicating the number of standard errors to use as the length of the error bars.*

---

## MISSING Subcommand

MISSING controls the treatment of missing values in the chart drawn by XGRAPH.

- For an aggregated categorical chart, if every aggregated series is empty in a category, the empty category is excluded.

Each keyword in the subcommand is followed by an equals sign (=) and the value for that keyword.

### USE Keyword

The USE keyword controls the exclusion of cases with missing values. Excluded cases are excluded from computations and charts. USE applies to variables used in summary functions for a chart.

**LISTWISE.** *Exclude a case with a missing value for any dependent variable. This is the default.*

**VARIABLEWISE.** *Exclude a case with a missing value for the dependent variable being analyzed.*

### REPORT Keyword

The REPORT keyword specifies whether to report on missing values by creating missing-values categories in the chart. REPORT applies only to categorical variables, including paneling variables and the splitter variable in a population pyramid.

**NO.** *Do not create a missing-values categories. This is the default.*

**YES.** *Create a missing-values categories.*

---

## PANEL Subcommand

The PANEL subcommand specifies the variables and method used for paneling.

Each keyword in the subcommand is followed by an equals sign (=) and the value for that keyword.

### COLVAR and ROWVAR Keywords

The COLVAR and ROWVAR keywords identify the column and row variables, respectively. Each category in a column variable appears as a vertical column in the resulting chart. Each category in a row variable appears as a horizontal row in the resulting chart.

- If multiple variables are specified for a keyword, the COLOP and ROWOP keywords can be used to change the way in which variable categories are rendered in the chart.
- The ROWVAR keyword is not available for population pyramids.

**varlist.** *The list of variables used for paneling.*

#### Examples

```
XGRAPH CHART=([COUNT] [BAR]) BY educ [c] BY gender [c]
/PANEL COLVAR=minority.
```

- There are two columns in the resulting paneled chart, one for minorities and one for non-minorities.
- Because there is only one paneling variable, there are only as many panels as there are variable values. Therefore, there are two panels.

```
XGRAPH CHART=([COUNT] [BAR]) BY educ [c] BY gender [c]
/PANEL COLVAR=minority ROWVAR=jobcat.
```

- There are two columns in the resulting paneled chart (for the *minority* variable values) and three rows (for the *jobcat* variable values).

### COLOP and ROWOP Keywords

The COLOP and ROWOP keywords specify the paneling method for the column and row variables, respectively. These keywords have no effect on the chart if there is only one variable in the rows and/or columns. They also have no effect if the data are not nested.

**CROSS.** *Cross variables in the rows or columns.* When the variables are crossed, a panel is created for every combination of categories in the variables. For example, if the categories in one variable are A and B and the categories in another variable are 1 and 2, the resulting chart will display a panel for the combinations of A and 1; A and 2; B and 1; and B and 2. A panel can be empty if the categories in that panel do not cross (for example, if there are no cases in the B category *and* the 1 category). This is the default.

**NEST.** *Nest variables in the rows or columns.* When the variables are nested, a panel is created for each category that is nested in the parent category. For example, if the data contain variables for states and cities, a panel is created for each city and the relevant state. However, panels are not created for cities that are not in certain states, as would happen with CROSS. See the following example. When nesting, make sure the variables specified for ROWVAR or COLVAR are in the correct order. Parent variables precede the child variables.

#### Example

Assume data like the following data:

*Table 118. Nested data*

state	city	temperature
NJ	Springfield	70

Table 118. Nested data (continued)

state	city	temperature
MA	Springfield	60
IL	Springfield	50
NJ	Trenton	70
MA	Boston	60

You can create a paneled chart from this data with the following syntax:

```
XGRAPH ([POINT]) BY temperature
/PANEL COLVAR=state city COLOP=CROSS.
```

The command crosses every variable value to create the panels. Because not every state contains every city, the resulting paneled chart will contain blank panels. For example, there will be a blank panel for Springfield and New Jersey. In this dataset, the *city* variable is really nested in the *state* variable. To nest the variables in the panels and eliminate any blank panels, use the following syntax:

```
XGRAPH ([POINT]) BY temperature
/PANEL COLVAR=state city COLOP=NEST.
```

---

## TEMPLATE Subcommand

TEMPLATE uses an existing file as a template and applies it to the chart requested by the current XGRAPH command. The template overrides the default settings that are used to create any chart, and the specifications on the current XGRAPH command override the template. Templates are created in the Chart Editor by saving an existing chart as a template.

### Example

```
XGRAPH CHART=([COUNT] [BAR]) BY jobcat [c] BY gender [c].
/TEMPLATE FILE='mytemplate.sgt'.
```

## FILE Keyword

The FILE keyword specifies the template file. The keyword is followed by an equals sign (=) and a file specification enclosed in quotes.

**filespec.** *Applies the specified template file to the chart being created.*

---

## TITLES Subcommand

The TITLES subcommand specifies the titles, subtitles, and footnotes. These are lines of text at the top or bottom of the chart.

- At least one keyword should be specified if the TITLES subcommand is used; otherwise the subcommand is treated as blank.
- If the subcommand is blank, an error is issued.
- Each line of text must be enclosed in quotes. The maximum length of any line is 255 bytes.
- When a keyword is specified with no text, an error is issued.

The following symbols can be used within the lines of text. Each must be specified using an opening right parenthesis and uppercase letters.

**)DATE.** *Displays the current date as a locale-appropriate date stamp that includes the year, month, and day.*

**)TIME.** *Displays the current time as a locale-appropriate time stamp.*

**CHART.** Displays the chart expression used to create the chart, stripped of measurement levels, statistics specifications, and CHART=. If variable labels are available, they are used instead of the variable names in the chart expression.

#### Example

```
XGRAPH CHART=([COUNT] [BAR]) BY jobcat [c] BY gender [c]
/TITLES TITLE='Counts by Job Category and Gender' 'Date: )DATE'.
```

### TITLE Keyword

'line1' 'line2'. The lines of text in the title. The title appears above the chart. Up to two lines can be specified.

### SUBTITLE Keyword

'line1'. The line of text in the subtitle. The subtitle appears below the title. Only one line can be specified.

### FOOTNOTE Keyword

'line1' 'line2'. The lines of text in the footnote. The footnote appears below the chart. Up to two lines can be specified.

---

## 3-D Bar Examples

A 3-D bar chart is a bar chart with two categorical axes ( $x$  and  $z$ ). The height of the bars is determined by a summary function. The categories on the  $x$ - and  $z$ -axes can be values of categorical variables, separate variables, or individual cases.

#### Examples of Summaries for Groups of Cases

```
XGRAPH CHART=([COUNT] [BAR]) BY jobcat[c] by gender[c].
```

- The bars in the chart represent counts for males and females in each job category.

```
XGRAPH CHART=(salary [MEAN] [BAR])> educ[PATTERN] BY jobcat[c] >
minority[COLOR] by gender[c].
```

- The bars in the chart represent the mean salary for males and females in each job category clustered by minority membership.
- The bars are also stacked by education level.
- Clusters are distinguished by color, and stacks are distinguished by pattern.

#### Example of Summaries of Separate Variables by Group

```
XGRAPH CHART=((salary + salbegin) [MEAN] [BAR]) BY 1 BY gender[c].
```

- The bars in the chart represent the mean current salary and mean beginning salary for males and females.
- The blending operator (+) indicates that the chart is for separate variables.
- The 1 placeholder indicates the axis on which the separate variables appear.
- The variables appear on the  $x$ -axis, and the gender categories are on the  $z$ -axis.

#### Examples of Individual Cases in Groups

```
XGRAPH CHART=(salary [VALUE] [BAR]) BY gender[c] BY $CASENUM.
```

- The bars in the chart represent the current salary for each case with the cases grouped by gender.
- VALUE is the only function available when creating charts of individual cases.

#### Examples for Values of Individual Cases for Separate Variables

```
XGRAPH CHART=((salary + salbegin) [VALUE] [BAR]) BY $CASENUM BY 1.
```

- The bars in the chart represent the value of the current salary and the value of the beginning salary for every case.

- The cases are on the *x*-axis, and the variables are on the *z*-axis.

```
XGRAPH CHART=((salary + salbegin) [VALUE] [BAR]) BY
$CASENUM[LABEL=gender] BY 1.
```

- This is the same as the previous example except that the bars are labeled by gender.

## Population Pyramid Examples

A population pyramid uses bars to show the shape of a distribution split by a categorical variable. The variable used for the distribution can be a scale or categorical. When the variable is scale, the data element type must be HISTOBAR. When the variable is categorical, the data element type is BAR.

### Example Using Continuous Data

```
XGRAPH CHART=( [HISTOBAR] ) BY age[s] BY gender[c]
/COORDINATE SPLIT=YES.
```

- The bars in the chart represent the number of cases in each *age* bin.
- The population pyramid is split by gender.

### Example Using Categorical Data

```
XGRAPH CHART=( [COUNT] [BAR] ) BY agecat[c] BY gender[c]
/COORDINATE SPLIT=YES.
```

- The *agecat* variable has categories for different age groups.
- The bars in the chart represent the number of cases in each *agecat* category. This is not necessarily the same as the previous example because the size of the bins and the size of the categories might not match.

### Example Using Pre-Aggregated Data

```
XGRAPH CHART=(population [SUM] [BAR] ) BY agecat[c] BY gender[c]
/COORDINATE SPLIT=YES.
```

- The bars in the chart represent the number of cases in each *agecat* category.
- The data include a *population* variable that specifies the count for each *agecat* category for each gender. In other words, the data are pre-aggregated.

### Example Using Pre-Aggregated Data Without a Categorical Splitter Variable

In the previous example, there was a categorical variable to use as the splitter variable. In some census data, the data are not organized in this manner. Instead of a splitter variable, there is one variable for each split value. An example follows:

*Table 119. Pre-aggregated data without a categorical splitter variable*

<b>agecat</b>	<b>malepop</b>	<b>femalepop</b>
1	247	228
2	306	300
3	311	303

Data in this format needs to be restructured by using the VARSTOCASES command:

```
VARSTOCASES /ID = id
/MAKE population FROM malepop femalepop
/INDEX = gender(2)
/KEEP = agecat
/NULL = KEEP.
```

Running this command results in the following. The splitter variable is *gender*.

Table 120. Pre-aggregated data with a categorical splitter variable

id	agecat	gender	population
1	1	1	247
1	1	2	228
2	2	1	306
2	2	2	300
3	3	1	311
3	3	2	303

Now a population pyramid can be created using the categorical splitter variable:

```
XGRAPH (population [SUM] [BAR]) BY agecat[c] BY gender[c]
/COORDINATE SPLIT=YES.
```

---

## Dot Plot Examples

A dot plot shows the value in one dimension (the *x*-axis) of each selected case. The variable on the *x*-axis can be scale or categorical.

```
XGRAPH CHART=([POINT]) BY jobcat[c].
```

- The chart shows cases represented as points.
- Cases are stacked at each *jobcat* value. So, if there are three categories for *jobcat*, there are only three stacks.

```
XGRAPH CHART=([POINT]) BY salary[s].
```

- Cases are stacked at each *salary* value. The *x*-axis is a continuous range of values.

```
XGRAPH CHART=([POINT]) BY salary[s]
/DISPLAY DOT=SYMMETRIC.
```

- Same as the previous example except the stacked dots are centered vertically in the chart.

---

## Chapter 303. XSAVE

```
XSAVE OUTFILE='filespec'
```

```
  [/KEEP={ALL** }] [/DROP=varlist]
    {varlist}
```

```
  [/RENAME=(old varlist=new varlist)...]
```

```
  [/MAP] [/{COMPRESSED  }
    {UNCOMPRESSED}
    {ZCOMPRESSED  }]
```

```
  [/PERMISSIONS={READONLY }
    {WRITEABLE}]
```

\*\*Default if the subcommand is omitted.

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. See the topic “Command Order” on page 40 for more information.

### Release history

#### Release 21.0

- ZCOMPRESSED subcommand added.

### Example

```
XSAVE OUTFILE='/data/empl.sav'.
```

---

## Overview

XSAVE produces IBM SPSS Statistics data files. IBM SPSS Statistics data files contain data plus a dictionary. The dictionary contains a name for each variable in the data file plus any assigned variable and value labels, missing-value flags, and variable print and write formats. The dictionary also contains document text created with the DOCUMENTS command.

SAVE also creates IBM SPSS Statistics data files. The principal difference is that XSAVE is not executed until data are read for the next procedure, while SAVE is executed by itself. Thus, XSAVE can reduce processing time by consolidating two data passes into one.

See SAVE TRANSLATE for information on saving data files that can be used by other programs.

### Options

**Variable Subsets and Order.** You can save a subset of variables and reorder the variables that are saved using the DROP and KEEP subcommands.

**Variable Names.** You can rename variables as they are copied into the data file using the RENAME subcommand.

**Variable Map.** To confirm the names and order of the variables saved in the data file, use the MAP subcommand. MAP displays the variables saved in the data file next to their corresponding names in the active dataset.

**Data Compression.** You can use the COMPRESSED or ZCOMPRESSED subcommand to write the data file in compressed form. You can use the UNCOMPRESSED subcommand to write the data file in an uncompressed form. See the topic “COMPRESSED, UNCOMPRESSED, and ZCOMPRESSED Subcommands” on page 2184 for more information.

## Basic Specification

The basic specification is the `OUTFILE` subcommand, which specifies a name for the data file to be saved.

## Subcommand Order

- Subcommands can be specified in any order.

## Syntax Rules

- `OUTFILE` is required and can be specified only once. If `OUTFILE` is specified more than once, only the last `OUTFILE` specification is in effect.
- `KEEP`, `DROP`, `RENAME`, and `MAP` can be used as many times as needed.
- Only one of the subcommands `COMPRESSED`, `UNCOMPRESSED`, or `ZCOMPRESSED` can be specified per `XSAVE` command.
- Documentary text can be dropped from the active dataset with the `DROP DOCUMENTS` command.
- `XSAVE` cannot appear within a `DO REPEAT–END REPEAT` structure.
- Multiple `XSAVE` commands writing to the same file are not permitted.

## Operations

- Unlike the `SAVE` command, `XSAVE` is a transformation command and is executed when the data are read for the next procedure.
- The new data file dictionary is arranged in the same order as the active dataset dictionary unless variables are reordered with the `KEEP` subcommand. Documentary text from the active dataset dictionary is always saved unless it is dropped with the `DROP DOCUMENTS` command before `XSAVE`.
- New variables created by transformations and procedures previous to the `XSAVE` command are included in the new data file, and variables altered by transformations are saved in their modified form. Results of any temporary transformations immediately preceding the `XSAVE` command are included in the file; scratch variables are not.
- IBM SPSS Statistics data files are binary files designed to be read and written by IBM SPSS Statistics only.
- The active dataset is still available for transformations and procedures after `XSAVE` is executed.
- `XSAVE` processes the dictionary first and displays a message that indicates how many variables will be saved. Once the data are written, `XSAVE` indicates how many cases were saved. If the second message does not appear, the file was probably not completely written.

## Limitations

- Maximum of 64 `XSAVE` commands are allowed within a single set of transformations.

---

## Examples

### Using XSAVE to Consolidate Two Data Passes Into One

```
GET FILE='/data/hubempl.sav'.
XSAVE OUTFILE='/data/empl88.sav'
  /RENAME=(AGE=AGE88) (JOB CAT=JOB CAT88).
MEANS RAISE88 BY DEPT88.
```

- The `GET` command retrieves the IBM SPSS Statistics data file *hubempl.sav*.
- The `RENAME` subcommand renames variable *AGE* to *AGE88* and variable *JOB CAT* to *JOB CAT88*.
- `XSAVE` is not executed until the program reads the data for procedure `MEANS`. The program saves file *empl88.sav* and generates a `MEANS` table in a single data pass.
- After `MEANS` is executed, the *hubempl.sav* file is still the active dataset. Variables *AGE* and *JOB CAT* retain their original names in the active dataset.

### Using Temporary Transformations With XSAVE

```

GET FILE=hubemp1.sav.
TEMPORARY.
RECODE DEPT85 TO DEPT88 (1,2=1) (3,4=2) (ELSE=9).
VALUE LABELS DEPT85 TO DEPT88 1 'MANAGEMENT' 2 'OPERATIONS' 3 'UNKNOWN'.
XSAVE OUTFILE='/data/hubtemp.sav'.
CROSSTABS DEPT85 TO DEPT88 BY JOBCAT.

```

- Both the saved data file and the CROSSTABS output will reflect the temporary recoding and labeling of the department variables.
- If SAVE were specified instead of XSAVE, the data would be read twice instead of once and the CROSSTABS output would not reflect the recoding.

---

## OUTFILE Subcommand

- OUTFILE specifies the IBM SPSS Statistics data file to be saved. OUTFILE is required and can be specified only once. If OUTFILE is specified more than once, only the last OUTFILE is in effect. The file specification should be enclosed in quotes.
- The OUTFILE specification cannot refer to a dataset in the current session. It must refer to an external IBM SPSS Statistics data file.

---

## DROP and KEEP Subcommands

DROP and KEEP are used to save a subset of variables. DROP specifies the variables not to save in the new data file, while KEEP specifies the variables to save in the new data file; variables not named on KEEP are dropped.

- Variables can be specified in any order. The order of variables on KEEP determines the order of variables in the data file. The order on DROP does not affect the order of variables in the data file.
- Keyword ALL on KEEP refers to all remaining variables not previously specified on KEEP. ALL must be the last specification on KEEP.
- If a variable is specified twice on the same subcommand, only the first mention is recognized.
- Multiple DROP and KEEP subcommands are allowed. Specifying a variable that is not in the active dataset or that has been dropped because of a previous DROP or KEEP subcommand results in an error, and the XSAVE command is not executed.
- Keyword T0 can be used to specify a group of consecutive variables in the data file.

### Dropping a Range of Variables

```

XSAVE OUTFILE='/data/hubtemp.sav'
/DROP=DEPT79 TO DEPT84 SALARY79.
CROSSTABS DEPT85 TO DEPT88 BY JOBCAT.

```

- The data file is saved as *hubtemp.sav*. All variables between and including *DEPT79* and *DEPT84*, as well as *SALARY79*, are excluded from the data file. All other variables are saved.

### Specifying Variable Order With XSAVE

```

GET FILE='/data/prsn1.sav'.
COMPUTE TENURE=(12-CMONTH +(12*(88-CYEAR)))/12.
COMPUTE JTENURE=(12-JMONTH +(12*(88-JYEAR)))/12.
VARIABLE LABELS  TENURE 'Tenure in Company'
                  JTENURE 'Tenure in Grade'.
XSAVE OUTFILE='/data/prsn188.sav' /DROP=GRADE STORE
/KEEP=LNAME NAME TENURE JTENURE ALL.
REPORT FORMAT=AUTO /VARS=AGE TENURE JTENURE SALARY
/BREAK=DIVISION /SUMMARY=MEAN.

```

- Variables *TENURE* and *JTENURE* are created by COMPUTE commands and assigned variable labels by the VARIABLE LABELS command. *TENURE* and *JTENURE* are added to the end of the active dataset.
- DROP excludes variables *GRADE* and *STORE* from file *PRSNL88*. KEEP specifies that *LNAME*, *NAME*, *TENURE*, and *JTENURE* are the first four variables in file *prsn188.sav*, followed by all remaining variables not specified on DROP. These remaining variables are saved in the same sequence as they appear in the original file.

---

## RENAME Subcommand

RENAME changes the names of variables as they are copied into the new data file.

- The specification on RENAME is a list of old variable names followed by an equals sign and a list of new variable names. The same number of variables must be specified on both lists. Keyword T0 can be used on the first list to refer to consecutive variables in the active dataset and on the second list to generate new variable names. The entire specification must be enclosed in parentheses.
- Alternatively, you can specify each old variable name individually, followed by an equals sign and the new variable name. Multiple sets of variable specifications are allowed. The parentheses around each set of specifications are optional.
- RENAME does not affect the active dataset. However, if RENAME precedes DROP or KEEP, variables must be referred to by their new names on DROP or KEEP.
- Old variable names do not need to be specified according to their order in the active dataset.
- Name changes take place in one operation. Therefore, variable names can be exchanged between two variables.
- Multiple RENAME subcommands are allowed.

### Examples

```
XSAVE OUTFILE='/data/empl88.sav'  
  /RENAME AGE=AGE88 JOBCAT=JOBCAT88.  
CROSSTABS DEPT85 TO DEPT88 BY JOBCAT.
```

- RENAME specifies two name changes for file *empl88.sav*: *AGE* is renamed to *AGE88* and *JOBCAT* is renamed to *JOBCAT88*.

```
XSAVE OUTFILE='/data/empl88.sav'  
  /RENAME (AGE JOBCAT=AGE88 JOBCAT88).  
CROSSTABS DEPT85 TO DEPT88 BY JOBCAT.
```

- The name changes are identical to those in the previous example: *AGE* is renamed to *AGE88* and *JOBCAT* is renamed to *JOBCAT88*. The parentheses are required with this method.

---

## MAP Subcommand

MAP displays a list of the variables in the data file and their corresponding names in the active dataset.

- The only specification is keyword MAP. There are no additional specifications.
- Multiple MAP subcommands are allowed. Each MAP subcommand maps the results of subcommands that precede it, but not results of subcommands that follow it.

### Example

```
GET FILE='/data/hubempl.sav'.  
XSAVE OUTFILE='/data/empl88.sav'  
  /RENAME=(AGE=AGE88) (JOBCAT=JOBCAT88)  
  /KEEP=LNAME NAME JOBCAT88 ALL /MAP.  
MEANS RAISE88 BY DEPT88.
```

- MAP is used to confirm the new names for *AGE* and *JOBCAT* and the order of variables in the *empl88.sav* file (*LNAME*, *NAME*, and *JOBCAT88*, followed by all remaining variables from the active dataset).

---

## COMPRESSED, UNCOMPRESSED, and ZCOMPRESSED Subcommands

COMPRESSED and ZCOMPRESSED save the file in compressed form. UNCOMPRESSED saves the file in uncompressed form.

- The only specification is the keyword COMPRESSED, UNCOMPRESSED, or ZCOMPRESSED. There are no additional specifications.
- In a file compressed with COMPRESSED, small integers (from -99 to 155) are stored in one byte instead of the eight bytes that are used in an uncompressed file.

- In a file compressed with ZCOMPRESSED, case data (regardless of type) are compressed block by block with a high compression ratio. Only IBM SPSS Statistics version 21 or later can open a file compressed with ZCOMPRESSED. Therefore, it is recommended that you use the *.zsav* file extension when saving files with ZCOMPRESSED. Older versions of IBM SPSS Statistics will ignore this extension.
- Compressed data files occupy less disk space than uncompressed data files. Files compressed with ZCOMPRESSED occupy the least disk space.
- Compressed files may take more or less time to open and save, depending on the file size and system configuration. Extra time is needed to de-compress and compress the files. However, because compressed files are smaller on disk, they reduce the time needed to read and write from disk. As the file size gets larger, this time savings surpasses the extra time needed to de-compress and compress the files. This is especially true for files compressed with ZCOMPRESSED, because these files are smallest on disk.
- The GET command, which reads IBM SPSS Statistics data files, does not need to specify whether the files it reads are compressed or uncompressed.

Only one COMPRESSED or UNCOMPRESSED subcommand can be specified per XSAVE command. COMPRESSED is the default.

---

## PERMISSIONS Subcommand

The PERMISSIONS subcommand sets the operating system read/write permissions for the file.

**READONLY.** *File permissions are set to read-only for all users.* The file cannot be saved using the same file name with subsequent changes unless the read/write permissions are changed in the operating system or the subsequent XSAVE command specifies PERMISSIONS=WRITEABLE.

**WRITEABLE.** *File permissions are set to allow writing for the file owner.* If file permissions were set to read-only for other users, the file remains read-only for them.

Your ability to change the read/write permissions may be restricted by the operating system.

---

## Chapter 304. Commands and Program States

Command order is determined only by the system's need to know and do certain things in logical sequence. You cannot label a variable before the variable exists in the file. Similarly, you cannot transform or analyze data before a active dataset is defined. This appendix briefly describes how the program handles various tasks in a logical sequence. It is not necessary to understand the program states in order to construct a command file, but some knowledge of how the program works will help you considerably when you encounter a problem or try to determine why the program doesn't seem to want to accept your commands or seems to be carrying out your instructions incorrectly.

---

### Program States

To run a program session, you need to define your active dataset, transform the data, and then analyze it. This order conforms very closely to the order the program must follow as it processes your commands. Specifically, the program checks command order according to the program state through which it passes. The **program state** is a characteristic of the program before and after a command is encountered. There are four program states. Each session starts in the **initial state**, followed by the **input program state**, the **transformation state**, and the **procedure state**. The four program states in turn enable the program to set up the environment, read data, modify data, and execute a procedure. The figure shows how the program moves through these states. The program determines the current state from the commands that it has already encountered and then identifies which commands are allowed in that state.

Figure 107. Program States

A session must go through initial, input program, and procedure states to be a complete session. Since all sessions start in the initial state, you need to be concerned primarily with what commands you need to define your active dataset and to analyze the data. The following commands define a very minimal session:

```
GET FILE=DATAIN.  
FREQUENCIES VARIABLES=ALL.
```

The GET command defines the active dataset and the FREQUENCIES command reads the data file and analyzes it. Thus, the program goes through the required three states: initial, input, and procedure.

Typically, a session also goes through the transformation state, but it can be skipped as shown in the example above and in the diagram in the preceding figure. Consider the following example:

```
TITLE 'PLOT FOR COLLEGE SURVEY'.  
  
DATA LIST FILE=TESTDATA  
/AGE 1-3 ITEM1 TO ITEM3 5-10.  
  
VARIABLE LABELS ITEM1 'Opinion on level of defense spending'  
ITEM2 'Opinion on level of welfare spending'  
ITEM3 'Opinion on level of health spending'.  
VALUE LABELS ITEM1 TO ITEM3 -1 'Disagree' 0 'No opinion' 1 'Agree'.  
MISSING VALUES AGE(-99,-98) ITEM1 TO ITEM3 (9).  
RECODE ITEM1 TO ITEM3 (0=1) (1=0) (2=-1) (9=9) (ELSE=SYSMIS).  
RECODE AGE (MISSING=9) (18 THRU HI=1) (LO THRU 18=0) INTO VOTER.  
PRINT /$CASENUM 1-2 AGE 4-6 VOTER 8-10.  
VALUE LABELS VOTER 0 'Under 18' 1 '18 or over'.
```

MISSING VALUES VOTER (9).  
 PRINT FORMATS VOTER (F1.0).

FREQUENCIES VARIABLES=VOTER, ITEM1 TO ITEM3.

The program starts in the initial state, where it processes the TITLE command. It then moves into the input state upon encountering the DATA LIST command. The program can then move into either the transformation or procedure state once the DATA LIST command has been processed.

In this example, the program remains in the transformation state after processing each of the commands from VARIABLE LABELS through PRINT FORMATS. The program then moves into the procedure state to process the FREQUENCIES command. As shown in the preceding figure, the program can repeat the procedure state if it encounters a second procedure. The program can return to the transformation state if it encounters additional transformation commands following the first procedure. Finally, in some sessions the program can return to the input program state when it encounters commands such as FILE TYPE or MATCH FILES.

## Determining Command Order

The table Table 121 shows where specific commands can be placed in the command file in terms of program states and what happens when the program encounters a command in each of the four program states. If a column contains a dash, the command is accepted in that program state and it leaves the program in that state. If one of the words *INIT*, *INPUT*, *TRANS*, or *PROC* appears in the column, the command is accepted in the program state indicated by the column heading, but it moves the program into the state indicated by *INIT*, *INPUT*, *TRANS*, or *PROC*. Asterisks in a column indicate errors when the program encounters the command in that program state. Commands marked with the dagger (†) in the column for the procedure state clear the active dataset.

The table shows six groups of commands: utility, file definition, input program, data transformation, restricted transformation, and procedure commands. These groups are discussed in the following sections.

To read the table, first locate the command. If you simply want to know where in the command stream it can go, look for columns without asterisks. For example, the COMPUTE command can be used when the program is in the input program state, the transformation state, or the procedure state, but it will cause an error if you try to use it in the initial state. If you want to know what can follow a command, look at each of the four columns next to the command. If the column is dashed, any commands not showing asterisks in the column for that program state can follow the command. If the column contains one of the words *INIT*, *INPUT*, *TRANS*, or *PROC*, any command not showing asterisks in the column for the program state indicated by that word can follow the command.

For example, if you want to know what commands can follow the INPUT PROGRAM command, note first that it is allowed only in the initial or procedure states. Then note that INPUT PROGRAM puts the program into the input program state wherever it occurs legally. This means that commands with dashes or words in the *INPUT* column can follow the INPUT PROGRAM command. This includes all the utility commands, the DATA LIST command, input program commands, and transformation commands like COMPUTE. Commands that are not allowed after the INPUT PROGRAM command are most of the file definition commands that are their own input program (such as GET), restricted transformations (such as SELECT IF), and procedures.

## Unrestricted Utility Commands

Most utility commands can appear in any state. The table Table 121 on page 2188 shows this by the absence of asterisks in the columns.

The dashed lines indicate that after a utility command is processed, the program remains in the same state it was in before the command execution. *INIT*, *TRANS*, or *PROC* indicates that the command moves the program to that state. For example, if the program is in the procedure state, *N OF CASES* moves the program to the transformation state. The *FINISH* command terminates command processing wherever it appears. Any commands appearing after *FINISH* will not be read and therefore will not cause an error.

## File Definition Commands

You can use most of the file definition commands in the initial state, the transformation state, and the procedure state. Most of these commands cause errors if you try to use them in the input program state. However, *DATA LIST* and *KEYED DATA LIST* can be and often are used in input programs.

After they are used in the initial state, most file definition commands move the program directly to the transformation state, since these commands are the entire input program. *FILE TYPE* and *INPUT PROGRAM* move the program into the input program state and require input program commands to complete the input program. Commands in the table Table 121 on page 2188 marked with a dagger (+) clear the active dataset.

## Input Program Commands

The commands associated with the complex file facility (*FILE TYPE*, *RECORD TYPE*, and *REPEATING DATA*) and commands associated with the *INPUT PROGRAM* command are allowed only in the input program state.

The END CASE, END FILE, POINT, RECORD TYPE, REPEATING DATA, and REREAD commands leave the program in the input program state. The two that move the program on to the transformation state are END FILE TYPE for input programs initiated with FILE TYPE and END INPUT PROGRAM for those initiated with INPUT PROGRAM.

## Transformation Commands

The entire set of transformation commands from ADD VALUE LABELS to XSAVE can appear in the input program state as part of an input program, in the transformation state, or in the procedure state. When you use transformation commands in the input program state or the transformation state, the program remains in the same state it was in before the command. When the program is in the procedure state, these commands move the program back to the transformation state.

Transformation commands and some file definition and input program commands can be categorized according to whether they are **declarative**, **status-switching**, or **executable**. Declarative commands alter the active dataset dictionary but do not affect the data. Status-switching commands change the program state but do not affect the data. Executable commands alter the data. The following table lists these commands and indicates which of the three categories applies.

Table 122. Taxonomy of transformation commands

Command	Type	Command	Type
ADD FILES	Exec*	LEAVE	Decl
ADD VALUE LABELS	Decl	LOOP	Exec
APPLY DICTIONARY	Decl	MATCH FILES	Exec*
BREAK	Exec	MISSING VALUES	Decl

GET OSIRIS	Exec*	WEIGHT	Decl
IF	Exec	WRITE	Exec
INPUT PROGRAM	Stat	WRITE FORMATS	Decl
KEYED DATA LIST	Exec*	XSAVE	Exec

\* This command is also declarative.

\*\*This command is also executable and declarative.

†This command does not fit into these categories; however, it is neither executable nor status-switching, so it is classified as declarative.

## Restricted Transformations

Commands REFORMAT, SAMPLE, SELECT IF, and TEMPORARY are restricted transformation commands because they are allowed in either the transformation state or the procedure state but cannot be used in the input program state.

If you use restricted transformation commands in the transformation state, the program remains in the transformation state. If you use them in the procedure state, they move the program back to the transformation state.

## Procedures

The procedures and the BEGIN DATA, EXECUTE, EXPORT, LIST, SAVE, SAVE SCSS, SAVE TRANSLATE, and SORT CASES commands cause the data to be read. These commands are allowed in either the transformation state or the procedure state.

When the program is in the transformation state, these commands move the program to the procedure state. When you use these commands in the procedure state, the program remains in that state.

---

## Chapter 305. Defining Complex Files

Most data files have a rectangular, case-ordered structure and can be read with the DATA LIST command. This chapter illustrates the use of commands for defining complex, nonrectangular files.

- **Nested** files contain several types of records with a hierarchical relationship among the record types. You can define nested files with the FILE TYPE NESTED command.
- **Grouped** files have several records per case, and a case's records are grouped together in a file. You can use DATA LIST and FILE TYPE GROUPED to define grouped files.
- In a **mixed** file, different types of cases have different kinds of records. You can define mixed files with the FILE TYPE MIXED command.
- A record in a **repeating data** file contains information for several cases. You can use the REPEATING DATA command to define files with repeating data.

It is a good idea to read the descriptions of the FILE TYPE and REPEATING DATA commands before proceeding.

---

### Rectangular File

The following figure shows contents of data file *RECTANG.DAT*, which contains 1988 sales data for salespeople working in different territories. Year, region, and unit sales are recorded for each salesperson. Like most data files, the sales data file has a **rectangular** format, since information on a record applies only to one case.

```
1988 CHICAGO    JONES    900
1988 CHICAGO    GREGORY  400
1988 BATON ROUGE RODRIGUEZ 300
1988 BATON ROUGE SMITH    333
1988 BATON ROUGE GRAU     100
```

Figure 108. File *RECTANG.DAT*

Since the sales data are rectangular, you can use the DATA LIST command to define these data:

```
DATA LIST FILE='RECTANG.DAT'
/ YEAR      1-4
  REGION    6-16(A)
  SALESPER 18-26(A)
  SALES     29-31.
```

- DATA LIST defines the variable *YEAR* in columns 1 through 4 and string variable *REGION* in columns 6 through 16 in file *RECTANG.DAT*. The program also reads variables *SALESPER* and *SALES* on each record.
- The LIST output below shows the contents of each variable.

```
YEAR REGION      SALESPER  SALES
1988 CHICAGO    JONES    900
1988 CHICAGO    GREGORY  400
1988 BATON ROUGE RODRIGUEZ 300
1988 BATON ROUGE SMITH    333
1988 BATON ROUGE GRAU     100
```

Figure 109. LIST output for *RECTANG.DAT*

---

## Nested Files

In a nested file, information on some records applies to several cases. The 1988 sales data are arranged in nested format in the figure below. The data contain three kinds of records. A code in the first column indicates whether a record is a year (Y), region (R), or person record (P).

```
Y 1988
R CHICAGO
P JONES 900
P GREGORY 400
R BATON ROUGE
P RODRIGUEZ 300
P SMITH 333
P GRAU 100
```

Figure 110. File *NESTED.DAT*

The record types are related to each other hierarchically. Year records represent the highest level in the hierarchy, since the year value 1988 applies to each salesperson in the file (only one year record is used in this example). Region records are intermediate-level records; region names apply to salesperson records that occur before the next region record in the file. For example, Chicago applies to salespersons Jones and Gregory. Baton Rouge applies to Rodriguez, Smith, and Grau. Person records represent the lowest level in the hierarchy. The information they contain—salesperson and unit sales—defines a case. Nested file structures minimize redundant information in a data file. For example, 1988 and Baton Rouge appear several times in the rectangular file, but only once in the nested file.

Since each record in the nested file has a code that indicates record type, you can use the `FILE TYPE` and `RECORD TYPE` commands to define the nested sales data:

```
FILE TYPE NESTED FILE='NESTED.DAT' RECORD=#TYPE 1 (A)
```

```
RECORD TYPE 'Y'.
DATA LIST / YEAR 5-8.
```

```
RECORD TYPE 'R'.
DATA LIST / REGION 5-15 (A).
```

```
RECORD TYPE 'P'.
DATA LIST / SALESPER 5-15 (A) SALES 20-23
```

```
END FILE TYPE.
```

- `FILE TYPE` indicates that data are in nested form in the file *NESTED.DAT*.
- `RECORD` defines the record type variable as string variable `#TYPE` in column 1. `#TYPE` is defined as scratch variable so it won't be saved in the active dataset.
- One pair of `RECORD TYPE` and `DATA LIST` statements is specified for each record type in the file. The first pair of `RECORD TYPE` and `DATA LIST` statements defines the variable `YEAR` in columns 5 through 8 on every year record. The second pair defines the string variable `REGION` on region records. The final pair defines `SALESPER` and `SALES` on person records.
- The order of `RECORD TYPE` statements defines the hierarchical relationship among the records. The first `RECORD TYPE` defines the highest-level record type. The next `RECORD TYPE` defines the next highest level, and so forth. The last `RECORD TYPE` defines a case in the active dataset.
- `END FILE TYPE` signals the end of file definition.
- In processing nested data, the program reads each record type you define. Information on the highest and intermediate-level records is spread to cases to which the information applies. The output from the `LIST` command is identical to that for the rectangular file.

## Nested Files with Missing Records

In a nested file, some cases may be missing one or more record types defined in `RECORD TYPE` commands. For example, in the figure below the region record for salespersons Jones and Gregory is missing.

```

Y 1988
P JONES 900
P GREGORY 400
R BATON ROUGE
P RODRIGUEZ 300
P SMITH 333
P GRAU 100

```

Figure 111. File *NESTED.DAT* with missing records

The program assigns missing values to variables that are not present for a case. Using the modified *NESTED.DAT* file, the commands in the previous example produce the output shown below. You can see that the program assigned missing values to *REGION* for Jones and Gregory.

```

YEAR REGION      SALESPER  SALES
1988          JONES      900
1988          GREGORY     400
1988 BATON ROUGE RODRIGUEZ 300
1988 BATON ROUGE SMITH    333
1988 BATON ROUGE GRAU     100

```

Figure 112. *LIST* output for nested data with missing records

You may want to examine cases with missing records, since these cases may indicate data errors. If you add the `MISSING=WARN` subcommand to your `FILE TYPE` command, the program prints a warning message when a case is missing a defined record type. For example, the program would print two warnings when processing data in *NESTED.DAT* with missing records. When `MISSING` is set to `WARN`, cases are built in the same way as when the default setting (`NOWARN`) is in effect.

---

## Grouped Data

In a grouped file, a case has several records that are grouped together in the file. You can use `DATA LIST` to define a grouped file if each case has the same number of records and records appear in the same order for each case. You can use `FILE TYPE GROUPED` whether the number of records per case and record order are fixed or vary. However, `FILE TYPE GROUPED` requires that each record have a case identifier and a record code.

## Using DATA LIST

The following table shows the organization of a grouped data file containing school subject scores for three students. Each student has three data records, and each record contains a score. The first record for each student also contains a case identifier. Records for each case are grouped together. Student 1 records appear first, followed by records for student 2 and student 3.

Record order determines whether a score is a reading, math, or science score. The reading score appears on the first record for a case, the math score appears on the second record, and the science score appears on the third record.

Table 123. Data for *GROUPED.DAT*

Student	Score
1	58
1	59
1	97
2	43
2	88
2	45
3	67
3	75
3	90

Since each case has the same number of records and record order is fixed across cases, you can use DATA LIST to define the student data:

```
DATA LIST FILE='GROUPED.DAT' RECORDS=3
  /STUDENT 1 READING 5-6
  /MATH 5-6
  /SCIENCE 5-6.
```

LIST.

- DATA LIST indicates that data are in file *GROUPED.DAT*.
- RECORDS defines three records per case. The program reads student ID number (*STUDENT*) and reading score (*READING*) in the first record for a case. Math and science scores are read in the second and third records.
- The output from the LIST command is shown below.

```
STUDENT READING MATH SCIENCE
 1      58     59     97
 2      43     88     45
 3      67     75     90
```

Figure 113. LIST output for *GROUPED.DAT*

## Using FILE TYPE GROUPED

To use FILE TYPE GROUPED to define a grouped file, each record must have a case identifier and a record code. In the following commands, each data record contains a student ID number coded 1, 2, or 3 and a code indicating whether the score on that record is a reading (R), math (M), or science (S) score:

```
FILE TYPE GROUPED RECORD=#REC 3(A) CASE=STUDENT 1.
```

```
RECORD TYPE 'R'.
DATA LIST / READING 5-6.
```

```
RECORD TYPE 'M'.
DATA LIST / MATH 5-6.
```

```
RECORD TYPE 'S'.
DATA LIST / SCIENCE 5-6.
```

```
END FILE TYPE.
```

```
BEGIN DATA
```

```
1 R 58
1 M 59
1 S 97
2 R 43
2 M 88
2 S 45
3 R 67
3 M 75
3 S 90
END DATA.
```

LIST.

- FILE TYPE indicates that data are in grouped format. RECORD defines the variable containing record codes as string variable #REC in column 3. CASE defines the case identifier variable *STUDENT* in the first column of each record.
- One pair of RECORD TYPE and DATA LIST statements appears for each record type in the file. The program reads reading score in every R record, math score in M records, and science score in S records.
- END FILE TYPE signals the end of file definition.
- BEGIN DATA and END DATA indicate that data are inline.
- The output from LIST is identical to the output using DATA LIST.

FILE TYPE GROUPED is most useful when record order varies across cases and when cases have missing or duplicate records. In the modified data shown below, only case 1 has all three record types. Also, record order varies across cases. For example, the first record for case 1 is a science record, whereas the first record for cases 2 and 3 is a reading record.

Table 124. Modified grouped data file

Student	Subject	Score
1	S	97
1	R	58
1	M	59
2	R	43
3	R	67
3	M	75

You can use the same FILE TYPE commands as above to read the modified file. As shown in the output from LIST below, the program assigns missing values to variables that are missing for a case.

```
STUDENT READING MATH SCIENCE
  1      58   59   97
  2      43   .    .
  3      67   75   .
```

Figure 114. LIST output for GROUPED.DAT

By default, the program generates a warning message when a case is missing a defined record type in a grouped file or when a record is not in the same order as in RECORD TYPE commands. Thus, four warnings are generated when the commands for the previous example are used to read the modified GROUPED.DAT file. You can suppress these warnings if you add the optional specifications MISSING=NOWARN and ORDERED=NO on your FILE TYPE command.

In the modified GROUPED.DAT file, the case identifier STUDENT appears in the same column position in each record. When the location of the case identifier varies for different types of records, you can use the CASE option of the RECORD TYPE command to specify different column positions for different records. For example, suppose the case identifier appears in first column position on reading and science records and in column 2 in math records. You could use the following commands to define the data:

```
FILE TYPE GROUPED RECORD=#REC 3(A) CASE=STUDENT 1.

RECORD TYPE 'R'.
DATA LIST / READING 5-6.

RECORD TYPE 'M' CASE=2.
DATA LIST / MATH 5-6.

RECORD TYPE 'S'.
DATA LIST / SCIENCE 5-6.

END FILE TYPE.

BEGIN DATA
1 S 97
1 R 58
  1M 59
2 R 43
3 R 67
  3M 75
END DATA.

LIST.
```

- FILE TYPE indicates that the data are in grouped format. RECORD defines the variable containing record codes as string variable #REC. CASE defines the case identifier variable as STUDENT in the first column of each record.
- One pair of RECORD TYPE and DATA LIST statements is coded for each record type in the file.
- The CASE specification on the RECORD TYPE statement for math records overrides the CASE value defined on FILE TYPE. Thus, the program reads STUDENT in column 2 in math records and column 1 in other records.
- END FILE TYPE signals the end of file definition.
- BEGIN DATA and END DATA indicate that data are inline.

- The output from LIST is identical to the output above.

## Mixed Files

In a mixed file, different types of cases have different kinds of records. You can use FILE TYPE MIXED to read each record or a subset of records in a mixed file.

### Reading Each Record in a Mixed File

The following example is for two hypothetical elementary school students referred to a remedial education teacher. Student 1, who was thought to need special reading attention, took reading tests (word identification and comprehension tests). The second student completed writing tests (handwriting, spelling, vocabulary, and grammar tests). Test code (READING or WRITING) indicates whether the record contains reading or writing scores.

The following commands define the test data:

```
FILE TYPE MIXED RECORD=TEST 1-7(A).

RECORD TYPE 'READING'.
DATA LIST / ID 9-10 GRADE 12-13 WORD 15-16 COMPRE 18-19.

RECORD TYPE 'WRITING'.
DATA LIST / ID 9-10 GRADE 12-13 HANDWRIT 15-16 SPELLING 18-19
          VOCAB 21-22 GRAMMAR 24-25.
END FILE TYPE.

BEGIN DATA
READING 1 04 65 35
WRITING 2 03 50 55 30 25
END DATA.
```

LIST.

- FILE TYPE specifies that the data contain mixed record types. RECORD reads the record identifier (variable *TEST*) in columns 1 through 7.
- One pair of RECORD TYPE and DATA LIST statements is coded for each record type in the file. The program reads variables *ID*, *GRADE*, *WORD*, and *COMPRE* in the record in which the value of *TEST* is READING, and *ID*, *GRADE*, *HANDWRIT*, *SPELLING*, *VOCAB*, and *GRAMMAR* in the WRITING record.
- END FILE TYPE signals the end of file definition.
- BEGIN DATA and END DATA indicate that data are inline. Data are mixed, since some column positions contain different variables for the two cases. For example, word identification score is recorded in columns 15 and 16 for student 1. For student 2, handwriting score is recorded in these columns.
- The following figure shows the output from LIST. Missing values are assigned for variables that are not recorded for a case.

```
TEST  ID GRADE WORD COMPRE HANDWRIT SPELLING VOCAB GRAMMAR
READING 1 4 65 35 . . . .
WRITING 2 3 . . 50 55 30 25
```

Figure 115. LIST output for mixed file

### Reading a Subset of Records in a Mixed File

You may want to process a subset of records in a mixed file. The following commands read only the data for the student who took reading tests:

```
FILE TYPE MIXED RECORD=TEST 1-7(A).

RECORD TYPE 'READING'.
DATA LIST / ID 9-10
          GRADE 12-13
          WORD 15-16
          COMPRE 18-19.
```

```
RECORD TYPE 'WRITING'.
```

```

DATA LIST / ID      9-10
          GRADE    12-13
          HANDWRIT 15-16
          SPELLING 18-19
          VOCAB    21-22
          GRAMMAR  24-25.

```

```
END FILE TYPE.
```

```

BEGIN DATA
READING 1  04 65 35
WRITING 2  03 50 55 30 25
END DATA.

```

```
LIST.
```

- FILE TYPE specifies that data contain mixed record types. RECORD defines the record identification variable as *TEST* in columns 1 through 7.
- RECORD TYPE defines variables on reading records. Since the program skips all record types that are not defined by default, the case with writing scores is not read.
- END FILE TYPE signals the end of file definition.
- BEGIN DATA and END DATA indicate that data are inline. Data are identical to those in the previous example.
- The following figure shows the output from LIST.

```

TEST   ID GRADE WORD COMPRE
READING 1   4 65 35

```

Figure 116. LIST output for reading record

## Repeating Data

You can use the REPEATING DATA command to read files in which each record contains repeating groups of variables that define several cases. Command syntax depends on whether the number of repeating groups is fixed across records.

### Fixed Number of Repeating Groups

The following table shows test score data for students in three classrooms. Each record contains a classroom number and two pairs of student ID and test score variables. For example, in class 101, student 182 has a score of 12 and student 134 has a score of 53. In class 103, student 15 has a score of 87 and student 203 has a score of 69. Each pair of ID and score variables is a repeating group, since these variables appear twice on each record.

Table 125. Data in REPEAT.DAT file

Class	ID	Score	ID	Score
101	182	12	134	53
102	99	112	200	150
103	15	87	203	69

The following commands generate a active dataset in which one case is built for each occurrence of SCORE and ID, and classroom number is spread to each case on a record.

```

INPUT PROGRAM.
DATA LIST / CLASS 3-5.
REPEATING DATA STARTS=6 / OCCURS=2
  /DATA STUDENT 1-4 SCORE 5-8.
END INPUT PROGRAM.

```

```

BEGIN DATA
  101 182 12 134 53
  102 99 112 200 150
  103 15 87 203 69
END DATA.

```

```
LIST.
```

- INPUT PROGRAM signals the beginning of data definition.
- DATA LIST defines variable *CLASS*, which is spread to each student on a classroom record.
- REPEATING DATA specifies that the input file contains repeating data. STARTS indicates that repeating data begin in column 6. OCCURS specifies that the repeating data group occurs twice in each record.
- DATA defines variables that are repeated (*STUDENT* and *SCORE*). The program begins reading the first repeating data group in column 6 (the value of STARTS). Since the value of OCCURS is 2, the program reads the repeating variables a second time, beginning in the next available column (column 14).
- END INPUT PROGRAM signals the end of data definition.
- BEGIN DATA and END DATA specify that data are inline.
- The output from LIST is shown below. Each student is a separate case.

```
CLASS STUDENT SCORE
101 182 12
101 134 53
102 99 112
102 200 150
103 15 87
103 203 69
```

Figure 117. LIST output for repeating data

## Varying Number of Repeating Groups

To use REPEATING DATA to define a file in which the number of repeating data groups varies across records, your data must contain a variable indicating the number of repeating data groups on a record. The following commands define such a file:

```
INPUT PROGRAM.
DATA LIST / #NUM 1 CLASS 3-5.
REPEATING DATA STARTS=6 / OCCURS=#NUM
 /DATA STUDENT 1-4 SCORE 5-8.
END INPUT PROGRAM.
```

```
BEGIN DATA
3 101 182 12 134 53 199 30
2 102 99 112 200 150
1 103 15 87
END DATA.
```

LIST.

- INPUT PROGRAM signals the beginning of data definition.
- DATA LIST defines variables *CLASS* in columns 3 through 5 and *#NUM*, a scratch variable in column 1 that contains the number of repeating data groups in a record.
- REPEATING DATA specifies that the input file contains repeating data. STARTS indicates that repeating data begin in column 6. OCCURS sets the number of repeating groups on a record equal to the value of *#NUM*.
- DATA defines variables that are repeated. Since *#NUM* is 3 in the first and third records, the program reads three sets of *STUDENT* and *SCORE* variables in these records. *STUDENT* and *SCORE* are read twice in record 2.
- END INPUT PROGRAM signals the end of data definition.
- Data appear between BEGIN DATA and END DATA.
- The following figure shows the output from LIST.

```
CLASS STUDENT SCORE
101 182 12
101 134 53
101 199 30
102 99 112
103 15 87
```

Figure 118. LIST output

If your data file does not have a variable indicating the number of repeating data groups per record, you can use the LOOP and REREAD commands to read the data, as in:

```
INPUT PROGRAM.
DATA LIST / CLASS 3-5 #ALL 6-29 (A).
LEAVE CLASS.

LOOP #I = 1 TO 17 BY 8 IF SUBSTR(#ALL, #I, 8) NE ''.
- REREAD COLUMN = #I + 5.
- DATA LIST / STUDENT 1-4 SCORE 5-8.
- END CASE.
END LOOP.
END INPUT PROGRAM.

BEGIN DATA
  101 182 12 134 53 199 30
  102 99 112 200 150
  103 15 87
END DATA.
```

LIST.

- INPUT PROGRAM signals the beginning of data definition.
- DATA LIST reads *CLASS* and *#ALL*, a temporary string variable that contains all of the repeating data groups for a classroom record. The column specifications for *#ALL* (6 through 29) are wide enough to accommodate the classroom record with the most repeating data groups (record 1).
- LOOP and END LOOP define an index loop. As the loop iterates, the program successively reads eight-character segments of *#ALL*, each of which contains a repeating data group or an empty field. The program reads the first eight characters of *#ALL* in the first iteration, the second eight characters in the second iteration, and so forth. The loop terminates when the program encounters an empty segment, which means that there are no more repeating data groups on a record.
- In each iteration of the loop in which an *#ALL* segment is not empty, DATA LIST reads *STUDENT* and *SCORE* in a classroom record. The program begins reading these variables in the first record, in the starting column specified by REREAD COLUMN. For example, in the first iteration, the program reads *STUDENT* and *SCORE* beginning in column 6. In the second iteration, the program reads *STUDENT* and *SCORE* starting in column 14 of the same record. When all repeating groups have been read for a record, loop processing begins on the following record.
- END CASE creates a new case for each repeating group.
- REREAD causes DATA LIST to read repeating data groups in the same record in which it last read *CLASS*. Without REREAD, each execution of DATA LIST would begin on a different record.
- LEAVE preserves the value of *CLASS* across the repeating data groups on a record. Thus, the same class number is read for each student on a classroom record.
- INPUT PROGRAM signals the beginning of data definition.
- BEGIN DATA and END DATA indicate that the data are inline. The data are identical to those in the previous example except that they do not contain a variable indicating the number of repeating groups per record.
- These commands generate the same output as shown in the figure above.

---

## Chapter 306. Using the Macro Facility

A macro is a set of commands that generates customized command syntax. Using macros can reduce the time and effort needed to perform complex and repetitive data analysis tasks.

Macros have two parts: a **macro definition**, which indicates the beginning and end of the macro and gives a name to the macro, and a **macro body**, which contains regular commands or macro commands that build command syntax. When a macro is invoked by the **macro call**, syntax is generated in a process called **macro expansion**. Then the generated syntax is executed as part of the normal command sequence.

This chapter shows how to construct macros that perform three data analysis tasks. In the first example, macros facilitate a file-matching task. In Example 2, macros automate a specialized statistical operation (testing a sample correlation coefficient against a nonzero population correlation coefficient). Macros in Example 3 generate random data. As shown in the following table, each example demonstrates various features of the macro facility. For information on specific macro commands, see the DEFINE command.

Table 126. Macro features

	Example 1	Example 2	Example 3
Macro argument			
Keyword	x	x	x
Default values	x		x
None	x		x
String manipulation	x		x
Looping			
Index	x		x
List processing		x	
Direct assignment	x		x

---

### Example 1: Automating a File-Matching Task

The following figure shows a listing of 1988 sales data for salespeople working in different regions. The listing shows that salesperson Jones sold 900 units in the Chicago sales territory, while Rodriguez sold 300 units in Baton Rouge.

```
YEAR REGION    SALESPER  SALES
1988 CHICAGO   JONES     900
1988 CHICAGO   GREGORY   400
1988 BATON ROUGE RODRIGUEZ  300
1988 BATON ROUGE SMITH    333
1988 BATON ROUGE GRAU     100
```

Figure 119. Listing of data file SALES88.SAV

You can use command syntax shown below to obtain each salesperson's percentage of total sales for their region.

```

GET FILE = 'SALES88.SAV'.

SORT CASES BY REGION.

AGGREGATE OUTFILE = 'TOTALS.SAV'
/PRESORTED
/BREAK = REGION
/TOTAL@ = SUM(SALES).

MATCH FILES FILE=**
/TABLE = 'TOTALS.SAV'
/BY REGION.

COMPUTE PCT = 100 * SALES / TOTAL@.

TITLE 1988 DATA.
LIST.

```

Figure 120. Commands for obtaining sales percentages

- The GET command opens *SALES88.SAV*. This file becomes the active dataset.
- SORT CASES sorts the active dataset in ascending alphabetical order by *REGION*.
- The AGGREGATE command saves total sales (variable *TOTAL@*) for each region in file *TOTALS.SAV*.
- MATCH FILES appends the regional totals to each salesperson's record in the active dataset. (See the MATCH FILES command for more information on matching files.)
- COMPUTE obtains the percentage of regional sales (*PCT*) for each salesperson.
- The LIST command output displayed below shows that Rodriguez sold 41% of the products sold in Baton Rouge. Gregory accounted for 31% of sales in the Chicago area.

YEAR	REGION	SALESPER	SALES	TOTAL@	PCT
1988	BATON ROUGE	RODRIGUEZ	300	733.00	41.00
1988	BATON ROUGE	SMITH	333	733.00	45.00
1988	BATON ROUGE	GRAU	100	733.00	14.00
1988	CHICAGO	JONES	900	1300.00	69.00
1988	CHICAGO	GREGORY	400	1300.00	69.00

Figure 121. Listing of data file *SALES88.SAV*

The following figure shows a macro that issues the commands for obtaining sales percentages. The macro consists of the commands that produce sales percentages imbedded between macro definition commands DEFINE and !ENDDDEFINE.

```

DEFINE !TOTMAC ().

GET FILE = 'SALES88.SAV'.

SORT CASES BY REGION.

AGGREGATE OUTFILE = 'TOTALS.SAV'
/PRESORTED
/BREAK = REGION
/TOTAL@ = SUM(SALES).

MATCH FILES FILE = *
/TABLE = 'TOTALS.SAV'
/BY REGION.

COMPUTE PCT = 100 * SALES / TOTAL@.

TITLE 1988 DATA.
LIST.

!ENDDDEFINE.

!TOTMAC.

```

Figure 122. *!TOTMAC* macro

- Macro definition commands DEFINE and !ENDDDEFINE signal the beginning and end of macro processing. DEFINE also assigns the name !TOTMAC to the macro (the parentheses following the name of the macro are required). The macro name begins with an exclamation point so that the macro does not conflict

with that of an existing variable or command. Otherwise, if the macro name matched a variable name, the variable name would invoke the macro whenever the variable name appeared in the command stream.

- Commands between DEFINE and !ENDDFINTE constitute the macro body. These commands produce sales percentages.
- The final statement, !TOTMAC, is the **macro call**, which invokes the macro. When the program reads the macro call, it issues the commands in the macro body. Then these commands are executed, generating identical output.

While the macro shows you how to construct a simple macro, it doesn't reduce the number of commands needed to calculate regional percentages. However, you can use macro features such as looping to minimize coding in more complicated tasks. For example, let's say that in addition to the 1988 data, you have sales data for 1989 (*SALES89.SAV*), and each file contains the variables *REGION*, *SALESPER*, and *SALES*. The modified !TOTMAC macro below calculates regional sales percentages for each salesperson for 1988 and 1989.

```
DEFINE !TOTMAC ().
!DO !I = 88 !TO 89.
- GET FILE = !CONCAT('SALES', !I, '.SAV').
- SORT CASES BY REGION.
- AGGREGATE OUTFILE = 'TOTALS.SAV'
  /PRESORTED
  /BREAK = REGION
  /TOTAL@ = SUM(SALES).
- MATCH FILES FILE = *
  /TABLE = 'TOTALS.SAV'
  /BY REGION.
- COMPUTE PCT= 100 * SALES / TOTAL@.
- !LET !YEAR = !CONCAT('19',!I).
- TITLE !YEAR DATA.
- LIST.
!DOEND.
!ENDDFINTE.
!TOTMAC.
```

Figure 123. !TOTMAC macro with index loop

- DEFINE and !ENDDFINTE signal the beginning and end of macro processing.
- Commands !DO and !DOEND define an **index loop**. Commands between !DO and !DOEND are issued once in each iteration of the loop. The value of **index variable** !I, which changes in each iteration, is 88 in the first iteration and 89 in the second (final) iteration.
- In each iteration of the loop, the GET command opens a data file. The name of the file is constructed using the **string manipulation function** !CONCAT, which creates a string that is the concatenation of SALES, the value of the index variable, and .sav. Thus the file *SALES88.SAV* is opened in the first iteration.
- Commands between AGGREGATE and COMPUTE calculate percentages on the active dataset.
- Next, a customized title is created. In the first iteration, the **direct assignment** command !LET assigns a value of 1988 to the macro variable !YEAR. This variable is used in the TITLE command on the following line to specify a title of *1988 DATA*.
- The LIST command displays the contents of each variable.
- In the second iteration of the loop, commands display percentages for the 1989 data file. The output from the !TOTMAC macro is shown below. Note that the listing for 1988 data is the same as before.

```

1988 DATA
YEAR REGION      SALESPER SALES  TOTAL@  PCT
1988 BATON ROUGE RODRIGUEZ 300  733.00  41.00
1988 BATON ROUGE SMITH    333  733.00  45.00
1988 BATON ROUGE GRAU     100  733.00  14.00
1988 CHICAGO     JONES   900  1300.00 69.00
1988 CHICAGO     GREGORY 400  1300.00 69.00

1989 DATA
YEAR REGION      SALESPER SALES  TOTAL@  PCT
1989 BATON ROUGE GRAU     320  1459.00 22.00
1989 BATON ROUGE SMITH    800  1459.00 55.00
1989 BATON ROUGE RODRIGUEZ 339  1459.00 23.00
1989 CHICAGO     JONES   300  1439.00 21.00
1989 CHICAGO     STEEL   899  1439.00 62.00
1989 CHICAGO     GREGORY 240  1439.00 17.00

```

Figure 124. Regional sales percentages for 1988 and 1989

Let's look at another application of the !TOTMAC macro, one that uses **keyword arguments** to make the application more flexible. The following figure shows the number of absences for students in two classrooms. Let's say you want to calculate deviation scores indicating how many more (or fewer) times a student was absent than the average student in his or her classroom. The first step in obtaining deviation scores is to compute the average number of absences per classroom. We can use the !TOTMAC macro to compute classroom means by modifying the macro so that it computes means and uses the absences data file (*SCHOOL.SAV*) as input.

```

CLASS STUDENT ABSENT
101 BARRY G 3
101 JENNI W 1
101 ED F 2
101 JOHN O 8
102 PAUL Y 2
102 AMY G 3
102 JOHN D 12
102 RICH H 4

```

Figure 125. Listing of file *SCHOOL.SAV*

The !TOTMAC macro below can produce a variety of group summary statistics such as sum, mean, and standard deviation for any IBM SPSS Statistics data file. In the macro call you specify values of keyword arguments indicating the data file (FILE), the break (grouping) variable (BREAKVR), the summary function (FUNC), and the variable to be used as input to the summary function (INVAR). For example, to obtain mean absences for each classroom, we specify *SCHOOL.SAV* as the data file, *CLASS* as the break variable, *MEAN* as the summary function, and *ABSENT* as the variable whose values are to be averaged.

```

DEFINE !TOTMAC ( BREAKVR = !TOKENS(1)
                /FUNC = !TOKENS(1)
                /INVAR = !TOKENS(1)
                /TEMP = !TOKENS(1) !DEFAULT(TOTALS.SAV)
                /FILE = !CMDEND).
GET FILE = !FILE.
SORT CASES BY !BREAKVR.
AGGREGATE OUTFILE = '!TEMP'
  /PRESORTED
  /BREAK = !BREAKVR
  /!CONCAT(!FUNC, '@') = !FUNC(!INVAR).

MATCH FILES FILE = *
  /TABLE = '!TEMP'
  /BY !BREAKVR.

!ENDDDEFINE.

!TOTMAC BREAKVR=CLASS FUNC=MEAN INVAR=ABSENT FILE=SCHOOL.SAV.

COMPUTE DIFF = ABSENT-MEAN@.

LIST.

!TOTMAC BREAKVR=REGION FUNC=SUM INVAR=SALES FILE=SALES89.SAV.

COMPUTE PCT = 100 * SALES / SUM@.

LIST.

```

Figure 126. !TOTMAC macro with keyword arguments

- The syntax for declaring keyword arguments follows the name of the macro in DEFINE.
- !TOKENS(1) specifies that the value of an argument is a string following the name of the argument in the macro call. Thus the first macro call specifies CLASS as the value of BREAKVR, MEAN as the value of FUNC, and ABSENT as the value of INVAR.
- !CMDEND indicates that the value for FILE is the remaining text in the macro call (*SCHOOL.SAV*).
- TEMP is an optional argument that names an intermediate file to contain the summary statistics. Since TEMP is not assigned a value in the macro call, summary statistics are written to the default intermediate file (*TOTALS.SAV*).
- In the body of the macro, GET FILE opens *SCHOOL.SAV*.
- SORT CASES sorts the file by CLASS.
- AGGREGATE computes the mean number of absences for each class. The name of the variable containing the means (*MEAN@*) is constructed using the !CONCAT function, which concatenates the value of FUNC and the @ symbol.
- MATCH FILES appends the means to student records.
- COMPUTE calculates the deviation from the classroom mean for each student (variable *DIFF*).
- LIST displays the deviation scores, as shown in the output below. For example, John D., who was absent 12 times, had 6.75 more absences than the average student in classroom 102. Rich H., who was absent 4 times, had 1.25 fewer absences than the average student in classroom 102.
- The second macro call and remaining commands generate regional sales percentages for the 1989 sales data.

CLASS	STUDENT	ABSENT	MEAN@	DIFF
101	BARRY G	3	3.50	-.50
101	JENNI W	1	3.50	-2.50
101	ED F	2	3.50	-1.50
101	JOHN O	8	3.50	4.50
102	PAUL Y	2	5.25	-3.25
102	AMY G	3	5.25	-2.25
102	JOHN D	12	5.25	6.75
102	RICH H	4	5.25	-1.25

1989 DATA					
YEAR	REGION	SALESPER	SALES	TOTAL@	PCT
1989	BATON ROUGE	GRAU	320	1459.00	22.00
1989	BATON ROUGE	SMITH	800	1459.00	55.00
1989	BATON ROUGE	RODRIGUEZ	339	1459.00	23.00
1989	CHICAGO	JONES	300	1439.00	21.00
1989	CHICAGO	STEEL	899	1439.00	62.00
1989	CHICAGO	GREGORY	240	1439.00	17.00

Figure 127. Student absences and 1989 sales percentages

You can modify the macro call to specify a different data file, input variable, break variable, or summary statistic. To get a different summary statistic (such as standard deviation), change the value of FUNC (see the AGGREGATE command for more information on summary functions available in the AGGREGATE procedure).

## Example 2: Testing Correlation Coefficients

While the program provides a large variety of statistical procedures, some specialized operations require the use of COMPUTE statements. For example, you may want to test a sample correlation coefficient against a population correlation coefficient. When the population coefficient is nonzero, you can compute a *Z* statistic to test the hypothesis that the sample and population values are equal.

The formula for *Z* is:

$$Z = \frac{0.5 \ln \left[ \frac{1+r}{1-r} \right] - 0.5 \ln \left[ \frac{1+p_0}{1-p_0} \right]}{1/(\sqrt{n-3})}$$

Figure 128. Formula for *Z*

Let's say you want to test an *r* of 0.66 obtained from a sample of 30 cases against a population coefficient of 0.85. The following figure shows commands for displaying *Z* and its two-tailed probability.

```
DATA LIST FREE / R N P.

BEGIN DATA
.66 30 .85
END DATA.

COMPUTE #ZR = .5* (LN ((1 + R) / (1 - R))).
COMPUTE #ZP = .5* (LN ((1 + P) / (1 - P))).

COMPUTE Z = (#ZR-#ZP)/(1/(SQRT(N-3))).
COMPUTE PROB = 2*(1-CDFNORM(ABS(Z))).

FORMAT PROB (F8.3).
LIST.
```

Figure 129. Commands for computing *Z* statistic

- DATA LIST defines variables containing the sample correlation coefficient (*R*), sample size (*N*), and population correlation coefficient (*P*).
- BEGIN DATA and END DATA indicate that data are inline.

- COMPUTE statements calculate  $Z$  and its probability. Variables #ZR and #ZP are scratch variables used in the intermediate steps of the calculation.
- The LIST command output is shown below. Since the absolute value of  $Z$  is large and the probability is small, we reject the hypothesis that the sample was drawn from a population having a correlation coefficient of 0.85.

```

R      N      P      Z      PROB
.66   30.00   .85   -2.41   .016

```

Figure 130.  $Z$  statistic and its probability

If you use the  $Z$  test frequently, you may want to construct a macro like that shown below. The !CORRTST macro computes  $Z$  and probability values for a sample correlation coefficient, sample size, and population coefficient specified as values of keyword arguments.

```

DEFINE !CORRTST ( R = !TOKENS(1)
                  /N = !TOKENS(1)
                  /P = !TOKENS(1)).

INPUT PROGRAM.
- END CASE.
- END FILE.
END INPUT PROGRAM.

COMPUTE #ZR = .5* (LN ((1 + !R) / (1 - !R))).
COMPUTE #ZP = .5* (LN ((1 + !P) / (1 - !P))).

COMPUTE Z = (#ZR-#ZP) / (1/(SQRT(!N-3))).
COMPUTE PROB = 2*(1-CDFNORM(ABS(Z))).
FORMAT PROB(F8.3).

TITLE SAMPLE R=!R, N=!N, POPULATION COEFFICIENT=!P.

LIST.

!ENDDDEFINE.

!CORRTST R=.66 N=30 P=.85.
!CORRTST R=.50 N=50 P=.85.

```

Figure 131. !CORRTST macro

- DEFINE names the macro as !CORRTST and declares arguments for the sample correlation coefficient ( $R$ ), the sample size ( $N$ ), and the population correlation coefficient ( $P$ ).
- !TOKENS(1) specifies that the value of an argument is a string that follows the name of the argument in the macro call. Thus the first macro call specifies values of 0.66, 30, and 0.85 for  $R$ ,  $N$ , and  $P$ .
- Commands between INPUT PROGRAM and END INPUT PROGRAM create an active dataset with one case. COMPUTE statements calculate the  $Z$  statistic and its probability using the values of macro arguments  $R$ ,  $N$ , and  $P$ . (INPUT PROGRAM commands would not be needed if COMPUTE statements operated on values in an existing file or inline data, rather than macro arguments.)
- A customized TITLE shows displays the values of macro arguments used in computing  $Z$ .
- The LIST command displays  $Z$  and its probability.
- The !CORRTST macro is called twice. The first invocation tests an  $r$  of 0.66 from a sample of 30 cases against a population coefficient of 0.85 (this generates the same  $Z$  value and probability as shown earlier). The second macro call tests an  $r$  of 0.50 from a sample of 50 cases against the same population correlation coefficient. The output from these macro calls is shown below.

```
SAMPLE R= .66 , N= 30 , POPULATION COEFFICIENT= .85
```

```
      Z      PROB  
-2.41    .016
```

```
SAMPLE R= .50 , N= 50 , POPULATION COEFFICIENT= .85
```

```
      Z      PROB  
-4.85    .000
```

Figure 132. Output from !CORRTST

The following figure shows a modified !CORRTST macro that you can use to test a sample  $r$  against each coefficient in a *list* of population coefficients.

```
DEFINE !CORRTST (R = !TOKENS(1)  
                /N = !TOKENS(1)  
                /P = !CMDEND).  
- INPUT PROGRAM.  
- END CASE.  
- END FILE.  
- END INPUT PROGRAM.  
  
!DO !I !IN (!P).  
- COMPUTE #ZR = .5* (LN ((1 + !R) / (1 - !R))).  
- COMPUTE #ZP = .5* (LN ((1 + !I) / (1 - !I))).  
  
- COMPUTE Z = (#ZR-#ZP)/(1/(SQRT(!N-3))).  
  
- COMPUTE PROB=2*(1-CDFNORM(ABS(Z))).  
- FORMAT PROB(F8.3).  
- TITLE SAMPLE R=!R, N=!N, POPULATION COEFFICIENT=!I.  
- LIST.  
!DOEND.  
  
!ENDDDEFINE.  
  
!CORRTST R=.66 N=30 P=.20 .40 .60 .80 .85 .90.
```

Figure 133. !CORRTST macro with list-processing loop

- DEFINE names the macro as !CORRTST and declares arguments for the sample correlation coefficient (R), the sample size (N), and the population correlation coefficient (P).
- !TOKENS(1) specifies that the value of an argument is a string that follows the name of the argument in the macro call. Thus, the macro call specifies the value of R as 0.66 and N as 30.
- !CMDEND indicates that the value for P is the remaining text in the macro call. Thus the value of P is a list containing the elements 0.20, 0.40, 0.60, 0.80, 0.85, and 0.90.
- Commands !DO !IN and !DOEND define a **list-processing loop**. Commands in the loop compute one Z statistic for each element in the list of population coefficients. For example, in the first iteration Z is computed using 0.20 as the population coefficient. In the second iteration 0.40 is used. The same sample size (30) and  $r$  value (0.66) are used for each Z statistic.
- The output from the macro call is shown below. One Z statistic is displayed for each population coefficient.

SAMPLE R= .66 , N= 30 , POPULATION COEFFICIENT= .20

```
Z      PROB
3.07   .002
```

SAMPLE R= .66 , N= 30 , POPULATION COEFFICIENT= .40

```
Z      PROB
1.92   .055
```

SAMPLE R= .66 , N= 30 , POPULATION COEFFICIENT= .60

```
Z      PROB
.52    .605
```

SAMPLE R= .66 , N= 30 , POPULATION COEFFICIENT= .80

```
Z      PROB
-1.59  .112
```

SAMPLE R= .66 , N= 30 , POPULATION COEFFICIENT= .85

```
Z      PROB
-2.41  .016
```

SAMPLE R= .66 , N= 30 , POPULATION COEFFICIENT= .90

```
Z      PROB
-3.53  .000
```

Figure 134. Output from modified !CORRTST macro

---

## Example 3: Generating Random Data

You can use command syntax to generate variables that have approximately a normal distribution. Commands for generating five standard normal variables (X1 through X5) for 1000 cases are shown in the following figure. As shown in the output below, each variable has a mean of approximately 0 and a standard deviation of approximately 1.

```
INPUT PROGRAM.
- VECTOR X(5).
- LOOP #I = 1 TO 1000.
- LOOP #J = 1 TO 5.
- COMPUTE X(#J) = NORMAL(1).
- END LOOP.
- END CASE.
- END LOOP.
- END FILE.
END INPUT PROGRAM.
```

DESCRIPTIVES VARIABLES X1 TO X5.

Figure 135. Data-generating commands

Variable	Mean	Std Dev	Minimum	Maximum	Valid N	Label
X1	-.01	1.02	-3.11	4.15	1000	
X2	.08	1.03	-3.19	3.22	1000	
X3	.02	1.00	-3.01	3.51	1000	
X4	.03	1.00	-3.35	3.19	1000	
X5	-.01	.96	-3.34	2.91	1000	

Figure 136. Descriptive statistics for generated data

The !DATAGEN macro below issues the data-generating commands shown above.

```

DEFINE !DATAGEN ().

INPUT PROGRAM.
- VECTOR X(5).
- LOOP #I = 1 TO 1000.
- LOOP #J = 1 TO 5.
- COMPUTE X(#J) = NORMAL(1).
- END LOOP.
- END CASE.
- END LOOP.
- END FILE.
END INPUT PROGRAM.

DESCRIPTIVES VARIABLES X1 TO X5.

!ENDDDEFINE.

!DATAGEN.

```

Figure 137. !DATAGEN macro

The data-generating commands are imbedded between macro definition commands. The macro produces the same data and descriptive statistics as shown above.

You can tailor the generation of normally distributed variables if you modify the !DATAGEN macro so it will accept keyword arguments, as shown in the following figure. The macro allows you to specify the number of variables and cases to be generated and the approximate standard deviation.

```

DEFINE !DATAGEN ( OBS =!TOKENS(1) !DEFAULT(1000)
/VARS =!TOKENS(1) !DEFAULT(5)
/SD =!CMDEND !DEFAULT(1)).

INPUT PROGRAM.
- VECTOR X(!VARS).
- LOOP #I = 1 TO !OBS.
- LOOP #J = 1 TO !VARS.
- COMPUTE X(#J) = NORMAL(!SD).
- END LOOP.
- END CASE.
- END LOOP.
- END FILE.
END INPUT PROGRAM.

!LET !LIST = !NULL.
!DO !I = 1 !TO !VARS.
- !LET !LIST = !CONCAT(!LIST, ' ', X, !I).
!DOEND.

DESCRIPTIVES VARIABLES !LIST.

!ENDDDEFINE.

!DATAGEN OBS=500 VARS=2 SD=1.
!DATAGEN.

```

Figure 138. !DATAGEN macro with keyword arguments

- The DEFINE statement declares arguments that specify the number of cases (OBS), variables (VARS), and standard deviation (SD). By default, the macro creates 1000 cases with 5 variables that have a standard deviation of 1.
- Commands between INPUT PROGRAM and END INPUT PROGRAM generate the new data using values of the macro arguments.
- Commands !LET and !DO/!DOEND construct a variable list (!LIST) that is used in DESCRIPTIVES. The first !LET command initializes the list to a null (blank) string value. For each new variable, the index loop adds to the list a string of the form X1, X2, X3, and so forth. Thus, DESCRIPTIVES requests means and standard deviations for each new variable.
- The first macro call generates 500 cases with two standard normal variables. The second call requests the default number of variables, cases, and standard deviation. Descriptive statistics (not shown) are also computed for each variable.

As shown in the following figure, you can declare additional keyword arguments that allow you to specify the distribution (normal or uniform) of the generated data and a parameter value that is used as

the standard deviation (for normally distributed data) or a range (for uniformly distributed data).

```

DEFINE !DATAGEN (OBS      =!TOKENS(1) !DEFAULT(1000)
                 /VARS    =!TOKENS(1) !DEFAULT(5)
                 /DIST    =!TOKENS(1) !DEFAULT(NORMAL)
                 /PARAM   =!TOKENS(1) !DEFAULT(1)).

INPUT PROGRAM.
- VECTOR X(!VARS).
- LOOP #I = 1 TO !OBS.
-   LOOP #J = 1 TO !VARS.
-     COMPUTE X(#J) = !DIST(!PARAM).
-   END LOOP.
- END LOOP.
- END CASE.
- END LOOP.
- END FILE.
END INPUT PROGRAM.

!LET !LIST = !NULL.
!DO !I = 1 !TO !VARS.
- !LET !LIST = !CONCAT(!LIST, ' ', X, !I).
!DOEND.

DESCRIPTIVES VARIABLES !LIST.
!ENDDDEFINE.

!DATAGEN OBS=500 VARS=2 DIST=UNIFORM PARAM=2.

```

Figure 139. !DATAGEN macro with additional keyword arguments

- The DEFINE statement declares arguments OBS, VARS, DIST, and PARAM. OBS and VARS represent the number of observations and cases to be generated. Arguments DIST and PARAM specify the shape and parameter of the distribution of generated data. By default, the macro generates 1000 observations with 5 standard normal variables.
- Statements between INPUT PROGRAM and END INPUT PROGRAM generate the new data using values of macro arguments.
- Remaining commands in the body of the macro obtain descriptive statistics for generated variables.
- The macro call in creates two approximately uniformly distributed variables with a range of 2. The output from the macro call is shown below.

Variable	Mean	Std Dev	Minimum	Maximum	Valid	
					N	Label
X1	.99	.57	.00	2.00	500	
X2	1.00	.57	.00	2.00	500	

Figure 140. Descriptive statistics for uniform variables

---

## Chapter 307. Canonical Correlation and Ridge Regression Macros

Two macro routines are installed with for performing canonical correlation and ridge regression. Macros are inherently less robust than regular commands. Error checking is minimal, and small errors produce large numbers of uninformative messages, giving little clue to the real cause of the problem. Syntax must be entered exactly as documented:

- Enter subcommands in the order shown.
- Do not include a slash before the first subcommand.
- Enter keywords exactly as shown. Do not abbreviate them, and do not extend them (even if they look like abbreviations).
- Do not omit equal signs, but do not add them if none are displayed in the syntax diagram.
- Remember that these "command names" are actually macro calls, which are expanded into (lengthy) sequences of commands and Matrix language statements. The command name should not appear anywhere within the specifications of the command, for example within a variable name.
- These macros create new files in the current directory. If you do not have write permission to the current directory (this can happen if you are running the program on a network), change the current directory. You can do this by opening or saving a file on your own hard disk.
- You cannot run these macros if split-file processing is in effect.

---

### Canonical Correlation Macro

```
INCLUDE '[installdir]/Samples/English/Canonical correlation.sps'.
CANCORR SET1=varlist1 /
        SET2=varlist2 / .
```

The two variable lists must be separated with a slash.  
[installdir] is the installation directory.

---

### Ridge Regression Macro

```
INCLUDE '[installdir]/Samples/English/Ridge regression.sps'.
RIDGEREG DEP=varname /ENTER = varlist
[/START={0**}] [/STOP={1**}] [/INC={0.05**}]
        {value}          {value}          {value }
[ /K=value] .
[installdir] is the installation directory.
```

---

## Chapter 308. File Specifications for IBM SPSS Collaboration and Deployment Services Repository Objects

Access to a IBM SPSS Collaboration and Deployment Services Repository is available with the Statistics Adapter option. Once a connection to a IBM SPSS Collaboration and Deployment Services Repository has been established, you can use a file specification for a IBM SPSS Collaboration and Deployment Services Repository object on nearly any keyword or subcommand where a file specification can be provided (including, but not limited to FILE, INFILE, or OUTFILE ). File specifications for IBM SPSS Collaboration and Deployment Services Repository objects can also be used in procedure dialog boxes that allow manual entry of a file specification—for example, XML model files or plan files for complex samples analyses.

A IBM SPSS Collaboration and Deployment Services Repository file specification has the following form:

```
SPSSCR://{directory path and/or file specification}
```

```
  [#{M.versionmarker}]  
  {#L.versionlabel }
```

*Note:* Specification of descriptions (#D) and keywords (#K) is obsolete for release 17.0 and higher.

### Basic Specification

The basic specification is the scheme name SPSSCR , followed by a colon, one or two slashes (forward or backward), and a directory path or file: for example:

```
GET FILE='SPSSCR://data/mydata.sav'.
```

- A IBM SPSS Collaboration and Deployment Services Repository file specification is included on a GET command. The latest version of the file */data/mydata.sav* that is accessible by the current user will be retrieved from the currently connected IBM SPSS Collaboration and Deployment Services Repository.

### Syntax Rules

- Paths can be specified with forward slashes (/) or backslashes (\).
- The optional components of a file specification--version marker (#M) and version label (#L)--can be specified in any order.
- When including an optional component, the character sequence that specifies the component--for example, #L--must be followed by a period (.).

### File Extensions

Files are stored to the IBM SPSS Collaboration and Deployment Services Repository with an associated MIME type that specifies the type of file; for example, IBM SPSS Statistics format data, or viewer output. Including a file extension, such as *.sav* or *.spv*, is not necessary in order for the correct MIME type to be determined; however, it is recommended.

- File extensions are not added to filenames when storing to a IBM SPSS Collaboration and Deployment Services Repository. For example, the following SAVE command results in the creation of a IBM SPSS Collaboration and Deployment Services Repository object with a MIME type of IBM SPSS Statistics-format data, and a fully qualified path of */data/mydata*, but no *sav* extension.  

```
SAVE OUTFILE='SPSSCR://data/mydata'.
```
- When retrieving IBM SPSS Collaboration and Deployment Services Repository objects, you must specify the filename exactly as provided when the file was stored. If the file was stored with an extension, then you must supply the extension. If the file was stored without an extension then do not include one.

## Permissions

- The PERMISSIONS, SAVE, and XSAVE commands will generate errors if you attempt to set permissions for IBM SPSS Collaboration and Deployment Services Repository objects. Permissions for IBM SPSS Collaboration and Deployment Services Repository objects are set with the REPOSITORY ATTRIBUTES command or using administration tools included with IBM SPSS Collaboration and Deployment Services.
- The ERASE FILE command will generate an error if you attempt to delete a IBM SPSS Collaboration and Deployment Services Repository object.

*Note:* For users upgrading from an IBM SPSS Collaboration and Deployment Services 3.5 system, be aware that command syntax that retrieved the version labelled *LATEST* (the default version retrieved by GET FILE='fileSpec') in a 3.5 system will retrieve an earlier version in an IBM SPSS Collaboration and Deployment Services 4.x system if the current user does not have permission to view objects with the *LATEST* label.

---

## Versions

By default, the latest version that is accessible by the current user is returned when a file is retrieved. You can optionally specify a particular version to retrieve by including the version marker or version label, if one exists. Version markers and labels are always ignored if the specification describes a directory path, as opposed to a specific file.

**Version label (#L).** A label is used to easily identify a version; for example, *production* or *development*.

- The version label, if provided, is displayed in the Label column in the Select Version dialog box. See the topic for more information.

**Version marker (#M).** The version marker consists of an integer version number followed by a time stamp that uniquely specifies a version—for example, *1:2006-07-26 15:19:49.237*.

- The version marker is displayed in the Version column in the Select Version dialog box. See the topic for more information.

## Examples

```
*Retrieve a labelled version.
GET FILE='SPSSCR://data/mydata.sav#L.development'.
```

- The version of */data/mydata.sav* with the label *development* is retrieved from the current IBM SPSS Collaboration and Deployment Services Repository.

```
*Retrieve a version using its version marker.
OUTPUT OPEN FILE=
  'SPSSCR://output/myoutput.spv#M.0:2006-07-26 15:18:15.862'.
```

- The version of the output file */output/myoutput.spv* with version marker *0:2006-07-26 15:18:15.862* is retrieved.

---

## Using File Handles for IBM SPSS Collaboration and Deployment Services Repository Locations

You can define a file handle to a file or a directory in a IBM SPSS Collaboration and Deployment Services Repository and use that file handle when storing or retrieving.

```
*Define and use a file handle for a directory.
FILE HANDLE cust /NAME='SPSSCR://CustomerValue'.
GET FILE='cust/data2002.sav'.
```

- The handle *cust* is associated with the IBM SPSS Collaboration and Deployment Services Repository directory */CustomerValue*, and the GET command retrieves the latest version of the file *data2002.sav* from this directory in the current IBM SPSS Collaboration and Deployment Services Repository.

```
*Define and use a file handle for a specific file.
FILE HANDLE cust /NAME='SPSSCR://CustomerValue/data2002.sav'.
GET FILE='cust'.
```

- The handle *cust* is associated with the IBM SPSS Collaboration and Deployment Services Repository file */CustomerValue/data2002.sav*, and the GET command retrieves the latest version of this file from the current IBM SPSS Collaboration and Deployment Services Repository.

---

## Setting the Working Directory to a IBM SPSS Collaboration and Deployment Services Repository Location

You can use the CD command to set the working directory to a directory in the currently connected IBM SPSS Collaboration and Deployment Services Repository.

```
CD 'SPSSCR://CustomerValue'.  
GET FILE='data2002.sav'.
```

- The working directory is set to the IBM SPSS Collaboration and Deployment Services Repository directory */CustomerValue*, and the GET command retrieves the latest version of the file *data2002.sav* from this directory in the current IBM SPSS Collaboration and Deployment Services Repository.

---

## Chapter 309. TABLES and IGRAPH Command Syntax Converter

If you have command syntax files that contain TABLES syntax that you want to convert to CTABLES syntax and/or IGRAPH syntax that you want to convert to GGRAPH syntax, a simple utility program is provided to help you get started with the conversion process. There are, however, significant functionality differences between TABLES and CTABLES and between IGRAPH and GGRAPH. It is likely that you will find that the utility program cannot convert some of your TABLES and IGRAPH syntax jobs or may generate CTABLES and GGRAPH syntax that produces tables and graphs that do not closely resemble the originals produced by the TABLES and IGRAPH commands. For most tables, you can edit the converted syntax to produce a table closely resembling the original.

The utility program is designed to:

- Create a new syntax file from an existing syntax file. The original syntax file is not altered.
- Convert only TABLES and IGRAPH commands in the syntax file. Other commands in the file are not altered.
- Retain the original TABLES and IGRAPH syntax in commented form.
- Identify the beginning and end of each conversion block with comments.
- Identify TABLES and IGRAPH syntax commands that could not be converted.
- Convert command syntax files that follow either interactive or production mode syntax rules.

This utility cannot convert commands that contain errors. The following other limitations also apply.

### TABLES Limitations

The utility program may convert TABLES commands incorrectly under some circumstances, including TABLES commands that contain:

- Parenthesized variable names with the initial letters "sta" or "lab" in the TABLES subcommand if the variable is parenthesized by itself—for example, var1 by (statvar) by (labvar). These will be interpreted as the (STATISTICS) and (LABELS) keywords.
- SORT subcommands that use the abbreviations A or D to indicate ascending or descending sort order. These will be interpreted as variable names.

The utility program cannot convert TABLES commands that contain:

- Syntax errors.
- OBSERVATION subcommands that refer to a range of variables using the T0 keyword (for example, var01 T0 var05).
- String literals broken into segments separated by plus signs (for example, TITLE "My" + "Title").
- Macro calls that, in the absence of macro expansion, would be invalid TABLES syntax. Since the converter does not expand the macro calls, it treats them as if they were simply part of the standard TABLES syntax.

The utility program will not convert TABLES commands contained in macros. All macros are unaffected by the conversion process.

### IGRAPH Limitations

IGRAPH changed significantly in release 16. Because of these changes, some subcommands and keywords in IGRAPH syntax created before that release may not be honored. See the IGRAPH section in the *Command Syntax Reference* for the complete revision history.

The conversion utility program may generate additional syntax that it stores in the INLINETEMPLATE keyword within the GGRAPH syntax. This keyword is created only by the conversion program. Its syntax is not intended to be user-editable.

### Using the Conversion Utility Program

The conversion utility program, *SyntaxConverter.exe*, can be found in the installation directory. It is designed to run from a command prompt. The general form of the command is:

```
syntaxconverter.exe [path]/inputfilename.sps [path]/outputfilename.sps
```

You must run this command from the installation directory.

If any directory names contain spaces, enclose the entire path and filename in quotation marks, as in:

```
syntaxconverter.exe /myfiles/oldfile.sps "/new files/newfile.sps"
```

### Interactive versus Production Mode Command Syntax Rules

The conversion utility program can convert command files that use interactive or production mode syntax rules.

**Interactive.** The interactive syntax rules are:

- Each command begins on a new line.
- Each command ends with a period (.).

**Production mode.** The Production Facility and commands in files accessed via the INCLUDE command in a different command file use production mode syntax rules:

- Each command must begin in the first column of a new line.
- Continuation lines must be indented at least one space.
- The period at the end of the command is optional.

If your command files use production mode syntax rules and don't contain periods at the end of each command, you need to include the command line switch -b (or /b) when you run *SyntaxConverter.exe*, as in:

```
syntaxconverter.exe -b /myfiles/oldfile.sps /myfiles/newfile.sps
```

### SyntaxConverter Script (Windows Only)

On Windows, you can also run the syntax converter with the script *SyntaxConverter.wvd*, located in the *Samples* directory of the installation directory.

1. From the menus choose:

**Utilities > Run Script...**

2. Navigate to the *Samples* directory and select *SyntaxConverter.wvd*.

This will open a simple dialog box where you can specify the names and locations of the old and new command syntax files.

---

## Notices

This information was developed for products and services offered in the US. This material might be available from IBM in other languages. However, you may be required to own a copy of the product or product version in that language in order to access it.

IBM may not offer the products, services, or features discussed in this document in other countries.
