Chapter 1. Advanced statistics

The following advanced statistics features are included in SPSS Statistics Standard Edition or the Advanced Statistics option.

Introduction to Advanced Statistics

The Advanced Statistics option includes procedures that offer more advanced modeling options than are available through the Statistics Base option.

- GLM Multivariate extends the general linear model provided by GLM Univariate to allow multiple dependent variables. A further extension, GLM Repeated Measures, allows repeated measurements of multiple dependent variables.
- Variance Components Analysis is a specific tool for decomposing the variability in a dependent variable into fixed and random components.
- Linear Mixed Models expands the general linear model so that the data are permitted to exhibit correlated and nonconstant variability. The mixed linear model, therefore, provides the flexibility of modeling not only the means of the data but the variances and covariances as well.
- Generalized Linear Models (GZLM) relaxes the assumption of normality for the error term and requires only that the dependent variable be linearly related to the predictors through a transformation, or link function. Generalized Estimating Equations (GEE) extends GZLM to allow repeated measurements.
- General Loglinear Analysis allows you to fit models for cross-classified count data, and Model Selection Loglinear Analysis can help you to choose between models.
- Logit Loglinear Analysis allows you to fit loglinear models for analyzing the relationship between a categorical dependent and one or more categorical predictors.
- Survival analysis is available through Life Tables for examining the distribution of time-to-event variables, possibly by levels of a factor variable; Kaplan-Meier Survival Analysis for examining the distribution of time-to-event variables, possibly by levels of a factor variable or producing separate analyses by levels of a stratification variable; and Cox Regression for modeling the time to a specified event, based upon the values of given covariates.

GLM Multivariate Analysis

The GLM Multivariate procedure provides regression analysis and analysis of variance for multiple dependent variables by one or more factor variables or covariates. The factor variables divide the population into groups. Using this general linear model procedure, you can test null hypotheses about the effects of factor variables on the means of various groupings of a joint distribution of dependent variables. You can investigate interactions between factors as well as the effects of individual factors. In addition, the effects of covariates and covariate interactions with factors can be included. For regression analysis, the independent (predictor) variables are specified as covariates.

Both balanced and unbalanced models can be tested. A design is balanced if each cell in the model contains the same number of cases. In a multivariate model, the sums of squares due to the effects in the model and error sums of squares are in matrix form rather than the scalar form found in univariate analysis. These matrices are called SSCP (sums-of-squares and cross-products) matrices. If more than one dependent variable is specified, the multivariate analysis of variance using Pillai's trace, Wilks' lambda, Hotelling's trace, and Roy's largest root criterion with approximate F statistic are provided as well as the univariate analysis of variance for each dependent variable. In addition to testing hypotheses, GLM Multivariate produces estimates of parameters.

Commonly used *a priori* contrasts are available to perform hypothesis testing. Additionally, after an overall F test has shown significance, you can use post hoc tests to evaluate differences among specific means. Estimated marginal means give estimates of predicted mean values for the cells in the model, and

profile plots (interaction plots) of these means allow you to visualize some of the relationships easily. The post hoc multiple comparison tests are performed for each dependent variable separately.

Residuals, predicted values, Cook's distance, and leverage values can be saved as new variables in your data file for checking assumptions. Also available are a residual SSCP matrix, which is a square matrix of sums of squares and cross-products of residuals, a residual covariance matrix, which is the residual SSCP matrix divided by the degrees of freedom of the residuals, and the residual correlation matrix, which is the standardized form of the residual covariance matrix.

WLS Weight allows you to specify a variable used to give observations different weights for a weighted least-squares (WLS) analysis, perhaps to compensate for different precision of measurement.

Example. A manufacturer of plastics measures three properties of plastic film: tear resistance, gloss, and opacity. Two rates of extrusion and two different amounts of additive are tried, and the three properties are measured under each combination of extrusion rate and additive amount. The manufacturer finds that the extrusion rate and the amount of additive individually produce significant results but that the interaction of the two factors is not significant.

Methods. Type I, Type II, Type III, and Type IV sums of squares can be used to evaluate different hypotheses. Type III is the default.

Statistics. Post hoc range tests and multiple comparisons: least significant difference, Bonferroni, Sidak, Scheffé, Ryan-Einot-Gabriel-Welsch multiple F , Ryan-Einot-Gabriel-Welsch multiple range, Student-Newman-Keuls, Tukey's honestly significant difference, Tukey's b , Duncan, Hochberg's GT2, Gabriel, Waller Duncan t test, Dunnett (one-sided and two-sided), Tamhane's T2, Dunnett's T3, Games-Howell, and Dunnett's C . Descriptive statistics: observed means, standard deviations, and counts for all of the dependent variables in all cells; the Levene test for homogeneity of variance; Box's M test of the homogeneity of the covariance matrices of the dependent variables; and Bartlett's test of sphericity.

Plots. Spread-versus-level, residual, and profile (interaction).

GLM Multivariate Data Considerations

Data. The dependent variables should be quantitative. Factors are categorical and can have numeric values or string values. Covariates are quantitative variables that are related to the dependent variable.

Assumptions. For dependent variables, the data are a random sample of vectors from a multivariate normal population; in the population, the variance-covariance matrices for all cells are the same. Analysis of variance is robust to departures from normality, although the data should be symmetric. To check assumptions, you can use homogeneity of variances tests (including Box's M) and spread-versus-level plots. You can also examine residuals and residual plots.

Related procedures. Use the Explore procedure to examine the data before doing an analysis of variance. For a single dependent variable, use GLM Univariate. If you measured the same dependent variables on several occasions for each subject, use GLM Repeated Measures.

Obtaining GLM Multivariate Tables

1. From the menus choose:

Analyze > General Linear Model > Multivariate...

2. Select at least two dependent variables.

Optionally, you can specify Fixed Factor(s), Covariate(s), and WLS Weight.

GLM Multivariate Model

Specify Model. A full factorial model contains all factor main effects, all covariate main effects, and all factor-by-factor interactions. It does not contain covariate interactions. Select **Custom** to specify only a subset of interactions or to specify factor-by-covariate interactions. You must indicate all of the terms to be included in the model.

Factors and Covariates. The factors and covariates are listed.

Model. The model depends on the nature of your data. After selecting **Custom**, you can select the main effects and interactions that are of interest in your analysis.

Sum of squares. The method of calculating the sums of squares. For balanced or unbalanced models with no missing cells, the Type III sum-of-squares method is most commonly used.

Include intercept in model. The intercept is usually included in the model. If you can assume that the data pass through the origin, you can exclude the intercept.

Build Terms and Custom Terms

Build terms

Use this choice when you want to include non-nested terms of a certain type (such as main effects) for all combinations of a selected set of factors and covariates.

Build custom terms

Use this choice when you want to include nested terms or when you want to explicitly build any term variable by variable. Building a nested term involves the following steps:

Sum of Squares

For the model, you can choose a type of sums of squares. Type III is the most commonly used and is the default.

Type I. This method is also known as the hierarchical decomposition of the sum-of-squares method. Each term is adjusted for only the term that precedes it in the model. Type I sums of squares are commonly used for:

- A balanced ANOVA model in which any main effects are specified before any first-order interaction effects, any first-order interaction effects are specified before any second-order interaction effects, and so on.
- A polynomial regression model in which any lower-order terms are specified before any higher-order terms.
- A purely nested model in which the first-specified effect is nested within the second-specified effect, the second-specified effect is nested within the third, and so on. (This form of nesting can be specified only by using syntax.)

Type II. This method calculates the sums of squares of an effect in the model adjusted for all other "appropriate" effects. An appropriate effect is one that corresponds to all effects that do not contain the effect being examined. The Type II sum-of-squares method is commonly used for:

- A balanced ANOVA model.
- Any model that has main factor effects only.
- Any regression model.
- A purely nested design. (This form of nesting can be specified by using syntax.)

Type III. The default. This method calculates the sums of squares of an effect in the design as the sums of squares, adjusted for any other effects that do not contain the effect, and orthogonal to any effects (if any) that contain the effect. The Type III sums of squares have one major advantage in that they are invariant with respect to the cell frequencies as long as the general form of estimability remains constant. Hence, this type of sums of squares is often considered useful for an unbalanced model with no missing cells. In a factorial design with no missing cells, this method is equivalent to the Yates' weighted-squares-of-means technique. The Type III sum-of-squares method is commonly used for:

- Any models listed in Type I and Type II.
- Any balanced or unbalanced model with no empty cells.

Type IV. This method is designed for a situation in which there are missing cells. For any effect F in the design, if F is not contained in any other effect, then Type IV = Type III = Type II. When F is contained in other effects, Type IV distributes the contrasts being made among the parameters in F to all higher-level effects equitably. The Type IV sum-of-squares method is commonly used for:

- Any models listed in Type I and Type II.
- Any balanced model or unbalanced model with empty cells.

GLM Multivariate Contrasts

Contrasts are used to test whether the levels of an effect are significantly different from one another. You can specify a contrast for each factor in the model. Contrasts represent linear combinations of the parameters.

Hypothesis testing is based on the null hypothesis $\mathbf{LBM} = \mathbf{0}$, where \mathbf{L} is the contrast coefficients matrix, \mathbf{M} is the identity matrix (which has dimension equal to the number of dependent variables), and \mathbf{B} is the parameter vector. When a contrast is specified, an \mathbf{L} matrix is created such that the columns corresponding to the factor match the contrast. The remaining columns are adjusted so that the \mathbf{L} matrix is estimable.

In addition to the univariate test using F statistics and the Bonferroni-type simultaneous confidence intervals based on Student's t distribution for the contrast differences across all dependent variables, the multivariate tests using Pillai's trace, Wilks' lambda, Hotelling's trace, and Roy's largest root criteria are provided.

Available contrasts are deviation, simple, difference, Helmert, repeated, and polynomial. For deviation contrasts and simple contrasts, you can choose whether the reference category is the last or first category.

Contrast Types

Deviation. Compares the mean of each level (except a reference category) to the mean of all of the levels (grand mean). The levels of the factor can be in any order.

Simple. Compares the mean of each level to the mean of a specified level. This type of contrast is useful when there is a control group. You can choose the first or last category as the reference.

Difference. Compares the mean of each level (except the first) to the mean of previous levels. (Sometimes called reverse Helmert contrasts.)

Helmert. Compares the mean of each level of the factor (except the last) to the mean of subsequent levels.

Repeated. Compares the mean of each level (except the last) to the mean of the subsequent level.

Polynomial. Compares the linear effect, quadratic effect, cubic effect, and so on. The first degree of freedom contains the linear effect across all categories; the second degree of freedom, the quadratic effect; and so on. These contrasts are often used to estimate polynomial trends.

GLM Multivariate Profile Plots

Profile plots (interaction plots) are useful for comparing marginal means in your model. A profile plot is a line plot in which each point indicates the estimated marginal mean of a dependent variable (adjusted for any covariates) at one level of a factor. The levels of a second factor can be used to make separate lines. Each level in a third factor can be used to create a separate plot. All factors are available for plots. Profile plots are created for each dependent variable.

A profile plot of one factor shows whether the estimated marginal means are increasing or decreasing across levels. For two or more factors, parallel lines indicate that there is no interaction between factors, which means that you can investigate the levels of only one factor. Nonparallel lines indicate an interaction.

Figure 1. Nonparallel plot (left) and parallel plot (right)

After a plot is specified by selecting factors for the horizontal axis and, optionally, factors for separate lines and separate plots, the plot must be added to the Plots list.

GLM Multivariate Post Hoc Comparisons

Post hoc multiple comparison tests. Once you have determined that differences exist among the means, post hoc range tests and pairwise multiple comparisons can determine which means differ. Comparisons are made on unadjusted values. The post hoc tests are performed for each dependent variable separately.

The Bonferroni and Tukey's honestly significant difference tests are commonly used multiple comparison tests. The **Bonferroni test**, based on Student's t statistic, adjusts the observed significance level for the fact that multiple comparisons are made. **Sidak's t test** also adjusts the significance level and provides tighter bounds than the Bonferroni test. **Tukey's honestly significant difference test** uses the Studentized range statistic to make all pairwise comparisons between groups and sets the experimentwise error rate to the error rate for the collection for all pairwise comparisons. When testing a large number of pairs of means, Tukey's honestly significant difference test is more powerful than the Bonferroni test. For a small number of pairs, Bonferroni is more powerful.

Hochberg's GT2 is similar to Tukey's honestly significant difference test, but the Studentized maximum modulus is used. Usually, Tukey's test is more powerful. **Gabriel's pairwise comparisons test** also uses the Studentized maximum modulus and is generally more powerful than Hochberg's GT2 when the cell sizes are unequal. Gabriel's test may become liberal when the cell sizes vary greatly.

Dunnett's pairwise multiple comparison t test compares a set of treatments against a single control mean. The last category is the default control category. Alternatively, you can choose the first category. You can also choose a two-sided or one-sided test. To test that the mean at any level (except the control category) of the factor is not equal to that of the control category, use a two-sided test. To test whether the mean at any level of the factor is smaller than that of the control category, select **< Control**. Likewise, to test whether the mean at any level of the factor is larger than that of the control category, select **> Control**.

Ryan, Einot, Gabriel, and Welsch (R-E-G-W) developed two multiple step-down range tests. Multiple step-down procedures first test whether all means are equal. If all means are not equal, subsets of means are tested for equality. **R-E-G-W F** is based on an F test and **R-E-G-W Q** is based on the Studentized range. These tests are more powerful than Duncan's multiple range test and Student-Newman-Keuls (which are also multiple step-down procedures), but they are not recommended for unequal cell sizes.

When the variances are unequal, use **Tamhane's T2** (conservative pairwise comparisons test based on a t test), **Dunnett's T3** (pairwise comparison test based on the Studentized maximum modulus), **Games-Howell pairwise comparison test** (sometimes liberal), or **Dunnett's C** (pairwise comparison test based on the Studentized range).

Duncan's multiple range test, Student-Newman-Keuls (**S-N-K**), and **Tukey's b** are range tests that rank group means and compute a range value. These tests are not used as frequently as the tests previously discussed.

The **Waller-Duncan t test** uses a Bayesian approach. This range test uses the harmonic mean of the sample size when the sample sizes are unequal.

The significance level of the **Scheffé test** is designed to allow all possible linear combinations of group means to be tested, not just pairwise comparisons available in this feature. The result is that the Scheffé

test is often more conservative than other tests, which means that a larger difference between means is required for significance.

The least significant difference (**LSD**) pairwise multiple comparison test is equivalent to multiple individual *t* tests between all pairs of groups. The disadvantage of this test is that no attempt is made to adjust the observed significance level for multiple comparisons.

Tests displayed. Pairwise comparisons are provided for LSD, Sidak, Bonferroni, Games-Howell, Tamhane's T2 and T3, Dunnett's C, and Dunnett's T3. Homogeneous subsets for range tests are provided for S-N-K, Tukey's *b*, Duncan, R-E-G-W *F*, R-E-G-W *Q*, and Waller. Tukey's honestly significant difference test, Hochberg's GT2, Gabriel's test, and Scheffé's test are both multiple comparison tests and range tests.

GLM Estimated Marginal Means

Select the factors and interactions for which you want estimates of the population marginal means in the cells. These means are adjusted for the covariates, if any.

Compare main effects

Provides uncorrected pairwise comparisons among estimated marginal means for any main effect in the model, for both between- and within-subjects factors. This item is available only if main effects are selected under the Display Means For list.

Compare simple main effects

The setting is enabled whenever the target list contains one or more product or interaction effects (for example, $A \times B$, $A \times B \times C$). The setting supports the specification of comparisons among simple main effects, which are main effects nested within the levels of other factors.

Confidence interval adjustment

Select least significant difference (LSD), Bonferroni, or Sidak adjustment to the confidence intervals and significance. This item is available only when **Compare main effects** and/or **Compare simple main effects** is selected.

Specifying Estimated Marginal Means

1. From the menus choose one of the procedures available under > **Analyze** > **General Linear Model**.
2. In the main dialog, click **EM Means**.

GLM Save

You can save values predicted by the model, residuals, and related measures as new variables in the Data Editor. Many of these variables can be used for examining assumptions about the data. To save the values for use in another IBM SPSS Statistics session, you must save the current data file.

Predicted Values. The values that the model predicts for each case.

- *Unstandardized.* The value the model predicts for the dependent variable.
- *Weighted.* Weighted unstandardized predicted values. Available only if a WLS variable was previously selected.
- *Standard error.* An estimate of the standard deviation of the average value of the dependent variable for cases that have the same values of the independent variables.

Diagnostics. Measures to identify cases with unusual combinations of values for the independent variables and cases that may have a large impact on the model.

- *Cook's distance.* A measure of how much the residuals of all cases would change if a particular case were excluded from the calculation of the regression coefficients. A large Cook's D indicates that excluding a case from computation of the regression statistics changes the coefficients substantially.
- *Leverage values.* Uncentered leverage values. The relative influence of each observation on the model's fit.

Residuals. An unstandardized residual is the actual value of the dependent variable minus the value predicted by the model. Standardized, Studentized, and deleted residuals are also available. If a WLS variable was chosen, weighted unstandardized residuals are available.

- *Unstandardized.* The difference between an observed value and the value predicted by the model.
- *Weighted.* Weighted unstandardized residuals. Available only if a WLS variable was previously selected.
- *Standardized.* The residual divided by an estimate of its standard deviation. Standardized residuals, which are also known as Pearson residuals, have a mean of 0 and a standard deviation of 1.
- *Studentized.* The residual divided by an estimate of its standard deviation that varies from case to case, depending on the distance of each case's values on the independent variables from the means of the independent variables. Sometimes referred to as internally studentized residuals.
- *Deleted.* The residual for a case when that case is excluded from the calculation of the regression coefficients. It is the difference between the value of the dependent variable and the adjusted predicted value.

Coefficient Statistics. Writes a variance-covariance matrix of the parameter estimates in the model to a new dataset in the current session or an external IBM SPSS Statistics data file. Also, for each dependent variable, there will be a row of parameter estimates, a row of standard errors of the parameter estimates, a row of significance values for the *t* statistics corresponding to the parameter estimates, and a row of residual degrees of freedom. For a multivariate model, there are similar rows for each dependent variable. When Heteroskedasticity-consistent statistics is selected (only available for univariate models), the variance-covariance matrix is calculated using a robust estimator, the row of standard errors displays the robust standard errors, and the significance values reflect the robust errors. You can use this matrix file in other procedures that read matrix files.

GLM Multivariate Options

Optional statistics are available from this dialog box. Statistics are calculated using a fixed-effects model.

Display. Select **Descriptive statistics** to produce observed means, standard deviations, and counts for all of the dependent variables in all cells. **Estimates of effect size** gives a partial eta-squared value for each effect and each parameter estimate. The eta-squared statistic describes the proportion of total variability attributable to a factor. Select **Observed power** to obtain the power of the test when the alternative hypothesis is set based on the observed value. Select **Parameter estimates** to produce the parameter estimates, standard errors, *t* tests, confidence intervals, and the observed power for each test. You can display the hypothesis and error **SSCP matrices** and the **Residual SSCP matrix** plus Bartlett's test of sphericity of the residual covariance matrix.

Homogeneity tests produces the Levene test of the homogeneity of variance for each dependent variable across all level combinations of the between-subjects factors, for between-subjects factors only. Also, homogeneity tests include Box's *M* test of the homogeneity of the covariance matrices of the dependent variables across all level combinations of the between-subjects factors. The spread-versus-level and residual plots options are useful for checking assumptions about the data. This item is disabled if there are no factors. Select **Residual plots** to produce an observed-by-predicted-by-standardized residuals plot for each dependent variable. These plots are useful for investigating the assumption of equal variance. Select **Lack of fit test** to check if the relationship between the dependent variable and the independent variables can be adequately described by the model. **General estimable function(s)** allows you to construct custom hypothesis tests based on the general estimable function(s). Rows in any contrast coefficient matrix are linear combinations of the general estimable function(s).

Display

Descriptive statistics

Produces observed means, standard deviations, and counts for all of the dependent variables in all cells.

Estimates of effect size

Gives a partial eta-squared value for each effect and each parameter estimate. The eta-squared statistic describes the proportion of total variability attributable to a factor.

Observed power

Obtains the power of the test when the alternative hypothesis is set based on the observed value.

Parameter estimates

Produces the parameter estimates, standard errors, *t* tests, confidence intervals, and the observed power for each test.

SSCP Matrices

Displays the hypothesis and error SSCP matrices.

Residual SSCP Matrix

Displays the hypothesis and error residual SSCP matrix.

Transformation Matrix

Displays Bartlett's test of sphericity of the residual covariance matrix.

Homogeneity tests

Produces the Levene test of the homogeneity of variance for each dependent variable across all level combinations of the between-subjects factors, for between-subjects factors only. Also, homogeneity tests include Box's *M* test of the homogeneity of the covariance matrices of the dependent variables across all level combinations of the between-subjects factors.

Spread vs. level plot

Useful for checking assumptions about the data for investigating the assumption of equal variance. This item is disabled if there are no factors.

Residual plot

Produces an observed-by-predicted-by-standardized residuals plot for each dependent variable. The plot is useful for investigating the assumption of equal variance.

Lack of fit

Check if the relationship between the dependent variable and the independent variables can be adequately described by the model.

General estimable function(s)

Allows you to construct custom hypothesis tests based on the general estimable function(s). Rows in any contrast coefficient matrix are linear combinations of the general estimable function(s).

Significance level

You might want to adjust the significance level used in post hoc tests and the confidence level used for constructing confidence intervals. The specified value is also used to calculate the observed power for the test. When you specify a significance level, the associated level of the confidence intervals is displayed in the dialog.

GLM Command Additional Features

These features may apply to univariate, multivariate, or repeated measures analysis. The command syntax language also allows you to:

- Specify nested effects in the design (using the DESIGN subcommand).
- Specify tests of effects versus a linear combination of effects or a value (using the TEST subcommand).
- Specify multiple contrasts (using the CONTRAST subcommand).
- Include user-missing values (using the MISSING subcommand).
- Specify EPS criteria (using the CRITERIA subcommand).
- Construct a custom **L** matrix, **M** matrix, or **K** matrix (using the LMATRIX, MMATRIX, or KMATRIX subcommands).
- For deviation or simple contrasts, specify an intermediate reference category (using the CONTRAST subcommand).
- Specify metrics for polynomial contrasts (using the CONTRAST subcommand).
- Specify error terms for post hoc comparisons (using the POSTHOC subcommand).
- Compute estimated marginal means for any factor or factor interaction among the factors in the factor list (using the EMMEANS subcommand).

- Specify names for temporary variables (using the SAVE subcommand).
- Construct a correlation matrix data file (using the OUTFILE subcommand).
- Construct a matrix data file that contains statistics from the between-subjects ANOVA table (using the OUTFILE subcommand).
- Save the design matrix to a new data file (using the OUTFILE subcommand).

See the *Command Syntax Reference* for complete syntax information.

GLM Repeated Measures

The GLM Repeated Measures procedure provides analysis of variance when the same measurement is made several times on each subject or case. If between-subjects factors are specified, they divide the population into groups. Using this general linear model procedure, you can test null hypotheses about the effects of both the between-subjects factors and the within-subjects factors. You can investigate interactions between factors as well as the effects of individual factors. In addition, the effects of constant covariates and covariate interactions with the between-subjects factors can be included.

In a doubly multivariate repeated measures design, the dependent variables represent measurements of more than one variable for the different levels of the within-subjects factors. For example, you could have measured both pulse and respiration at three different times on each subject.

The GLM Repeated Measures procedure provides both univariate and multivariate analyses for the repeated measures data. Both balanced and unbalanced models can be tested. A design is balanced if each cell in the model contains the same number of cases. In a multivariate model, the sums of squares due to the effects in the model and error sums of squares are in matrix form rather than the scalar form found in univariate analysis. These matrices are called SSCP (sums-of-squares and cross-products) matrices. In addition to testing hypotheses, GLM Repeated Measures produces estimates of parameters.

Commonly used *a priori* contrasts are available to perform hypothesis testing on between-subjects factors. Additionally, after an overall *F* test has shown significance, you can use post hoc tests to evaluate differences among specific means. Estimated marginal means give estimates of predicted mean values for the cells in the model, and profile plots (interaction plots) of these means allow you to visualize some of the relationships easily.

Residuals, predicted values, Cook's distance, and leverage values can be saved as new variables in your data file for checking assumptions. Also available are a residual SSCP matrix, which is a square matrix of sums of squares and cross-products of residuals, a residual covariance matrix, which is the residual SSCP matrix divided by the degrees of freedom of the residuals, and the residual correlation matrix, which is the standardized form of the residual covariance matrix.

WLS Weight allows you to specify a variable used to give observations different weights for a weighted least-squares (WLS) analysis, perhaps to compensate for different precision of measurement.

Example. Twelve students are assigned to a high- or low-anxiety group based on their scores on an anxiety-rating test. The anxiety rating is called a between-subjects factor because it divides the subjects into groups. The students are each given four trials on a learning task, and the number of errors for each trial is recorded. The errors for each trial are recorded in separate variables, and a within-subjects factor (trial) is defined with four levels for the four trials. The trial effect is found to be significant, while the trial-by-anxiety interaction is not significant.

Methods. Type I, Type II, Type III, and Type IV sums of squares can be used to evaluate different hypotheses. Type III is the default.

Statistics. Post hoc range tests and multiple comparisons (for between-subjects factors): least significant difference, Bonferroni, Sidak, Scheffé, Ryan-Einot-Gabriel-Welsch multiple *F*, Ryan-Einot-Gabriel-Welsch multiple range, Student-Newman-Keuls, Tukey's honestly significant difference, Tukey's *b*, Duncan, Hochberg's GT2, Gabriel, Waller Duncan *t* test, Dunnett (one-sided and two-sided), Tamhane's T2, Dunnett's T3, Games-Howell, and Dunnett's *C*. Descriptive statistics: observed means, standard deviations, and counts for all of the dependent variables in all cells; the Levene test for homogeneity of variance; Box's *M*; and Mauchly's test of sphericity.

Plots. Spread-versus-level, residual, and profile (interaction).

GLM Repeated Measures Data Considerations

Data. The dependent variables should be quantitative. Between-subjects factors divide the sample into discrete subgroups, such as male and female. These factors are categorical and can have numeric values or string values. Within-subjects factors are defined in the Repeated Measures Define Factor(s) dialog box. Covariates are quantitative variables that are related to the dependent variable. For a repeated measures analysis, these should remain constant at each level of a within-subjects variable.

The data file should contain a set of variables for each group of measurements on the subjects. The set has one variable for each repetition of the measurement within the group. A within-subjects factor is defined for the group with the number of levels equal to the number of repetitions. For example, measurements of weight could be taken on different days. If measurements of the same property were taken on five days, the within-subjects factor could be specified as *day* with five levels.

For multiple within-subjects factors, the number of measurements for each subject is equal to the product of the number of levels of each factor. For example, if measurements were taken at three different times each day for four days, the total number of measurements is 12 for each subject. The within-subjects factors could be specified as *day*(4) and *time*(3).

Assumptions. A repeated measures analysis can be approached in two ways, univariate and multivariate.

The univariate approach (also known as the split-plot or mixed-model approach) considers the dependent variables as responses to the levels of within-subjects factors. The measurements on a subject should be a sample from a multivariate normal distribution, and the variance-covariance matrices are the same across the cells formed by the between-subjects effects. Certain assumptions are made on the variance-covariance matrix of the dependent variables. The validity of the *F* statistic used in the univariate approach can be assured if the variance-covariance matrix is circular in form (Huynh and Mandeville, 1979).

To test this assumption, Mauchly's test of sphericity can be used, which performs a test of sphericity on the variance-covariance matrix of an orthonormalized transformed dependent variable. Mauchly's test is automatically displayed for a repeated measures analysis. For small sample sizes, this test is not very powerful. For large sample sizes, the test may be significant even when the impact of the departure on the results is small. If the significance of the test is large, the hypothesis of sphericity can be assumed. However, if the significance is small and the sphericity assumption appears to be violated, an adjustment to the numerator and denominator degrees of freedom can be made in order to validate the univariate *F* statistic. Three estimates of this adjustment, which is called **epsilon**, are available in the GLM Repeated Measures procedure. Both the numerator and denominator degrees of freedom must be multiplied by epsilon, and the significance of the *F* ratio must be evaluated with the new degrees of freedom.

The multivariate approach considers the measurements on a subject to be a sample from a multivariate normal distribution, and the variance-covariance matrices are the same across the cells formed by the between-subjects effects. To test whether the variance-covariance matrices across the cells are the same, Box's *M* test can be used.

Related procedures. Use the Explore procedure to examine the data before doing an analysis of variance. If there are *not* repeated measurements on each subject, use GLM Univariate or GLM Multivariate. If there are only two measurements for each subject (for example, pre-test and post-test) and there are no between-subjects factors, you can use the Paired-Samples T Test procedure.

Obtaining GLM Repeated Measures

1. From the menus choose:

Analyze > General Linear Model > Repeated Measures...

2. Type a within-subject factor name and its number of levels.

3. Click **Add**.

4. Repeat these steps for each within-subjects factor.

To define measure factors for a doubly multivariate repeated measures design:

5. Type the measure name.

6. Click **Add**.

After defining all of your factors and measures:

7. Click **Define**.

8. Select a dependent variable that corresponds to each combination of within-subjects factors (and optionally, measures) on the list.

To change positions of the variables, use the up and down arrows.

To make changes to the within-subjects factors, you can reopen the Repeated Measures Define Factor(s) dialog box without closing the main dialog box. Optionally, you can specify between-subjects factor(s) and covariates.

GLM Repeated Measures Define Factors

GLM Repeated Measures analyzes groups of related dependent variables that represent different measurements of the same attribute. This dialog box lets you define one or more within-subjects factors for use in GLM Repeated Measures. Note that the order in which you specify within-subjects factors is important. Each factor constitutes a level within the previous factor.

To use Repeated Measures, you must set up your data correctly. You must define within-subjects factors in this dialog box. Notice that these factors are not existing variables in your data but rather factors that you define here.

Example. In a weight-loss study, suppose the weights of several people are measured each week for five weeks. In the data file, each person is a subject or case. The weights for the weeks are recorded in the variables *weight1*, *weight2*, and so on. The gender of each person is recorded in another variable. The weights, measured for each subject repeatedly, can be grouped by defining a within-subjects factor. The factor could be called *week*, defined to have five levels. In the main dialog box, the variables *weight1*, ..., *weight5* are used to assign the five levels of *week*. The variable in the data file that groups males and females (*gender*) can be specified as a between-subjects factor to study the differences between males and females.

Measures. If subjects were tested on more than one measure at each time, define the measures. For example, the pulse and respiration rate could be measured on each subject every day for a week. These measures do not exist as variables in the data file but are defined here. A model with more than one measure is sometimes called a doubly multivariate repeated measures model.

GLM Repeated Measures Model

Specify Model. A full factorial model contains all factor main effects, all covariate main effects, and all factor-by-factor interactions. It does not contain covariate interactions. Select **Custom** to specify only a subset of interactions or to specify factor-by-covariate interactions. You must indicate all of the terms to be included in the model.

Between-Subjects. The between-subjects factors and covariates are listed.

Model. The model depends on the nature of your data. After selecting **Custom**, you can select the within-subjects effects and interactions and the between-subjects effects and interactions that are of interest in your analysis.

Sum of squares. The method of calculating the sums of squares for the between-subjects model. For balanced or unbalanced between-subjects models with no missing cells, the Type III sum-of-squares method is the most commonly used.

Build Terms and Custom Terms

Build terms

Use this choice when you want to include non-nested terms of a certain type (such as main effects) for all combinations of a selected set of factors and covariates.

Build custom terms

Use this choice when you want to include nested terms or when you want to explicitly build any term variable by variable. Building a nested term involves the following steps:

Sum of Squares

For the model, you can choose a type of sums of squares. Type III is the most commonly used and is the default.

Type I. This method is also known as the hierarchical decomposition of the sum-of-squares method. Each term is adjusted for only the term that precedes it in the model. Type I sums of squares are commonly used for:

- A balanced ANOVA model in which any main effects are specified before any first-order interaction effects, any first-order interaction effects are specified before any second-order interaction effects, and so on.
- A polynomial regression model in which any lower-order terms are specified before any higher-order terms.
- A purely nested model in which the first-specified effect is nested within the second-specified effect, the second-specified effect is nested within the third, and so on. (This form of nesting can be specified only by using syntax.)

Type II. This method calculates the sums of squares of an effect in the model adjusted for all other "appropriate" effects. An appropriate effect is one that corresponds to all effects that do not contain the effect being examined. The Type II sum-of-squares method is commonly used for:

- A balanced ANOVA model.
- Any model that has main factor effects only.
- Any regression model.
- A purely nested design. (This form of nesting can be specified by using syntax.)

Type III. The default. This method calculates the sums of squares of an effect in the design as the sums of squares, adjusted for any other effects that do not contain the effect, and orthogonal to any effects (if any) that contain the effect. The Type III sums of squares have one major advantage in that they are invariant with respect to the cell frequencies as long as the general form of estimability remains constant. Hence, this type of sums of squares is often considered useful for an unbalanced model with no missing cells. In a factorial design with no missing cells, this method is equivalent to the Yates' weighted-squares-of-means technique. The Type III sum-of-squares method is commonly used for:

- Any models listed in Type I and Type II.
- Any balanced or unbalanced model with no empty cells.

Type IV. This method is designed for a situation in which there are missing cells. For any effect F in the design, if F is not contained in any other effect, then Type IV = Type III = Type II. When F is contained in other effects, Type IV distributes the contrasts being made among the parameters in F to all higher-level effects equitably. The Type IV sum-of-squares method is commonly used for:

- Any models listed in Type I and Type II.
- Any balanced model or unbalanced model with empty cells.

GLM Repeated Measures Contrasts

Contrasts are used to test for differences among the levels of a between-subjects factor. You can specify a contrast for each between-subjects factor in the model. Contrasts represent linear combinations of the parameters.

Hypothesis testing is based on the null hypothesis $\mathbf{L}\mathbf{B}\mathbf{M}=0$, where \mathbf{L} is the contrast coefficients matrix, \mathbf{B} is the parameter vector, and \mathbf{M} is the average matrix that corresponds to the average transformation for the dependent variable. You can display this transformation matrix by selecting **Transformation matrix** in the Repeated Measures Options dialog box. For example, if there are four dependent variables, a

within-subjects factor of four levels, and polynomial contrasts (the default) are used for within-subjects factors, the **M** matrix will be (0.5 0.5 0.5 0.5)'. When a contrast is specified, an **L** matrix is created such that the columns corresponding to the between-subjects factor match the contrast. The remaining columns are adjusted so that the **L** matrix is estimable.

Available contrasts are deviation, simple, difference, Helmert, repeated, and polynomial. For deviation contrasts and simple contrasts, you can choose whether the reference category is the last or first category.

A contrast other than **None** must be selected for within-subjects factors.

Contrast Types

Deviation. Compares the mean of each level (except a reference category) to the mean of all of the levels (grand mean). The levels of the factor can be in any order.

Simple. Compares the mean of each level to the mean of a specified level. This type of contrast is useful when there is a control group. You can choose the first or last category as the reference.

Difference. Compares the mean of each level (except the first) to the mean of previous levels. (Sometimes called reverse Helmert contrasts.)

Helmert. Compares the mean of each level of the factor (except the last) to the mean of subsequent levels.

Repeated. Compares the mean of each level (except the last) to the mean of the subsequent level.

Polynomial. Compares the linear effect, quadratic effect, cubic effect, and so on. The first degree of freedom contains the linear effect across all categories; the second degree of freedom, the quadratic effect; and so on. These contrasts are often used to estimate polynomial trends.

GLM Repeated Measures Profile Plots

Profile plots (interaction plots) are useful for comparing marginal means in your model. A profile plot is a line plot in which each point indicates the estimated marginal mean of a dependent variable (adjusted for any covariates) at one level of a factor. The levels of a second factor can be used to make separate lines. Each level in a third factor can be used to create a separate plot. All factors are available for plots. Profile plots are created for each dependent variable. Both between-subjects factors and within-subjects factors can be used in profile plots.

A profile plot of one factor shows whether the estimated marginal means are increasing or decreasing across levels. For two or more factors, parallel lines indicate that there is no interaction between factors, which means that you can investigate the levels of only one factor. Nonparallel lines indicate an interaction.

Figure 2. Nonparallel plot (left) and parallel plot (right)

After a plot is specified by selecting factors for the horizontal axis and, optionally, factors for separate lines and separate plots, the plot must be added to the Plots list.

GLM Repeated Measures Post Hoc Comparisons

Post hoc multiple comparison tests. Once you have determined that differences exist among the means, post hoc range tests and pairwise multiple comparisons can determine which means differ. Comparisons

are made on unadjusted values. These tests are not available if there are no between-subjects factors, and the post hoc multiple comparison tests are performed for the average across the levels of the within-subjects factors.

The Bonferroni and Tukey's honestly significant difference tests are commonly used multiple comparison tests. The **Bonferroni test**, based on Student's t statistic, adjusts the observed significance level for the fact that multiple comparisons are made. **Sidak's t test** also adjusts the significance level and provides tighter bounds than the Bonferroni test. **Tukey's honestly significant difference test** uses the Studentized range statistic to make all pairwise comparisons between groups and sets the experimentwise error rate to the error rate for the collection for all pairwise comparisons. When testing a large number of pairs of means, Tukey's honestly significant difference test is more powerful than the Bonferroni test. For a small number of pairs, Bonferroni is more powerful.

Hochberg's GT2 is similar to Tukey's honestly significant difference test, but the Studentized maximum modulus is used. Usually, Tukey's test is more powerful. **Gabriel's pairwise comparisons test** also uses the Studentized maximum modulus and is generally more powerful than Hochberg's GT2 when the cell sizes are unequal. Gabriel's test may become liberal when the cell sizes vary greatly.

Dunnett's pairwise multiple comparison t test compares a set of treatments against a single control mean. The last category is the default control category. Alternatively, you can choose the first category. You can also choose a two-sided or one-sided test. To test that the mean at any level (except the control category) of the factor is not equal to that of the control category, use a two-sided test. To test whether the mean at any level of the factor is smaller than that of the control category, select **< Control**. Likewise, to test whether the mean at any level of the factor is larger than that of the control category, select **> Control**.

Ryan, Einot, Gabriel, and Welsch (R-E-G-W) developed two multiple step-down range tests. Multiple step-down procedures first test whether all means are equal. If all means are not equal, subsets of means are tested for equality. **R-E-G-W F** is based on an F test and **R-E-G-W Q** is based on the Studentized range. These tests are more powerful than Duncan's multiple range test and Student-Newman-Keuls (which are also multiple step-down procedures), but they are not recommended for unequal cell sizes.

When the variances are unequal, use **Tamhane's T2** (conservative pairwise comparisons test based on a t test), **Dunnett's T3** (pairwise comparison test based on the Studentized maximum modulus), **Games-Howell pairwise comparison test** (sometimes liberal), or **Dunnett's C** (pairwise comparison test based on the Studentized range).

Duncan's multiple range test, Student-Newman-Keuls (**S-N-K**), and **Tukey's b** are range tests that rank group means and compute a range value. These tests are not used as frequently as the tests previously discussed.

The **Waller-Duncan t test** uses a Bayesian approach. This range test uses the harmonic mean of the sample size when the sample sizes are unequal.

The significance level of the **Scheffé test** is designed to allow all possible linear combinations of group means to be tested, not just pairwise comparisons available in this feature. The result is that the Scheffé test is often more conservative than other tests, which means that a larger difference between means is required for significance.

The least significant difference (**LSD**) pairwise multiple comparison test is equivalent to multiple individual t tests between all pairs of groups. The disadvantage of this test is that no attempt is made to adjust the observed significance level for multiple comparisons.

Tests displayed. Pairwise comparisons are provided for LSD, Sidak, Bonferroni, Games-Howell, Tamhane's T2 and T3, Dunnett's C, and Dunnett's T3. Homogeneous subsets for range tests are provided for S-N-K, Tukey's b , Duncan, R-E-G-W F , R-E-G-W Q , and Waller. Tukey's honestly significant difference test, Hochberg's GT2, Gabriel's test, and Scheffé's test are both multiple comparison tests and range tests.

GLM Estimated Marginal Means

Select the factors and interactions for which you want estimates of the population marginal means in the cells. These means are adjusted for the covariates, if any.

Compare main effects

Provides uncorrected pairwise comparisons among estimated marginal means for any main effect in the model, for both between- and within-subjects factors. This item is available only if main effects are selected under the Display Means For list.

Compare simple main effects

The setting is enabled whenever the target list contains one or more product or interaction effects (for example, $A \times B$, $A \times B \times C$). The setting supports the specification of comparisons among simple main effects, which are main effects nested within the levels of other factors.

Confidence interval adjustment

Select least significant difference (LSD), Bonferroni, or Sidak adjustment to the confidence intervals and significance. This item is available only when **Compare main effects** and/or **Compare simple main effects** is selected.

Specifying Estimated Marginal Means

1. From the menus choose one of the procedures available under > **Analyze** > **General Linear Model**.
2. In the main dialog, click **EM Means**.

GLM Repeated Measures Save

You can save values predicted by the model, residuals, and related measures as new variables in the Data Editor. Many of these variables can be used for examining assumptions about the data. To save the values for use in another IBM SPSS Statistics session, you must save the current data file.

Predicted Values. The values that the model predicts for each case.

- *Unstandardized.* The value the model predicts for the dependent variable.
- *Standard error.* An estimate of the standard deviation of the average value of the dependent variable for cases that have the same values of the independent variables.

Diagnostics. Measures to identify cases with unusual combinations of values for the independent variables and cases that may have a large impact on the model. Available are Cook's distance and uncentered leverage values.

- *Cook's distance.* A measure of how much the residuals of all cases would change if a particular case were excluded from the calculation of the regression coefficients. A large Cook's D indicates that excluding a case from computation of the regression statistics changes the coefficients substantially.
- *Leverage values.* Uncentered leverage values. The relative influence of each observation on the model's fit.

Residuals. An unstandardized residual is the actual value of the dependent variable minus the value predicted by the model. Standardized, Studentized, and deleted residuals are also available.

- *Unstandardized.* The difference between an observed value and the value predicted by the model.
- *Standardized.* The residual divided by an estimate of its standard deviation. Standardized residuals, which are also known as Pearson residuals, have a mean of 0 and a standard deviation of 1.
- *Studentized.* The residual divided by an estimate of its standard deviation that varies from case to case, depending on the distance of each case's values on the independent variables from the means of the independent variables. Sometimes referred to as internally studentized residuals.
- *Deleted.* The residual for a case when that case is excluded from the calculation of the regression coefficients. It is the difference between the value of the dependent variable and the adjusted predicted value.

Coefficient Statistics. Saves a variance-covariance matrix of the parameter estimates to a dataset or a data file. Also, for each dependent variable, there will be a row of parameter estimates, a row of significance values for the t statistics corresponding to the parameter estimates, and a row of residual degrees of freedom. For a multivariate model, there are similar rows for each dependent variable. You can use this matrix data in other procedures that read matrix files. Datasets are available for subsequent

use in the same session but are not saved as files unless explicitly saved prior to the end of the session. Dataset names must conform to variable naming rules.

GLM Repeated Measures Options

Optional statistics are available from this dialog box. Statistics are calculated using a fixed-effects model.

Display

Descriptive statistics

Produces observed means, standard deviations, and counts for all of the dependent variables in all cells.

Estimates of effect size

Gives a partial eta-squared value for each effect and each parameter estimate. The eta-squared statistic describes the proportion of total variability attributable to a factor.

Observed power

Obtains the power of the test when the alternative hypothesis is set based on the observed value.

Parameter estimates

Produces the parameter estimates, standard errors, *t* tests, confidence intervals, and the observed power for each test.

SSCP matrices

Display the hypothesis and error SSCP matrices.

Residual SSCP matrix

Displays the Residual SSCP matrix.

Transformation Matrix

Displays Bartlett's test of sphericity of the residual covariance matrix.

Homogeneity tests

Produces the Levene test of the homogeneity of variance for each dependent variable across all level combinations of the between-subjects factors, for between-subjects factors only. Also, homogeneity tests include Box's *M* test of the homogeneity of the covariance matrices of the dependent variables across all level combinations of the between-subjects factors.

Spread vs. level plot

Useful for checking assumptions about the data. This option is disabled if there are no factors.

Residual plot

Produces an observed-by-predicted-by-standardized residuals plot for each dependent variable. These plots are useful for investigating the assumption of equal variance. This option is disabled if there are no factors.

Lack of fit

Checks if the relationship between the dependent variable and the independent variables can be adequately described by the model.

General estimable function(s)

Allows you to construct custom hypothesis tests based on the general estimable function(s). Rows in any contrast coefficient matrix are linear combinations of the general estimable function(s).

Significance level

You might want to adjust the significance level used in post hoc tests and the confidence level used for constructing confidence intervals. The specified value is also used to calculate the observed power for the test. When you specify a significance level, the associated level of the confidence intervals is displayed in the dialog.

GLM Command Additional Features

These features may apply to univariate, multivariate, or repeated measures analysis. The command syntax language also allows you to:

- Specify nested effects in the design (using the DESIGN subcommand).

- Specify tests of effects versus a linear combination of effects or a value (using the TEST subcommand).
- Specify multiple contrasts (using the CONTRAST subcommand).
- Include user-missing values (using the MISSING subcommand).
- Specify EPS criteria (using the CRITERIA subcommand).
- Construct a custom **L** matrix, **M** matrix, or **K** matrix (using the LMATRIX, MMATRIX, and KMATRIX subcommands).
- For deviation or simple contrasts, specify an intermediate reference category (using the CONTRAST subcommand).
- Specify metrics for polynomial contrasts (using the CONTRAST subcommand).
- Specify error terms for post hoc comparisons (using the POSTHOC subcommand).
- Compute estimated marginal means for any factor or factor interaction among the factors in the factor list (using the EMMEANS subcommand).
- Specify names for temporary variables (using the SAVE subcommand).
- Construct a correlation matrix data file (using the OUTFILE subcommand).
- Construct a matrix data file that contains statistics from the between-subjects ANOVA table (using the OUTFILE subcommand).
- Save the design matrix to a new data file (using the OUTFILE subcommand).

See the *Command Syntax Reference* for complete syntax information.

Variance Components Analysis

The Variance Components procedure, for mixed-effects models, estimates the contribution of each random effect to the variance of the dependent variable. This procedure is particularly interesting for analysis of mixed models such as split plot, univariate repeated measures, and random block designs. By calculating variance components, you can determine where to focus attention in order to reduce the variance.

Four different methods are available for estimating the variance components: minimum norm quadratic unbiased estimator (MINQUE), analysis of variance (ANOVA), maximum likelihood (ML), and restricted maximum likelihood (REML). Various specifications are available for the different methods.

Default output for all methods includes variance component estimates. If the ML method or the REML method is used, an asymptotic covariance matrix table is also displayed. Other available output includes an ANOVA table and expected mean squares for the ANOVA method and an iteration history for the ML and REML methods. The Variance Components procedure is fully compatible with the GLM Univariate procedure.

WLS Weight allows you to specify a variable used to give observations different weights for a weighted analysis, perhaps to compensate for variations in precision of measurement.

Example. At an agriculture school, weight gains for pigs in six different litters are measured after one month. The litter variable is a random factor with six levels. (The six litters studied are a random sample from a large population of pig litters.) The investigator finds out that the variance in weight gain is attributable to the difference in litters much more than to the difference in pigs within a litter.

Variance Components Data Considerations

Data. The dependent variable is quantitative. Factors are categorical. They can have numeric values or string values of up to eight bytes. At least one of the factors must be random. That is, the levels of the factor must be a random sample of possible levels. Covariates are quantitative variables that are related to the dependent variable.

Assumptions. All methods assume that model parameters of a random effect have zero means and finite constant variances and are mutually uncorrelated. Model parameters from different random effects are also uncorrelated.

The residual term also has a zero mean and finite constant variance. It is uncorrelated with model parameters of any random effect. Residual terms from different observations are assumed to be uncorrelated.

Based on these assumptions, observations from the same level of a random factor are correlated. This fact distinguishes a variance component model from a general linear model.

ANOVA and MINQUE do not require normality assumptions. They are both robust to moderate departures from the normality assumption.

ML and REML require the model parameter and the residual term to be normally distributed.

Related procedures. Use the Explore procedure to examine the data before doing variance components analysis. For hypothesis testing, use GLM Univariate, GLM Multivariate, and GLM Repeated Measures.

Obtaining Variance Components Tables

1. From the menus choose:

Analyze > General Linear Model > Variance Components...

2. Select a dependent variable.

3. Select variables for Fixed Factor(s), Random Factor(s), and Covariate(s), as appropriate for your data. For specifying a weight variable, use WLS Weight.

Variance Components Model

Specify Model. A full factorial model contains all factor main effects, all covariate main effects, and all factor-by-factor interactions. It does not contain covariate interactions. Select **Custom** to specify only a subset of interactions or to specify factor-by-covariate interactions. You must indicate all of the terms to be included in the model.

Factors & Covariates. The factors and covariates are listed.

Model. The model depends on the nature of your data. After selecting **Custom**, you can select the main effects and interactions that are of interest in your analysis. The model must contain a random factor.

For the selected factors and covariates:

Interaction

Creates the highest-level interaction term of all selected variables. This is the default.

Main effects

Creates a main-effects term for each variable selected.

All 2-way

Creates all possible two-way interactions of the selected variables.

All 3-way

Creates all possible three-way interactions of the selected variables.

All 4-way

Creates all possible four-way interactions of the selected variables.

All 5-way

Creates all possible five-way interactions of the selected variables.

Include intercept in model. Usually the intercept is included in the model. If you can assume that the data pass through the origin, you can exclude the intercept.

Build Terms and Custom Terms

Build terms

Use this choice when you want to include non-nested terms of a certain type (such as main effects) for all combinations of a selected set of factors and covariates.

Build custom terms

Use this choice when you want to include nested terms or when you want to explicitly build any term variable by variable. Building a nested term involves the following steps:

Variance Components Options

Method. You can choose one of four methods to estimate the variance components.

- **MINQUE** (minimum norm quadratic unbiased estimator) produces estimates that are invariant with respect to the fixed effects. If the data are normally distributed and the estimates are correct, this method produces the least variance among all unbiased estimators. You can choose a method for random-effect prior weights.
- **ANOVA** (analysis of variance) computes unbiased estimates using either the Type I or Type III sums of squares for each effect. The ANOVA method sometimes produces negative variance estimates, which can indicate an incorrect model, an inappropriate estimation method, or a need for more data.
- **Maximum likelihood** (ML) produces estimates that would be most consistent with the data actually observed, using iterations. These estimates can be biased. This method is asymptotically normal. ML and REML estimates are invariant under translation. This method does not take into account the degrees of freedom used to estimate the fixed effects.
- **Restricted maximum likelihood** (REML) estimates reduce the ANOVA estimates for many (if not all) cases of balanced data. Because this method is adjusted for the fixed effects, it should have smaller standard errors than the ML method. This method takes into account the degrees of freedom used to estimate the fixed effects.

Random Effect Priors. Uniform implies that all random effects and the residual term have an equal impact on the observations. The **Zero** scheme is equivalent to assuming zero random-effect variances. Available only for the MINQUE method.

Sum of Squares. Type I sums of squares are used for the hierarchical model, which is often used in variance component literature. If you choose **Type III**, the default in GLM, the variance estimates can be used in GLM Univariate for hypothesis testing with Type III sums of squares. Available only for the ANOVA method.

Criteria. You can specify the convergence criterion and the maximum number of iterations. Available only for the ML or REML methods.

Display. For the ANOVA method, you can choose to display sums of squares and expected mean squares. If you selected **Maximum likelihood** or **Restricted maximum likelihood**, you can display a history of the iterations.

Sum of Squares (Variance Components)

For the model, you can choose a type of sum of squares. Type III is the most commonly used and is the default.

Type I. This method is also known as the hierarchical decomposition of the sum-of-squares method. Each term is adjusted for only the term that precedes it in the model. The Type I sum-of-squares method is commonly used for:

- A balanced ANOVA model in which any main effects are specified before any first-order interaction effects, any first-order interaction effects are specified before any second-order interaction effects, and so on.
- A polynomial regression model in which any lower-order terms are specified before any higher-order terms.
- A purely nested model in which the first-specified effect is nested within the second-specified effect, the second-specified effect is nested within the third, and so on. (This form of nesting can be specified only by using syntax.)

Type III. The default. This method calculates the sums of squares of an effect in the design as the sums of squares adjusted for any other effects that do not contain it and orthogonal to any effects (if any) that

contain it. The Type III sums of squares have one major advantage in that they are invariant with respect to the cell frequencies as long as the general form of estimability remains constant. Therefore, this type is often considered useful for an unbalanced model with no missing cells. In a factorial design with no missing cells, this method is equivalent to the Yates' weighted-squares-of-means technique. The Type III sum-of-squares method is commonly used for:

- Any models listed in Type I.
- Any balanced or unbalanced models with no empty cells.

Variance Components Save to New File

You can save some results of this procedure to a new IBM SPSS Statistics data file.

Variance component estimates. Saves estimates of the variance components and estimate labels to a data file or dataset. These can be used in calculating more statistics or in further analysis in the GLM procedures. For example, you can use them to calculate confidence intervals or test hypotheses.

Component covariation. Saves a variance-covariance matrix or a correlation matrix to a data file or dataset. Available only if **Maximum likelihood** or **Restricted maximum likelihood** has been specified.

Destination for created values. Allows you to specify a dataset name or external filename for the file containing the variance component estimates and/or the matrix. Datasets are available for subsequent use in the same session but are not saved as files unless explicitly saved prior to the end of the session. Dataset names must conform to variable naming rules.

You can use the MATRIX command to extract the data you need from the data file and then compute confidence intervals or perform tests.

VARCOMP Command Additional Features

The command syntax language also allows you to:

- Specify nested effects in the design (using the DESIGN subcommand).
- Include user-missing values (using the MISSING subcommand).
- Specify EPS criteria (using the CRITERIA subcommand).

See the *Command Syntax Reference* for complete syntax information.

Linear Mixed Models

The Linear Mixed Models procedure expands the general linear model so that the data are permitted to exhibit correlated and nonconstant variability. The mixed linear model, therefore, provides the flexibility of modeling not only the means of the data but their variances and covariances as well.

The Linear Mixed Models procedure is also a flexible tool for fitting other models that can be formulated as mixed linear models. Such models include multilevel models, hierarchical linear models, and random coefficient models.

Example

A grocery store chain is interested in the effects of various coupons on customer spending. Taking a random sample of their regular customers, they follow the spending of each customer for 10 weeks. In each week, a different coupon is mailed to the customers. Linear Mixed Models is used to estimate the effect of different coupons on spending while adjusting for correlation due to repeated observations on each subject over the 10 weeks.

Methods

Maximum likelihood (ML) and restricted maximum likelihood (REML) estimation.

Statistics

Descriptive statistics: sample sizes, means, and standard deviations of the dependent variable and covariates for each distinct level combination of the factors. Factor-level information: sorted values of the levels of each factor and their frequencies. Also, parameter estimates and confidence intervals for

fixed effects and Wald tests and confidence intervals for parameters of covariance matrices. Type I and Type III sums of squares can be used to evaluate different hypotheses. Type III is the default.

Linear Mixed Models data considerations

Data

The dependent variable should be quantitative. Factors should be categorical and can have numeric values or string values. Covariates and the weight variable should be quantitative. Subjects and repeated variables may be of any type.

Assumptions

The dependent variable is assumed to be linearly related to the fixed factors, random factors, and covariates. The fixed effects model the mean of the dependent variable. The random effects model the covariance structure of the dependent variable. Multiple random effects are considered independent of each other, and separate covariance matrices will be computed for each; however, model terms specified on the same random effect can be correlated. The repeated measures model the covariance structure of the residuals. The dependent variable is also assumed to come from a normal distribution.

Related procedures

Use the Explore procedure to examine the data before running an analysis. If you do not suspect there to be correlated or nonconstant variability, you can use the GLM Univariate or GLM Repeated Measures procedure. You can alternatively use the Variance Components Analysis procedure if the random effects have a variance components covariance structure and there are no repeated measures.

Obtaining a Linear Mixed Models Analysis

1. From the menus choose:

Analyze > Mixed Models > Linear...

2. Optionally, select one or more subject variables.

3. Optionally, select one or more repeated variables. If repeated variables are defined, select a **Repeated Covariance Type** from the drop-down list.

4. Optionally, select one or more Kronecker measure variables.

5. Optionally, select a residual covariance structure.

6. Click **Continue**.

7. Select a dependent variable.

8. Select at least one factor or covariate.

9. Click **Fixed** or **Random** and specify at least a fixed-effects or random-effects model.

Optionally, select a weighting variable.

Linear Mixed Models: Subjects and Repeated

This dialog allows you to select variables that define subjects, repeated observations, Kronecker measures, and to choose a covariance structure for the residuals.

Subjects

A subject is an observational unit that can be considered independent of other subjects. For example, the blood pressure readings from a patient in a medical study can be considered independent of the readings from other patients. Defining subjects becomes particularly important when there are repeated measurements per subject and you want to model the correlation between these observations. For example, you might expect that blood pressure readings from a single patient during consecutive visits to the doctor are correlated.

Subjects can also be defined by the factor-level combination of multiple variables; for example, you can specify *Gender* and *Age category* as subject variables to model the belief that *males over the age of 65* are similar to each other but independent of *males under 65* and *females*.

All of the variables specified in the **Subjects** list are used to define subjects for the residual covariance structure. You can use some or all of the variables to define subjects for the random-effects covariance structure.

Repeated

The variables specified in this list are used to identify repeated observations. For example, a single variable *Week* might identify the 10 weeks of observations in a medical study, or *Month* and *Day* might be used together to identify daily observations over the course of a year.

Repeated Covariance Type

This specifies the covariance structure for the residuals. The available structures are as follows:

- Ante-Dependence: First Order
- AR(1)
- Direct product AR1 (UN_AR1)
- Direct product unstructured (UN_UN)
- Direct product compound symmetry (UN_CS)
- AR(1): Heterogeneous
- ARMA(1,1)
- Compound Symmetry
- Compound Symmetry: Correlation Metric
- Compound Symmetry: Heterogeneous
- Diagonal
- Factor Analytic: First Order
- Factor Analytic: First Order, Heterogeneous
- Huynh-Feldt
- Scaled Identity
- Toeplitz
- Toeplitz: Heterogeneous
- Unstructured
- Unstructured: Correlation Metric
- Spatial: Power
- Spatial: Exponential
- Spatial: Gaussian
- Spatial: Linear
- Spatial: Linear-log
- Spatial: Spherical

Kronecker Measures

Select variables that specify the subject structure for Kronecker covariance measurements and determine how the measurement errors are correlated. The field is available only when one of the following **Repeated Covariance Type** is selected:

- Direct product AR1 (UN_AR1)
- Direct product unstructured (UN_UN)
- Direct product compound symmetry (UN_CS)

Spatial Covariance Coordinates

The variables in this list specify the coordinates of the repeated observations when one of the spatial covariance types is selected for the repeated covariance type.

See the topic [“Covariance Structures”](#) on page 96 for more information.

Linear Mixed Models Fixed Effects

Fixed Effects. There is no default model, so you must explicitly specify the fixed effects. Alternatively, you can build nested or non-nested terms.

Include Intercept. The intercept is usually included in the model. If you can assume the data pass through the origin, you can exclude the intercept.

Sum of Squares. The method of calculating the sums of squares. For models with no missing cells, the Type III method is most commonly used.

Build Non-Nested Terms

For the selected factors and covariates:

Factorial. Creates all possible interactions and main effects of the selected variables. This is the default.

Interaction. Creates the highest-level interaction term of all selected variables.

Main Effects. Creates a main-effects term for each variable selected.

All 2-Way. Creates all possible two-way interactions of the selected variables.

All 3-Way. Creates all possible three-way interactions of the selected variables.

All 4-Way. Creates all possible four-way interactions of the selected variables.

All 5-Way. Creates all possible five-way interactions of the selected variables.

Build Nested Terms

You can build nested terms for your model in this procedure. Nested terms are useful for modeling the effect of a factor or covariate whose values do not interact with the levels of another factor. For example, a grocery store chain may follow the spending of their customers at several store locations. Since each customer frequents only one of those locations, the *Customer* effect can be said to be **nested within** the *Store location* effect.

Additionally, you can include interaction effects or add multiple levels of nesting to the nested term.

Limitations. Nested terms have the following restrictions:

- All factors within an interaction must be unique. Thus, if *A* is a factor, then specifying *A*A* is invalid.
- All factors within a nested effect must be unique. Thus, if *A* is a factor, then specifying *A(A)* is invalid.
- No effect can be nested within a covariate. Thus, if *A* is a factor and *X* is a covariate, then specifying *A(X)* is invalid.

Sum of Squares

For the model, you can choose a type of sums of squares. Type III is the most commonly used and is the default.

Type I. This method is also known as the hierarchical decomposition of the sum-of-squares method. Each term is adjusted only for the term that precedes it in the model. Type I sums of squares are commonly used for:

- A balanced ANOVA model in which any main effects are specified before any first-order interaction effects, any first-order interaction effects are specified before any second-order interaction effects, and so on.

- A polynomial regression model in which any lower-order terms are specified before any higher-order terms.
- A purely nested model in which the first-specified effect is nested within the second-specified effect, the second-specified effect is nested within the third, and so on. (This form of nesting can be specified only by using syntax.)

Type III. The default. This method calculates the sums of squares of an effect in the design as the sums of squares adjusted for any other effects that do not contain it and orthogonal to any effects (if any) that contain it. The Type III sums of squares have one major advantage in that they are invariant with respect to the cell frequencies as long as the general form of estimability remains constant. Hence, this type of sums of squares is often considered useful for an unbalanced model with no missing cells. In a factorial design with no missing cells, this method is equivalent to the Yates' weighted-squares-of-means technique. The Type III sum-of-squares method is commonly used for:

- Any models listed in Type I.
- Any balanced or unbalanced models with no empty cells.

Linear Mixed Models Random Effects

Covariance type. This allows you to specify the covariance structure for the random-effects model. A separate covariance matrix is estimated for each random effect. The available structures are as follows:

- Ante-Dependence: First Order
- AR(1)
- AR(1): Heterogeneous
- ARMA(1,1)
- Compound Symmetry
- Compound Symmetry: Correlation Metric
- Compound Symmetry: Heterogeneous
- Diagonal
- Factor Analytic: First Order
- Factor Analytic: First Order, Heterogeneous
- Huynh-Feldt
- Scaled Identity
- Toeplitz
- Toeplitz: Heterogeneous
- Unstructured
- Unstructured: Correlation Metric
- Variance Components

See the topic [“Covariance Structures”](#) on page 96 for more information.

Random Effects. There is no default model, so you must explicitly specify the random effects. Alternatively, you can build nested or non-nested terms. You can also choose to include an intercept term in the random-effects model.

You can specify multiple random-effects models. After building the first model, click **Next** to build the next model. Click **Previous** to scroll back through existing models. Each random-effect model is assumed to be independent of every other random-effect model; that is, separate covariance matrices will be computed for each. Terms specified in the same random-effect model can be correlated.

Subject Groupings. The variables listed are those that you selected as subject variables in the Select Subjects/Repeated Variables dialog box. Choose some or all of these in order to define the subjects for the random-effects model.

Display parameter predictions for this set of random effects. Specifies to display the random-effects parameter estimates.

Linear Mixed Models Estimation

Method

Select the maximum likelihood or restricted maximum likelihood estimation.

Degrees of freedom

Provides options for defining the degrees of freedom for all tests.

Residual method

The residual method has a fixed degrees of freedom for all tests. It is useful if your sample size is sufficiently large, or the data are balanced, or the model uses a simpler covariance type (for example, scaled identity or diagonal).

Satterthwaite approximation

The Satterthwaite method has a field degrees of freedom across tests. It is useful if your sample size is small, or the data are unbalanced, or the model uses a complicated covariance type (for example, unstructured).

Kenward-Roger approximation

The Kenward-Roger method offers a more precise small-sample estimator for the variance-covariance of the fixed effects parameters and the approximate denominator degrees of freedom in t-tests and F-tests. The method introduces a scale factor for the F-statistic and estimates it and the denominator degrees of freedom by using a Taylor series expansion for the estimated random structure within the data.

Note: The Kenward-Roger method is used in the model based covariance (instead of robust covariance). When both the Kenward-Roger method and robust covariance is selected, the Kenward-Roger method is applied to model based covariance, and the following warning is presented: “Since Kenward-Roger method is selected, the robust covariance method is changed to model-based covariance method”.

Iterations

The following options are available:

Maximum iterations

Specify a non-negative integer.

Maximum step-halvings

At each iteration, the step size is reduced by a factor of 0.5 until the log-likelihood increases or maximum step-halving is reached. Specify a positive integer.

Print iteration history for every n step(s)

Displays a table containing the log-likelihood function value and parameter estimates at every n iteration beginning with the 0th iteration (the initial estimates). If you choose to print the iteration history, the last iteration is always printed regardless of the value of n .

Log-Likelihood Convergence

Convergence is assumed if the absolute change or relative change in the log-likelihood function is less than the value specified, which must be non-negative. The criterion is not used if the value specified equals 0.

Parameter Convergence

Convergence is assumed if the maximum absolute change or maximum relative change in the parameter estimates is less than the value specified, which must be non-negative. The criterion is not used if the value specified equals 0.

Hessian Convergence

For the **Absolute** specification, convergence is assumed if a statistic based on the Hessian is less than the value specified. For the **Relative** specification, convergence is assumed if the statistic is less than the product of the value specified and the absolute value of the log-likelihood. The criterion is not used if the value specified equals 0.

Maximum scoring steps

Requests to use the Fisher scoring algorithm up to iteration number n . Specify a non-negative integer.

Singularity tolerance

This value is used as the tolerance in checking singularity. Specify a positive value.

Linear Mixed Models Statistics

Summary Statistics. Produces tables for:

- **Descriptive statistics.** Displays the sample sizes, means, and standard deviations of the dependent variable and covariates (if specified). These statistics are displayed for each distinct level combination of the factors.
- **Case Processing Summary.** Displays the sorted values of the factors, the repeated measure variables, the repeated measure subjects, and the random-effects subjects and their frequencies.

Model Statistics. Produces tables for:

- **Parameter estimates for fixed effects.** Displays the fixed-effects parameter estimates and their approximate standard errors.
- **Tests for covariance parameters.** Displays the asymptotic standard errors and Wald tests for the covariance parameters.
- **Correlations of parameter estimates.** Displays the asymptotic correlation matrix of the fixed-effects parameter estimates.
- **Covariances of parameter estimates.** Displays the asymptotic covariance matrix of the fixed-effects parameter estimates.
- **Covariances of random effects.** Displays the estimated covariance matrix of random effects. This option is available only when at least one random effect is specified. If a subject variable is specified for a random effect, then the common block is displayed.
- **Covariances of residuals.** Displays the estimated residual covariance matrix. This option is available only when a repeated variable has been specified. If a subject variable is specified, the common block is displayed.
- **Contrast coefficient matrix.** This option displays the estimable functions used for testing the fixed effects and the custom hypotheses.

Confidence interval. This value is used whenever a confidence interval is constructed. Specify a value greater than or equal to 0 and less than 100. The default value is 95.

Linear Mixed Models EM Means

Estimated Marginal Means of Fitted Models. This group allows you to request model-predicted estimated marginal means of the dependent variable in the cells and their standard errors for the specified factors. Moreover, you can request that factor levels of main effects be compared.

- **Factor(s) and Factor Interactions.** This list contains factors and factor interactions that have been specified in the Fixed dialog box, plus an OVERALL term. Model terms built from covariates are excluded from this list.
- **Display Means for.** The procedure will compute the estimated marginal means for factors and factor interactions selected to this list. If OVERALL is selected, the estimated marginal means of the dependent variable are displayed, collapsing over all factors. Note that any selected factors or factor interactions remain selected unless an associated variable has been removed from the Factors list in the main dialog box.
- **Compare Main Effects.** This option allows you to request pairwise comparisons of levels of selected main effects. The Confidence Interval Adjustment allows you to apply an adjustment to the confidence intervals and significance values to account for multiple comparisons. The available methods are LSD (no adjustment), Bonferroni, and Sidak. Finally, for each factor, you can select a reference category to which comparisons are made. If no reference category is selected, all pairwise comparisons will be

constructed. The options for the reference category are first, last, or custom (in which case, you enter the value of the reference category).

Linear Mixed Models Save

This dialog box allows you to save various model results to the working file.

Fixed Predicted Values. Saves variables related to the regression means without the effects.

- **Predicted values.** The regression means without the random effects.
- **Standard errors.** The standard errors of the estimates.
- **Degrees of freedom.** The degrees of freedom associated with the estimates.

Predicted Values & Residuals. Saves variables related to the model fitted value.

- **Predicted values.** The model fitted value.
- **Standard errors.** The standard errors of the estimates.
- **Degrees of freedom.** The degrees of freedom associated with the estimates.
- **Residuals.** The data value minus the predicted value.

Linear Mixed Models- Export

This dialog allows you to export the contents of EBLUPS (Empirical Best Linear Unbiased Predictions) output tables to datasets or .sav files. The Export button in the Linear Mixed Models dialog is enabled if at least one random effect is specified via the Random dialog and the box to “Display parameter predictions for this block” is checked.

Export EBLUPS

Select a Destination: **Dataset** or **Data file**

Optionally, supply a name.

If multiple random effects with EBLUPS produced have been specified, uncheck the check box to have each table of results appear in a separate dataset or file.

MIXED Command Additional Features

The command syntax language also allows you to:

- Specify tests of effects versus a linear combination of effects or a value (using the TEST subcommand).
- Include user-missing values (using the MISSING subcommand).
- Compute estimated marginal means for specified values of covariates (using the WITH keyword of the EMMEANS subcommand).
- Compare simple main effects of interactions (using the EMMEANS subcommand).

See the *Command Syntax Reference* for complete syntax information.

Generalized Linear Models

The generalized linear model expands the general linear model so that the dependent variable is linearly related to the factors and covariates via a specified link function. Moreover, the model allows for the dependent variable to have a non-normal distribution. It covers widely used statistical models, such as linear regression for normally distributed responses, logistic models for binary data, loglinear models for count data, complementary log-log models for interval-censored survival data, plus many other statistical models through its very general model formulation.

Examples. A shipping company can use generalized linear models to fit a Poisson regression to damage counts for several types of ships constructed in different time periods, and the resulting model can help determine which ship types are most prone to damage.

A car insurance company can use generalized linear models to fit a gamma regression to damage claims for cars, and the resulting model can help determine the factors that contribute the most to claim size.

Medical researchers can use generalized linear models to fit a complementary log-log regression to interval-censored survival data to predict the time to recurrence for a medical condition.

Generalized Linear Models Data Considerations

Data. The response can be scale, counts, binary, or events-in-trials. Factors are assumed to be categorical. The covariates, scale weight, and offset are assumed to be scale.

Assumptions. Cases are assumed to be independent observations.

To Obtain a Generalized Linear Model

From the menus choose:

Analyze > Generalized Linear Models > Generalized Linear Models...

1. Specify a distribution and link function (see below for details on the various options).
2. On the Response tab, select a dependent variable.
3. On the Predictors tab, select factors and covariates for use in predicting the dependent variable.
4. On the Model tab, specify model effects using the selected factors and covariates.

The Type of Model tab allows you to specify the distribution and link function for your model, providing short cuts for several common models that are categorized by response type.

Model Types

Scale Response. The following options are available:

- **Linear.** Specifies Normal as the distribution and Identity as the link function.
- **Gamma with log link.** Specifies Gamma as the distribution and Log as the link function.

Ordinal Response. The following options are available:

- **Ordinal logistic.** Specifies Multinomial (ordinal) as the distribution and Cumulative logit as the link function.
- **Ordinal probit.** Specifies Multinomial (ordinal) as the distribution and Cumulative probit as the link function.

Counts. The following options are available:

- **Poisson loglinear.** Specifies Poisson as the distribution and Log as the link function.
- **Negative binomial with log link.** Specifies Negative binomial (with a value of 1 for the ancillary parameter) as the distribution and Log as the link function. To have the procedure estimate the value of the ancillary parameter, specify a custom model with Negative binomial distribution and select **Estimate value** in the Parameter group.

Binary Response or Events/Trials Data. The following options are available:

- **Binary logistic.** Specifies Binomial as the distribution and Logit as the link function.
- **Binary probit.** Specifies Binomial as the distribution and Probit as the link function.
- **Interval censored survival.** Specifies Binomial as the distribution and Complementary log-log as the link function.

Mixture. The following options are available:

- **Tweedie with log link.** Specifies Tweedie as the distribution and Log as the link function.
- **Tweedie with identity link.** Specifies Tweedie as the distribution and Identity as the link function.

Custom. Specify your own combination of distribution and link function.

Distribution

This selection specifies the distribution of the dependent variable. The ability to specify a non-normal distribution and non-identity link function is the essential improvement of the generalized linear model over the general linear model. There are many possible distribution-link function combinations, and several may be appropriate for any given dataset, so your choice can be guided by a priori theoretical considerations or which combination seems to fit best.

- **Binomial.** This distribution is appropriate only for variables that represent a binary response or number of events.
- **Gamma.** This distribution is appropriate for variables with positive scale values that are skewed toward larger positive values. If a data value is less than or equal to 0 or is missing, then the corresponding case is not used in the analysis.
- **Inverse Gaussian.** This distribution is appropriate for variables with positive scale values that are skewed toward larger positive values. If a data value is less than or equal to 0 or is missing, then the corresponding case is not used in the analysis.
- **Negative binomial.** This distribution can be thought of as the number of trials required to observe k successes and is appropriate for variables with non-negative integer values. If a data value is non-integer, less than 0, or missing, then the corresponding case is not used in the analysis. The value of the negative binomial distribution's ancillary parameter can be any number greater than or equal to 0; you can set it to a fixed value or allow it to be estimated by the procedure. When the ancillary parameter is set to 0, using this distribution is equivalent to using the Poisson distribution.
- **Normal.** This is appropriate for scale variables whose values take a symmetric, bell-shaped distribution about a central (mean) value. The dependent variable must be numeric.
- **Poisson.** This distribution can be thought of as the number of occurrences of an event of interest in a fixed period of time and is appropriate for variables with non-negative integer values. If a data value is non-integer, less than 0, or missing, then the corresponding case is not used in the analysis.
- **Tweedie.** This distribution is appropriate for variables that can be represented by Poisson mixtures of gamma distributions; the distribution is "mixed" in the sense that it combines properties of continuous (takes non-negative real values) and discrete distributions (positive probability mass at a single value, 0). The dependent variable must be numeric, with data values greater than or equal to zero. If a data value is less than zero or missing, then the corresponding case is not used in the analysis. The fixed value of the Tweedie distribution's parameter can be any number greater than one and less than two.
- **Multinomial.** This distribution is appropriate for variables that represent an ordinal response. The dependent variable can be numeric or string, and it must have at least two distinct valid data values.

Link Functions

The link function is a transformation of the dependent variable that allows estimation of the model. The following functions are available:

- **Identity.** $f(x)=x$. The dependent variable is not transformed. This link can be used with any distribution.
- **Complementary log-log.** $f(x)=\log(-\log(1-x))$. This is appropriate only with the binomial distribution.
- **Cumulative Cauchit.** $f(x) = \tan(\pi (x - 0.5))$, applied to the cumulative probability of each category of the response. This is appropriate only with the multinomial distribution.
- **Cumulative complementary log-log.** $f(x)=\ln(-\ln(1-x))$, applied to the cumulative probability of each category of the response. This is appropriate only with the multinomial distribution.
- **Cumulative logit.** $f(x)=\ln(x / (1-x))$, applied to the cumulative probability of each category of the response. This is appropriate only with the multinomial distribution.
- **Cumulative negative log-log.** $f(x)=-\ln(-\ln(x))$, applied to the cumulative probability of each category of the response. This is appropriate only with the multinomial distribution.
- **Cumulative probit.** $f(x)=\Phi^{-1}(x)$, applied to the cumulative probability of each category of the response, where Φ^{-1} is the inverse standard normal cumulative distribution function. This is appropriate only with the multinomial distribution.
- **Log.** $f(x)=\log(x)$. This link can be used with any distribution.
- **Log complement.** $f(x)=\log(1-x)$. This is appropriate only with the binomial distribution.

- **Logit.** $f(x)=\log(x / (1-x))$. This is appropriate only with the binomial distribution.
- **Negative binomial.** $f(x)=\log(x / (x+k^{-1}))$, where k is the ancillary parameter of the negative binomial distribution. This is appropriate only with the negative binomial distribution.
- **Negative log-log.** $f(x)=-\log(-\log(x))$. This is appropriate only with the binomial distribution.
- **Odds power.** $f(x)=[(x/(1-x))^{\alpha}-1]/\alpha$, if $\alpha \neq 0$. $f(x)=\log(x)$, if $\alpha=0$. α is the required number specification and must be a real number. This is appropriate only with the binomial distribution.
- **Probit.** $f(x)=\Phi^{-1}(x)$, where Φ^{-1} is the inverse standard normal cumulative distribution function. This is appropriate only with the binomial distribution.
- **Power.** $f(x)=x^{\alpha}$, if $\alpha \neq 0$. $f(x)=\log(x)$, if $\alpha=0$. α is the required number specification and must be a real number. This link can be used with any distribution.

Generalized Linear Models Response

In many cases, you can simply specify a dependent variable; however, variables that take only two values and responses that record events in trials require extra attention.

- **Binary response.** When the dependent variable takes only two values, you can specify the reference category for parameter estimation. A binary response variable can be string or numeric.
- **Number of events occurring in a set of trials.** When the response is a number of events occurring in a set of trials, the dependent variable contains the number of events and you can select an additional variable containing the number of trials. Alternatively, if the number of trials is the same across all subjects, then trials may be specified using a fixed value. The number of trials should be greater than or equal to the number of events for each case. Events should be non-negative integers, and trials should be positive integers.

For ordinal multinomial models, you can specify the category order of the response: ascending, descending, or data (data order means that the first value encountered in the data defines the first category, the last value encountered defines the last category).

Scale Weight. The scale parameter is an estimated model parameter related to the variance of the response. The scale weights are "known" values that can vary from observation to observation. If the scale weight variable is specified, the scale parameter, which is related to the variance of the response, is divided by it for each observation. Cases with scale weight values that are less than or equal to 0 or are missing are not used in the analysis.

Generalized Linear Models Reference Category

For binary response, you can choose the reference category for the dependent variable. This can affect certain output, such as parameter estimates and saved values, but it should not change the model fit. For example, if your binary response takes values 0 and 1:

- By default, the procedure makes the last (highest-valued) category, or 1, the reference category. In this situation, model-saved probabilities estimate the chance that a given case takes the value 0, and parameter estimates should be interpreted as relating to the likelihood of category 0.
- If you specify the first (lowest-valued) category, or 0, as the reference category, then model-saved probabilities estimate the chance that a given case takes the value 1.
- If you specify the custom category and your variable has defined labels, you can set the reference category by choosing a value from the list. This can be convenient when, in the middle of specifying a model, you don't remember exactly how a particular variable was coded.

Generalized Linear Models Predictors

The Predictors tab allows you to specify the factors and covariates used to build model effects and to specify an optional offset.

Factors. Factors are categorical predictors; they can be numeric or string.

Covariates. Covariates are scale predictors; they must be numeric.

Note: When the response is binomial with binary format, the procedure computes deviance and chi-square goodness-of-fit statistics by subpopulations that are based on the cross-classification of observed values of the selected factors and covariates. You should keep the same set of predictors across multiple runs of the procedure to ensure a consistent number of subpopulations.

Offset. The offset term is a "structural" predictor. Its coefficient is not estimated by the model but is assumed to have the value 1; thus, the values of the offset are simply added to the linear predictor of the target. This is especially useful in Poisson regression models, where each case may have different levels of exposure to the event of interest.

For example, when modeling accident rates for individual drivers, there is an important difference between a driver who has been at fault in one accident in three years of experience and a driver who has been at fault in one accident in 25 years! The number of accidents can be modeled as a Poisson or negative binomial response with a log link if the natural log of the experience of the driver is included as an offset term.

Other combinations of distribution and link types would require other transformations of the offset variable.

Generalized Linear Models Options

These options are applied to all factors specified on the Predictors tab.

User-Missing Values. Factors must have valid values for a case to be included in the analysis. These controls allow you to decide whether user-missing values are treated as valid among factor variables.

Category Order. This is relevant for determining a factor's last level, which may be associated with a redundant parameter in the estimation algorithm. Changing the category order can change the values of factor-level effects, since these parameter estimates are calculated relative to the "last" level. Factors can be sorted in ascending order from lowest to highest value, in descending order from highest to lowest value, or in "data order." This means that the first value encountered in the data defines the first category, and the last unique value encountered defines the last category.

Generalized Linear Models Model

Specify Model Effects

The default model is intercept-only, so you must explicitly specify other model effects. Alternatively, you can build nested or non-nested terms.

Non-nested terms

For the selected factors and covariates:

Main effects

Creates a main-effects term for each variable selected.

Interaction

Creates the highest-level interaction term for all selected variables.

Factorial

Creates all possible interactions and main effects of the selected variables.

All 2-way

Creates all possible two-way interactions of the selected variables.

All 3-way

Creates all possible three-way interactions of the selected variables.

All 4-way

Creates all possible four-way interactions of the selected variables.

All 5-way

Creates all possible five-way interactions of the selected variables.

Nested terms

You can build nested terms for your model in this procedure. Nested terms are useful for modeling the effect of a factor or covariate whose values do not interact with the levels of another factor. For example, a grocery store chain may follow the spending habits of its customers at several store locations. Since each customer frequents only one of these locations, the *Customer* effect can be said to be **nested within** the *Store location* effect.

Additionally, you can include interaction effects, such as polynomial terms involving the same covariate, or add multiple levels of nesting to the nested term.

Limitations: Nested terms have the following restrictions:

- All factors within an interaction must be unique. Thus, if *A* is a factor, then specifying *A*A* is invalid.
- All factors within a nested effect must be unique. Thus, if *A* is a factor, then specifying *A(A)* is invalid.
- No effect can be nested within a covariate. Thus, if *A* is a factor and *X* is a covariate, then specifying *A(X)* is invalid.

Generalized Linear Models Estimation

Parameter Estimation. The controls in this group allow you to specify estimation methods and to provide initial values for the parameter estimates.

- **Method.** You can select a parameter estimation method. Choose between Newton-Raphson, Fisher scoring, or a hybrid method in which Fisher scoring iterations are performed before switching to the Newton-Raphson method. If convergence is achieved during the Fisher scoring phase of the hybrid method before the maximum number of Fisher iterations is reached, the algorithm continues with the Newton-Raphson method.
- **Scale parameter method.** You can select the scale parameter estimation method. Maximum-likelihood jointly estimates the scale parameter with the model effects; note that this option is not valid if the response has a negative binomial, Poisson, binomial, or multinomial distribution. The deviance and Pearson chi-square options estimate the scale parameter from the value of those statistics. Alternatively, you can specify a fixed value for the scale parameter.
- **Initial values.** The procedure will automatically compute initial values for parameters. Alternatively, you can specify [initial values](#) for the parameter estimates.

Covariance matrix. The model-based estimator is the negative of the generalized inverse of the Hessian matrix. The robust (also called the Huber/White/sandwich) estimator is a "corrected" model-based estimator that provides a consistent estimate of the covariance, even when the specification of the variance and link functions is incorrect.

Iterations. The following options are available:

- **Maximum iterations.** The maximum number of iterations the algorithm will execute. Specify a non-negative integer.
- **Maximum step-halving.** At each iteration, the step size is reduced by a factor of 0.5 until the log-likelihood increases or maximum step-halving is reached. Specify a positive integer.
- **Check for separation of data points.** When selected, the algorithm performs tests to ensure that the parameter estimates have unique values. Separation occurs when the procedure can produce a model that correctly classifies every case. This option is available for multinomial responses and binomial responses with binary format.

Convergence Criteria. The following options are available

- **Parameter convergence.** When selected, the algorithm stops after an iteration in which the absolute or relative change in the parameter estimates is less than the value specified, which must be positive.
- **Log-likelihood convergence.** When selected, the algorithm stops after an iteration in which the absolute or relative change in the log-likelihood function is less than the value specified, which must be positive.

- **Hessian convergence.** For the Absolute specification, convergence is assumed if a statistic based on the Hessian convergence is less than the positive value specified. For the Relative specification, convergence is assumed if the statistic is less than the product of the positive value specified and the absolute value of the log-likelihood.

Singularity tolerance. Singular (or non-invertible) matrices have linearly dependent columns, which can cause serious problems for the estimation algorithm. Even near-singular matrices can lead to poor results, so the procedure will treat a matrix whose determinant is less than the tolerance as singular. Specify a positive value.

Generalized Linear Models Initial Values

If initial values are specified, they must be supplied for all parameters (including redundant parameters) in the model. In the dataset, the ordering of variables from left to right must be: *RowType_*, *VarName_*, *P1*, *P2*, ..., where *RowType_* and *VarName_* are string variables and *P1*, *P2*, ... are numeric variables corresponding to an ordered list of the parameters.

- Initial values are supplied on a record with value *EST* for variable *RowType_*; the actual initial values are given under variables *P1*, *P2*, The procedure ignores all records for which *RowType_* has a value other than *EST* as well as any records beyond the first occurrence of *RowType_* equal to *EST*.
- The intercept, if included in the model, or threshold parameters, if the response has a multinomial distribution, must be the first initial values listed.
- The scale parameter and, if the response has a negative binomial distribution, the negative binomial parameter, must be the last initial values specified.
- If Split File is in effect, then the variables must begin with the split-file variable or variables in the order specified when creating the Split File, followed by *RowType_*, *VarName_*, *P1*, *P2*, ... as above. Splits must occur in the specified dataset in the same order as in the original dataset.

Note: The variable names *P1*, *P2*, ... are not required; the procedure will accept any valid variable names for the parameters because the mapping of variables to parameters is based on variable position, not variable name. Any variables beyond the last parameter are ignored.

The file structure for the initial values is the same as that used when exporting the model as data; thus, you can use the final values from one run of the procedure as input in a subsequent run.

Generalized Linear Models Statistics

Model Effects. The following options are available:

- **Analysis type.** Specify the type of analysis to produce. Type I analysis is generally appropriate when you have a priori reasons for ordering predictors in the model, while Type III is more generally applicable. Wald or likelihood-ratio statistics are computed based upon the selection in the Chi-Square Statistics group.
- **Confidence intervals.** Specify a confidence level greater than 50 and less than 100. Wald intervals are based on the assumption that parameters have an asymptotic normal distribution; profile likelihood intervals are more accurate but can be computationally expensive. The tolerance level for profile likelihood intervals is the criteria used to stop the iterative algorithm used to compute the intervals.
- **Log-likelihood function.** This controls the display format of the log-likelihood function. The full function includes an additional term that is constant with respect to the parameter estimates; it has no effect on parameter estimation and is left out of the display in some software products.

Print. The following output is available:

- **Case processing summary.** Displays the number and percentage of cases included and excluded from the analysis and the Correlated Data Summary table.
- **Descriptive statistics.** Displays descriptive statistics and summary information about the dependent variable, covariates, and factors.
- **Model information.** Displays the dataset name, dependent variable or events and trials variables, offset variable, scale weight variable, probability distribution, and link function.

- **Goodness of fit statistics.** Displays deviance and scaled deviance, Pearson chi-square and scaled Pearson chi-square, log-likelihood, Akaike's information criterion (AIC), finite sample corrected AIC (AICC), Bayesian information criterion (BIC), and consistent AIC (CAIC).
- **Model summary statistics.** Displays model fit tests, including likelihood-ratio statistics for the model fit omnibus test and statistics for the Type I or III contrasts for each effect.
- **Parameter estimates.** Displays parameter estimates and corresponding test statistics and confidence intervals. You can optionally display exponentiated parameter estimates in addition to the raw parameter estimates.
- **Covariance matrix for parameter estimates.** Displays the estimated parameter covariance matrix.
- **Correlation matrix for parameter estimates.** Displays the estimated parameter correlation matrix.
- **Contrast coefficient (L) matrices.** Displays contrast coefficients for the default effects and for the estimated marginal means, if requested on the EM Means tab.
- **General estimable functions.** Displays the matrices for generating the contrast coefficient (L) matrices.
- **Iteration history.** Displays the iteration history for the parameter estimates and log-likelihood and prints the last evaluation of the gradient vector and the Hessian matrix. The iteration history table displays parameter estimates for every n^{th} iterations beginning with the 0^{th} iteration (the initial estimates), where n is the value of the print interval. If the iteration history is requested, then the last iteration is always displayed regardless of n .
- **Lagrange multiplier test of scale parameter or negative binomial ancillary parameter.** Displays Lagrange multiplier test statistics for assessing the validity of a scale parameter that is computed using the deviance or Pearson chi-square, or set at a fixed number, for the normal, gamma, inverse Gaussian, and Tweedie distributions. For the negative binomial distribution, this tests the fixed ancillary parameter.

Generalized Linear Models EM Means

This tab allows you to display the estimated marginal means for levels of factors and factor interactions. You can also request that the overall estimated mean be displayed. Estimated marginal means are not available for ordinal multinomial models.

Factors and Interactions. This list contains factors specified on the Predictors tab and factor interactions specified on the Model tab. Covariates are excluded from this list. Terms can be selected directly from this list or combined into an interaction term using the **By *** button.

Display Means For. Estimated means are computed for the selected factors and factor interactions. The contrast determines how hypothesis tests are set up to compare the estimated means. The simple contrast requires a reference category or factor level against which the others are compared.

- **Pairwise.** Pairwise comparisons are computed for all-level combinations of the specified or implied factors. This is the only available contrast for factor interactions.
- *Simple.* Compares the mean of each level to the mean of a specified level. This type of contrast is useful when there is a control group.
- **Deviation.** Each level of the factor is compared to the grand mean. Deviation contrasts are not orthogonal.
- *Difference.* Compares the mean of each level (except the first) to the mean of previous levels. They are sometimes called reverse Helmert contrasts.
- *Helmert.* Compares the mean of each level of the factor (except the last) to the mean of subsequent levels.
- *Repeated.* Compares the mean of each level (except the last) to the mean of the subsequent level.
- *Polynomial.* Compares the linear effect, quadratic effect, cubic effect, and so on. The first degree of freedom contains the linear effect across all categories; the second degree of freedom, the quadratic effect; and so on. These contrasts are often used to estimate polynomial trends.

Scale. Estimated marginal means can be computed for the response, based on the original scale of the dependent variable, or for the linear predictor, based on the dependent variable as transformed by the link function.

Adjustment for Multiple Comparisons. When performing hypothesis tests with multiple contrasts, the overall significance level can be adjusted from the significance levels for the included contrasts. This group allows you to choose the adjustment method.

- **Least significant difference.** This method does not control the overall probability of rejecting the hypotheses that some linear contrasts are different from the null hypothesis values.
- *Bonferroni.* This method adjusts the observed significance level for the fact that multiple contrasts are being tested.
- *Sequential Bonferroni.* This is a sequentially step-down rejective Bonferroni procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.
- *Sidak.* This method provides tighter bounds than the Bonferroni approach.
- *Sequential Sidak.* This is a sequentially step-down rejective Sidak procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.

Generalized Linear Models Save

Checked items are saved with the specified name; you can choose to overwrite existing variables with the same name as the new variables or avoid name conflicts by appendix suffixes to make the new variable names unique.

Predicted value of mean of response

Saves model-predicted values for each case in the original response metric. When the response distribution is binomial and the dependent variable is binary, the procedure saves predicted probabilities. When the response distribution is multinomial, the item label becomes **Cumulative predicted probability**, and the procedure saves the cumulative predicted probability for each category of the response, except the last, up to the number of specified categories to save.

Lower bound of confidence interval for mean of response

Saves the lower bound of the confidence interval for the mean of the response. When the response distribution is multinomial, the item label becomes **Lower bound of confidence interval for cumulative predicted probability**, and the procedure saves the lower bound for each category of the response, except the last, up to the number of specified categories to save.

Upper bound of confidence interval for mean of response

Saves the upper bound of the confidence interval for the mean of the response. When the response distribution is multinomial, the item label becomes **Upper bound of confidence interval for cumulative predicted probability**, and the procedure saves the upper bound for each category of the response, except the last, up to the number of specified categories to save.

Predicted category

For models with binomial distribution and binary dependent variable, or multinomial distribution, this saves the predicted response category for each case. This option is not available for other response distributions.

Predicted value of linear predictor

Saves model-predicted values for each case in the metric of the linear predictor (transformed response via the specified link function). When the response distribution is multinomial, the procedure saves the predicted value for each category of the response, except the last, up to the number of specified categories to save.

Estimated standard error of predicted value of linear predictor

When the response distribution is multinomial, the procedure saves the estimated standard error for each category of the response, except the last, up to the number of specified categories to save.

The following items are not available when the response distribution is multinomial.

Cook's distance

A measure of how much the residuals of all cases would change if a particular case were excluded from the calculation of the regression coefficients. A large Cook's D indicates that excluding a case from computation of the regression statistics changes the coefficients substantially.

Leverage value

Measures the influence of a point on the fit of the regression. The centered leverage ranges from 0 (no influence on the fit) to $(N-1)/N$.

Residual

The difference between an observed value and the value predicted by the model.

Pearson residual

The square root of the contribution of a case to the Pearson chi-square statistic, with the sign of the raw residual.

Standardized Pearson residual

The Pearson residual multiplied by the square root of the inverse of the product of the scale parameter and $1 - \text{leverage}$ for the case.

Deviance residual

The square root of the contribution of a case to the Deviance statistic, with the sign of the raw residual.

Standardized deviance residual

The Deviance residual multiplied by the square root of the inverse of the product of the scale parameter and $1 - \text{leverage}$ for the case.

Likelihood residual

The square root of a weighted average (based on the leverage of the case) of the squares of the standardized Pearson and standardized Deviance residuals, with the sign of the raw residual.

Generalized Linear Models Export

Export model as data. Writes a dataset in IBM SPSS Statistics format containing the parameter correlation or covariance matrix with parameter estimates, standard errors, significance values, and degrees of freedom. The order of variables in the matrix file is as follows.

- **Split variables.** If used, any variables defining splits.
- **RowType_.** Takes values (and value labels) *COV* (covariances), *CORR* (correlations), *EST* (parameter estimates), *SE* (standard errors), *SIG* (significance levels), and *DF* (sampling design degrees of freedom). There is a separate case with row type *COV* (or *CORR*) for each model parameter, plus a separate case for each of the other row types.
- **VarName_.** Takes values *P1*, *P2*, ..., corresponding to an ordered list of all estimated model parameters (except the scale or negative binomial parameters), for row types *COV* or *CORR*, with value labels corresponding to the parameter strings shown in the Parameter estimates table. The cells are blank for other row types.
- **P1, P2, ...** These variables correspond to an ordered list of all model parameters (including the scale and negative binomial parameters, as appropriate), with variable labels corresponding to the parameter strings shown in the Parameter estimates table, and take values according to the row type.

For redundant parameters, all covariances are set to zero, correlations are set to the system-missing value; all parameter estimates are set at zero; and all standard errors, significance levels, and residual degrees of freedom are set to the system-missing value.

For the scale parameter, covariances, correlations, significance level and degrees of freedom are set to the system-missing value. If the scale parameter is estimated via maximum likelihood, the standard error is given; otherwise it is set to the system-missing value.

For the negative binomial parameter, covariances, correlations, significance level and degrees of freedom are set to the system-missing value. If the negative binomial parameter is estimated via maximum likelihood, the standard error is given; otherwise it is set to the system-missing value.

If there are splits, then the list of parameters must be accumulated across all splits. In a given split, some parameters may be irrelevant; this is not the same as redundant. For irrelevant parameters, all covariances or correlations, parameter estimates, standard errors, significance levels, and degrees of freedom are set to the system-missing value.

You can use this matrix file as the initial values for further model estimation; note that this file is not immediately usable for further analyses in other procedures that read a matrix file unless those procedures accept all the row types exported here. Even then, you should take care that all parameters in this matrix file have the same meaning for the procedure reading the file.

Export model as XML. Saves the parameter estimates and the parameter covariance matrix, if selected, in XML (PMML) format. You can use this model file to apply the model information to other data files for scoring purposes.

GENLIN Command Additional Features

The command syntax language also allows you to:

- Specify initial values for parameter estimates as a list of numbers (using the CRITERIA subcommand).
- Fix covariates at values other than their means when computing estimated marginal means (using the EMMEANS subcommand).
- Specify custom polynomial contrasts for estimated marginal means (using the EMMEANS subcommand).
- Specify a subset of the factors for which estimated marginal means are displayed to be compared using the specified contrast type (using the TABLES and COMPARE keywords of the EMMEANS subcommand).

See the *Command Syntax Reference* for complete syntax information.

Generalized Estimating Equations

The Generalized Estimating Equations procedure extends the generalized linear model to allow for analysis of repeated measurements or other correlated observations, such as clustered data.

Example. Public health officials can use generalized estimating equations to fit a repeated measures logistic regression to study effects of air pollution on children.

Generalized Estimating Equations Data Considerations

Data. The response can be scale, counts, binary, or events-in-trials. Factors are assumed to be categorical. The covariates, scale weight, and offset are assumed to be scale. Variables used to define subjects or within-subject repeated measurements cannot be used to define the response but can serve other roles in the model.

Assumptions. Cases are assumed to be dependent within subjects and independent between subjects. The correlation matrix that represents the within-subject dependencies is estimated as part of the model.

Obtaining Generalized Estimating Equations

From the menus choose:

Analyze > Generalized Linear Models > Generalized Estimating Equations...

1. Select one or more subject variables (see below for further options).

The combination of values of the specified variables should uniquely define **subjects** within the dataset. For example, a single *Patient ID* variable should be sufficient to define subjects in a single hospital, but the combination of *Hospital ID* and *Patient ID* may be necessary if patient identification numbers are not unique across hospitals. In a repeated measures setting, multiple observations are recorded for each subject, so each subject may occupy multiple cases in the dataset.

2. On the Type of Model tab, specify a distribution and link function.
3. On the Response tab, select a dependent variable.
4. On the Predictors tab, select factors and covariates for use in predicting the dependent variable.
5. On the Model tab, specify model effects using the selected factors and covariates.

Optionally, on the Repeated tab you can specify:

Within-subject variables. The combination of values of the within-subject variables defines the ordering of measurements within subjects; thus, the combination of within-subject and subject variables uniquely defines each measurement. For example, the combination of *Period*, *Hospital ID*, and *Patient ID* defines, for each case, a particular office visit for a particular patient within a particular hospital.

If the dataset is already sorted so that each subject's repeated measurements occur in a contiguous block of cases and in the proper order, it is not strictly necessary to specify a within-subjects variable, and you can deselect **Sort cases by subject and within-subject variables** and save the processing time required to perform the (temporary) sort. Generally, it's a good idea to make use of within-subject variables to ensure proper ordering of measurements.

Subject and within-subject variables cannot be used to define the response, but they can perform other functions in the model. For example, *Hospital ID* could be used as a factor in the model.

Covariance Matrix. The model-based estimator is the negative of the generalized inverse of the Hessian matrix. The robust estimator (also called the Huber/White/sandwich estimator) is a "corrected" model-based estimator that provides a consistent estimate of the covariance, even when the working correlation matrix is misspecified. This specification applies to the parameters in the linear model part of the generalized estimating equations, while the specification on the Estimation tab applies only to the initial generalized linear model.

Working Correlation Matrix. This correlation matrix represents the within-subject dependencies. Its size is determined by the number of measurements and thus the combination of values of within-subject variables. You can specify one of the following structures:

- **Independent.** Repeated measurements are uncorrelated.
- **AR(1).** Repeated measurements have a first-order autoregressive relationship. The correlation between any two elements is equal to ρ for adjacent elements, ρ^2 for elements that are separated by a third, and so on. is constrained so that $-1 < \rho < 1$.
- **Exchangeable.** This structure has homogenous correlations between elements. It is also known as a compound symmetry structure.
- **M-dependent.** Consecutive measurements have a common correlation coefficient, pairs of measurements separated by a third have a common correlation coefficient, and so on, through pairs of measurements separated by $m-1$ other measurements. For example, if you give students standardized tests each year from 3rd through 7th grade. This structure assumes that the 3rd and 4th, 4th and 5th, 5th and 6th, and 6th and 7th grade scores will have the same correlation; 3rd and 5th, 4th and 6th, and 5th and 7th will have the same correlation; 3rd and 6th and 4th and 7th will have the same correlation. Measurements with separation greater than m are assumed to be uncorrelated. When choosing this structure, specify a value of m less than the order of the working correlation matrix.
- **Unstructured.** This is a completely general correlation matrix.

By default, the procedure will adjust the correlation estimates by the number of nonredundant parameters. Removing this adjustment may be desirable if you want the estimates to be invariant to subject-level replication changes in the data.

- **Maximum iterations.** The maximum number of iterations the generalized estimating equations algorithm will execute. Specify a non-negative integer. This specification applies to the parameters in the linear model part of the generalized estimating equations, while the specification on the Estimation tab applies only to the initial generalized linear model.
- **Update matrix.** Elements in the working correlation matrix are estimated based on the parameter estimates, which are updated in each iteration of the algorithm. If the working correlation matrix is not updated at all, the initial working correlation matrix is used throughout the estimation process. If the matrix is updated, you can specify the iteration interval at which to update working correlation matrix elements. Specifying a value greater than 1 may reduce processing time.

Convergence criteria. These specifications apply to the parameters in the linear model part of the generalized estimating equations, while the specification on the Estimation tab applies only to the initial generalized linear model.

- **Parameter convergence.** When selected, the algorithm stops after an iteration in which the absolute or relative change in the parameter estimates is less than the value specified, which must be positive.
- **Hessian convergence.** Convergence is assumed if a statistic based on the Hessian is less than the value specified, which must be positive.

Generalized Estimating Equations Type of Model

The Type of Model tab allows you to specify the distribution and link function for your model, providing shortcuts for several common models that are categorized by response type.

Model Types

Scale Response. The following options are available:

- **Linear.** Specifies Normal as the distribution and Identity as the link function.
- **Gamma with log link.** Specifies Gamma as the distribution and Log as the link function.

Ordinal Response. The following options are available:

- **Ordinal logistic.** Specifies Multinomial (ordinal) as the distribution and Cumulative logit as the link function.
- **Ordinal probit.** Specifies Multinomial (ordinal) as the distribution and Cumulative probit as the link function.

Counts. The following options are available:

- **Poisson loglinear.** Specifies Poisson as the distribution and Log as the link function.
- **Negative binomial with log link.** Specifies Negative binomial (with a value of 1 for the ancillary parameter) as the distribution and Log as the link function. To have the procedure estimate the value of the ancillary parameter, specify a custom model with Negative binomial distribution and select **Estimate value** in the Parameter group.

Binary Response or Events/Trials Data. The following options are available:

- **Binary logistic.** Specifies Binomial as the distribution and Logit as the link function.
- **Binary probit.** Specifies Binomial as the distribution and Probit as the link function.
- **Interval censored survival.** Specifies Binomial as the distribution and Complementary log-log as the link function.

Mixture. The following options are available:

- **Tweedie with log link.** Specifies Tweedie as the distribution and Log as the link function.
- **Tweedie with identity link.** Specifies Tweedie as the distribution and Identity as the link function.

Custom. Specify your own combination of distribution and link function.

Distribution

This selection specifies the distribution of the dependent variable. The ability to specify a non-normal distribution and non-identity link function is the essential improvement of the generalized linear model over the general linear model. There are many possible distribution-link function combinations, and several may be appropriate for any given dataset, so your choice can be guided by a priori theoretical considerations or which combination seems to fit best.

- **Binomial.** This distribution is appropriate only for variables that represent a binary response or number of events.
- **Gamma.** This distribution is appropriate for variables with positive scale values that are skewed toward larger positive values. If a data value is less than or equal to 0 or is missing, then the corresponding case is not used in the analysis.
- **Inverse Gaussian.** This distribution is appropriate for variables with positive scale values that are skewed toward larger positive values. If a data value is less than or equal to 0 or is missing, then the corresponding case is not used in the analysis.

- **Negative binomial.** This distribution can be thought of as the number of trials required to observe k successes and is appropriate for variables with non-negative integer values. If a data value is non-integer, less than 0, or missing, then the corresponding case is not used in the analysis. The value of the negative binomial distribution's ancillary parameter can be any number greater than or equal to 0; you can set it to a fixed value or allow it to be estimated by the procedure. When the ancillary parameter is set to 0, using this distribution is equivalent to using the Poisson distribution.
- **Normal.** This is appropriate for scale variables whose values take a symmetric, bell-shaped distribution about a central (mean) value. The dependent variable must be numeric.
- **Poisson.** This distribution can be thought of as the number of occurrences of an event of interest in a fixed period of time and is appropriate for variables with non-negative integer values. If a data value is non-integer, less than 0, or missing, then the corresponding case is not used in the analysis.
- **Tweedie.** This distribution is appropriate for variables that can be represented by Poisson mixtures of gamma distributions; the distribution is "mixed" in the sense that it combines properties of continuous (takes non-negative real values) and discrete distributions (positive probability mass at a single value, 0). The dependent variable must be numeric, with data values greater than or equal to zero. If a data value is less than zero or missing, then the corresponding case is not used in the analysis. The fixed value of the Tweedie distribution's parameter can be any number greater than one and less than two.
- **Multinomial.** This distribution is appropriate for variables that represent an ordinal response. The dependent variable can be numeric or string, and it must have at least two distinct valid data values.

Link Function

The link function is a transformation of the dependent variable that allows estimation of the model. The following functions are available:

- **Identity.** $f(x)=x$. The dependent variable is not transformed. This link can be used with any distribution.
- **Complementary log-log.** $f(x)=\log(-\log(1-x))$. This is appropriate only with the binomial distribution.
- **Cumulative Cauchit.** $f(x) = \tan(\pi (x - 0.5))$, applied to the cumulative probability of each category of the response. This is appropriate only with the multinomial distribution.
- **Cumulative complementary log-log.** $f(x)=\ln(-\ln(1-x))$, applied to the cumulative probability of each category of the response. This is appropriate only with the multinomial distribution.
- **Cumulative logit.** $f(x)=\ln(x / (1-x))$, applied to the cumulative probability of each category of the response. This is appropriate only with the multinomial distribution.
- **Cumulative negative log-log.** $f(x)=-\ln(-\ln(x))$, applied to the cumulative probability of each category of the response. This is appropriate only with the multinomial distribution.
- **Cumulative probit.** $f(x)=\Phi^{-1}(x)$, applied to the cumulative probability of each category of the response, where Φ^{-1} is the inverse standard normal cumulative distribution function. This is appropriate only with the multinomial distribution.
- **Log.** $f(x)=\log(x)$. This link can be used with any distribution.
- **Log complement.** $f(x)=\log(1-x)$. This is appropriate only with the binomial distribution.
- **Logit.** $f(x)=\log(x / (1-x))$. This is appropriate only with the binomial distribution.
- **Negative binomial.** $f(x)=\log(x / (x+k^{-1}))$, where k is the ancillary parameter of the negative binomial distribution. This is appropriate only with the negative binomial distribution.
- **Negative log-log.** $f(x)=-\log(-\log(x))$. This is appropriate only with the binomial distribution.
- **Odds power.** $f(x)=[(x/(1-x))^\alpha-1]/\alpha$, if $\alpha \neq 0$. $f(x)=\log(x)$, if $\alpha=0$. α is the required number specification and must be a real number. This is appropriate only with the binomial distribution.
- **Probit.** $f(x)=\Phi^{-1}(x)$, where Φ^{-1} is the inverse standard normal cumulative distribution function. This is appropriate only with the binomial distribution.
- **Power.** $f(x)=x^\alpha$, if $\alpha \neq 0$. $f(x)=\log(x)$, if $\alpha=0$. α is the required number specification and must be a real number. This link can be used with any distribution.

Generalized Estimating Equations Response

In many cases, you can simply specify a dependent variable; however, variables that take only two values and responses that record events in trials require extra attention.

- **Binary response.** When the dependent variable takes only two values, you can specify the reference category for parameter estimation. A binary response variable can be string or numeric.
- **Number of events occurring in a set of trials.** When the response is a number of events occurring in a set of trials, the dependent variable contains the number of events and you can select an additional variable containing the number of trials. Alternatively, if the number of trials is the same across all subjects, then trials may be specified using a fixed value. The number of trials should be greater than or equal to the number of events for each case. Events should be non-negative integers, and trials should be positive integers.

For ordinal multinomial models, you can specify the category order of the response: ascending, descending, or data (data order means that the first value encountered in the data defines the first category, the last value encountered defines the last category).

Scale Weight. The scale parameter is an estimated model parameter related to the variance of the response. The scale weights are "known" values that can vary from observation to observation. If the scale weight variable is specified, the scale parameter, which is related to the variance of the response, is divided by it for each observation. Cases with scale weight values that are less than or equal to 0 or are missing are not used in the analysis.

Generalized Estimating Equations Reference Category

For binary response, you can choose the reference category for the dependent variable. This can affect certain output, such as parameter estimates and saved values, but it should not change the model fit. For example, if your binary response takes values 0 and 1:

- By default, the procedure makes the last (highest-valued) category, or 1, the reference category. In this situation, model-saved probabilities estimate the chance that a given case takes the value 0, and parameter estimates should be interpreted as relating to the likelihood of category 0.
- If you specify the first (lowest-valued) category, or 0, as the reference category, then model-saved probabilities estimate the chance that a given case takes the value 1.
- If you specify the custom category and your variable has defined labels, you can set the reference category by choosing a value from the list. This can be convenient when, in the middle of specifying a model, you don't remember exactly how a particular variable was coded.

Generalized Estimating Equations Predictors

The Predictors tab allows you to specify the factors and covariates used to build model effects and to specify an optional offset.

Factors. Factors are categorical predictors; they can be numeric or string.

Covariates. Covariates are scale predictors; they must be numeric.

Note: When the response is binomial with binary format, the procedure computes deviance and chi-square goodness-of-fit statistics by subpopulations that are based on the cross-classification of observed values of the selected factors and covariates. You should keep the same set of predictors across multiple runs of the procedure to ensure a consistent number of subpopulations.

Offset. The offset term is a "structural" predictor. Its coefficient is not estimated by the model but is assumed to have the value 1; thus, the values of the offset are simply added to the linear predictor of the target. This is especially useful in Poisson regression models, where each case may have different levels of exposure to the event of interest.

For example, when modeling accident rates for individual drivers, there is an important difference between a driver who has been at fault in one accident in three years of experience and a driver who has been at fault in one accident in 25 years! The number of accidents can be modeled as a Poisson or

negative binomial response with a log link if the natural log of the experience of the driver is included as an offset term.

Other combinations of distribution and link types would require other transformations of the offset variable.

Generalized Estimating Equations Options

These options are applied to all factors specified on the Predictors tab.

User-Missing Values. Factors must have valid values for a case to be included in the analysis. These controls allow you to decide whether user-missing values are treated as valid among factor variables.

Category Order. This is relevant for determining a factor's last level, which may be associated with a redundant parameter in the estimation algorithm. Changing the category order can change the values of factor-level effects, since these parameter estimates are calculated relative to the "last" level. Factors can be sorted in ascending order from lowest to highest value, in descending order from highest to lowest value, or in "data order." This means that the first value encountered in the data defines the first category, and the last unique value encountered defines the last category.

Generalized Estimating Equations Model

Specify Model Effects. The default model is intercept-only, so you must explicitly specify other model effects. Alternatively, you can build nested or non-nested terms.

Non-Nested Terms

For the selected factors and covariates:

Main effects. Creates a main-effects term for each variable selected.

Interaction. Creates the highest-level interaction term for all selected variables.

Factorial. Creates all possible interactions and main effects of the selected variables.

All 2-way. Creates all possible two-way interactions of the selected variables.

All 3-way. Creates all possible three-way interactions of the selected variables.

All 4-way. Creates all possible four-way interactions of the selected variables.

All 5-way. Creates all possible five-way interactions of the selected variables.

Nested Terms

You can build nested terms for your model in this procedure. Nested terms are useful for modeling the effect of a factor or covariate whose values do not interact with the levels of another factor. For example, a grocery store chain may follow the spending habits of its customers at several store locations. Since each customer frequents only one of these locations, the *Customer* effect can be said to be **nested within** the *Store location* effect.

Additionally, you can include interaction effects or add multiple levels of nesting to the nested term.

Limitations. Nested terms have the following restrictions:

- All factors within an interaction must be unique. Thus, if *A* is a factor, then specifying *A*A* is invalid.
- All factors within a nested effect must be unique. Thus, if *A* is a factor, then specifying *A(A)* is invalid.
- No effect can be nested within a covariate. Thus, if *A* is a factor and *X* is a covariate, then specifying *A(X)* is invalid.

Intercept. The intercept is usually included in the model. If you can assume the data pass through the origin, you can exclude the intercept.

Models with the multinomial ordinal distribution do not have a single intercept term; instead there are threshold parameters that define transition points between adjacent categories. The thresholds are always included in the model.

Generalized Estimating Equations Estimation

Parameter Estimation. The controls in this group allow you to specify estimation methods and to provide initial values for the parameter estimates.

- **Method.** You can select a parameter estimation method; choose between Newton-Raphson, Fisher scoring, or a hybrid method in which Fisher scoring iterations are performed before switching to the Newton-Raphson method. If convergence is achieved during the Fisher scoring phase of the hybrid method before the maximum number of Fisher iterations is reached, the algorithm continues with the Newton-Raphson method.
- **Scale Parameter Method.** You can select the scale parameter estimation method.

Maximum-likelihood jointly estimates the scale parameter with the model effects; note that this option is not valid if the response has a negative binomial, Poisson, or binomial distribution. Since the concept of likelihood does not enter into generalized estimating equations, this specification applies only to the initial generalized linear model; this scale parameter estimate is then passed to the generalized estimating equations, which update the scale parameter by the Pearson chi-square divided by its degrees of freedom.

The deviance and Pearson chi-square options estimate the scale parameter from the value of those statistics in the initial generalized linear model; this scale parameter estimate is then passed to the generalized estimating equations, which treat it as fixed.

Alternatively, specify a fixed value for the scale parameter. It will be treated as fixed in estimating the initial generalized linear model and the generalized estimating equations.

- **Initial values.** The procedure will automatically compute initial values for parameters. Alternatively, you can specify [initial values](#) for the parameter estimates.

The iterations and convergence criteria specified on this tab are applicable only to the initial generalized linear model. For estimation criteria used in fitting the generalized estimating equations, see the [Repeated](#) tab.

Iterations. The following options are available:

- **Maximum iterations.** The maximum number of iterations the algorithm will execute. Specify a non-negative integer.
- **Maximum step-halving.** At each iteration, the step size is reduced by a factor of 0.5 until the log-likelihood increases or maximum step-halving is reached. Specify a positive integer.
- **Check for separation of data points.** When selected, the algorithm performs tests to ensure that the parameter estimates have unique values. Separation occurs when the procedure can produce a model that correctly classifies every case. This option is available for multinomial responses and binomial responses with binary format.

Convergence Criteria. The following options are available

- **Parameter convergence.** When selected, the algorithm stops after an iteration in which the absolute or relative change in the parameter estimates is less than the value specified, which must be positive.
- **Log-likelihood convergence.** When selected, the algorithm stops after an iteration in which the absolute or relative change in the log-likelihood function is less than the value specified, which must be positive.
- **Hessian convergence.** For the Absolute specification, convergence is assumed if a statistic based on the Hessian convergence is less than the positive value specified. For the Relative specification, convergence is assumed if the statistic is less than the product of the positive value specified and the absolute value of the log-likelihood.

Singularity tolerance. Singular (or non-invertible) matrices have linearly dependent columns, which can cause serious problems for the estimation algorithm. Even near-singular matrices can lead to poor results, so the procedure will treat a matrix whose determinant is less than the tolerance as singular. Specify a positive value.

Generalized Estimating Equations Initial Values

The procedure estimates an initial generalized linear model, and the estimates from this model are used as initial values for the parameter estimates in the linear model part of the generalized estimating equations. Initial values are not needed for the working correlation matrix because matrix elements are based on the parameter estimates. Initial values specified on this dialog box are used as the starting point for the initial generalized linear model, not the generalized estimating equations, unless the Maximum iterations on the [Estimation](#) tab is set to 0.

If initial values are specified, they must be supplied for all parameters (including redundant parameters) in the model. In the dataset, the ordering of variables from left to right must be: *RowType_*, *VarName_*, *P1*, *P2*, ..., where *RowType_* and *VarName_* are string variables and *P1*, *P2*, ... are numeric variables corresponding to an ordered list of the parameters.

- Initial values are supplied on a record with value *EST* for variable *RowType_*; the actual initial values are given under variables *P1*, *P2*, The procedure ignores all records for which *RowType_* has a value other than *EST* as well as any records beyond the first occurrence of *RowType_* equal to *EST*.
- The intercept, if included in the model, or threshold parameters, if the response has a multinomial distribution, must be the first initial values listed.
- The scale parameter and, if the response has a negative binomial distribution, the negative binomial parameter, must be the last initial values specified.
- If Split File is in effect, then the variables must begin with the split-file variable or variables in the order specified when creating the Split File, followed by *RowType_*, *VarName_*, *P1*, *P2*, ... as above. Splits must occur in the specified dataset in the same order as in the original dataset.

Note: The variable names *P1*, *P2*, ... are not required; the procedure will accept any valid variable names for the parameters because the mapping of variables to parameters is based on variable position, not variable name. Any variables beyond the last parameter are ignored.

The file structure for the initial values is the same as that used when exporting the model as data; thus, you can use the final values from one run of the procedure as input in a subsequent run.

Generalized Estimating Equations Statistics

Model Effects. The following options are available:

- **Analysis type.** Specify the type of analysis to produce for testing model effects. Type I analysis is generally appropriate when you have a priori reasons for ordering predictors in the model, while Type III is more generally applicable. Wald or generalized score statistics are computed based upon the selection in the Chi-Square Statistics group.
- **Confidence intervals.** Specify a confidence level greater than 50 and less than 100. Wald intervals are always produced regardless of the type of chi-square statistics selected, and are based on the assumption that parameters have an asymptotic normal distribution.
- **Log quasi-likelihood function.** This controls the display format of the log quasi-likelihood function. The full function includes an additional term that is constant with respect to the parameter estimates; it has no effect on parameter estimation and is left out of the display in some software products.

Print. The following output is available.

- **Case processing summary.** Displays the number and percentage of cases included and excluded from the analysis and the Correlated Data Summary table.
- **Descriptive statistics.** Displays descriptive statistics and summary information about the dependent variable, covariates, and factors.
- **Model information.** Displays the dataset name, dependent variable or events and trials variables, offset variable, scale weight variable, probability distribution, and link function.
- **Goodness of fit statistics.** Displays two extensions of Akaike's Information Criterion for model selection: Quasi-likelihood under the independence model criterion (QIC) for choosing the best correlation structure and another QIC measure for choosing the best subset of predictors.

- **Model summary statistics.** Displays model fit tests, including likelihood-ratio statistics for the model fit omnibus test and statistics for the Type I or III contrasts for each effect.
- **Parameter estimates.** Displays parameter estimates and corresponding test statistics and confidence intervals. You can optionally display exponentiated parameter estimates in addition to the raw parameter estimates.
- **Covariance matrix for parameter estimates.** Displays the estimated parameter covariance matrix.
- **Correlation matrix for parameter estimates.** Displays the estimated parameter correlation matrix.
- **Contrast coefficient (L) matrices.** Displays contrast coefficients for the default effects and for the estimated marginal means, if requested on the EM Means tab.
- **General estimable function(s).** Displays the matrices for generating the contrast coefficient (L) matrices.
- **Iteration history.** Displays the iteration history for the parameter estimates and log-likelihood and prints the last evaluation of the gradient vector and the Hessian matrix. The iteration history table displays parameter estimates for every n^{th} iterations beginning with the 0^{th} iteration (the initial estimates), where n is the value of the print interval. If the iteration history is requested, then the last iteration is always displayed regardless of n .
- **Working correlation matrix.** Displays the values of the matrix representing the within-subject dependencies. Its structure depends upon the specifications in the [Repeated](#) tab.

Generalized Estimating Equations EM Means

This tab allows you to display the estimated marginal means for levels of factors and factor interactions. You can also request that the overall estimated mean be displayed. Estimated marginal means are not available for ordinal multinomial models.

Factors and Interactions. This list contains factors specified on the Predictors tab and factor interactions specified on the Model tab. Covariates are excluded from this list. Terms can be selected directly from this list or combined into an interaction term using the **By *** button.

Display Means For. Estimated means are computed for the selected factors and factor interactions. The contrast determines how hypothesis tests are set up to compare the estimated means. The simple contrast requires a reference category or factor level against which the others are compared.

- **Pairwise.** Pairwise comparisons are computed for all-level combinations of the specified or implied factors. This is the only available contrast for factor interactions.
- *Simple.* Compares the mean of each level to the mean of a specified level. This type of contrast is useful when there is a control group.
- **Deviation.** Each level of the factor is compared to the grand mean. Deviation contrasts are not orthogonal.
- *Difference.* Compares the mean of each level (except the first) to the mean of previous levels. They are sometimes called reverse Helmert contrasts.
- *Helmert.* Compares the mean of each level of the factor (except the last) to the mean of subsequent levels.
- *Repeated.* Compares the mean of each level (except the last) to the mean of the subsequent level.
- *Polynomial.* Compares the linear effect, quadratic effect, cubic effect, and so on. The first degree of freedom contains the linear effect across all categories; the second degree of freedom, the quadratic effect; and so on. These contrasts are often used to estimate polynomial trends.

Scale. Estimated marginal means can be computed for the response, based on the original scale of the dependent variable, or for the linear predictor, based on the dependent variable as transformed by the link function.

Adjustment for Multiple Comparisons. When performing hypothesis tests with multiple contrasts, the overall significance level can be adjusted from the significance levels for the included contrasts. This group allows you to choose the adjustment method.

- **Least significant difference.** This method does not control the overall probability of rejecting the hypotheses that some linear contrasts are different from the null hypothesis values.
- *Bonferroni.* This method adjusts the observed significance level for the fact that multiple contrasts are being tested.
- *Sequential Bonferroni.* This is a sequentially step-down rejective Bonferroni procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.
- *Sidak.* This method provides tighter bounds than the Bonferroni approach.
- *Sequential Sidak.* This is a sequentially step-down rejective Sidak procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.

Generalized Estimating Equations Save

Checked items are saved with the specified name; you can choose to overwrite existing variables with the same name as the new variables or avoid name conflicts by appendix suffixes to make the new variable names unique.

- **Predicted value of mean of response.** Saves model-predicted values for each case in the original response metric. When the response distribution is binomial and the dependent variable is binary, the procedure saves predicted probabilities. When the response distribution is multinomial, the item label becomes **Cumulative predicted probability**, and the procedure saves the cumulative predicted probability for each category of the response, except the last, up to the number of specified categories to save.
- **Lower bound of confidence interval for mean of response.** Saves the lower bound of the confidence interval for the mean of the response. When the response distribution is multinomial, the item label becomes **Lower bound of confidence interval for cumulative predicted probability**, and the procedure saves the lower bound for each category of the response, except the last, up to the number of specified categories to save.
- **Upper bound of confidence interval for mean of response.** Saves the upper bound of the confidence interval for the mean of the response. When the response distribution is multinomial, the item label becomes **Upper bound of confidence interval for cumulative predicted probability**, and the procedure saves the upper bound for each category of the response, except the last, up to the number of specified categories to save.
- **Predicted category.** For models with binomial distribution and binary dependent variable, or multinomial distribution, this saves the predicted response category for each case. This option is not available for other response distributions.
- **Predicted value of linear predictor.** Saves model-predicted values for each case in the metric of the linear predictor (transformed response via the specified link function). When the response distribution is multinomial, the procedure saves the predicted value for each category of the response, except the last, up to the number of specified categories to save.
- **Estimated standard error of predicted value of linear predictor.** When the response distribution is multinomial, the procedure saves the estimated standard error for each category of the response, except the last, up to the number of specified categories to save.

The following items are not available when the response distribution is multinomial.

- *Raw residual.* The difference between an observed value and the value predicted by the model.
- **Pearson residual.** The square root of the contribution of a case to the Pearson chi-square statistic, with the sign of the raw residual.

Generalized Estimating Equations Export

Export model as data. Writes a dataset in IBM SPSS Statistics format containing the parameter correlation or covariance matrix with parameter estimates, standard errors, significance values, and degrees of freedom. The order of variables in the matrix file is as follows.

- **Split variables.** If used, any variables defining splits.
- **RowType_.** Takes values (and value labels) *COV* (covariances), *CORR* (correlations), *EST* (parameter estimates), *SE* (standard errors), *SIG* (significance levels), and *DF* (sampling design degrees of freedom). There is a separate case with row type *COV* (or *CORR*) for each model parameter, plus a separate case for each of the other row types.
- **VarName_.** Takes values *P1*, *P2*, ..., corresponding to an ordered list of all estimated model parameters (except the scale or negative binomial parameters), for row types *COV* or *CORR*, with value labels corresponding to the parameter strings shown in the Parameter estimates table. The cells are blank for other row types.
- **P1, P2, ...** These variables correspond to an ordered list of all model parameters (including the scale and negative binomial parameters, as appropriate), with variable labels corresponding to the parameter strings shown in the Parameter estimates table, and take values according to the row type.

For redundant parameters, all covariances are set to zero, correlations are set to the system-missing value; all parameter estimates are set at zero; and all standard errors, significance levels, and residual degrees of freedom are set to the system-missing value.

For the scale parameter, covariances, correlations, significance level and degrees of freedom are set to the system-missing value. If the scale parameter is estimated via maximum likelihood, the standard error is given; otherwise it is set to the system-missing value.

For the negative binomial parameter, covariances, correlations, significance level and degrees of freedom are set to the system-missing value. If the negative binomial parameter is estimated via maximum likelihood, the standard error is given; otherwise it is set to the system-missing value.

If there are splits, then the list of parameters must be accumulated across all splits. In a given split, some parameters may be irrelevant; this is not the same as redundant. For irrelevant parameters, all covariances or correlations, parameter estimates, standard errors, significance levels, and degrees of freedom are set to the system-missing value.

You can use this matrix file as the initial values for further model estimation; note that this file is not immediately usable for further analyses in other procedures that read a matrix file unless those procedures accept all the row types exported here. Even then, you should take care that all parameters in this matrix file have the same meaning for the procedure reading the file.

Export model as XML. Saves the parameter estimates and the parameter covariance matrix, if selected, in XML (PMML) format. You can use this model file to apply the model information to other data files for scoring purposes.

GENLIN Command Additional Features

The command syntax language also allows you to:

- Specify initial values for parameter estimates as a list of numbers (using the *CRITERIA* subcommand).
- Specify a fixed working correlation matrix (using the *REPEATED* subcommand).
- Fix covariates at values other than their means when computing estimated marginal means (using the *EMMEANS* subcommand).
- Specify custom polynomial contrasts for estimated marginal means (using the *EMMEANS* subcommand).
- Specify a subset of the factors for which estimated marginal means are displayed to be compared using the specified contrast type (using the *TABLES* and *COMPARE* keywords of the *EMMEANS* subcommand).

See the *Command Syntax Reference* for complete syntax information.

Generalized linear mixed models

Generalized linear mixed models extend the linear model so that:

- The target is linearly related to the factors and covariates via a specified link function.
- The target can have a non-normal distribution.

- The observations can be correlated.

Generalized linear mixed models cover a wide variety of models, from simple linear regression to complex multilevel models for non-normal longitudinal data.

Examples

The district school board can use a generalized linear mixed model to determine whether an experimental teaching method is effective at improving math scores. Students from the same classroom should be correlated since they are taught by the same teacher, and classrooms within the same school may also be correlated, so we can include random effects at school and class levels to account for different sources of variability.

Medical researchers can use a generalized linear mixed model to determine whether a new anticonvulsant drug can reduce a patient's rate of epileptic seizures. Repeated measurements from the same patient are typically positively correlated so a mixed model with some random effects should be appropriate. The target field, the number of seizures, takes positive integer values, so a generalized linear mixed model with a Poisson distribution and log link may be appropriate.

Executives at a cable provider of television, phone, and internet services can use a generalized linear mixed model to know more about potential customers. Since possible answers have nominal measurement levels, the company analyst uses a generalized logit mixed model with a random intercept to capture correlation between answers to the service usage questions across service types (tv, phone, internet) within a given survey responder's answers.

The Data Structure tab allows you to specify the structural relationships between records in your dataset when observations are correlated. If the records in the dataset represent independent observations, you do not need to specify anything on this tab.

Effects options

Subjects

The combination of values of the specified categorical fields should uniquely define subjects within the dataset. For example, a single *Patient ID* field should be sufficient to define subjects in a single hospital, but the combination of *Hospital ID* and *Patient ID* may be necessary if patient identification numbers are not unique across hospitals. In a repeated measures setting, multiple observations are recorded for each subject, so each subject may occupy multiple records in the dataset.

A **subject** is an observational unit that can be considered independent of other subjects. For example, the blood pressure readings from a patient in a medical study can be considered independent of the readings from other patients. Defining subjects becomes particularly important when there are repeated measurements per subject and you want to model the correlation between these observations. For example, you might expect that blood pressure readings from a single patient during consecutive visits to the doctor are correlated.

All of the fields specified as **Subjects** on the Variables dialog are used to define subjects for the residual covariance structure, and provide the list of possible fields for defining subjects for random-effects covariance structures on the [Random Effect Block](#).

Repeated Measures

The fields specified here are used to identify repeated observations. For example, a single variable *Week* might identify the 10 weeks of observations in a medical study, or *Month* and *Day* might be used together to identify daily observations over the course of a year.

Covariance options

Define covariance groups by

The categorical fields specified here define independent sets of repeated effects covariance parameters; one for each category defined by the cross-classification of the grouping fields. All subjects have the same covariance type; subjects within the same covariance grouping will have the same values for the parameters.

Repeated covariance type

This specifies the covariance structure for the residuals. Different covariance options are available based on the selected **Repeated covariance type**. The available structures are:

- First-order autoregressive (AR1)
- Direct product AR1 (UN_AR1)
- Direct product unstructured (UN_UN)
- Direct product compound symmetry (UN_CS)
- Heterogeneous compound symmetry (CSH)
- Heterogeneous autoregressive (ARH1)
- Autoregressive moving average (1,1) (ARMA11)
- Compound symmetry
- Diagonal
- Scaled identity
- Toeplitz
- Unstructured
- Variance components
- Spatial: Power
- Spatial: Exponential
- Spatial: Gaussian
- Spatial: Linear
- Spatial: Linear-log
- Spatial: Spherical

Kronecker Measures

Select variables that specify the subject structure for Kronecker covariance measurements and determine how the measurement errors are correlated. The field is available only when one of the following **Repeated Covariance Type** is selected:

- Direct product AR1 (UN_AR1)
- Direct product unstructured (UN_UN)
- Direct product compound symmetry (UN_CS)

Spatial covariance coordinates

The variables in this list specify the coordinates of the repeated observations when one of the spatial covariance types is selected for the repeated covariance type.

See the topic [“Covariance Structures”](#) on page 96 for more information.

Pseudo R² measures

Pseudo-R² measures and the intra-class correlation coefficient are included in GLMM output (when appropriate). The pseudo-R² measures are based entirely on the final estimates and are produced after estimation has been completed. The coefficient of determination R² is a commonly reported statistic, because it represents the proportion of variance explained by a linear model. The intra-class correlation coefficient (ICC) is a related statistic that quantifies the proportion of variance explained by a grouping (random) factor in multilevel/ hierarchical data.

Obtaining a generalized linear mixed model

This feature requires SPSS Statistics Standard Edition or the Advanced Statistics Option.

From the menus choose:

Analyze > Mixed Models > Generalized Linear...

1. Define the subject structure of your dataset on the **Data Structure** tab. The tab provides options for specifying both the model effects and the repeated covariance type.
2. On the **Fields and Effects** tab, there must be a single target, which can have any measurement level, or an events/trials specification, in which case the events and trials specifications must be continuous. Optionally specify its distribution and link function, the fixed effects, and any random effects blocks, offset, or analysis weights.
3. Click **Build Options** to specify optional build settings.
4. Click **Model Options** to save scores to the active dataset and export the model to an external file.
5. Click **Run** to run the procedure and create the Model objects.

Target

These settings define the target, its distribution, and its relationship to the predictors through the link function.

Target. The target is required. It can have any measurement level, and the measurement level of the target restricts which distributions and link functions are appropriate.

- **Use number of trials as denominator.** When the target response is a number of events occurring in a set of trials, the target field contains the number of events and you can select an additional field containing the number of trials. For example, when testing a new pesticide you might expose samples of ants to different concentrations of the pesticide and then record the number of ants killed and the number of ants in each sample. In this case, the field recording the number of ants killed should be specified as the target (events) field, and the field recording the number of ants in each sample should be specified as the trials field. If the number of ants is the same for each sample, then the number of trials may be specified using a fixed value.

The number of trials should be greater than or equal to the number of events for each record. Events should be non-negative integers, and trials should be positive integers.

- **Customize reference category.** For a categorical target, you can choose the reference category. This can affect certain output, such as parameter estimates, but it should not change the model fit. For example, if your target takes values 0, 1, and 2, by default, the procedure makes the last (highest-valued) category, or 2, the reference category. In this situation, parameter estimates should be interpreted as relating to the likelihood of category 0 or 1 *relative* to the likelihood of category 2. If you specify a custom category and your target has defined labels, you can set the reference category by choosing a value from the list. This can be convenient when, in the middle of specifying a model, you don't remember exactly how a particular field was coded.

Target Distribution and Relationship (Link) with the Linear Model. Given the values of the predictors, the model expects the distribution of values of the target to follow the specified shape, and for the target values to be linearly related to the predictors through the specified link function. Short cuts for several common models are provided, or choose a **Custom** setting if there is a particular distribution and link function combination you want to fit that is not on the short list.

- **Linear model.** Specifies a normal distribution with an identity link, which is useful when the target can be predicted using a linear regression or ANOVA model.
- **Gamma regression.** Specifies a Gamma distribution with a log link, which should be used when the target contains all positive values and is skewed towards larger values.
- **Loglinear.** Specifies a Poisson distribution with a log link, which should be used when the target represents a count of occurrences in a fixed period of time.
- **Negative binomial regression.** Specifies a negative binomial distribution with a log link, which should be used when the target and denominator represent the number of trials required to observe k successes.
- **Multinomial logistic regression.** Specifies a multinomial distribution, which should be used when the target is a multi-category response. It uses either a cumulative logit link (ordinal outcomes) or a generalized logit link (multi-category nominal responses).

- **Binary logistic regression.** Specifies a binomial distribution with a logit link, which should be used when the target is a binary response predicted by a logistic regression model.
- **Binary probit.** Specifies a binomial distribution with a probit link, which should be used when the target is a binary response with an underlying normal distribution.
- **Interval censored survival.** Specifies a binomial distribution with a complementary log-log link, which is useful in survival analysis when some observations have no termination event.

Distribution

This selection specifies the distribution of the target. The ability to specify a non-normal distribution and non-identity link function is the essential improvement of the generalized linear mixed model over the linear mixed model. There are many possible distribution-link function combinations, and several may be appropriate for any given dataset, so your choice can be guided by a priori theoretical considerations or which combination seems to fit best.

- **Binomial.** This distribution is appropriate only for a target that represents a binary response or number of events.
- **Gamma.** This distribution is appropriate for a target with positive scale values that are skewed toward larger positive values. If a data value is less than or equal to 0 or is missing, then the corresponding case is not used in the analysis.
- **Inverse Gaussian.** This distribution is appropriate for a target with positive scale values that are skewed toward larger positive values. If a data value is less than or equal to 0 or is missing, then the corresponding case is not used in the analysis.
- **Multinomial.** This distribution is appropriate for a target that represents a multi-category response. The form of the model will depend on the measurement level of the target.

A **nominal** target will result in a nominal multinomial model in which a separate set of model parameters are estimated for each category of the target (except the reference category). The parameter estimates for a given predictor show the relationship between that predictor and the likelihood of each category of the target, relative to the reference category.

An **ordinal** target will result in an ordinal multinomial model in which the traditional intercept term is replaced with a set of **threshold** parameters that relate to the cumulative probability of the target categories.

- **Negative binomial.** Negative binomial regression uses a negative binomial distribution with a log link, which should be used when the target represents a count of occurrences with high variance.
- **Normal.** This is appropriate for a continuous target whose values take a symmetric, bell-shaped distribution about a central (mean) value.
- **Poisson.** This distribution can be thought of as the number of occurrences of an event of interest in a fixed period of time and is appropriate for variables with non-negative integer values. If a data value is non-integer, less than 0, or missing, then the corresponding case is not used in the analysis.

Link Functions

The link function is a transformation of the target that allows estimation of the model. The following functions are available:

- **Identity.** $f(x)=x$. The target is not transformed. This link can be used with any distribution, except the multinomial.
- **Complementary log-log.** $f(x)=\log(-\log(1-x))$. This is appropriate only with the binomial or multinomial distribution.
- **Cauchit.** $f(x) = \tan(\pi(x - 0.5))$. This is appropriate only with the binomial or multinomial distribution.
- **Log.** $f(x)=\log(x)$. This link can be used with any distribution, except the multinomial.
- **Log complement.** $f(x)=\log(1-x)$. This is appropriate only with the binomial distribution.
- **Logit.** $f(x)=\log(x / (1-x))$. This is appropriate only with the binomial or multinomial distribution.
- **Negative log-log.** $f(x)=-\log(-\log(x))$. This is appropriate only with the binomial or multinomial distribution.

- **Probit.** $f(x)=\Phi^{-1}(x)$, where Φ^{-1} is the inverse standard normal cumulative distribution function. This is appropriate only with the binomial or multinomial distribution.
- **Power.** $f(x)=x^\alpha$, if $\alpha \neq 0$. $f(x)=\log(x)$, if $\alpha=0$. α is the required number specification and must be a real number. This link can be used with any distribution, except the multinomial.

Fixed Effects

Fixed effects factors are generally thought of as fields whose values of interest are all represented in the dataset, and can be used for scoring. By default, fields with the predefined input role that are not specified elsewhere in the dialog are entered in the fixed effects portion of the model. Categorical (nominal, and ordinal) fields are used as factors in the model and continuous fields are used as covariates.

Enter effects into the model by selecting one or more fields in the source list and dragging to the effects list. The type of effect created depends upon which hotspot you drop the selection.

- **Main.** Dropped fields appear as separate main effects at the bottom of the effects list.
- **2-way.** All possible pairs of the dropped fields appear as 2-way interactions at the bottom of the effects list.
- **3-way.** All possible triplets of the dropped fields appear as 3-way interactions at the bottom of the effects list.
- *****. The combination of all dropped fields appear as a single interaction at the bottom of the effects list.

Buttons to the right of the Effect Builder allow you to perform various actions.

Table 1. Effect builder button descriptions

Icon	Description
	Delete terms from the fixed effects model by selecting the terms you want to delete and clicking the delete button.
 	Reorder the terms within the fixed effects model by selecting the terms you want to reorder and clicking the up or down arrow.
	Add nested terms to the model using the “Add a Custom Term ” on page 52 dialog, by clicking on the Add a Custom Term button.

Include Intercept. The intercept is usually included in the model. If you can assume the data pass through the origin, you can exclude the intercept.

Add a Custom Term

You can build nested terms for your model in this procedure. Nested terms are useful for modeling the effect of a factor or covariate whose values do not interact with the levels of another factor. For example, a grocery store chain may follow the spending habits of its customers at several store locations. Since each customer frequents only one of these locations, the *Customer* effect can be said to be **nested within** the *Store location* effect.

Additionally, you can include interaction effects, such as polynomial terms involving the same covariate, or add multiple levels of nesting to the nested term.

Limitations. Nested terms have the following restrictions:

- All factors within an interaction must be unique. Thus, if *A* is a factor, then specifying *A*A* is invalid.
- All factors within a nested effect must be unique. Thus, if *A* is a factor, then specifying *A(A)* is invalid.
- No effect can be nested within a covariate. Thus, if *A* is a factor and *X* is a covariate, then specifying *A(X)* is invalid.

Constructing a nested term

1. Select a factor or covariate that is nested within another factor, and then click the arrow button.
2. Click **(Within)**.
3. Select the factor within which the previous factor or covariate is nested, and then click the arrow button.
4. Click **Add Term**.

Optionally, you can include interaction effects or add multiple levels of nesting to the nested term.

Random Effects

Random effects factors are fields whose values in the data file can be considered a random sample from a larger population of values. They are useful for explaining excess variability in the target. By default, if you have selected more than one subject in the Data Structure tab, a Random Effect block will be created for each subject beyond the innermost subject. For example, if you selected School, Class, and Student as subjects on the Data Structure tab, the following random effect blocks are automatically created:

- Random Effect 1: subject is school (with no effects, intercept only)
- Random Effect 2: subject is school * class (no effects, intercept only)

You can work with random effects blocks in the following ways:

1. To add a new block, click **Add Block...** This opens the “Random Effect Block ” on page 53 dialog.
2. To edit an existing block, select the block you want to edit and click **Edit Block...** This opens the “Random Effect Block ” on page 53 dialog.
3. To delete one or more blocks, select the blocks you want to delete and click the delete button.

Random Effect Block

Enter effects into the model by selecting one or more fields in the source list and adding them to the **Effect builder** list.

The type of effect created depends upon which **Type** you select. Categorical (nominal, and ordinal) fields are used as factors in the model and continuous fields are used as covariates.

Interaction

The combination of all fields appear as a single interaction at the bottom of the effects list.

Main effects

Dropped fields appear as separate main effects at the bottom of the effects list.

All 2-way

All possible pairs of the dropped fields appear as 2-way interactions at the bottom of the effects list.

All 3-way

All possible triplets of the dropped fields appear as 3-way interactions at the bottom of the effects list.

All 4-way

All possible triplets of the dropped fields appear as 4-way interactions at the bottom of the effects list.

All 5-way

All possible triplets of the dropped fields appear as 5-way interactions at the bottom of the effects list.

Include Intercept

The intercept is not included in the random effects model by default. If you can assume the data pass through the origin, you can exclude the intercept.

Display parameter predictions for this block

Specifies to display the random-effects parameter estimates.

Subject Combination

This allows you to specify random effect subjects from preset combinations of subjects from the Variables dialog. For example, if *School*, *Class*, and *Student* are defined as subjects on the Variables dialog, and in that order, then the Subject Combination dropdown list will have **None**, **School**, **School * Class**, and **School * Class * Student** as options.

Random effect covariance type

This specifies the covariance structure for the residuals. The available structures are:

- First-order autoregressive (AR1)
- Autoregressive moving average (1,1) (ARMA11)
- Compound symmetry
- Diagonal
- Scaled identity
- Toeplitz
- Unstructured
- Variance components

Define covariance groups by

The categorical fields specified here define independent sets of random effects covariance parameters; one for each category defined by the cross-classification of the grouping fields. A different set of grouping fields can be specified for each random effect block. All subjects have the same covariance type; subjects within the same covariance grouping will have the same values for the parameters.

Weight and Offset

Analysis weight. The scale parameter is an estimated model parameter related to the variance of the response. The analysis weights are "known" values that can vary from observation to observation. If the analysis weight field is specified, the scale parameter, which is related to the variance of the response, is divided by the analysis weight values for each observation. Records with analysis weight values that are less than or equal to 0 or are missing are not used in the analysis.

Offset. The offset term is a "structural" predictor. Its coefficient is not estimated by the model but is assumed to have the value 1; thus, the values of the offset are simply added to the linear predictor of the target. This is especially useful in Poisson regression models, where each case may have different levels of exposure to the event of interest.

For example, when modeling accident rates for individual drivers, there is an important difference between a driver who has been at fault in one accident in three years of experience and a driver who has been at fault in one accident in 25 years! The number of accidents can be modeled as a Poisson or negative binomial response with a log link if the natural log of the experience of the driver is included as an offset term.

Other combinations of distribution and link types would require other transformations of the offset variable.

General Build Options

These selections specify some more advanced criteria used to build the model.

Sorting Order

These controls determine the order of the categories for the target and factors (categorical inputs) for purposes of determining the "last" category. The target sort order setting is ignored if the target is not categorical or if a custom reference category is specified on the ["Target" on page 50 settings](#).

Stopping Rules

You can specify the maximum number of iterations the algorithm will execute. The algorithm uses a doubly iterative process that consists of an inner loop and an outer loop. The value that is specified for

the maximum number of iterations applies to both loops. Specify a non-negative integer. The default is 100.

Post-Estimation Settings

These settings determine how some of the model output is computed for viewing.

Confidence level (%)

This is the level of confidence used to compute interval estimates of the model coefficients. Specify a value greater than 0 and less than 100. The default is 95.

Degrees of freedom

This specifies how degrees of freedom are computed for significance tests. Choose **Residual method** if your sample size is sufficiently large, or the data are balanced, or the model uses a simpler covariance type (for example, scaled identity or diagonal). This is the default setting. Choose **Satterthwaite approximation** if your sample size is small, or the data are unbalanced, or the model uses a complicated covariance type (for example, unstructured). Choose **Kenward-Roger approximation** if your sample size is small and you have a Restricted Maximum Likelihood (REML) model.

Tests of fixed effects and coefficients

This is the method for computing the parameter estimates covariance matrix. Choose the robust estimate if you are concerned that the model assumptions are violated.

Estimation

The model building algorithm uses a doubly iterative process that consists of an inner loop and an outer loop. The following settings apply to the inner loop.

Parameter Convergence.

Convergence is assumed if the maximum absolute change or maximum relative change in the parameter estimates is less than the value specified, which must be non-negative. The criterion is not used if the value specified equals 0.

Log-likelihood Convergence.

Convergence is assumed if the absolute change or relative change in the log-likelihood function is less than the value specified, which must be non-negative. The criterion is not used if the value specified equals 0.

Hessian Convergence.

For the **Absolute** specification, convergence is assumed if a statistic based on the Hessian is less than the value specified. For the **Relative** specification, convergence is assumed if the statistic is less than the product of the value specified and the absolute value of the log-likelihood. The criterion is not used if the value specified equals 0.

Maximum Fisher scoring steps.

Specify a non-negative integer. A value of 0 specifies the Newton-Raphson method. Values greater than 0 specify to use the Fisher scoring algorithm up to iteration number n , where n is the specified integer, and Newton-Raphson thereafter.

Singularity tolerance.

This value is used as the tolerance in checking singularity. Specify a positive value.

Note: By default, Parameter Convergence is used, where the maximum **Absolute** change at a tolerance of $1E-6$ is checked. This setting might produce results that differ from the results that are obtained in versions before version 22. To reproduce results from pre-22 versions, use **Relative** for the Parameter Convergence criterion and keep the default tolerance value of $1E-6$.

Estimated Means

This tab allows you to display the estimated marginal means for levels of factors and factor interactions. Estimated marginal means are not available for multinomial models.

Terms. The model terms in the Fixed Effects that are entirely comprised of categorical fields are listed here. Check each term for which you want the model to produce estimated marginal means.

- **Contrast Type.** This specifies the type of contrast to use for the levels of the contrast field. If **None** is selected, no contrasts are produced. **Pairwise** produces pairwise comparisons for all level combinations of the specified factors. This is the only available contrast for factor interactions. **Deviation** contrasts compare each level of the factor to the grand mean. **Simple** contrasts compare each level of the factor, except the last, to the last level. The "last" level is determined by the sort order for factors specified on the Build Options. Note that all of these contrast types are not orthogonal.
- **Contrast Field.** This specifies a factor, the levels of which are compared using the selected contrast type. If **None** is selected as the contrast type, no contrast field can (or need) be selected.

Continuous Fields. The listed continuous fields are extracted from the terms in the Fixed Effects that use continuous fields. When computing estimated marginal means, covariates are fixed at the specified values. Select the mean or specify a custom value.

Display estimated means in terms of. This specifies whether to compute estimated marginal means based on the original scale of the target or based on the link function transformation. **Original target scale** computes estimated marginal means for the target. Note that when the target is specified using the events/trials option, this gives the estimated marginal means for the events/trials proportion rather than for the number of events. **Link function transformation** computes estimated marginal means for the linear predictor.

Adjust for multiple comparisons using. When performing hypothesis tests with multiple contrasts, the overall significance level can be adjusted from the significance levels for the included contrasts. This allows you to choose the adjustment method.

- **Least significant difference.** This method does not control the overall probability of rejecting the hypotheses that some linear contrasts are different from the null hypothesis values.
- *Sequential Bonferroni.* This is a sequentially step-down rejective Bonferroni procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.
- *Sequential Sidak.* This is a sequentially step-down rejective Sidak procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.

The least significant difference method is less conservative than the sequential Sidak method, which in turn is less conservative than the sequential Bonferroni; that is, least significant difference will reject at least as many individual hypotheses as sequential Sidak, which in turn will reject at least as many individual hypotheses as sequential Bonferroni.

Save

Checked items are saved with the specified name; conflicts with existing field names are not allowed.

Predicted values - Saves the predicted value of the target. The default field name is *PredictedValue*.

Predicted probability for categorical targets - If the target is categorical, this keyword saves the predicted probabilities of the first *n* categories, up to the value specified as the **Maximum categories to save**. The calculated values are cumulative probabilities for ordinal targets. The default root name is *PredictedProbability*. To save the predicted probability of the predicted category, save the confidence (see below).

Confidence intervals - Saves upper and lower bounds of the confidence interval for the predicted value or predicted probability. For all distributions except the multinomial, this creates two variables and the default root name is *CI*, with *_Lower* and *_Upper* as the suffixes.

For the multinomial distribution and a nominal target, one field is created for each dependent variable category. This saves the lower and upper bounds of the predicted probability for the first *n* categories up to the value specified as the **Maximum categories to save**. The default root name is *CI*, and the default field names are *CI_Lower_1*, *CI_Upper_1*, *CI_Lower_2*, *CI_Upper_2*, and so on, corresponding to the order of the target categories.

For the multinomial distribution and an ordinal target, one field is created for each dependent variable category except the last (See the topic [“General Build Options”](#) on page 54 for more information.). This

saves the lower and upper bounds of the cumulative predicted probability for the first n categories, up to but not including the last, and up to the value specified as the **Maximum categories to save**. The default root name is *CI*, and the default field names are *CI_Lower_1*, *CI_Upper_1*, *CI_Lower_2*, *CI_Upper_2*, and so on, corresponding to the order of the target categories.

Pearson residuals - Saves the Pearson residual for each record, which can be used in post-estimation diagnostics of the model fit. The default field name is *PearsonResidual*.

Confidences - Saves the confidence in the predicted value for the categorical target. The computed confidence can be based on the probability of the predicted value (the highest predicted probability) or the difference between the highest predicted probability and the second highest predicted probability. The default field name is *Confidence*.

Export

Export model. This writes the model to an external *.zip* file. You can use this model file to apply the model information to other data files for scoring purposes. See the topic [Scoring Wizard](#) for more information. Specify a unique, valid filename. If the file specification refers to an existing file, then the file is overwritten.

Export output

Export EBLUPS. This section is enabled if at least one random effects block is created through the Random Effects item dialog on the Fields & Effects tab and the check box to display parameter predictions for that block is selected. If multiple such blocks have been specified, you can choose to have results saved to separate datasets or files, or combined into a single dataset or file.

Model view

The procedure creates a Model object in the Viewer. By activating (double-clicking) this object, you gain an interactive view of the model.

By default, the Model Summary view is shown. To see another model view, select it from the view thumbnails.

As an alternative to the Model object, you can generate pivot tables and charts by selecting **Pivot tables and charts** in the Output Display group on the Output tab of the Options dialog (Edit > Options). The topics that follow describe the Model object.

Model Summary

This view is a snapshot, at-a-glance summary of the model and its fit.

Table. The table identifies the target, probability distribution, and link function specified on the **Target settings**. If the target is defined by events and trials, the cell is split to show the events field and the trials field or fixed number of trials. Additionally the finite sample corrected Akaike information criterion (AICC) and Bayesian information criterion (BIC) are displayed.

- *Akaike Corrected.* A measure for selecting and comparing mixed models based on the -2 (Restricted) log likelihood. Smaller values indicate better models. The AICC "corrects" the AIC for small sample sizes. As the sample size increases, the AICC converges to the AIC.
- *Bayesian.* A measure for selecting and comparing models based on the -2 log likelihood. Smaller values indicate better models. The BIC also "penalizes" overparameterized models (complex models with a large number of inputs, for example), but more strictly than the AIC.

Chart. If the target is categorical, a chart displays the accuracy of the final model, which is the percentage of correct classifications.

Data Structure

This view provides a summary of the data structure you specified, and helps you to check that the subjects and repeated measures have been specified correctly. The observed information for the first

subject is displayed for each subject field and repeated measures field, and the target. Additionally, the number of levels for each subject field and repeated measures field is displayed.

Predicted by Observed

For continuous targets, including targets specified as events/trials, this displays a binned scatterplot of the predicted values on the vertical axis by the observed values on the horizontal axis. Ideally, the points should lie on a 45-degree line; this view can tell you whether any records are predicted particularly badly by the model.

Classification

For categorical targets, this displays the cross-classification of observed versus predicted values in a heat map, plus the overall percent correct.

Table styles. There are several different display styles, which are accessible from the **Style** dropdown list.

- **Row percents.** This displays the row percentages (the cell counts expressed as a percent of the row totals) in the cells. This is the default.
- **Cell counts.** This displays the cell counts in the cells. The shading for the heat map is still based on the row percentages.
- **Heat map.** This displays no values in the cells, just the shading.
- **Compressed.** This displays no row or column headings, or values in the cells. It can be useful when the target has a lot of categories.

Missing. If any records have missing values on the target, they are displayed in a **(Missing)** row under all valid rows. Records with missing values do not contribute to the overall percent correct.

Multiple targets. If there are multiple categorical targets, then each target is displayed in a separate table and there is a **Target** dropdown list that controls which target to display.

Large tables. If the displayed target has more than 100 categories, no table is displayed.

Fixed Effects

This view displays the size of each fixed effect in the model.

Styles. There are different display styles, which are accessible from the **Style** dropdown list.

- **Diagram.** This is a chart in which effects are sorted from top to bottom in the order in which they were specified on the Fixed Effects settings. Connecting lines in the diagram are weighted based on effect significance, with greater line width corresponding to more significant effects (smaller p -values). This is the default.
- **Table.** This is an ANOVA table for the overall model and the individual model effects. The individual effects are sorted from top to bottom in the order in which they were specified on the Fixed Effects settings.

Significance. There is a Significance slider that controls which effects are shown in the view. Effects with significance values greater than the slider value are hidden. This does not change the model, but simply allows you to focus on the most important effects. By default the value is 1.00, so that no effects are filtered based on significance.

Fixed Coefficients

This view displays the value of each fixed coefficient in the model. Note that factors (categorical predictors) are indicator-coded within the model, so that **effects** containing factors will generally have multiple associated **coefficients**; one for each category except the category corresponding to the redundant coefficient.

Styles. There are different display styles, which are accessible from the **Style** dropdown list.

- **Diagram.** This is a chart which displays the intercept first, and then sorts effects from top to bottom in the order in which they were specified on the Fixed Effects settings. Within effects containing factors, coefficients are sorted by ascending order of data values. Connecting lines in the diagram are colored and weighted based on coefficient significance, with greater line width corresponding to more significant coefficients (smaller p -values). This is the default style.
- **Table.** This shows the values, significance tests, and confidence intervals for the individual model coefficients. After the intercept, the effects are sorted from top to bottom in the order in which they were specified on the Fixed Effects settings. Within effects containing factors, coefficients are sorted by ascending order of data values.

Multinomial. If the multinomial distribution is in effect, then the Multinomial drop-down list controls which target category to display. The sort order of the values in the list is determined by the specification on the Build Options settings.

Exponential. This displays exponential coefficient estimates and confidence intervals for certain model types, including Binary logistic regression (binomial distribution and logit link), Nominal logistic regression (multinomial distribution and logit link), Negative binomial regression (negative binomial distribution and log link), and Log-linear model (Poisson distribution and log link).

Significance. There is a Significance slider that controls which coefficients are shown in the view. Coefficients with significance values greater than the slider value are hidden. This does not change the model, but simply allows you to focus on the most important coefficients. By default the value is 1.00, so that no coefficients are filtered based on significance.

Random Effect Covariances

This view displays the random effects covariance matrix (**G**).

Styles. There are different display styles, which are accessible from the **Style** dropdown list.

- **Covariance values.** This is a heat map of the covariance matrix in which effects are sorted from top to bottom in the order in which they were specified on the Fixed Effects settings. Colors in the corrgram correspond to the cell values as shown in the key. This is the default.
- **Corrgram.** This is a heat map of the covariance matrix.
- **Compressed.** This is a heat map of the covariance matrix without the row and column headings.

Blocks. If there are multiple random effect blocks, then there is a Block dropdown list for selecting the block to display.

Groups. If a random effect block has a group specification, then there is a Group dropdown list for selecting the group level to display.

Multinomial. If the multinomial distribution is in effect, then the Multinomial drop-down list controls which target category to display. The sort order of the values in the list is determined by the specification on the Build Options settings.

Covariance Parameters

This view displays the covariance parameter estimates and related statistics for residual and random effects. These are advanced, but fundamental, results that provide information on whether the covariance structure is suitable.

Summary table. This is a quick reference for the number of parameters in the residual (**R**) and random effect (**G**) covariance matrices, the rank (number of columns) in the fixed effect (**X**) and random effect (**Z**) design matrices, and the number of subjects defined by the subject fields that define the data structure.

Covariance parameter table. For the selected effect, the estimate, standard error, and confidence interval are displayed for each covariance parameter. The number of parameters shown depends upon the covariance structure for the effect and, for random effect blocks, the number of effects in the block. If you see that the off-diagonal parameters are not significant, you may be able to use a simpler covariance structure.

Effects. If there are random effect blocks, then there is an Effect dropdown list for selecting the residual or random effect block to display. The residual effect is always available.

Groups. If a residual or random effect block has a group specification, then there is a Group dropdown list for selecting the group level to display.

Multinomial. If the multinomial distribution is in effect, then the Multinomial drop-down list controls which target category to display. The sort order of the values in the list is determined by the specification on the Build Options settings.

Estimated Means: Significant Effects

These are charts displayed for the 10 "most significant" fixed all-factor effects, starting with the three-way interactions, then the two-way interactions, and finally main effects. The chart displays the model-estimated value of the target on the vertical axis for each value of the main effect (or first listed effect in an interaction) on the horizontal axis; a separate line is produced for each value of the second listed effect in an interaction; a separate chart is produced for each value of the third listed effect in a three-way interaction; all other predictors are held constant. It provides a useful visualization of the effects of each predictor's coefficients on the target. Note that if no predictors are significant, no estimated means are produced.

Confidence. This displays upper and lower confidence limits for the marginal means, using the confidence level specified as part of the Build Options.

Estimated Means: Custom Effects

These are tables and charts for user-requested fixed all-factor effects.

Styles. There are different display styles, which are accessible from the **Style** dropdown list.

- **Diagram.** This style displays a line chart of the model-estimated value of the target on the vertical axis for each value of the main effect (or first listed effect in an interaction) on the horizontal axis; a separate line is produced for each value of the second listed effect in an interaction; a separate chart is produced for each value of the third listed effect in a three-way interaction; all other predictors are held constant.

If contrasts were requested, another chart is displayed to compare levels of the contrast field; for interactions, a chart is displayed for each level combination of the effects other than the contrast field. For **pairwise** contrasts, it is a distance network chart; that is, a graphical representation of the comparisons table in which the distances between nodes in the network correspond to differences between samples. Yellow lines correspond to statistically significant differences; black lines correspond to non-significant differences. Hovering over a line in the network displays a tooltip with the adjusted significance of the difference between the nodes connected by the line.

For **deviation** contrasts, a bar chart is displayed with the model-estimated value of the target on the vertical axis and the values of the contrast field on the horizontal axis; for interactions, a chart is displayed for each level combination of the effects other than the contrast field. The bars show the difference between each level of the contrast field and the overall mean, which is represented by a black horizontal line.

For **simple** contrasts, a bar chart is displayed with the model-estimated value of the target on the vertical axis and the values of the contrast field on the horizontal axis; for interactions, a chart is displayed for each level combination of the effects other than the contrast field. The bars show the difference between each level of the contrast field (except the last) and the last level, which is represented by a black horizontal line.

- **Table.** This style displays a table of the model-estimated value of the target, its standard error, and confidence interval for each level combination of the fields in the effect; all other predictors are held constant.

If contrasts were requested, another table is displayed with the estimate, standard error, significance test, and confidence interval for each contrast; for interactions, there a separate set of rows for each level combination of the effects other than the contrast field. Additionally, a table with the overall test

results is displayed; for interactions, there is a separate overall test for each level combination of the effects other than the contrast field.

Confidence. This toggles the display of upper and lower confidence limits for the marginal means, using the confidence level specified as part of the Build Options.

Layout. This toggles the layout of the pairwise contrasts diagram. The circle layout is less revealing of contrasts than the network layout but avoids overlapping lines.

Model Selection Loglinear Analysis

The Model Selection Loglinear Analysis procedure analyzes multiway crosstabulations (contingency tables). It fits hierarchical loglinear models to multidimensional crosstabulations using an iterative proportional-fitting algorithm. This procedure helps you find out which categorical variables are associated. To build models, forced entry and backward elimination methods are available. For saturated models, you can request parameter estimates and tests of partial association. A saturated model adds 0.5 to all cells.

Example. In a study of user preference for one of two laundry detergents, researchers counted people in each group, combining various categories of water softness (soft, medium, or hard), previous use of one of the brands, and washing temperature (cold or hot). They found how temperature is related to water softness and also to brand preference.

Statistics. Frequencies, residuals, parameter estimates, standard errors, confidence intervals, and tests of partial association. For custom models, plots of residuals and normal probability plots.

Model Selection Loglinear Analysis Data Considerations

Data. Factor variables are categorical. All variables to be analyzed must be numeric. Categorical string variables can be recoded to numeric variables before starting the model selection analysis.

Avoid specifying many variables with many levels. Such specifications can lead to a situation where many cells have small numbers of observations, and the chi-square values may not be useful.

Related procedures. The Model Selection procedure can help identify the terms needed in the model. Then you can continue to evaluate the model using General Loglinear Analysis or Logit Loglinear Analysis. You can use Autorecode to recode string variables. If a numeric variable has empty categories, use Recode to create consecutive integer values.

Obtaining a Model Selection Loglinear Analysis

From the menus choose:

Analyze > Loglinear > Model Selection...

1. Select two or more numeric categorical factors.
2. Select one or more factor variables in the Factor(s) list, and click **Define Range**.
3. Define the range of values for each factor variable.
4. Select an option in the Model Building group.

Optionally, you can select a cell weight variable to specify structural zeros.

Loglinear Analysis Define Range

You must indicate the range of categories for each factor variable. Values for Minimum and Maximum correspond to the lowest and highest categories of the factor variable. Both values must be integers, and the minimum value must be less than the maximum value. Cases with values outside of the bounds are excluded. For example, if you specify a minimum value of 1 and a maximum value of 3, only the values 1, 2, and 3 are used. Repeat this process for each factor variable.

Loglinear Analysis Model

Specify Model. A saturated model contains all factor main effects and all factor-by-factor interactions. Select **Custom** to specify a generating class for an unsaturated model.

Generating Class. A generating class is a list of the highest-order terms in which factors appear. A hierarchical model contains the terms that define the generating class and all lower-order relatives. Suppose you select variables *A*, *B*, and *C* in the Factors list and then select **Interaction** from the Build Terms drop-down list. The resulting model will contain the specified 3-way interaction $A*B*C$, the 2-way interactions $A*B$, $A*C$, and $B*C$, and main effects for *A*, *B*, and *C*. Do not specify the lower-order relatives in the generating class.

For the selected factors:

Interaction

Creates the highest-level interaction term of all selected variables. This is the default.

Main effects

Creates a main-effects term for each variable selected.

All 2-way

Creates all possible two-way interactions of the selected variables.

All 3-way

Creates all possible three-way interactions of the selected variables.

All 4-way

Creates all possible four-way interactions of the selected variables.

All 5-way

Creates all possible five-way interactions of the selected variables.

Build Terms and Custom Terms

Build terms

Use this choice when you want to include non-nested terms of a certain type (such as main effects) for all combinations of a selected set of factors and covariates.

Build custom terms

Use this choice when you want to include nested terms or when you want to explicitly build any term variable by variable. Building a nested term involves the following steps:

Model Selection Loglinear Analysis Options

Display. You can choose **Frequencies**, **Residuals**, or both. In a saturated model, the observed and expected frequencies are equal, and the residuals are equal to 0.

Plot. For custom models, you can choose one or both types of plots, **Residuals** and **Normal Probability**. These will help determine how well a model fits the data.

Display for Saturated Model. For a saturated model, you can choose **Parameter estimates**. The parameter estimates may help determine which terms can be dropped from the model. An association table, which lists tests of partial association, is also available. This option is computationally expensive for tables with many factors.

Model Criteria. An iterative proportional-fitting algorithm is used to obtain parameter estimates. You can override one or more of the estimation criteria by specifying **Maximum iterations**, **Convergence**, or **Delta** (a value added to all cell frequencies for saturated models).

HILOGLINEAR Command Additional Features

The command syntax language also allows you to:

- Specify cell weights in matrix form (using the **CWEIGHT** subcommand).
- Generate analyses of several models with a single command (using the **DESIGN** subcommand).

See the *Command Syntax Reference* for complete syntax information.

General Loglinear Analysis

The General Loglinear Analysis procedure analyzes the frequency counts of observations falling into each cross-classification category in a crosstabulation or a contingency table. Each cross-classification in the table constitutes a cell, and each categorical variable is called a factor. The dependent variable is the number of cases (frequency) in a cell of the crosstabulation, and the explanatory variables are factors and covariates. This procedure estimates maximum likelihood parameters of hierarchical and nonhierarchical loglinear models using the Newton-Raphson method. Either a Poisson or a multinomial distribution can be analyzed.

You can select up to 10 factors to define the cells of a table. A cell structure variable allows you to define structural zeros for incomplete tables, include an offset term in the model, fit a log-rate model, or implement the method of adjustment of marginal tables. Contrast variables allow computation of generalized log-odds ratios (GLOR).

Model information and goodness-of-fit statistics are automatically displayed. You can also display a variety of statistics and plots or save residuals and predicted values in the active dataset.

Example. Data from a report of automobile accidents in Florida are used to determine the relationship between wearing a seat belt and whether an injury was fatal or nonfatal. The odds ratio indicates significant evidence of a relationship.

Statistics. Observed and expected frequencies; raw, adjusted, and deviance residuals; design matrix; parameter estimates; odds ratio; log-odds ratio; GLOR; Wald statistic; and confidence intervals. Plots: adjusted residuals, deviance residuals, and normal probability.

General Loglinear Analysis Data Considerations

Data. Factors are categorical, and cell covariates are continuous. When a covariate is in the model, the mean covariate value for cases in a cell is applied to that cell. Contrast variables are continuous. They are used to compute generalized log-odds ratios. The values of the contrast variable are the coefficients for the linear combination of the logs of the expected cell counts.

A cell structure variable assigns weights. For example, if some of the cells are structural zeros, the cell structure variable has a value of either 0 or 1. Do not use a cell structure variable to weight aggregated data. Instead, choose **Weight Cases** from the Data menu.

Assumptions. Two distributions are available in General Loglinear Analysis: Poisson and multinomial.

Under the Poisson distribution assumption:

- The total sample size is not fixed before the study, or the analysis is not conditional on the total sample size.
- The event of an observation being in a cell is statistically independent of the cell counts of other cells.

Under the multinomial distribution assumption:

- The total sample size is fixed, or the analysis is conditional on the total sample size.
- The cell counts are not statistically independent.

Related procedures. Use the Crosstabs procedure to examine the crosstabulations. Use the Logit Loglinear procedure when it is natural to regard one or more categorical variables as the response variables and the others as the explanatory variables.

Obtaining a General Loglinear Analysis

1. From the menus choose:

Analyze > Loglinear > General...

2. In the General Loglinear Analysis dialog box, select up to 10 factor variables.

Optionally, you can:

- Select cell covariates.
- Select a cell structure variable to define structural zeros or include an offset term.
- Select a contrast variable.

General Loglinear Analysis Model

Specify Model. A saturated model contains all main effects and interactions involving factor variables. It does not contain covariate terms. Select **Custom** to specify only a subset of interactions or to specify factor-by-covariate interactions.

Factors & Covariates. The factors and covariates are listed.

Terms in Model. The model depends on the nature of your data. After selecting **Custom**, you can select the main effects and interactions that are of interest in your analysis. You must indicate all of the terms to be included in the model.

For the selected factors and covariates:

Interaction

Creates the highest-level interaction term of all selected variables. This is the default.

Main effects

Creates a main-effects term for each variable selected.

All 2-way

Creates all possible two-way interactions of the selected variables.

All 3-way

Creates all possible three-way interactions of the selected variables.

All 4-way

Creates all possible four-way interactions of the selected variables.

All 5-way

Creates all possible five-way interactions of the selected variables.

Build Terms and Custom Terms

Build terms

Use this choice when you want to include non-nested terms of a certain type (such as main effects) for all combinations of a selected set of factors and covariates.

Build custom terms

Use this choice when you want to include nested terms or when you want to explicitly build any term variable by variable. Building a nested term involves the following steps:

General Loglinear Analysis Options

The General Loglinear Analysis procedure displays model information and goodness-of-fit statistics. In addition, you can choose one or more of the following:

Display. Several statistics are available for display--observed and expected cell frequencies; raw, adjusted, and deviance residuals; a design matrix of the model; and parameter estimates for the model.

Plot. Plots, available for custom models only, include two scatterplot matrices (adjusted residuals or deviance residuals against observed and expected cell counts). You can also display normal probability and detrended normal plots of adjusted residuals or deviance residuals.

Confidence Interval. The confidence interval for parameter estimates can be adjusted.

Criteria. The Newton-Raphson method is used to obtain maximum likelihood parameter estimates. You can enter new values for the maximum number of iterations, the convergence criterion, and delta (a constant added to all cells for initial approximations). Delta remains in the cells for saturated models.

General Loglinear Analysis Save

Select the values you want to save as new variables in the active dataset. The suffix n in the new variable names increments to make a unique name for each saved variable.

The saved values refer to the aggregated data (cells in the contingency table), even if the data are recorded in individual observations in the Data Editor. If you save residuals or predicted values for unaggregated data, the saved value for a cell in the contingency table is entered in the Data Editor for each case in that cell. To make sense of the saved values, you should aggregate the data to obtain the cell counts.

Four types of residuals can be saved: raw, standardized, adjusted, and deviance. The predicted values can also be saved.

- *Residuals*. Also called the simple or raw residual, it is the difference between the observed cell count and its expected count.
- *Standardized residuals*. The residual divided by an estimate of its standard error. Standardized residuals are also known as Pearson residuals.
- *Adjusted residuals*. The standardized residual divided by its estimated standard error. Since the adjusted residuals are asymptotically standard normal when the selected model is correct, they are preferred over the standardized residuals for checking for normality.
- *Deviance residuals*. The signed square root of an individual contribution to the likelihood-ratio chi-square statistic (G squared), where the sign is the sign of the residual (observed count minus expected count). Deviance residuals have an asymptotic standard normal distribution.

GENLOG Command Additional Features

The command syntax language also allows you to:

- Calculate linear combinations of observed cell frequencies and expected cell frequencies and print residuals, standardized residuals, and adjusted residuals of that combination (using the GERESID subcommand).
- Change the default threshold value for redundancy checking (using the CRITERIA subcommand).
- Display the standardized residuals (using the PRINT subcommand).

See the *Command Syntax Reference* for complete syntax information.

Logit Loglinear Analysis

The Logit Loglinear Analysis procedure analyzes the relationship between dependent (or response) variables and independent (or explanatory) variables. The dependent variables are always categorical, while the independent variables can be categorical (factors). Other independent variables (cell covariates) can be continuous, but they are not applied on a case-by-case basis. The weighted covariate mean for a cell is applied to that cell. The logarithm of the odds of the dependent variables is expressed as a linear combination of parameters. A multinomial distribution is automatically assumed; these models are sometimes called multinomial logit models. This procedure estimates parameters of logit loglinear models using the Newton-Raphson algorithm.

You can select from 1 to 10 dependent and factor variables combined. A cell structure variable allows you to define structural zeros for incomplete tables, include an offset term in the model, fit a log-rate model, or implement the method of adjustment of marginal tables. Contrast variables allow computation of generalized log-odds ratios (GLOR). The values of the contrast variable are the coefficients for the linear combination of the logs of the expected cell counts.

Model information and goodness-of-fit statistics are automatically displayed. You can also display a variety of statistics and plots or save residuals and predicted values in the active dataset.

Example. A study in Florida included 219 alligators. How does the alligators' food type vary with their size and the four lakes in which they live? The study found that the odds of a smaller alligator preferring

reptiles to fish is 0.70 times lower than for larger alligators; also, the odds of selecting primarily reptiles instead of fish were highest in lake 3.

Statistics. Observed and expected frequencies; raw, adjusted, and deviance residuals; design matrix; parameter estimates; generalized log-odds ratio; Wald statistic; and confidence intervals. Plots: adjusted residuals, deviance residuals, and normal probability plots.

Logit Loglinear Analysis Data Considerations

Data. The dependent variables are categorical. Factors are categorical. Cell covariates can be continuous, but when a covariate is in the model, the mean covariate value for cases in a cell is applied to that cell. Contrast variables are continuous. They are used to compute generalized log-odds ratios (GLOR). The values of the contrast variable are the coefficients for the linear combination of the logs of the expected cell counts.

A cell structure variable assigns weights. For example, if some of the cells are structural zeros, the cell structure variable has a value of either 0 or 1. Do not use a cell structure variable to weight aggregate data. Instead, use Weight Cases on the Data menu.

Assumptions. The counts within each combination of categories of explanatory variables are assumed to have a multinomial distribution. Under the multinomial distribution assumption:

- The total sample size is fixed, or the analysis is conditional on the total sample size.
- The cell counts are not statistically independent.

Related procedures. Use the Crosstabs procedure to display the contingency tables. Use the General Loglinear Analysis procedure when you want to analyze the relationship between an observed count and a set of explanatory variables.

Obtaining a Logit Loglinear Analysis

1. From the menus choose:

Analyze > Loglinear > Logit...

2. In the Logit Loglinear Analysis dialog box, select one or more dependent variables.
3. Select one or more factor variables.

The total number of dependent and factor variables must be less than or equal to 10.

Optionally, you can:

- Select cell covariates.
- Select a cell structure variable to define structural zeros or include an offset term.
- Select one or more contrast variables.

Logit Loglinear Analysis Model

Specify Model. A saturated model contains all main effects and interactions involving factor variables. It does not contain covariate terms. Select **Custom** to specify only a subset of interactions or to specify factor-by-covariate interactions.

Factors & Covariates. The factors and covariates are listed.

Terms in Model. The model depends on the nature of your data. After selecting **Custom**, you can select the main effects and interactions that are of interest in your analysis. You must indicate all of the terms to be included in the model.

For the selected factors and covariates:

Interaction

Creates the highest-level interaction term of all selected variables. This is the default.

Main effects

Creates a main-effects term for each variable selected.

All 2-way

Creates all possible two-way interactions of the selected variables.

All 3-way

Creates all possible three-way interactions of the selected variables.

All 4-way

Creates all possible four-way interactions of the selected variables.

All 5-way

Creates all possible five-way interactions of the selected variables.

Terms are added to the design by taking all possible combinations of the dependent terms and matching each combination with each term in the model list. If **Include constant for dependent** is selected, there is also a unit term (1) added to the model list.

For example, suppose variables $D1$ and $D2$ are the dependent variables. A dependent terms list is created by the Logit Loglinear Analysis procedure ($D1, D2, D1*D2$). If the Terms in Model list contains $M1$ and $M2$ and a constant is included, the model list contains 1, $M1$, and $M2$. The resultant design includes combinations of each model term with each dependent term:

$D1, D2, D1*D2$

$M1*D1, M1*D2, M1*D1*D2$

$M2*D1, M2*D2, M2*D1*D2$

Include constant for dependent. Includes a constant for the dependent variable in a custom model.

Build Terms and Custom Terms

Build terms

Use this choice when you want to include non-nested terms of a certain type (such as main effects) for all combinations of a selected set of factors and covariates.

Build custom terms

Use this choice when you want to include nested terms or when you want to explicitly build any term variable by variable. Building a nested term involves the following steps:

Logit Loglinear Analysis Options

The Logit Loglinear Analysis procedure displays model information and goodness-of-fit statistics. In addition, you can choose one or more of the following options:

Display. Several statistics are available for display: observed and expected cell frequencies; raw, adjusted, and deviance residuals; a design matrix of the model; and parameter estimates for the model.

Plot. Plots available for custom models include two scatterplot matrices (adjusted residuals or deviance residuals against observed and expected cell counts). You can also display normal probability and detrended normal plots of adjusted residuals or deviance residuals.

Confidence Interval. The confidence interval for parameter estimates can be adjusted.

Criteria. The Newton-Raphson method is used to obtain maximum likelihood parameter estimates. You can enter new values for the maximum number of iterations, the convergence criterion, and delta (a constant added to all cells for initial approximations). Delta remains in the cells for saturated models.

Logit Loglinear Analysis Save

Select the values you want to save as new variables in the active dataset. The suffix n in the new variable names increments to make a unique name for each saved variable.

The saved values refer to the aggregated data (to cells in the contingency table), even if the data are recorded in individual observations in the Data Editor. If you save residuals or predicted values for unaggregated data, the saved value for a cell in the contingency table is entered in the Data Editor for

each case in that cell. To make sense of the saved values, you should aggregate the data to obtain the cell counts.

Four types of residuals can be saved: raw, standardized, adjusted, and deviance. The predicted values can also be saved.

- *Residuals*. Also called the simple or raw residual, it is the difference between the observed cell count and its expected count.
- *Standardized residuals*. The residual divided by an estimate of its standard error. Standardized residuals are also known as Pearson residuals.
- *Adjusted residuals*. The standardized residual divided by its estimated standard error. Since the adjusted residuals are asymptotically standard normal when the selected model is correct, they are preferred over the standardized residuals for checking for normality.
- *Deviance residuals*. The signed square root of an individual contribution to the likelihood-ratio chi-square statistic (G squared), where the sign is the sign of the residual (observed count minus expected count). Deviance residuals have an asymptotic standard normal distribution.

GENLOG Command Additional Features

The command syntax language also allows you to:

- Calculate linear combinations of observed cell frequencies and expected cell frequencies, and print residuals, standardized residuals, and adjusted residuals of that combination (using the GERESID subcommand).
- Change the default threshold value for redundancy checking (using the CRITERIA subcommand).
- Display the standardized residuals (using the PRINT subcommand).

See the *Command Syntax Reference* for complete syntax information.

Life Tables

There are many situations in which you would want to examine the distribution of times between two events, such as length of employment (time between being hired and leaving the company). However, this kind of data usually includes some cases for which the second event isn't recorded (for example, people still working for the company at the end of the study). This can happen for several reasons: for some cases, the event simply doesn't occur before the end of the study; for other cases, we lose track of their status sometime before the end of the study; still other cases may be unable to continue for reasons unrelated to the study (such as an employee becoming ill and taking a leave of absence). Collectively, such cases are known as **censored cases**, and they make this kind of study inappropriate for traditional techniques such as *t* tests or linear regression.

A statistical technique useful for this type of data is called a follow-up **life table**. The basic idea of the life table is to subdivide the period of observation into smaller time intervals. For each interval, all people who have been observed at least that long are used to calculate the probability of a terminal event occurring in that interval. The probabilities estimated from each of the intervals are then used to estimate the overall probability of the event occurring at different time points.

Example. Is a new nicotine patch therapy better than traditional patch therapy in helping people to quit smoking? You could conduct a study using two groups of smokers, one of which received the traditional therapy and the other of which received the experimental therapy. Constructing life tables from the data would allow you to compare overall abstinence rates between the two groups to determine if the experimental treatment is an improvement over the traditional therapy. You can also plot the survival or hazard functions and compare them visually for more detailed information.

Statistics. Number entering, number leaving, number exposed to risk, number of terminal events, proportion terminating, proportion surviving, cumulative proportion surviving (and standard error), probability density (and standard error), and hazard rate (and standard error) for each time interval for each group; median survival time for each group; and Wilcoxon (Gehan) test for comparing survival

distributions between groups. Plots: function plots for survival, log survival, density, hazard rate, and one minus survival.

Life Tables Data Considerations

Data. Your time variable should be quantitative. Your status variable should be dichotomous or categorical, coded as integers, with events being coded as a single value or a range of consecutive values. Factor variables should be categorical, coded as integers.

Assumptions. Probabilities for the event of interest should depend only on time after the initial event-- they are assumed to be stable with respect to absolute time. That is, cases that enter the study at different times (for example, patients who begin treatment at different times) should behave similarly. There should also be no systematic differences between censored and uncensored cases. If, for example, many of the censored cases are patients with more serious conditions, your results may be biased.

Related procedures. The Life Tables procedure uses an actuarial approach to this kind of analysis (known generally as Survival Analysis). The Kaplan-Meier Survival Analysis procedure uses a slightly different method of calculating life tables that does not rely on partitioning the observation period into smaller time intervals. This method is recommended if you have a small number of observations, such that there would be only a small number of observations in each survival time interval. If you have variables that you suspect are related to survival time or variables that you want to control for (covariates), use the Cox Regression procedure. If your covariates can have different values at different points in time for the same case, use Cox Regression with Time-Dependent Covariates.

Creating Life Tables

1. From the menus choose:

Analyze > Survival > Life Tables...

2. Select one *numeric* survival variable.

3. Specify the time intervals to be examined.

4. Select a status variable to define cases for which the terminal event has occurred.

5. Click **Define Event** to specify the value of the status variable that indicates that an event occurred.

Optionally, you can select a first-order factor variable. Actuarial tables for the survival variable are generated for each category of the factor variable.

You can also select a second-order *by factor* variable. Actuarial tables for the survival variable are generated for every combination of the first- and second-order factor variables.

Life Tables Define Range

Cases with values for the factor variable in the range you specify will be included in the analysis, and separate tables (and plots, if requested) will be generated for each unique value in the range.

Life Tables Options

You can control various aspects of your Life Tables analysis.

Life table(s). To suppress the display of life tables in the output, deselect **Life table(s)**.

Plot. Allows you to request plots of the survival functions. If you have defined factor variable(s), plots are generated for each subgroup defined by the factor variable(s). Available plots are survival, log survival, hazard, density, and one minus survival.

- *Survival.* Displays the cumulative survival function on a linear scale.
- *Log survival.* Displays the cumulative survival function on a logarithmic scale.
- *Hazard.* Displays the cumulative hazard function on a linear scale.
- *Density.* Displays the density function.
- *One minus survival.* Plots one-minus the survival function on a linear scale.

Compare Levels of First Factor. If you have a first-order control variable, you can select one of the alternatives in this group to perform the Wilcoxon (Gehan) test, which compares the survival of subgroups. Tests are performed on the first-order factor. If you have defined a second-order factor, tests are performed for each level of the second-order variable.

SURVIVAL Command Additional Features

The command syntax language also allows you to:

- Specify more than one dependent variable.
- Specify unequally spaced intervals.
- Specify more than one status variable.
- Specify comparisons that do not include all the factor and all the control variables.
- Calculate approximate, rather than exact, comparisons.

See the *Command Syntax Reference* for complete syntax information.

Parametric Accelerated Failure Time Models

A Parametric Accelerated Failure Time (AFT) Model analysis invokes the parametric survival models procedure with nonrecurrent life time data. Parametric survival models assume that survival time follow a known distribution, and this analysis fits accelerated failure time models with their model effects proportional with respect to survival time.

Obtaining a Parametric Accelerated Failure Time Models analysis

1. From the menus choose:

Analyze > Survival > Parametric Accelerated Failure Time (AFT) Models

2. Select a source variable.

Time

Survival

Single numeric variable denoting the duration of the survival time.

Start/End

Numeric variables denoting **Start Time** and **End Time**.

Status

Single optional string or numeric variable that determines one of the following status settings:

Failure/Event

Maps a record to a failure/event category. The default value for a string status variable is F.

Right Censoring

Maps a record to a right censoring category. The default value for a string status variable is R.

Left Censoring

Maps a record to a left censoring category. The default value for a string status variable is L.

Interval Censoring

Maps a record to an interval censoring category. For **Start/End** only. The default value for a string status variable is I.

Unmapped Values Treatment

Controls which category to map the unmapped records to. To delete the records which failed to be mapped, select **Exclude them from analysis**.

For **Survival**, the default status for all cases is **Failure/Event**. For **Start/End**, the default status is **Interval Censoring**. Click the **Define event** button to define an event for the status variable.

Covariate(s)

One or more optional numeric variables to be treated as covariates. Note that a variable cannot be specified by both **Covariate(s)** and **Fixed Factor(s)**.

Fixed Factor(s)

One or more optional variables to be treated as factors. A variable cannot be specified by both **Fixed Factor(s)** and **Covariate(s)**.

Left Truncation

Single optional numeric variable for left truncation for **Survival** only.

Parametric Accelerated Failure Time Models: Criteria

Criteria

An optional panel to specify the general criteria.

Confidence Interval

An optional percentage to specify the level for the confidence intervals of regression parameters. It must be a single numeric value between 0 and 100. The default is 95.

Missing Values

An option to control how the user-missing values are treated:

Exclude both user-missing and system missing values

Treats the user-missing values as valid values. This is the default.

User-missing values are treated as valid

Ignores the user-missing value designations and treats them as valid values.

Status Treatment

For **Start/End** only. An option to control how to deal with records with incorrect status fields:

Discard conflicted record

Drops the conflicted records. This is the default setting.

Obtain the time information according to the status

Gets the time information according to the status.

Derive the status according to the time information

Changes the status according to the time information.

Parametric Accelerated Failure Time Models: Model

Model

An optional panel to specify the model options and settings.

Distribution of Survival Time

An option to specify the distribution of the survival time.

Weibull

Specifies Weibull distribution. This is the default setting.

Exponential

Specifies exponential distribution.

Log-Normal

Specifies log-normal distribution.

Log-Logistic

Specifies log-logistic distribution.

Covariate Settings

Specify covariate variables.

Factor Settings

Specify factor variables.

Initial Value of Intercept

An option to specify the initial value of the intercept term. If specified, it must be a single numeric value, and cannot be 0.

Initial Value of Scale Parameter

An option to control the setting of the scale parameter.

Standard error of the corresponding OLS regression

Uses the standard error of the corresponding ordinary least squares regression as the initial value.

Inverses standard error of the corresponding OLS regression

Uses the reciprocal of the standard error.

User-supplied value

If a single numeric value is specified, the value is used as the initial value. If specified, it must be greater than 0.

Parametric Accelerated Failure Time Models: Estimate

Estimate

An optional panel to specify the settings to control the estimation of the accelerated failure time models and the optional feature selection process.

Alternating Direction Method or Multipliers (ADMM)

Fast

Applies the fast alternating direction method of multipliers (ADMM). This is the default.

Traditional

Applies the traditional ADMM algorithm.

Apply L-1 regularization

Conducts the process to control feature selection. The **Penalty Parameter** field specifies the penalty parameter that controls the regularization process. It must be a single value greater than 0. The default setting is 0.001.

Model Convergence Criteria

Parameter Convergence

Specifies the convergence criteria for the parameter. It must be a single numeric value belonging to [0, 1). The default setting is 0.000001. For **Type**, you can select either **ABSOLUTE** to apply the absolute convergence to the inner optimization or **RELATIVE** to apply the relative convergence to the inner optimization. The optional **Value** field specifies a keyword.

Objective Function Convergence

Specifies the convergence criteria for the objective function. It must be a single numeric value belonging to [0, 1). The default setting is 0, which does not apply the convergence criteria. For **Type**, you can select either **ABSOLUTE** to apply the absolute convergence to the inner optimization or **RELATIVE** to apply the relative convergence to the inner optimization. The optional **Value** field specifies a keyword.

Hessian Convergence

Specifies the convergence criteria for the Hessian matrix. It must be a single numeric value belonging to [0, 1). The default setting is 0, which does not apply the convergence criteria. For **Type**, you can select either **ABSOLUTE** to apply the absolute convergence to the inner optimization or **RELATIVE** to apply the relative convergence to the inner optimization. The optional **Value** field specifies a keyword.

Residual Convergence Criteria

An option to control the optimization process.

Both primal and dual residual

Applies both primal and dual residual convergence criterion. This is the default setting.

Primal residual only

Applies the primal residual convergence criterion.

Dual residual only

Applies the dual residual convergence criterion.

Method

An optional parameter to specify the estimation method.

Auto

Automatically chooses the method based on the sample data set. This is the default. The **Threshold number of predictors** field specifies the threshold of the number of predictors, and must be a single integer greater than 1. The default value is 1000.

Newton-Raphson

Applies the Newton-Raphson's method.

L-BFGS

Applies the limited-memory BFGS algorithm. The **Update** field specifies the number of the past updates maintained by the limited-memory BFGS algorithm, and must be a single integer greater than or equal to 1. The default value is 5.

Iteration**Maximum iterations**

Specifies the maximum number of iterations. It must be a single integer belonging to [1, 100]. The default setting is 20.

Maximum step-halving

Specifies the maximum number of step-halving. It must be a single integer belonging to [1, 20]. The default setting is 5.

Maximum number of line searches

Specifies the maximum number of the line searches. It must be a single integer belonging to [1, 100]. The default setting is 20.

Absolute convergence for iteration process

Specifies the absolute convergence for the outer iteration process. It must be a single numeric value belonging to (0, 1). The default setting is 0.0001.

Relative convergence for iteration process

Specifies the relative convergence for the outer iteration process. It must be a single numeric value belonging to (0, 1). The default setting is 0.01.

Parametric Accelerated Failure Time Models: Print

Print

An optional panel to control the table outputs.

Factor encoding details

If selected, displays and prints the encoding details of the factors. The process is ignored if there are no factors in effect.

Initial values assigned to the regression parameters

If selected, displays the initial values used in the estimation process.

Model iteration history

If selected, displays the iteration history of survival analysis. In the **Number of steps** field, specify the number of steps between 1 and 99999999. The default setting is 1.

Selection results containing

Controls the display of the details of the feature selection.

Both selected and unselected variables

Display both selected and unselected variables in the table.

Only selected variables

Only display the selected variables.

Only unselected variables

Only display the unselected variables. The **Maximum variables to display** field specifies the maximum number of the variables printed in the table. The default setting is 30.

Parametric Accelerated Failure Time Models: Predict

Predict

An optional panel to score and save the predicted statistics to the active data set.

Time Values for Scoring

Time Values defined by dependent variable(s)

Scores the **Predictions** based on the time variable specified for the parametric survival model.

Regular intervals

Scores the **Predictions** based on future time values. The **Time interval** field specifies the time interval, and must be a single numeric value greater than 0. The **Number of time periods** field specifies the number of the time periods, and must be a single numeric integer between 2 and 100.

Time duration

Scores the **Predictions** based on the time duration to define the future time values. It must be a single numeric variable.

Predictions

Survival

Scores and saves the predicted survival statistics to the active data set. The default custom variable name (or root name) is `PredSurvival`.

Hazard

Scores and saves the predicted hazards to the active data set. The default custom variable name (or root name) is `PredHazard`.

Cumulative hazard

Scores and saves the predicted cumulative hazards to the active data set. The default custom variable name (or root name) is `PredCumHazard`.

Conditional survival

Scores and saves the predicted conditional survival statistics to the active data set. The default custom variable name (or root name) is `PredConditionalSurvival`. The process will be ignored if `PASTTIME` is not specified. A **Past survival time** value is required, and specifies the past time values for scoring. It must be a single numeric variable.

Parametric Accelerated Failure Time Models: Plot

Plot

Cox-Snell residual plot

Select **Display the plot** to create a Cox-Snell residual plot. In the **Number of binning cut points** field, specify a number from 1 to 10000. The default setting is 100.

Function Plots

An option to control the function plots.

Type**Survival**

Creates the plot for survival functions.

Hazard

Creates the plot for the hazard functions.

Density

Creates a plot for the density functions.

Number of points to display

Specifies the number of function points between 1 and 200. The default setting is 100.

Covariate Values for Plot

An optional to specify the user-supplied values and assign them to the predictors. By default, the designated plots will be created at the **Mean** of each covariate in effect and the category frequency of each factor in effect. If specified, the designated plots will be created based on the pattern's setting. In the presence of any duplicated variables, the one specified first would be recognized and the rest would be ignored. A valid variable must be contained in a model effect. For a covariate, the user-supplied value must be numeric. Omission of a variable in effect indicates that the category frequency and the **Mean** would be used by default for the factor and the covariate, respectively. If an invalid value is assigned to a variable, the pattern requested will not be plotted.

Factor Values for Plot

An optional to specify the user-supplied values and assign them to the predictors. In the presence of any duplicated variables, the one specified first would be recognized and the rest would be ignored. A valid variable must be contained in a model effect. Omission of a variable in effect indicates that the category frequency and the mean would be used by default for the factor and the covariate, respectively. If an invalid value is assigned to a variable, the pattern requested will not be plotted.

Separate lines for

An option to specify a categorical variable by which the line plots will be drawn.

Maximum number of lines in a chart

Specifies the maximum number of the lines in a chart if **Separate lines for** is specified. The default setting is 10.

Parametric Accelerated Failure Time Models: Export

Export

Select **Export model information to XML file** to write the model and parameter information to a PMML file for scoring. You must specify the directory and file name of the PMML file to be saved.

Survival AFT Define Events for Status Variables

Occurrences of the selected value or values for the status variable indicate that the terminal event occurred for those cases. All other cases are considered to be censored. Enter either a single value or a range of values that identifies the event of interest.

Parametric Accelerated Failure Time Models: Select Category

The Select Category setting provides options to choose a value that denotes the category to be modeled as a baseline for comparison.

Selecting the category

Click on 'Last Category' to open the 'Select category' dialog box.

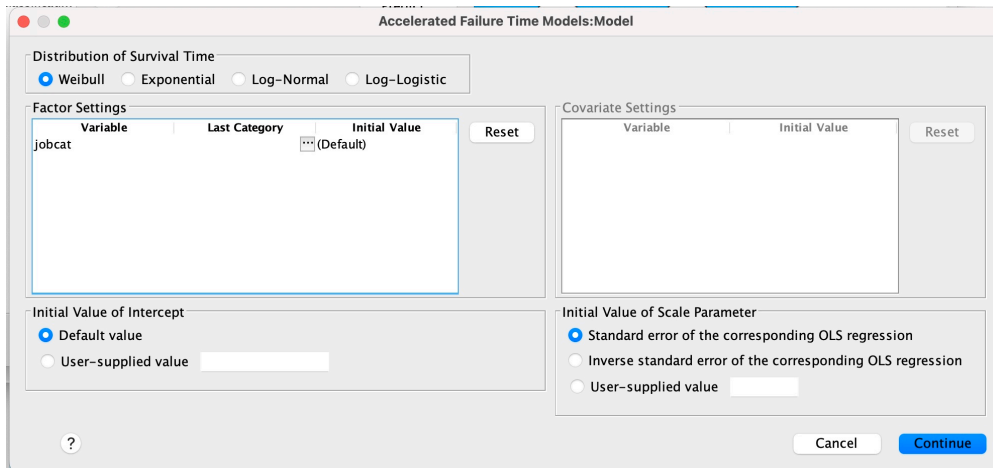

Figure 3. Accelerated Life Time Models- Dialog box-Category

To designate a category as the baseline, select a value from the 'Select category' dialog box.

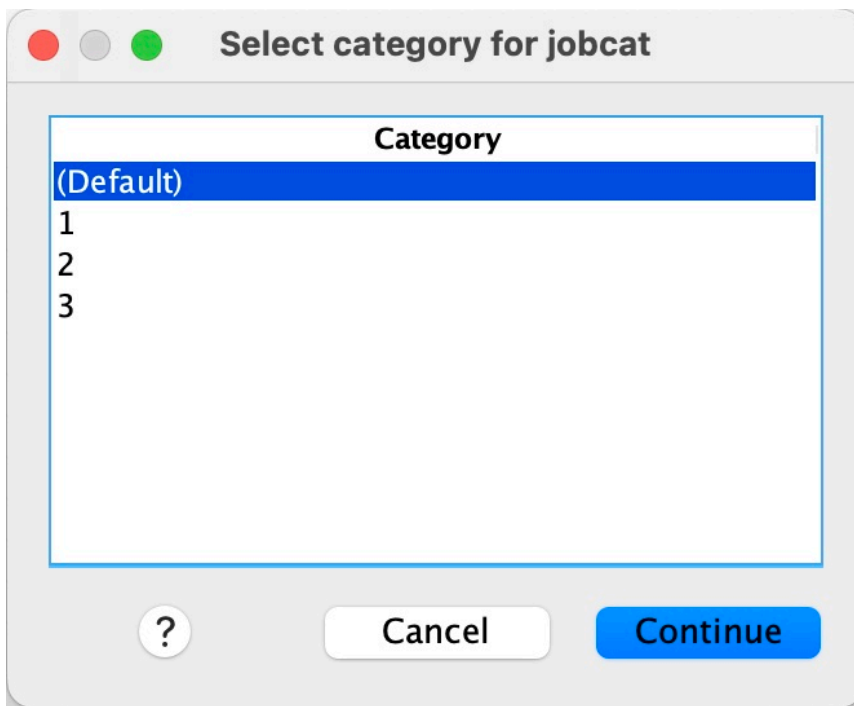

Figure 4. Accelerated Life Time Models- Dialog box-Select category

Click Continue.

Parametric Shared Frailty Models

A Parametric Shared Frailty Models Survival analysis starts the parametric survival models procedure with recurrent life time data input. Parametric survival models assume that survival time follows a known distribution, and this analysis incorporates a frailty term into a parametric survival model. It is treated as a random component to account for an unobserved effect due to individual or group level variability.

Obtaining a Parametric Shared Frailty Models analysis

1. From the menu, choose:

Analyze > Survival > Parametric Shared Frailty Models

2. Select a source variable.

Time

Survival

Survival time is represented by one variable to denote the end time. The start time would be set to 0.

Start / End

Numeric variables that denote **Start Time** and **End Time**.

Subject

Required to run the procedure. Specifies a single variable for the subject ID.

Interval

Specifies a single and numeric variable for the interval number that is used to identify the different recurrent records that share the same subject ID.

Status

Single optional string or numeric variable that determines one of the following status settings:

Failure/Event

Maps a record to a failure/event category. The default value for a string status variable is F.

Right Censoring

Maps a record to a right censoring category. The default value for a string status variable is R.

Unmapped Values Treatment

Controls which category to map the unmapped records to. To delete the records that failed to be mapped, select **Exclude them from analysis**.

Click the **Define event** button to define an event for the status variable.

Covariate(s)

One or more optional numeric variables to be treated as covariates. Note that a variable cannot be specified by both **Covariate(s)** and **Fixed Factor(s)**.

Fixed Factor(s)

One or more optional variables to be treated as factors. A variable cannot be specified by both **Fixed Factor(s)** and **Covariate(s)**.

Parametric Shared Frailty Models: Criteria

Criteria

An optional panel to specify the general criteria.

Confidence Interval

An optional percentage to specify the level for the confidence intervals of regression parameters. It must be a single numeric value between 0 and 100. The default is 95.

Significance Level

An option to specify the significance level of the likelihood ratio test for the frailty component. It must be a single numeric value between 0 and 1. The default setting is 0.05.

Missing Values

An option to control how the user-missing values are treated:

Exclude both user-missing and system missing values

Treats the user-missing values as valid values. This is the default.

User-missing values are treated as valid

Ignores the user-missing value designations and treats them as valid values.

Interval Treatment

An option to control how to deal with records whose interval conflicts with the begin and end time. It takes effect if there are two time variables with an Interval variable specified in the main dialogue.

Discard the conflicted records

Discards the entire subject serial records if the interval value conflicts with the begin and end time. This is the default setting.

Discover interval values based on the start and end time

Discovers the interval value from the begin and end time.

Parametric Shared Frailty Models: Model

Model

An optional panel to specify the model options and settings.

Distribution of Survival Time

An option to specify the distribution of the survival time.

Weibull

Specifies Weibull distribution. This is the default setting.

Exponential

Specifies Exponential distribution.

Log-Normal

Specifies Log-normal distribution.

Log-Logistic

Specifies Log-logistic distribution.

Covariate Settings

Specify covariate variables.

Factor Settings

Specify factor variables.

Initial Value of Intercept

An option to specify the initial value of the intercept term. If specified, it must be a single numeric value, and cannot be 0.

Initial Value of Scale Parameter

An option to control the setting of the scale parameter.

Standard error of the corresponding OLS regression

Uses the standard error of the corresponding ordinary least squares regression as the initial value.

Inverses standard error of the corresponding OLS regression

Uses the reciprocal of the standard error.

User-supplied value

If a single numeric value is specified, the value is used as the initial value. If specified, it must be greater than 0.

Frailty Component

An optional parameter to specify the **Distribution** of the frailty component.

Gamma

Specifies the Gamma distribution. This is the default setting.

Inverse-Gaussian

Specifies the inverse-Gaussian distribution.

Initial value of variance

Specifies the initial value of the variance of the frailty component. It must be a single numeric value greater than 0. The default value is 1.0 for Gamma distribution and 0.1 for inverse-Gaussian distribution.

Parametric Shared Frailty Models: Estimate

Estimate

An optional panel to specify the settings to control the estimation of the shared frailty models and the optional feature selection process.

Alternating Direction Method or Multipliers (ADMM)

Fast

Applies the fast alternating direction method of multipliers (ADMM). This is the default.

Traditional

Applies the traditional ADMM algorithm.

Apply L-1 regularization

Conducts the process to control feature selection. The **Penalty Parameter** field specifies the penalty parameter that controls the regularization process. It must be a single value greater than 0. The default setting is 0.001.

Model Convergence Criteria

Parameter Convergence

Specifies the convergence criteria for the parameter. It must be a single numeric value belonging to $[0, 1)$. The default setting is 0.000001. For **Type**, you can select either **ABSOLUTE** to apply the absolute convergence to the inner optimization or **RELATIVE** to apply the relative convergence to the inner optimization. The optional **Value** specifies a numeric threshold for the convergence type.

Objective Function Convergence

Specifies the convergence criteria for the objective function. It must be a single numeric value that belongs to $[0, 1)$. The default setting is 0, which does not apply the convergence criteria. For **Type**, you can select either **ABSOLUTE** to apply the absolute convergence to the inner optimization or **RELATIVE** to apply the relative convergence to the inner optimization. The optional **Value** specifies a numeric threshold for the convergence type.

Hessian Convergence

Specifies the convergence criteria for the Hessian matrix. It must be a single numeric value that belongs to $[0, 1)$. The default setting is 0, which does not apply the convergence criteria. For **Type**, you can select either **ABSOLUTE** to apply the absolute convergence to the inner optimization or **RELATIVE** to apply the relative convergence to the inner optimization. The optional **Value** specifies a numeric threshold for the convergence type.

Residual Convergence Criteria

An option to control the optimization process.

Both primal and dual residual

Applies both primal and dual residual convergence criterion. This setting is by default.

Primal residual only

Applies the primal residual convergence criterion.

Dual residual only

Applies the dual residual convergence criterion.

Method

An optional parameter to specify the estimation method.

Auto

Automatically chooses the method based on the sample data set. This method is selected by default. The **Threshold number of predictors** field specifies the threshold of the number of predictors, and must be a single integer greater than 1. The default value is 1000.

Newton-Raphson

Applies the Newton-Raphson's method.

L-BFGS

Applies the limited-memory BFGS algorithm. The **Update** field specifies the number of the past updates that are maintained by the limited-memory BFGS algorithm, and must be a single integer greater than or equal to 1. The default value is 5.

Iteration

Maximum iterations

Specifies the maximum number of iterations. It must be a single integer that belongs to [1, 300]. The default setting is 20.

Maximum step-halving

Specifies the maximum number of step-halving. It must be a single integer that belongs to [1, 200]. The default setting is 5.

Maximum number of line searches

Specifies the maximum number of line searches. It must be a single integer that belongs to [1, 300]. The default setting is 20.

Absolute convergence for iteration process

Specifies the absolute convergence for the outer iteration process. It must be a single numeric value that belongs to (0, 1). The default setting is 0.0001.

Relative convergence for iteration process

Specifies the relative convergence for the outer iteration process. It must be a single numeric value that belongs to (0, 1). The default setting is 0.01.

Parametric Shared Frailty Models: Print

Print

An optional panel that controls the table outputs.

Factor encoding details

If selected, displays and prints the encoding details of the factors. The process is ignored if there are no factors in effect.

Initial values that are assigned to the regression parameters

If selected, displays the initial values that are used in the estimation process.

Model iteration history

If selected, displays the iteration history of survival analysis. In the **Number of steps** field, specify the number of steps between 1 and 99999999. The default setting is 1.

Parametric Shared Frailty Models: Predict

Predict

An optional panel to score and save the predicted statistics to the active data set.

Time Values for Scoring

Time Values defined by dependent variable(s)

Scores the **Predictions** based on the time variable specified for the parametric survival model.

Regular intervals

Scores the **Predictions** based on future time values. The **Time interval** field specifies the time interval, and must be a single numeric value greater than 0. The **Number of time periods** field

specifies the number of the time periods, and must be a single numeric integer between 2 and 100.

Time duration

Scores the **Predictions** based on the time duration to define the future time values. It must be a single numeric variable.

Predictions

Survival

Scores and saves the predicted survival statistics to the active data set. The default custom variable name (or root name) is `PredSurvival`.

Hazard

Scores and saves the predicted hazards to the active data set. The default custom variable name (or root name) is `PredHazard`.

Cumulative hazard

Scores and saves the predicted cumulative hazards to the active data set. The default custom variable name (or root name) is `PredCumHazard`.

Conditional survival

Scores and saves the predicted conditional survival statistics to the active data set. The default custom variable name (or root name) is `PredConditionalSurvival`. The process is ignored if `PASTTIME` is not specified. A **Past survival time** value is required, and specifies the past time values for scoring. It must be a single numeric variable.

Unconditional survival

Scores and saves the predicted unconditional survival statistics to the active data set. The keyword is suppressed by default. If specified, it could be followed by an optional user-supplied variable name (or root name) specified within parentheses. The default name is `PredUnCondSurvival`.

Unconditional hazard

Scores and saves the predicted unconditional hazard statistics to the active data set. The keyword is suppressed by default. If specified, it could be followed by an optional user-supplied variable name (or root name) specified within parentheses. The default name is `PredUnCondHazard`.

Unconditional cum hazard

Scores and saves the predicted unconditional cumulative hazard statistics to the active data set. The keyword is suppressed by default. If specified, it might be followed by an optional user-supplied variable name (or root name that is specified within parentheses. The default name is `PredUnCondCumHazard`.

Parametric Shared Frailty Models: Plot

Plot

Function Plots

An option to control the function plots.

Type

Survival

Creates the plot for the unconditional survival functions.

Hazard

Creates the plot for the unconditional hazard functions.

Density

Creates a plot for the density functions.

Number of points to display

Specifies the number of function points between 1 and 200. The default setting is 100.

Covariate Values for Plot

An option to specify the user-supplied values and assign them to the predictors. By default, the designated plots will be created at the Mean of each covariate in effect. If specified, the designated plots will be created based on the pattern's setting. In the presence of any duplicated variables, the one specified first would be recognized and the rest would be ignored. A valid variable must be contained in a model effect. For a covariate, the user-supplied value must be numeric. The omission of a variable in effect indicates that the Mean would be used by default for the covariate. If an invalid value is assigned to a variable, the pattern requested will not be plotted.

Factor Values for Plot

An option to specify the user-supplied values and assign them to the predictors. By default, the designated plots will be created at the category frequency of each factor in effect. If specified, the designated plots will be created based on the pattern's setting. In the presence of any duplicated variables, the one specified first would be recognized and the rest would be ignored. A valid variable must be contained in a model effect. The omission of a variable in effect indicates that the category frequency would be used by default for the factor. If an invalid value is assigned to a variable, the pattern requested will not be plotted.

Separate lines for

An option to specify a categorical variable by which the line plots will be drawn.

Maximum number of lines in a chart

Specifies the maximum number of the lines in a chart if **Separate lines for** is specified. The default setting is 10.

Parametric Shared Frailty Models: Export

Export

Select **Export model information to XML file** to write the model and parameter information to a PMML file for scoring. You must specify the directory and file name of the PMML file to be saved.

Parametric Shared Frailty Models: Define Events

An option to define status. If the status variable is omitted, failure or event becomes the default status for all cases.

1. From the menu choose,

Analyze > Survival > Parametric Shared Frailty Models...

Figure 5. Shared Frailty Models - dialog box- Status

Figure 6. Shared Frailty Models- dialog box-Status-Define Event

Parametric Shared Frailty Models- Examples

Example 1

SURVREG RECURRENT y WITH x1 BY x2

/MODEL SUBJECT=id FRAILTY=GAMMA DISTRIBUTION=WEIBULL.

- A parametric shared-frailty survival model is fitted of y on a covariate x1 and factor x2.
- Survival time is represented by a single variable y.
- The subjects are identified by the variable id.
- The survival time is assumed to follow a Weibull distribution.
- The variance of the frailty is assumed to follow a Gamma distribution.

- All valid records are used in the survival analysis.

Example 2

```
SURVREG RECURRENT y WITH x1 BY x2
/MODEL SUBJECT=id FRAILITY=INV_GAUSSIAN DISTRIBUTION=LOG_NORMAL INTERVAL=z.
```

- A parametric shared-frailty survival model is fitted of y on a covariate x1 and factor x2.
- Survival time is represented by two variables y1 and y2 denoting start and end time.
- The subjects are identified by the variable id.
- The survival time is assumed to follow a Log-normal distribution.
- The variance of the frailty is assumed to follow an inverse Gaussian distribution.
- Time intervals are defined by the variable z. For each subject, the procedure only uses the nonconflicted records and excludes from the analysis all the records after the first failure status.

Example 3

```
SURVREG RECURRENT y1 y2 WITH x1 BY x2(1)
/MODEL SUBJECT=id FRAILITY=INV_GAUSSIAN DISTRIBUTION=LOG_LOGISTIC
/STATUS VARIABLE=event FAILURE=1 RIGHT=0.
```

- A parametric shared-frailty survival model is fitted of y on a covariate x1 and factor x2. Survival time is represented two variables y1 and y2 denoting start and end time, respectively. For the factor x2, the category “1” is designated as a baseline to be modeled.
- The subjects are identified by the variable id.
- The survival time is assumed to follow a Log-logistic distribution.
- The variance of the frailty is assumed to follow an inverse Gaussian distribution.
- The variable event is specified to define the status with 1 and 0 denoting failure and right-censoring, respectively.

Example 4

```
SURVREG RECURRENT y WITH x1 BY x2
/MODEL SUBJECT=id
/STATUS VARIABLE=event FAILURE=1 RIGHT=0
/PREDICT UNCONDSURVIVAL UNCONDHAZARD UNCONDCUMHAZARD
/FUNCTIONPLOT SURVIVAL HAZARD DENSITY PLOTBY(x2).
```

- A parametric shared-frailty survival model is fitted of y on a covariate x1 and factor x2. Survival time is represented by a single variable y.
- The subjects are identified by the variable id.
- Unconditional or population-based survival, hazard, and cumulative hazard are scored and saved to the active data set.
- Unconditional or population-based survival and hazard curves are plotted separated by the categories in x2.

Example 5

```
SURVREG RECURRENT y WITH x1 BY x2
```

```
/MODEL SUBJECT=id FRAILITY=GAMMA DISTRIBUTION=WEIBULL
```

```
/STATUS VARIABLE=event FAILURE=1 RIGHT=0
```

```
/ESTIMATION HCONVERGE=1e-12(RELATIVE) PCONVERGE=0 FCONVERGE=0  
SELECTFEATURES=TRUE PENALTY=0.01.
```

- A parametric shared-frailty survival model is fitted of y on a covariate x_1 and factor x_2 . Survival time is represented by a single variable y .
- The subjects are identified by the variable id .
- The survival time is assumed to follow a Weibull distribution.
- The variance of the frailty is assumed to follow a Gamma distribution.
- The convergence criteria are based on the Hessian matrix. It uses $1e-12$ as the relative convergence.
- The model includes a penalty term to control the regularization process. The penalty parameter is set to be 0.01.

Example 6

```
SURVREG RECURRENT y WITH x1 BY x2
```

```
/MODEL SUBJECT=id
```

```
/STATUS VARIABLE=infect FAILURE=1 RIGHT=0
```

```
/ESTIMATION MAXLINESEARCH=100 MAXITER=50 MAXSTEPHALVING=20.
```

- A parametric shared-frailty survival model is fitted of y on a covariate x_1 and factor x_2 . Survival time is represented by a single variable y .
- The subjects are identified by the variable id .
- The procedure specifies the maximum number of the line search to be 100, the maximum number of iterations to be 50, and the maximum number of step-halving to be 20.

Parametric Shared Frailty Models - A Case Study for Recurrent Data

Parametric Shared Frailty Models - A Case Study for Recurrent Data

- Use case name - Treatment Side Effect.
- Actors - Public health investigator and practitioner.
- Preconditions - A cleaned data set available based on survival time, side effect status, and predictors to be adjusted.
- Description - Patrick, a public health investigator, is investigating a data sample that includes 20 participants. These participants are recruited in a study on a mild side effect that is potentially caused by a new treatment. The treatment designer claims that there would be no differences between males and females, regarding the side effect. Patrick would like to evaluate such a hypothesis. The variables that are included in the data sample are listed as follows:
 - $patID$: ID number to identify a unique participant.
 - $endTime$: Survival time (in days) of the side effect, following a treatment, which is measured from the start of a treatment to either a side effect reported or censoring within 60 days.
 - $sideEffect$: Side effect status, $status = 0$ if censored and $status = 1$ if the mild sided effect is reported.
 - age : Participant's age at the research period.
 - $female$: $female = 0$ if male and $female = 1$ if female.

Multiple treatments might apply, which results in the multiple records of recurrence times that are measured for a certain participant. The start time is always 0 for each record, which is omitted in the data sample. Patrick is interested in visualizing the survival and hazard functions to draw a comparison between a male and a female by controlling their age and frailty. He is aware that those treatments that are administered to the same participant are more correlated. By assuming that the survival time follows a Weibull distribution, Patrick decides to build a parametric shared-frailty survival model in SPSS Statistics to account for the treatment dependence for the same participant.

Synopsis:

The syntax that is specified by Patrick designates endTime as a single dependent time variable. The procedure automatically assumes that the start time is 0 for each record. The variables age and female are modeled as a covariate and a factor, respectively. The recurrence survival times are assumed to follow a Weibull distribution. The unobserved frailty term is assumed to follow a Gamma distribution, and its variance component is modeled. Regarding the outputs, the Model Summary table provides the procedure and model information. The Case Processing Summary table gives a comprehensive listing of the failure/censoring status and also those cases that are excluded from the analysis.

In Patrick’s data sample, all the records are valid and included in the analysis. By comparing the log likelihood with that of the corresponding model without the frailty component, the shared-frailty model fails to reach a significant level (p-value = 0.168). Patrick is wondering if it is necessary to include a shared-frailty term in the model. The estimated acceleration factor of a male participant is 1.017, which is obtained by calculating exponent of the estimated regression coefficient 0.017 of [female = 0.0]. Its associated 95% confidence interval is (.688, 1.504). These results suggest that a male individual has almost the same acceleration factor as a female individual with the same age and frailty. On the

population level, Patrick plots the unconditional survival and hazard curves separately for males and females who are evaluated at the sample mean of age (37.45 years old).

Patrick confirms that, for any fixed value of survival time, a male and a female on average are supposed to have the same survival probability. Interestingly, despite a unimodal shape that is shown in the unconditional hazard chart, Patrick discovers that within a period of 60 days the population hazard is actually increasing. This behavior might imply the existence of the frailty effect. To further investigate the side effect caused by the treatments, Patrick may continue with a model without the frailty component and compare behavior of males and females. In addition, he may consider following up with the participants for a period longer than 60 days to collect more data.

Kaplan-Meier Survival Analysis

There are many situations in which you would want to examine the distribution of times between two events, such as length of employment (time between being hired and leaving the company). However, this kind of data usually includes some censored cases. Censored cases are cases for which the second event isn't recorded (for example, people still working for the company at the end of the study). The Kaplan-Meier procedure is a method of estimating time-to-event models in the presence of censored cases. The Kaplan-Meier model is based on estimating conditional probabilities at each time point when an event occurs and taking the product limit of those probabilities to estimate the survival rate at each point in time.

Example. Does a new treatment for AIDS have any therapeutic benefit in extending life? You could conduct a study using two groups of AIDS patients, one receiving traditional therapy and the other receiving the experimental treatment. Constructing a Kaplan-Meier model from the data would allow you to compare overall survival rates between the two groups to determine whether the experimental treatment is an improvement over the traditional therapy. You can also plot the survival or hazard functions and compare them visually for more detailed information.

Statistics. Survival table, including time, status, cumulative survival and standard error, cumulative events, and number remaining; and mean and median survival time, with standard error and 95% confidence interval. Plots: survival, hazard, log survival, and one minus survival.

Kaplan-Meier Data Considerations

Data. The time variable should be continuous, the status variable can be categorical or continuous, and the factor and strata variables should be categorical.

Assumptions. Probabilities for the event of interest should depend only on time after the initial event--they are assumed to be stable with respect to absolute time. That is, cases that enter the study at different times (for example, patients who begin treatment at different times) should behave similarly. There should also be no systematic differences between censored and uncensored cases. If, for example, many of the censored cases are patients with more serious conditions, your results may be biased.

Related procedures. The Kaplan-Meier procedure uses a method of calculating life tables that estimates the survival or hazard function at the time of each event. The Life Tables procedure uses an actuarial approach to survival analysis that relies on partitioning the observation period into smaller time intervals and may be useful for dealing with large samples. If you have variables that you suspect are related to survival time or variables that you want to control for (covariates), use the Cox Regression procedure. If your covariates can have different values at different points in time for the same case, use Cox Regression with Time-Dependent Covariates.

Obtaining a Kaplan-Meier Survival Analysis

1. From the menus choose:

Analyze > Survival > Kaplan-Meier...

2. Select a time variable.

3. Select a status variable to identify cases for which the terminal event has occurred. This variable can be numeric or *short string*. Then click **Define Event**.

Optionally, you can select a factor variable to examine group differences. You can also select a strata variable, which will produce separate analyses for each level (stratum) of the variable.

Kaplan-Meier Define Event for Status Variable

Enter the value or values indicating that the terminal event has occurred. You can enter a single value, a range of values, or a list of values. The Range of Values option is available only if your status variable is numeric.

Kaplan-Meier Compare Factor Levels

You can request statistics to test the equality of the survival distributions for the different levels of the factor. Available statistics are log rank, Breslow, and Tarone-Ware. Select one of the alternatives to specify the comparisons to be made: pooled over strata, for each stratum, pairwise over strata, or pairwise for each stratum.

Linear trend for factor levels. Allows you to test for a linear trend across levels of the factor. This option is available only for overall (rather than pairwise) comparisons of factor levels.

- *Log rank.* A test for comparing the equality of survival distributions. All time points are weighted equally in this test.
- *Breslow.* A test for comparing the equality of survival distributions. Time points are weighted by the number of cases at risk at each time point.
- *Tarone-Ware.* A test for comparing the equality of survival distributions. Time points are weighted by the square root of the number of cases at risk at each time point.
- *Pooled over strata.* Compares all factor levels in a single test to test the equality of survival curves.
- *Pairwise over strata.* Compares each distinct pair of factor levels. Pairwise trend tests are not available.
- *For each stratum.* Performs a separate test of equality of all factor levels for each stratum. If you do not have a stratification variable, the tests are not performed.
- *Pairwise for each stratum.* Compares each distinct pair of factor levels for each stratum. Pairwise trend tests are not available. If you do not have a stratification variable, the tests are not performed.

Kaplan-Meier Save New Variables

You can save information from your Kaplan-Meier table as new variables, which can then be used in subsequent analyses to test hypotheses or check assumptions. You can save survival, standard error of survival, hazard, and cumulative events as new variables.

- *Survival.* Cumulative survival probability estimate. The default variable name is the prefix `sur_` with a sequential number appended to it. For example, if `sur_1` already exists, Kaplan-Meier assigns the variable name `sur_2`.
- *Standard error of survival.* Standard error of the cumulative survival estimate. The default variable name is the prefix `se_` with a sequential number appended to it. For example, if `se_1` already exists, Kaplan-Meier assigns the variable name `se_2`.
- *Hazard.* Cumulative hazard function estimate. The default variable name is the prefix `haz_` with a sequential number appended to it. For example, if `haz_1` already exists, Kaplan-Meier assigns the variable name `haz_2`.
- *Cumulative events.* Cumulative frequency of events when cases are sorted by their survival times and status codes. The default variable name is the prefix `cum_` with a sequential number appended to it. For example, if `cum_1` already exists, Kaplan-Meier assigns the variable name `cum_2`.

Kaplan-Meier Options

You can request various output types from Kaplan-Meier analysis.

Statistics. You can select statistics displayed for the survival functions computed, including survival table(s), mean and median survival, and quartiles. If you have included factor variables, separate statistics are generated for each group.

Plots. Plots allow you to examine the survival, one-minus-survival, hazard, and log-survival functions visually. If you have included factor variables, functions are plotted for each group.

- *Survival.* Displays the cumulative survival function on a linear scale.
- *One minus survival.* Plots one-minus the survival function on a linear scale.
- *Hazard.* Displays the cumulative hazard function on a linear scale.
- *Log survival.* Displays the cumulative survival function on a logarithmic scale.

KM Command Additional Features

The command syntax language also allows you to:

- Obtain frequency tables that consider cases lost to follow-up as a separate category from censored cases.
- Specify unequal spacing for the test for linear trend.
- Obtain percentiles other than quartiles for the survival time variable.

See the *Command Syntax Reference* for complete syntax information.

Cox Regression Analysis

Cox Regression builds a predictive model for time-to-event data. The model produces a survival function that predicts the probability that the event of interest has occurred at a given time t for given values of the predictor variables. The shape of the survival function and the regression coefficients for the predictors are estimated from observed subjects; the model can then be applied to new cases that have measurements for the predictor variables. Note that information from censored subjects, that is, those that do not experience the event of interest during the time of observation, contributes usefully to the estimation of the model.

Example. Do men and women have different risks of developing lung cancer based on cigarette smoking? By constructing a Cox Regression model, with cigarette usage (cigarettes smoked per day) and gender entered as covariates, you can test hypotheses regarding the effects of gender and cigarette usage on time-to-onset for lung cancer.

Statistics. For each model: $-2LL$, the likelihood-ratio statistic, and the overall chi-square. For variables in the model: parameter estimates, standard errors, and Wald statistics. For variables not in the model: score statistics and residual chi-square.

Cox Regression Data Considerations

Data. Your time variable should be quantitative, but your status variable can be categorical or continuous. Independent variables (covariates) can be continuous or categorical; if categorical, they should be dummy- or indicator-coded (there is an option in the procedure to recode categorical variables automatically). Strata variables should be categorical, coded as integers or short strings.

Assumptions. Observations should be independent, and the hazard ratio should be constant across time; that is, the proportionality of hazards from one case to another should not vary over time. The latter assumption is known as the **proportional hazards assumption**.

Related procedures. If the proportional hazards assumption does not hold (see above), you may need to use the Cox with Time-Dependent Covariates procedure. If you have no covariates, or if you have only one categorical covariate, you can use the Life Tables or Kaplan-Meier procedure to examine survival or hazard functions for your sample(s). If you have no censored data in your sample (that is, every case experienced the terminal event), you can use the Linear Regression procedure to model the relationship between predictors and time-to-event.

Obtaining a Cox Regression Analysis

1. From the menus choose:

Analyze > Survival > Cox Regression...

2. Select a time variable. Cases whose time values are negative are not analyzed.

3. Select a status variable, and then click **Define Event**.

4. Select one or more covariates. To include interaction terms, select all of the variables involved in the interaction and then click **>a*b>**.

Optionally, you can compute separate models for different groups by defining a strata variable.

Cox Regression Define Categorical Variables

You can specify details of how the Cox Regression procedure will handle categorical variables.

Covariates. Lists all of the covariates specified in the main dialog box, either by themselves or as part of an interaction, in any layer. If some of these are string variables or are categorical, you can use them only as categorical covariates.

Categorical Covariates. Lists variables identified as categorical. Each variable includes a notation in parentheses indicating the contrast coding to be used. String variables (denoted by the symbol < following their names) are already present in the Categorical Covariates list. Select any other categorical covariates from the Covariates list and move them into the Categorical Covariates list.

Change Contrast. Allows you to change the contrast method. Available contrast methods are:

- **Indicator.** Contrasts indicate the presence or absence of category membership. The reference category is represented in the contrast matrix as a row of zeros.
- **Simple.** Each category of the predictor variable except the reference category is compared to the reference category.
- **Difference.** Each category of the predictor variable except the first category is compared to the average effect of previous categories. Also known as reverse Helmert contrasts.
- **Helmert.** Each category of the predictor variable except the last category is compared to the average effect of subsequent categories.
- **Repeated.** Each category of the predictor variable except the first category is compared to the category that precedes it.
- **Polynomial.** Orthogonal polynomial contrasts. Categories are assumed to be equally spaced. Polynomial contrasts are available for numeric variables only.
- **Deviation.** Each category of the predictor variable except the reference category is compared to the overall effect.

If you select **Deviation**, **Simple**, or **Indicator**, select either **First** or **Last** as the reference category. Note that the method is not actually changed until you click **Change**.

String covariates must be categorical covariates. To remove a string variable from the Categorical Covariates list, you must remove all terms containing the variable from the Covariates list in the main dialog box.

Cox Regression Plots

Plots can help you to evaluate your estimated model and interpret the results. You can plot the survival, hazard, log-minus-log, and one-minus-survival functions.

Plot Type

Survival

Displays the cumulative survival function on a linear scale.

Hazard

Displays the cumulative hazard function on a linear scale.

Log minus log

The cumulative survival estimate after the $\ln(-\ln)$ transformation is applied to the estimate.

One minus survival

Plots one-minus the survival function on a linear scale.

Covariate Values Plotted at

You can plot a separate line for each value of a categorical covariate by moving that covariate into the **Separate Lines for** text box. This option is available only for categorical covariates, which are denoted by **(Cat)** after their names in the **Covariate Values Plotted at** list.

Change Value

Because these functions depend on values of the covariates, you must use constant values for the covariates to plot the functions versus time. The default is to use the mean of each covariate as a constant value, but you can enter your own values for the plot using the **Change Value** control group.

Cox Regression Save New Variables

You can save various results of your analysis as new variables. These variables can then be used in subsequent analyses to test hypotheses or to check assumptions.

Save Model Variables

Allows you to save the survival function and its standard error, log-minus-log estimates, hazard function, partial residuals, DfBeta(s) for the regression, and the linear predictor X^*Beta as new variables.

Survival function

The value of the cumulative survival function for a given time. It equals the probability of survival to that time period.

Standard error of survival function

Standard error of the cumulative survival estimate.

Log minus log survival function

The cumulative survival estimate after the $\ln(-\ln)$ transformation is applied to the estimate.

Hazard function

Saves the cumulative hazard function estimate (also called the Cox-Snell residual).

Partial residuals

You can plot partial residuals against survival time to test the proportional hazards assumption. One variable is saved for each covariate in the final model. Partial residuals are available only for models containing at least one covariate.

DfBeta(s)

Estimated change in a coefficient if a case is removed. One variable is saved for each covariate in the final model. DfBetas are only available for models containing at least one covariate.

 X^*Beta

Linear predictor score. The sum of the product of mean-centered covariate values and their corresponding parameter estimates for each case.

Note: Only the DfBeta(s) are saved if you are running Cox with a time-dependent covariate.

Export Model Information to XML File

Parameter estimates are exported to the specified file in XML format. You can use this model file to apply the model information to other data files for scoring purposes.

Cox Regression Options

You can control various aspects of your analysis and output.

Model Statistics. You can obtain statistics for your model parameters, including confidence intervals for $\exp(B)$ and correlation of estimates. You can request these statistics either at each step or at the last step only.

Probability for Stepwise. If you have selected a stepwise method, you can specify the probability for either entry or removal from the model. A variable is entered if the significance level of its F -to-enter is less than the Entry value, and a variable is removed if the significance level is greater than the Removal value. The Entry value must be less than the Removal value.

Maximum Iterations. Allows you to specify the maximum iterations for the model, which controls how long the procedure will search for a solution.

Display baseline function. Allows you to display the baseline hazard function and cumulative survival at the mean of the covariates. This display is not available if you have specified time-dependent covariates.

Cox Regression Define Event for Status Variable

Enter the value or values indicating that the terminal event has occurred. You can enter a single value, a range of values, or a list of values. The Range of Values option is available only if your status variable is numeric.

COXREG Command Additional Features

The command syntax language also allows you to:

- Obtain frequency tables that consider cases lost to follow-up as a separate category from censored cases.
- Select a reference category, other than first or last, for the deviation, simple, and indicator contrast methods.
- Specify unequal spacing of categories for the polynomial contrast method.
- Specify additional iteration criteria.
- Control the treatment of missing values.
- Specify the names for saved variables.
- Write output to an external IBM SPSS Statistics data file.
- Hold data for each split-file group in an external scratch file during processing. This can help conserve memory resources when running analyses with large datasets. This is not available with time-dependent covariates.

See the *Command Syntax Reference* for complete syntax information.

Computing Time-Dependent Covariates

In certain situations, you would want to compute a Cox Regression model but the proportional hazards assumption does not hold. That is, hazard ratios change across time; the values of one (or more) of your covariates are different at different time points. In such cases, you need to use an extended Cox Regression model, in which you can specify **time-dependent covariates**.

To analyze such a model, you must first define the time-dependent covariate. To facilitate this, a 'system variable' that represents time is available. This variable is called T_* . You can use this variable to define time-dependent covariates in two general ways:

- To test the proportional hazards assumption with respect to a particular covariate or estimate an extended Cox regression model that allows nonproportional hazards, you need to define time-dependent covariate as a function of the time variable T_* and the covariate in question. A common example would be the simple product of the time variable and the covariate, but more complex functions can be specified as well. Testing the significance of the coefficient of the time-dependent covariate tells whether the proportional hazards assumption is reasonable.
- Some variables can have different values at different time periods but aren't systematically related to time. In such cases, you need to define a **segmented time-dependent covariate**, which can be done by using **logical expressions**. Logical expressions take the value 1 if true and 0 if false. Using a series of logical expressions, you can create your time-dependent covariate from a set of measurements. For example, if you have blood pressure that is measured once a week for the four weeks of your study

(identified as *BP1* to *BP4*), you can define the time-dependent covariate as $(T_ < 1) * BP1 + (T_ >= 1 \& T_ < 2) * BP2 + (T_ >= 2 \& T_ < 3) * BP3 + (T_ >= 3 \& T_ < 4) * BP4$. You notice that exactly one of the terms in parentheses are equal to 1 for any specific case and the rest will all equal 0. To sum up, this function means that if time is less than one week, use *BP1*; if it is more than one week but less than two weeks, use *BP2*, and so on.

In the Compute Time-Dependent Covariate dialog box, you can use the function-building controls to build the expression for a time-dependent covariate, or you can enter it directly in the Name text area. Note that string constants must be enclosed in quotation marks or apostrophes, and numeric constants must be typed in American format, with the dot as the decimal delimiter. Any resulting time-dependent covariates need to be included as covariates in your Cox Regression model.

Computing a Time-Dependent Covariate

1. From the menu, choose
Analyze > Survival > Cox w/ Time-Dep Cov...
2. Enter an expression for the time-dependent covariate.
3. Click **Model** to proceed with your Cox Regression.

Note- Ensure that you include the new variables that are added as covariates in your Cox Regression model.

Categorical Variable Coding Schemes

In many procedures, you can request automatic replacement of a categorical independent variable with a set of contrast variables, which will then be entered or removed from an equation as a block. You can specify how the set of contrast variables is to be coded, usually on the CONTRAST subcommand. This appendix explains and illustrates how different contrast types requested on CONTRAST actually work.

Deviation

Deviation from the grand mean. In matrix terms, these contrasts have the form:

```

mean ( 1/k  1/k  ...  1/k  1/k)
df(1) (1-1/k -1/k  ... -1/k -1/k)
df(2) (-1/k  1-1/k ... -1/k -1/k)
.
.
df(k-1) (-1/k  -1/k  ...  1-1/k -1/k)

```

where *k* is the number of categories for the independent variable and the last category is omitted by default. For example, the deviation contrasts for an independent variable with three categories are as follows:

```

( 1/3  1/3  1/3)
( 2/3 -1/3 -1/3)
(-1/3  2/3 -1/3)

```

To omit a category other than the last, specify the number of the omitted category in parentheses after the DEVIATION keyword. For example, the following subcommand obtains the deviations for the first and third categories and omits the second:

```
/CONTRAST (FACTOR)=DEVIATION(2)
```

Suppose that *factor* has three categories. The resulting contrast matrix will be

```

( 1/3  1/3  1/3)
( 2/3 -1/3 -1/3)
(-1/3 -1/3  2/3)

```

Simple

Simple contrasts. Compares each level of a factor to the last. The general matrix form is

```
mean ( 1/k  1/k  ...  1/k  1/k)
df(1) (  1   0  ...   0  -1)
df(2) (  0   1  ...   0  -1)
      .
      .
df(k-1) (  0   0  ...   1  -1)
```

where k is the number of categories for the independent variable. For example, the simple contrasts for an independent variable with four categories are as follows:

```
( 1/4  1/4  1/4  1/4)
(  1   0   0  -1)
(  0   1   0  -1)
(  0   0   1  -1)
```

To use another category instead of the last as a reference category, specify in parentheses after the SIMPLE keyword the sequence number of the reference category, which is not necessarily the value associated with that category. For example, the following CONTRAST subcommand obtains a contrast matrix that omits the second category:

```
/CONTRAST(FACTOR) = SIMPLE(2)
```

Suppose that *factor* has four categories. The resulting contrast matrix will be

```
( 1/4  1/4  1/4  1/4)
(  1  -1   0   0)
(  0  -1   1   0)
(  0  -1   0   1)
```

Helmert

Helmert contrasts. Compares categories of an independent variable with the mean of the subsequent categories. The general matrix form is

```
mean ( 1/k  1/k  ...  1/k  1/k  1/k)
df(1) (  1  -1/(k-1)  ...  -1/(k-1)  -1/(k-1)  -1/(k-1) )
df(2) (  0   1  ...  -1/(k-2)  -1/(k-2)  -1/(k-2) )
      .
      .
df(k-2) (  0   0  ...   1  -1/2  -1/2)
df(k-1) (  0   0  ...   0   1  -1)
```

where k is the number of categories of the independent variable. For example, an independent variable with four categories has a Helmert contrast matrix of the following form:

```
( 1/4  1/4  1/4  1/4)
(  1  -1/3  -1/3  -1/3)
(  0   1  -1/2  -1/2)
(  0   0   1  -1)
```

Difference

Difference or reverse Helmert contrasts. Compares categories of an independent variable with the mean of the previous categories of the variable. The general matrix form is

```
mean ( 1/k  1/k  1/k  ...  1/k)
df(1) (  0  -1   1   0  ...  0)
df(2) (  0  -1/2  -1/2  1  ...  0)
      .
      .
df(k-1) (-1/(k-1)  -1/(k-1)  -1/(k-1)  ...  1)
```

where k is the number of categories for the independent variable. For example, the difference contrasts for an independent variable with four categories are as follows:

```
( 1/4  1/4  1/4  1/4)
( -1   1   0   0)
(-1/2  -1/2  1   0)
(-1/3  -1/3  -1/3  1)
```

Polynomial

Orthogonal polynomial contrasts. The first degree of freedom contains the linear effect across all categories; the second degree of freedom, the quadratic effect; the third degree of freedom, the cubic; and so on, for the higher-order effects.

You can specify the spacing between levels of the treatment measured by the given categorical variable. Equal spacing, which is the default if you omit the metric, can be specified as consecutive integers from 1 to k , where k is the number of categories. If the variable *drug* has three categories, the subcommand

```
/CONTRAST (DRUG)=POLYNOMIAL
```

is the same as

```
/CONTRAST (DRUG)=POLYNOMIAL (1,2,3)
```

Equal spacing is not always necessary, however. For example, suppose that *drug* represents different dosages of a drug given to three groups. If the dosage administered to the second group is twice that given to the first group and the dosage administered to the third group is three times that given to the first group, the treatment categories are equally spaced, and an appropriate metric for this situation consists of consecutive integers:

```
/CONTRAST (DRUG)=POLYNOMIAL (1,2,3)
```

If, however, the dosage administered to the second group is four times that given to the first group, and the dosage administered to the third group is seven times that given to the first group, an appropriate metric is

```
/CONTRAST (DRUG)=POLYNOMIAL (1,4,7)
```

In either case, the result of the contrast specification is that the first degree of freedom for *drug* contains the linear effect of the dosage levels and the second degree of freedom contains the quadratic effect.

Polynomial contrasts are especially useful in tests of trends and for investigating the nature of response surfaces. You can also use polynomial contrasts to perform nonlinear curve fitting, such as curvilinear regression.

Repeated

Compares adjacent levels of an independent variable. The general matrix form is

```
mean (1/k 1/k 1/k ... 1/k 1/k)
df(1) ( 1 -1 0 ... 0 0)
df(2) ( 0 1 -1 ... 0 0)
      :
      :
df(k-1) ( 0 0 0 ... 1 -1)
```

where k is the number of categories for the independent variable. For example, the repeated contrasts for an independent variable with four categories are as follows:

```
(1/4 1/4 1/4 1/4)
( 1 -1 0 0)
( 0 1 -1 0)
( 0 0 1 -1)
```

These contrasts are useful in profile analysis and wherever difference scores are needed.

Special

A user-defined contrast. Allows entry of special contrasts in the form of square matrices with as many rows and columns as there are categories of the given independent variable. For MANOVA and LOGLINEAR, the first row entered is always the mean, or constant, effect and represents the set of weights indicating how to average other independent variables, if any, over the given variable. Generally, this contrast is a vector of ones.

The remaining rows of the matrix contain the special contrasts indicating the comparisons between categories of the variable. Usually, orthogonal contrasts are the most useful. Orthogonal contrasts are statistically independent and are nonredundant. Contrasts are orthogonal if:

- For each row, contrast coefficients sum to 0.
- The products of corresponding coefficients for all pairs of disjoint rows also sum to 0.

For example, suppose that treatment has four levels and that you want to compare the various levels of treatment with each other. An appropriate special contrast is

```
(1  1  1  1) weights for mean calculation
(3 -1 -1 -1) compare 1st with 2nd through 4th
(0  2 -1 -1) compare 2nd with 3rd and 4th
(0  0  1 -1) compare 3rd with 4th
```

which you specify by means of the following CONTRAST subcommand for MANOVA, LOGISTIC REGRESSION, and COXREG:

```
/CONTRAST(TREATMNT)=SPECIAL( 1  1  1  1
                             3 -1 -1 -1
                             0  2 -1 -1
                             0  0  1 -1 )
```

For LOGLINEAR, you need to specify:

```
/CONTRAST(TREATMNT)=BASIS SPECIAL( 1  1  1  1
                                    3 -1 -1 -1
                                    0  2 -1 -1
                                    0  0  1 -1 )
```

Each row except the means row sums to 0. Products of each pair of disjoint rows sum to 0 as well:

```
Rows 2 and 3: (3)(0) + (-1)(2) + (-1)(-1) + (-1)(-1) = 0
Rows 2 and 4: (3)(0) + (-1)(0) + (-1)(1) + (-1)(-1) = 0
Rows 3 and 4: (0)(0) + (2)(0) + (-1)(1) + (-1)(-1) = 0
```

The special contrasts need not be orthogonal. However, they must not be linear combinations of each other. If they are, the procedure reports the linear dependency and ceases processing. Helmert, difference, and polynomial contrasts are all orthogonal contrasts.

Indicator

Indicator variable coding. Also known as dummy coding, this is not available in LOGLINEAR or MANOVA. The number of new variables coded is $k-1$. Cases in the reference category are coded 0 for all $k-1$ variables. A case in the i^{th} category is coded 0 for all indicator variables except the i^{th} , which is coded 1.

Covariance Structures

This section provides additional information on covariance structures.

Ante-Dependence: First-Order. This covariance structure has heterogenous variances and heterogenous correlations between adjacent elements. The correlation between two nonadjacent elements is the product of the correlations between the elements that lie between the elements of interest.

$$\begin{pmatrix}
 \sigma_1^2 & \sigma_2\sigma_1\rho_1 & \sigma_3\sigma_1\rho_1\rho_2 & \sigma_4\sigma_1\rho_1\rho_2\rho_3 \\
 \sigma_2\sigma_1\rho_1 & \sigma_2^2 & \sigma_3\sigma_2\rho_2 & \sigma_4\sigma_2\rho_2\rho_3 \\
 \sigma_3\sigma_1\rho_1\rho_2 & \sigma_3\sigma_2\rho_2 & \sigma_3^2 & \sigma_4\sigma_3\rho_3 \\
 \sigma_4\sigma_1\rho_1\rho_2\rho_3 & \sigma_4\sigma_2\rho_2\rho_3 & \sigma_4\sigma_3\rho_3 & \sigma_4^2
 \end{pmatrix}$$

AR(1). This is a first-order autoregressive structure with homogenous variances. The correlation between any two elements is equal to ρ for adjacent elements, ρ^2 for elements that are separated by a third, and so on. is constrained so that $-1 < \rho < 1$.

$$\begin{pmatrix}
 \sigma^2 & \sigma^2\rho & \sigma^2\rho^2 & \sigma^2\rho^3
 \end{pmatrix}$$

$(\sigma^2\rho$	σ^2	$\sigma^2\rho$	$\sigma^2\rho^2)$
$(\sigma^2\rho^2$	$\sigma^2\rho$	σ^2	$\sigma^2\rho)$
$(\sigma^2\rho^3$	$\sigma^2\rho^2$	$\sigma^2\rho$	$\sigma^2)$

AR(1): Heterogenous. This is a first-order autoregressive structure with heterogenous variances. The correlation between any two elements is equal to r for adjacent elements, r^2 for two elements separated by a third, and so on. is constrained to lie between -1 and 1 .

$(\sigma_1^2$	$\sigma_2\sigma_1\rho$	$\sigma_3\sigma_1\rho^2$	$\sigma_4\sigma_1\rho^3)$
$(\sigma_2\sigma_1\rho$	σ_2^2	$\sigma_3\sigma_2\rho$	$\sigma_4\sigma_2\rho^2)$
$(\sigma_3\sigma_1\rho^2$	$\sigma_3\sigma_2\rho$	σ_3^2	$\sigma_4\sigma_3\rho)$
$(\sigma_4\sigma_1\rho^3$	$\sigma_4\sigma_2\rho^2$	$\sigma_4\sigma_3\rho$	$\sigma_4^2)$

ARMA(1,1). This is a first-order autoregressive moving average structure. It has homogenous variances. The correlation between two elements is equal to ϕ for adjacent elements, ϕ^2 for elements separated by a third, and so on. and are the autoregressive and moving average parameters, respectively, and their values are constrained to lie between -1 and 1 , inclusive.

$(\sigma^2$	$\sigma^2\phi\rho$	$\sigma^2\phi\rho^2$	$\sigma^2\phi\rho^3)$
$(\sigma^2\phi\rho$	σ^2	$\sigma^2\phi\rho$	$\sigma^2\phi\rho^2)$
$(\sigma^2\phi\rho^2$	$\sigma^2\phi\rho$	σ^2	$\sigma^2\phi\rho)$
$(\sigma^2\phi\rho^3$	$\sigma^2\phi\rho^2$	$\sigma^2\phi\rho$	$\sigma^2)$

Compound Symmetry. This structure has constant variance and constant covariance.

$(\sigma^2 + \sigma_1^2$	σ_1	σ_1	$\sigma_1)$
$(\sigma_1$	$\sigma^2 + \sigma_1^2$	σ_1	$\sigma_1)$
$(\sigma_1$	σ_1	$\sigma^2 + \sigma_1^2$	$\sigma_1)$
$(\sigma_1$	σ_1	σ_1	$\sigma^2 + \sigma_1^2)$

Compound Symmetry: Correlation Metric. This covariance structure has homogenous variances and homogenous correlations between elements.

$(\sigma^2$	$\sigma^2\rho$	$\sigma^2\rho$	$\sigma^2\rho)$
$(\sigma^2\rho$	σ^2	$\sigma^2\rho$	$\sigma^2\rho)$
$(\sigma^2\rho$	$\sigma^2\rho$	σ^2	$\sigma^2\rho)$
$(\sigma^2\rho$	$\sigma^2\rho$	$\sigma^2\rho$	$\sigma^2)$

Compound Symmetry: Heterogenous. This covariance structure has heterogenous variances and constant correlation between elements.

$(\sigma_1^2$	$\sigma_2\sigma_1\rho$	$\sigma_3\sigma_1\rho$	$\sigma_4\sigma_1\rho)$
$(\sigma_2\sigma_1\rho$	σ_2^2	$\sigma_3\sigma_2\rho$	$\sigma_4\sigma_2\rho)$
$(\sigma_3\sigma_1\rho$	$\sigma_3\sigma_2\rho$	σ_3^2	$\sigma_4\sigma_3\rho)$
$(\sigma_4\sigma_1\rho$	$\sigma_4\sigma_2\rho$	$\sigma_4\sigma_3\rho$	$\sigma_4^2)$

Diagonal. This covariance structure has heterogenous variances and zero correlation between elements.

$(\sigma_1^2$	0	0	$0)$
---------------	-----	-----	------

(0	σ_2^2	0	0)
(0	0	σ_3^2	0)
(0	0	0	σ_4^2)

Direct product AR1 (UN_AR1). Specifies the Kronecker product of one unstructured matrix and the other first-order auto-regression covariance matrix. The first unstructured matrix models the multivariate observation, and the second first-order auto-regression covariance structure models the data covariance across time or another factor.

Direct product unstructured (UN_UN). Specifies the Kronecker product of two unstructured matrices, with the first one modeling the multivariate observation, and second one modeling the data covariance across time or another factor.

Direct product compound symmetry (UN_CS). Specifies the Kronecker product of one unstructured matrix and the other compound-symmetry covariance matrix with constant variance and covariance. The first unstructured matrix models the multivariate observation, and the second compound symmetry covariance structure models the data covariance across time or another factor.

Factor Analytic: First-Order. This covariance structure has heterogenous variances that are composed of a term that is heterogenous across elements and a term that is homogenous across elements. The covariance between any two elements is the square root of the product of their heterogenous variance terms.

$(\lambda_1^2 + d$	$\lambda_2\lambda_1$	$\lambda_3\lambda_1$	$\lambda_4\lambda_1)$
$(\lambda_2\lambda_1$	$\lambda_2^2 + d$	$\lambda_3\lambda_2$	$\lambda_4\lambda_2)$
$(\lambda_3\lambda_1$	$\lambda_3\lambda_2$	$\lambda_3^2 + d$	$\lambda_4\lambda_3)$
$(\lambda_4\lambda_1$	$\lambda_4\lambda_2$	$\lambda_4\lambda_3$	$\lambda_4^2 + d)$

Factor Analytic: First-Order, Heterogenous. This covariance structure has heterogenous variances that are composed of two terms that are heterogenous across elements. The covariance between any two elements is the square root of the product of the first of their heterogenous variance terms.

$(\lambda_1^2 + d_1$	$\lambda_2\lambda_1$	$\lambda_3\lambda_1$	$\lambda_4\lambda_1)$
$(\lambda_2\lambda_1$	$\lambda_2^2 + d_2$	$\lambda_3\lambda_2$	$\lambda_4\lambda_2)$
$(\lambda_3\lambda_1$	$\lambda_3\lambda_2$	$\lambda_3^2 + d_3$	$\lambda_4\lambda_3)$
$(\lambda_4\lambda_1$	$\lambda_4\lambda_2$	$\lambda_4\lambda_3$	$\lambda_4^2 + d_4)$

Huynh-Feldt. This is a "circular" matrix in which the covariance between any two elements is equal to the average of their variances minus a constant. Neither the variances nor the covariances are constant.

$(\sigma_1^2$	$[\sigma_1^2 + \sigma_2^2]/2 - \lambda$	$[\sigma_1^2 + \sigma_3^2]/2 - \lambda$	$[\sigma_1^2 + \sigma_4^2]/2 - \lambda)$
$([\sigma_1^2 + \sigma_2^2]/2 - \lambda$	σ_2^2	$[\sigma_2^2 + \sigma_3^2]/2 - \lambda$	$[\sigma_2^2 + \sigma_4^2]/2 - \lambda)$
$([\sigma_1^2 + \sigma_3^2]/2 - \lambda$	$[\sigma_2^2 + \sigma_3^2]/2 - \lambda$	σ_3^2	$[\sigma_3^2 + \sigma_4^2]/2 - \lambda)$
$([\sigma_1^2 + \sigma_4^2]/2 - \lambda$	$[\sigma_2^2 + \sigma_4^2]/2 - \lambda$	$[\sigma_3^2 + \sigma_4^2]/2 - \lambda$	$\sigma_4^2)$

Scaled Identity. This structure has constant variance. There is assumed to be no correlation between any elements.

$(\sigma^2$	0	0	0)
(0	σ^2	0	0)
(0	0	σ^2	0)
(0	0	0	$\sigma^2)$

Spatial: Power. This covariance structure has homogenous variances and heterogenous correlations between elements. d_{ij} is the estimated Euclidean distance between the i^{th} and j^{th} measurement.

$$\begin{pmatrix} \sigma^2 & \sigma^2 \rho^{d_{12}} & \sigma^2 \rho^{d_{13}} & \sigma^2 \rho^{d_{14}} \\ (\sigma^2 \rho^{d_{12}} & \sigma^2 & \sigma^2 \rho^{d_{23}} & \sigma^2 \rho^{d_{24}} \\ (\sigma^2 \rho^{d_{13}} & \sigma^2 \rho^{d_{23}} & \sigma^2 & \sigma^2 \rho^{d_{34}} \\ (\sigma^2 \rho^{d_{14}} & \sigma^2 \rho^{d_{24}} & \sigma^2 \rho^{d_{34}} & \sigma^2 \end{pmatrix}$$

Spatial: Exponential. This covariance structure has homogenous variances and heterogenous correlations between elements. d_{ij} is the estimated Euclidean distance between the i^{th} and j^{th} measurement.

$$\begin{pmatrix} \sigma^2 & \sigma^2 \exp\{-d_{12}/\theta\} & \sigma^2 \exp\{-d_{13}/\theta\} & \sigma^2 \exp\{-d_{14}/\theta\} \\ (\sigma^2 \exp\{-d_{12}/\theta\} & \sigma^2 & \sigma^2 \exp\{-d_{23}/\theta\} & \sigma^2 \exp\{-d_{24}/\theta\} \\ (\sigma^2 \exp\{-d_{13}/\theta\} & \sigma^2 \exp\{-d_{23}/\theta\} & \sigma^2 & \sigma^2 \exp\{-d_{34}/\theta\} \\ (\sigma^2 \exp\{-d_{14}/\theta\} & \sigma^2 \exp\{-d_{24}/\theta\} & \sigma^2 \exp\{-d_{34}/\theta\} & \sigma^2 \end{pmatrix}$$

Spatial: Gaussian. This covariance structure has homogenous variances and heterogenous correlations between elements. d_{ij} is the estimated Euclidean distance between the i^{th} and j^{th} measurement.

$$\begin{pmatrix} \sigma^2 & \sigma^2 \exp\{-d_{12}/\rho^2\} & \sigma^2 \exp\{-d_{13}/\rho^2\} & \sigma^2 \exp\{-d_{14}/\rho^2\} \\ (\sigma^2 \exp\{-d_{12}/\rho^2\} & \sigma^2 & \sigma^2 \exp\{-d_{23}/\rho^2\} & \sigma^2 \exp\{-d_{24}/\rho^2\} \\ (\sigma^2 \exp\{-d_{13}/\rho^2\} & \sigma^2 \exp\{-d_{23}/\rho^2\} & \sigma^2 & \sigma^2 \exp\{-d_{34}/\rho^2\} \\ (\sigma^2 \exp\{-d_{14}/\rho^2\} & \sigma^2 \exp\{-d_{24}/\rho^2\} & \sigma^2 \exp\{-d_{34}/\rho^2\} & \sigma^2 \end{pmatrix}$$

Spatial: Linear. This covariance structure has homogenous variances and heterogenous correlations between elements. d_{ij} is the estimated Euclidean distance between the i^{th} and j^{th} measurement, and 1_{ij} is an indicator function which is 1 if $\rho d_{ij} \leq 0$ and 0 otherwise.

$$\begin{pmatrix} \sigma^2 & \sigma^2(1 - \rho d_{12}) 1_{12} & \sigma^2(1 - \rho d_{13}) 1_{13} & \sigma^2(1 - \rho d_{14}) 1_{14} \\ (\sigma^2(1 - \rho d_{12}) 1_{12} & \sigma^2 & \sigma^2(1 - \rho d_{23}) 1_{23} & \sigma^2(1 - \rho d_{24}) 1_{24} \\ (\sigma^2(1 - \rho d_{13}) 1_{13} & \sigma^2(1 - \rho d_{23}) 1_{23} & \sigma^2 & \sigma^2(1 - \rho d_{34}) 1_{34} \\ (\sigma^2(1 - \rho d_{14}) 1_{14} & \sigma^2(1 - \rho d_{24}) 1_{24} & \sigma^2(1 - \rho d_{34}) 1_{34} & \sigma^2 \end{pmatrix}$$

Spatial: Linear-log. This covariance structure has homogenous variances and heterogenous correlations between elements. d_{ij} is the estimated Euclidean distance between the i^{th} and j^{th} measurement, and 1_{ij} is an indicator function which is 1 if $\rho \log(d_{ij}) \leq 0$ and 0 otherwise.

$$\begin{pmatrix} \sigma^2 & \sigma^2(1 - \rho \log(d_{12})) 1_{12} & \sigma^2(1 - \rho \log(d_{13})) 1_{13} & \sigma^2(1 - \rho \log(d_{14})) 1_{14} \\ (\sigma^2(1 - \rho \log(d_{12})) 1_{12} & \sigma^2 & \sigma^2(1 - \rho \log(d_{23})) 1_{23} & \sigma^2(1 - \rho \log(d_{24})) 1_{24} \\ (\sigma^2(1 - \rho \log(d_{13})) 1_{13} & \sigma^2(1 - \rho \log(d_{23})) 1_{23} & \sigma^2 & \sigma^2(1 - \rho \log(d_{34})) 1_{34} \\ (\sigma^2(1 - \rho \log(d_{14})) 1_{14} & \sigma^2(1 - \rho \log(d_{24})) 1_{24} & \sigma^2(1 - \rho \log(d_{34})) 1_{34} & \sigma^2 \end{pmatrix}$$

Spatial: Spherical. This covariance structure has homogenous variances and heterogenous correlations between elements. $r_{ij} = d_{ij}/\rho$, where d_{ij} is the estimated Euclidean distance between the i^{th} and j^{th} measurement. 1_{ij} is an indicator function which is 1 if $d_{ij} \leq \rho$ and 0 otherwise.

$$\begin{pmatrix} \sigma^2 & \sigma^2(1 - 3/2r_{12} + 1/2r_{12}^3) 1_{12} & \sigma^2(1 - 3/2r_{13} + 1/2r_{13}^3) 1_{13} & \sigma^2(1 - 3/2r_{14} + 1/2r_{14}^3) 1_{14} \\ (\sigma^2(1 - 3/2r_{12} + 1/2r_{12}^3) 1_{12} & \sigma^2 & \sigma^2(1 - 3/2r_{23} + 1/2r_{23}^3) 1_{23} & \sigma^2(1 - 3/2r_{24} + 1/2r_{24}^3) 1_{24} \\ (\sigma^2(1 - 3/2r_{13} + 1/2r_{13}^3) 1_{13} & \sigma^2(1 - 3/2r_{23} + 1/2r_{23}^3) 1_{23} & \sigma^2 & \sigma^2(1 - 3/2r_{34} + 1/2r_{34}^3) 1_{34} \\ (\sigma^2(1 - 3/2r_{14} + 1/2r_{14}^3) 1_{14} & \sigma^2(1 - 3/2r_{24} + 1/2r_{24}^3) 1_{24} & \sigma^2(1 - 3/2r_{34} + 1/2r_{34}^3) 1_{34} & \sigma^2 \end{pmatrix}$$

$$\begin{pmatrix}
\sigma^2(1 - 3/2r_{12} + 1/2r_{12}^3) & \sigma^2 & \sigma^2(1 - 3/2r_{23} + 1/2r_{23}^3) & \sigma^2(1 - 3/2r_{24} + 1/2r_{24}^3) \\
(\sigma^2(1 - 3/2r_{13} + 1/2r_{13}^3) & \sigma^2(1 - 3/2r_{23} + 1/2r_{23}^3) & \sigma^2 & \sigma^2(1 - 3/2r_{34} + 1/2r_{34}^3) \\
(\sigma^2(1 - 3/2r_{14} + 1/2r_{14}^3) & \sigma^2(1 - 3/2r_{24} + 1/2r_{24}^3) & \sigma^2(1 - 3/2r_{34} + 1/2r_{34}^3) & \sigma^2
\end{pmatrix}$$

Toeplitz. This covariance structure has homogenous variances and heterogenous correlations between elements. The correlation between adjacent elements is homogenous across pairs of adjacent elements. The correlation between elements separated by a third is again homogenous, and so on.

$$\begin{pmatrix}
\sigma^2 & \sigma^2\rho_1 & \sigma^2\rho_2 & \sigma^2\rho_3 \\
(\sigma^2\rho_1 & \sigma^2 & \sigma^2\rho_1 & \sigma^2\rho_2) \\
(\sigma^2\rho_2 & \sigma^2\rho_1 & \sigma^2 & \sigma^2\rho_1) \\
(\sigma^2\rho_3 & \sigma^2\rho_2 & \sigma^2\rho_1 & \sigma^2)
\end{pmatrix}$$

Toeplitz: Heterogenous. This covariance structure has heterogenous variances and heterogenous correlations between elements. The correlation between adjacent elements is homogenous across pairs of adjacent elements. The correlation between elements separated by a third is again homogenous, and so on.

$$\begin{pmatrix}
\sigma_1^2 & \sigma_2\sigma_1\rho_1 & \sigma_3\sigma_1\rho_2 & \sigma_4\sigma_1\rho_3 \\
(\sigma_2\sigma_1\rho_1 & \sigma_2^2 & \sigma_3\sigma_2\rho_1 & \sigma_4\sigma_2\rho_2) \\
(\sigma_3\sigma_1\rho_2 & \sigma_3\sigma_2\rho_1 & \sigma_3^2 & \sigma_4\sigma_3\rho_1) \\
(\sigma_4\sigma_1\rho_3 & \sigma_4\sigma_2\rho_2 & \sigma_4\sigma_3\rho_1 & \sigma_4^2)
\end{pmatrix}$$

Unstructured. This is a completely general covariance matrix.

$$\begin{pmatrix}
\sigma_1^2 & \sigma_{21} & \sigma_{31} & \sigma_{41} \\
(\sigma_{21} & \sigma_2^2 & \sigma_{32} & \sigma_{42}) \\
(\sigma_{31} & \sigma_{32} & \sigma_3^2 & \sigma_{43}) \\
(\sigma_{41} & \sigma_{42} & \sigma_{43} & \sigma_4^2)
\end{pmatrix}$$

Unstructured: Correlation Metric. This covariance structure has heterogenous variances and heterogenous correlations.

$$\begin{pmatrix}
\sigma_1^2 & \sigma_2\sigma_1\rho_{21} & \sigma_3\sigma_1\rho_{31} & \sigma_4\sigma_1\rho_{41} \\
(\sigma_2\sigma_1\rho_{21} & \sigma_2^2 & \sigma_3\sigma_2\rho_{32} & \sigma_4\sigma_2\rho_{42}) \\
(\sigma_3\sigma_1\rho_{31} & \sigma_3\sigma_2\rho_{32} & \sigma_3^2 & \sigma_4\sigma_3\rho_{43}) \\
(\sigma_4\sigma_1\rho_{41} & \sigma_4\sigma_2\rho_{42} & \sigma_4\sigma_3\rho_{43} & \sigma_4^2)
\end{pmatrix}$$

Variance Components. This structure assigns a scaled identity (ID) structure to each of the specified random effects.

Bayesian statistics

IBM SPSS Statistics provides support for the following Bayesian statistics.

One Sample and Paired Sample T-tests

The Bayesian One Sample Inference procedure provides options for making Bayesian inference on one-sample and two-sample paired t-test by characterizing posterior distributions. When you have normal data, you can use a normal prior to obtain a normal posterior.

Binomial Proportion tests

The Bayesian One Sample Inference: Binomial procedure provides options for executing Bayesian one-sample inference on Binomial distribution. The parameter of interest is π , which denotes the probability of success in a fixed number of trials that may lead to either success or failure. Note that each trial is independent of each other, and the probability π remains the same in each trial. A binomial random variable can be seen as the sum of a fixed number of independent Bernoulli trials.

Poisson Distribution Analysis

The Bayesian One Sample Inference: Poisson procedure provides options for executing Bayesian one-sample inference on Poisson distribution. Poisson distribution, a useful model for rare events, assumes that within small time intervals, the probability of an event to occur is proportional to the length of waiting time. A conjugate prior within the Gamma distribution family is used when drawing Bayesian statistical inference on Poisson distribution.

Related Samples

The Bayesian related sample inference design is quite similar to the Bayesian one-sample inference in terms of handling paired samples. You can specify the variable names in pairs, and run the Bayesian analysis on the mean difference.

Independent Samples T-tests

The Bayesian independent sample inference procedure provides options for using a group variable to define two unrelated groups, and make Bayesian inference on the difference of the two group means. You can estimate the Bayes factors by using different approaches, and also characterize the desired posterior distribution either assuming the variances are known or unknown.

Pairwise Correlation (Pearson)

The Bayesian inference about Pearson correlation coefficient measures the linear relation between two scale variables jointly following a bivariate normal distribution. The conventional statistical inference about the correlation coefficient has been broadly discussed, and its practice has long been offered in IBM SPSS Statistics. The design of the Bayesian inference about Pearson correlation coefficient allows you to draw Bayesian inference by estimating Bayes factors and characterizing posterior distributions.

Linear Regression

Bayesian inference about Linear Regression is a statistical method that is broadly used in quantitative modeling. Linear regression is a basic and standard approach in which researchers use the values of several variables to explain or predict values of a scale outcome. Bayesian univariate linear regression is an approach to Linear Regression where the statistical analysis is undertaken within the context of Bayesian inference.

One-way ANOVA

The Bayesian One-Way ANOVA procedure produces a one-way analysis of variance for a quantitative dependent variable by a single factor (independent) variable. Analysis of variance is used to test the hypothesis that several means are equal. SPSS Statistics supports Bayes-factors, conjugate priors, and non-informative priors.

Log-Linear Regression Models

The design for testing the independence of two factors requires two categorical variables for the construction of a contingency table, and makes Bayesian inference on the row-column association. You can estimate the Bayes factors by assuming different models, and characterize the desired posterior distribution by simulating the simultaneous credible interval for the interaction terms.

One-way Repeated Measures ANOVA

The Bayesian One-way Repeated Measures ANOVA procedure measures one factor from the same subject at each distinct time point or condition, and allows subjects to be crossed within the levels. It is assumed that each subject has a single observation for each time point or condition (as such, the subject-treatment interaction is not accounted for).

Bayesian One Sample Inference: Normal

This feature requires SPSS Statistics Standard Edition or the Advanced Statistics option.

The Bayesian One Sample Inference: Normal procedure provides options for making Bayesian inference on one-sample and two-sample paired t-test by characterizing posterior distributions. When you have normal data, you can use a normal prior to obtain a normal posterior.

1. From the menus choose:

Analyze > Bayesian Statistics > One Sample Normal

2. Select the appropriate **Test Variables** from the **Available Variables** list. At least one variable must be selected.

Note: The available variables list provides all variables except for Date and String variables.

3. Select the desired **Bayesian Analysis:**

- **Characterize Posterior Distribution:** When selected, the Bayesian inference is made from a perspective that is approached by characterizing posterior distributions. You can investigate the marginal posterior distribution of the parameter(s) of interest by integrating out the other nuisance parameters, and further construct credible intervals to draw direct inference. This is the default setting.
- **Estimate Bayes Factor:** When selected, estimating Bayes factors (one of the notable methodologies in Bayesian inference) constitutes a natural ratio to compare the marginal likelihoods between a null and an alternative hypothesis.

Bayes Factor	Evidence Category	Bayes Factor	Evidence Category	Bayes Factor	Evidence Category
>100	Extreme Evidence for H1	1-3	Anecdotal Evidence for H1	1/30-1/10	Strong Evidence for H0
30-100	Very Strong Evidence for H1	1	No Evidence	1/100-1/30	Very Strong Evidence for H0
10-30	Strong Evidence for H1	1/3-1	Anecdotal Evidence for H0	1/100	Extreme Evidence for H0
3-10	Moderate Evidence for H1	1/10-1/3	Moderate Evidence for H0		

H0: Null Hypothesis

H1: Alternative Hypothesis

1

2

- **Use Both Methods:** When selected, both the **Characterize Posterior Distribution** and **Estimate Bayes Factor** inference methods as used.

4. Select and/or enter the appropriate **Data Variance and Hypothesis Values** settings. The table reflects the variables that are currently in the **Test Variables** list. As variables are added or removed from

¹ Lee, M.D., and Wagenmakers, E.-J. 2013. *Bayesian Modeling for Cognitive Science: A Practical Course*. Cambridge University Press.

² Jeffreys, H. 1961. *Theory of probability*. Oxford University Press.

the **Test Variables** list, the table automatically adds or removes the same variables from its variable columns.

- When one or more variables are in the **Test Variables** list, the **Variable Known**, and **Variance Value** columns are enabled.

Variance Known

Select this option for each variable when the variance is known.

Variance Value

An optional parameter that specifies the variance value, if known, for observed data.

- When one or more variables are in the **Test Variables** list, and **Characterize Posterior Distribution** is not selected, the **Null Test Value** and **g Value** columns are enabled.

Null Test Value

A required parameter that specifies the null value in the Bayes factor estimation. Only one value is allowed, and 0 is the default value.

g Value

Specifies the value to define $\psi^2 = g\sigma^2_x$ in the Bayes factor estimation. When the **Variance Value** is specified, the **g Value** defaults to 1. When the **Variance Value** is not specified, you can specify a fixed *g* or omit the value to integrate it out.

5. You can optionally click **Criteria** to specify “Bayesian One Sample Inference: Criteria” on page 103 settings (credible interval percentage, missing values options, and numerical method settings), or click **Priors** to specify “Bayesian One Sample Inference: Normal Priors” on page 104 settings (type of priors, such as inference parameters, mean given variance, or precision).

Bayesian One Sample Inference: Criteria

You can specify the following analysis criteria for your Bayesian One-Sample Inference:

Credible interval percentage %

Specify the significance level for computing credible intervals. The default level is 95%.

Missing Values

Specify the method in which to control missing values.

Exclude cases pairwise

This is the default setting and excludes records with missing values on a analysis by analysis basis. Records that include missing values, for a field that is used for a specific test, are omitted from the test.

Exclude cases listwise

This setting excludes records that include missing values listwise. Records that include missing values for any field that is named on any subcommand are excluded from all analysis.

Note: The following options are available only when either the **Estimate Bayes Factor** or **Use Both Methods** option is selected for **Bayesian Analysis**.

Numerical Method

Specify the numerical method that is used to estimate the integral.

Adaptive Gauss-Lobatto Quadrature

This is the default setting and calls the Adaptive Gauss-Lobatto Quadrature approach.

Tolerance

Specify the tolerance value for the numerical methods. The default setting is 0.000001. The option is available only when the **Adaptive Gauss-Lobatto Quadrature** setting is selected.

Maximum iterations

Specify the maximum number of Adaptive Gauss-Lobatto Quadrature method iterations. The value must be a positive integer. The default setting is 2000. The option is available only when the **Adaptive Gauss-Lobatto Quadrature** setting is selected.

Monte Carlo Approximation

This option calls the Monte Carlo approximation approach.

Set custom seed

When selected, you can specify a custom seed value in the **Seed** field.

Seed

Specify a random seed set for the Monte Carlo Approximation method. The value must be a positive integer. By default, a random seed value is assigned.

Number of Monte Carlo Samples

Specify the number of points that are sampled for the Monte Carlo approximation. The value must be a positive integer. The default value is 1000000. The option is available only when the **Monte Carlo Approximation** setting is selected.

Bayesian One Sample Inference: Normal Priors

You can specify the following prior distribution criteria for your Bayesian One-Sample Inference:

Note: Many applied researchers may question the need to specify a prior. Reference priors minimize the concern where the prior is generally overwhelmed as the data increases. When informative prior information is specified, Bayesian methods can effectively use the information. The requirement to specify a prior should not be viewed as a deterrent to using Bayesian analysis.

Prior on Variance/Precision

Provides options for defining variance and precision values.

Variance

Select to specify the prior distribution for the variance parameter. When this option is selected, the **Prior Distribution** list provides the following options:

Note: When the data variance is already specified for some variables, the following settings are ignored for those variables.

- **Diffuse** - the default setting. Specifies the diffuse prior.
- **Inverse Chi-Square** - Specifies the distribution and parameters for inverse- $\chi^2(v_0, \sigma^2_0)$, where $v_0 > 0$ is the degree of freedom, and $\sigma^2_0 > 0$ is the scale parameter.
- **Inverse Gamma** - Specifies the distribution and parameters for inverse-Gamma(α_0, β_0), where $\alpha_0 > 0$ is the shape parameter, and $\beta_0 > 0$ is the scale parameter.
- **Jeffreys S2** - Specifies the non-informative prior $\propto 1/\sigma^2_0$.
- **Jeffreys S4** - Specifies the non-informative prior $\propto 1/\sigma^4_0$.

Precision

Select to specify the prior distribution for the precision parameter. When this option is selected, the **Prior Distribution** list provides the following options:

- **Gamma** - Specifies the distribution and parameters for Gamma (α_0, β_0), where $\alpha_0 > 0$ is the shape parameter, and $\beta_0 > 0$ is the scale parameter.
- **Chi-Square** - Specifies the distribution and parameters for $\chi^2(v_0)$, where $v_0 > 0$ is the degree of freedom.

Shape Parameter

Specify the shape parameter a_0 for Inverse-Gamma distribution. You must enter a single value that is greater than 0.

Scale Parameter

Specify the scale parameter b_0 for Inverse-Gamma distribution. You must enter a single value that is greater than 0. The larger the scale parameter, the more spread out the distribution.

Prior on Mean Given Variance/Precision

Specify the prior distribution for the mean parameter that is conditional on the variance or the precision parameter.

Normal

Specifies the distribution and parameters for Normal($\mu_0, K^{-1}_0\sigma^2_0$) on variance or Normal($\mu_0, K_0/\sigma^2_0$) on precision, where $\mu_0 \in (-\infty, \infty)$ and $\sigma^2 > 0$.

Location Parameter

Enter a numeric value that specifies the location parameter for the distribution.

Scale Parameter

Specify the scale parameter b_0 for Inverse-Gamma distribution. You must enter a single value that is greater than 0.

Kappa

Specify the value of K_0 in Normal($\mu_0, K^{-1}_0\sigma^2_0$) or Normal($\mu_0, K_0/\sigma^2_0$). You must enter a single value that is greater than 0 (1 is the default value).

Diffuse

The default setting that specifies the diffuse prior $\propto 1$.

Bayesian One Sample Inference: Binomial

This feature requires SPSS Statistics Standard Edition or the Advanced Statistics option.

The Bayesian One Sample Inference: Binomial procedure provides options for executing Bayesian one-sample inference on Binomial distribution. The parameter of interest is π , which denotes the probability of success in a fixed number of trials that may lead to either success or failure. Note that each trial is independent of each other, and the probability π remains the same in each trial. A binomial random variable can be seen as the sum of a fixed number of independent Bernoulli trials.

Although it is not necessary, a prior from the Beta distribution family is normally chosen when estimating a binomial parameter. The Beta family is conjugate for the binomial family, and as such leads to the posterior distribution with a closed form still in the Beta distribution family.

1. From the menus choose:

Analyze > Bayesian Statistics > One Sample Binomial

2. Select the appropriate **Test Variables** from the **Available Variables** list. At least one variable must be selected.

Note: The available variables list provides all variables except for Date and String variables.

3. Select the desired **Bayesian Analysis:**

- **Characterize Posterior Distribution:** When selected, the Bayesian inference is made from a perspective that is approached by characterizing posterior distributions. You can investigate the marginal posterior distribution of the parameter(s) of interest by integrating out the other nuisance parameters, and further construct credible intervals to draw direct inference. This is the default setting.
- **Estimate Bayes Factor:** When selected, estimating Bayes factors (one of the notable methodologies in Bayesian inference) constitutes a natural ratio to compare the marginal likelihoods between a null and an alternative hypothesis.

Bayes Factor	Evidence Category	Bayes Factor	Evidence Category	Bayes Factor	Evidence Category
>100	Extreme Evidence for H1	1-3	Anecdotal Evidence for H1	1/30-1/10	Strong Evidence for H0
30-100	Very Strong Evidence for H1	1	No Evidence	1/100-1/30	Very Strong Evidence for H0

Table 3. Commonly used thresholds to define significance of evidence (continued)

Bayes Factor	Evidence Category	Bayes Factor	Evidence Category	Bayes Factor	Evidence Category
10-30	Strong Evidence for H1	1/3-1	Anecdotal Evidence for H0	1/100	Extreme Evidence for H0
3-10	Moderate Evidence for H1	1/10-1/3	Moderate Evidence for H0		

H0: Null Hypothesis

H1: Alternative Hypothesis

3

4

- **Use Both Methods:** When selected, both the **Characterize Posterior Distribution** and **Estimate Bayes Factor** inference methods as used.
4. Select and/or enter the appropriate **Success Categories and Hypothesis Values** settings. The table reflects the variables that are currently in the **Test Variables** list. As variables are added or removed from the **Test Variables**, the table automatically adds or removes the same variables from its variable pair columns.
- When **Characterize Posterior Distribution** is selected as the **Bayesian Analysis**, the **Success Categories** column is enabled.
 - When **Estimate Bayes Factor** or **Use Both Methods** are selected as the **Bayesian Analysis**, all editable columns are enabled.

Point Null

Enables and disables the **Null Proportion** option. When the setting is enabled, both the **Null Prior Shape** and **Null Prior Scale** options are disabled.

Null Prior Shape

Specifies the shape parameter a_0 under the null hypothesis of Binomial inference.

Null Prior Scale

Specifies the scale parameter b_0 under the null hypothesis of Binomial inference.

Null Proportion

Specifies the shape parameter a_0 and the scale parameter b_0 under the null hypothesis for a conjugate prior distribution (to accommodate the Beta and the Haldane's priors). The valid range is numeric values between 0 and 1.

Alternate Prior Shape

A required parameter to specify a_0 under the alternative hypothesis of Binomial inference if Bayes factor is to be estimated.

Alternate Prior Scale

A required parameter to specify b_0 under the alternative hypothesis of Binomial inference if Bayes factor is to be estimated.

Success Categories

Provides options for defining conjugate prior distributions. The provided options specify how success is defined, for numerical and string variables, when the data value(s) are tested against the test value.

³ Lee, M.D., and Wagenmakers, E.-J. 2013. *Bayesian Modeling for Cognitive Science: A Practical Course*. Cambridge University Press.

⁴ Jeffreys, H. 1961. *Theory of probability*. Oxford University Press.

Last Category

The default setting that performs the binomial test using the last numerical value found in the category after it is sorted in an ascending order.

First Category

Performs the binomial test using the first numerical value found in the category after it is sorted in an ascending order.

Midpoint

Uses the numerical values \geq the midpoint as cases. A midpoint value is the average of the minimum and maximum sample data.

Cutpoint

Uses the numerical values \geq a specified cutoff value as cases. The setting must be a single numeric value.

Level

Treats user specified string values (can be more than 1) as cases. Use commas to separate the different values.

5. You can optionally click **Criteria** to specify “Bayesian One Sample Inference: Criteria” on page 103 settings (credible interval percentage, missing values options, and numerical method settings), or click **Priors** to specify “Bayesian One Sample Inference: Binomial/Poisson Priors” on page 107 settings (conjugate or custom prior distributions).

Bayesian One Sample Inference: Binomial/Poisson Priors

You can specify the following prior distribution criteria for your Bayesian One-Sample Inference:

Note: Many applied researchers may question the need to specify a prior. Reference priors minimize the concern where the prior is generally overwhelmed as the data increases. When informative prior information is specified, Bayesian methods can effectively use the information. The requirement to specify a prior should not be viewed as a deterrent to using Bayesian analysis.

Shape Parameter

For Binomial priors, specify the shape parameter a_0 for Beta distribution.

For Poisson priors, specify the shape parameter a_0 for Gamma distribution.

You must enter a single value that is greater than 0.

Scale Parameter

For Binomial priors, specify the scale parameter b_0 for Beta distribution.

For Poisson priors, specify the scale parameter b_0 for Gamma distribution.

You must enter a single value that is greater than 0.

Bayesian One Sample Inference: Poisson

This feature requires SPSS Statistics Standard Edition or the Advanced Statistics option.

The Bayesian One Sample Inference: Poisson procedure provides options for executing Bayesian one-sample inference on Poisson distribution. Poisson distribution, a useful model for rare events, assumes that within small time intervals, the probability of an event to occur is proportional to the length of waiting time. A conjugate prior within the Gamma distribution family is used when drawing Bayesian statistical inference on Poisson distribution.

1. From the menus choose:

Analyze > Bayesian Statistics > One Sample Poisson

2. Select the appropriate **Test Variables** from the **Available Variables** list. At least one variable must be selected.

Note: The available variables list provides all variables except for Date and String variables.

3. Select the desired **Bayesian Analysis**:

- **Characterize Posterior Distribution:** When selected, the Bayesian inference is made from a perspective that is approached by characterizing posterior distributions. You can investigate the marginal posterior distribution of the parameter(s) of interest by integrating out the other nuisance parameters, and further construct credible intervals to draw direct inference. This is the default setting.
- **Estimate Bayes Factor:** When selected, estimating Bayes factors (one of the notable methodologies in Bayesian inference) constitutes a natural ratio to compare the marginal likelihoods between a null and an alternative hypothesis.

Table 4. Commonly used thresholds to define significance of evidence

Bayes Factor	Evidence Category	Bayes Factor	Evidence Category	Bayes Factor	Evidence Category
>100	Extreme Evidence for H1	1-3	Anecdotal Evidence for H1	1/30-1/10	Strong Evidence for H0
30-100	Very Strong Evidence for H1	1	No Evidence	1/100-1/30	Very Strong Evidence for H0
10-30	Strong Evidence for H1	1/3-1	Anecdotal Evidence for H0	1/100	Extreme Evidence for H0
3-10	Moderate Evidence for H1	1/10-1/3	Moderate Evidence for H0		

H0: Null Hypothesis

H1: Alternative Hypothesis

5

6

- **Use Both Methods:** When selected, both the **Characterize Posterior Distribution** and **Estimate Bayes Factor** inference methods are used.
4. Select and/or enter the appropriate **Hypothesis Values** settings. The table reflects the variables that are currently in the **Test Variables** list. As variables are added or removed from the **Test Variables**, the table automatically adds or removes the same variables from its variable pair columns.
- When **Characterize Posterior Distribution** is selected as the **Bayesian Analysis**, none of the columns are enabled.
 - When **Estimate Bayes Factor** or **Use Both Methods** are selected as the **Bayesian Analysis**, all editable columns are enabled.

Point Null

Enables and disables the **Null Rate** option. When the setting is enabled, both the **Null Prior Shape** and **Null Prior Scale** options are disabled.

Null Prior Shape

Specifies the shape parameter a_0 under the null hypothesis of Poisson inference.

Null Prior Scale

Specifies the scale parameter b_0 under the null hypothesis of Poisson inference.

⁵ Lee, M.D., and Wagenmakers, E.-J. 2013. *Bayesian Modeling for Cognitive Science: A Practical Course*. Cambridge University Press.

⁶ Jeffreys, H. 1961. *Theory of probability*. Oxford University Press.

Null Rate

Specifies the shape parameter a_0 and the scale parameter b_0 under the null hypothesis for a conjugate prior distribution (to accommodate the Poisson-Gamma relationship). The minimum value must be an numeric value greater than 0; the maximum value must be a max double value.

Alternate Prior Shape

A required parameter to specify a_1 under the alternative hypothesis of Poisson inference if Bayes factor is to be estimated.

Alternate Prior Scale

A required parameter to specify b_1 under the alternative hypothesis of Poisson inference if Bayes factor is to be estimated.

5. You can optionally click **Criteria** to specify “Bayesian One Sample Inference: Criteria” on page 103 settings (credible interval percentage, missing values options, and numerical method settings), or click **Priors** to specify “Bayesian One Sample Inference: Binomial/Poisson Priors” on page 107 settings (conjugate or custom prior distributions).

Bayesian Related Sample Inference: Normal

This feature requires SPSS Statistics Standard Edition or the Advanced Statistics option.

The Bayesian Related Sample Inference: Normal procedure provides Bayesian one-sample inference options for paired samples. You can specify the variable names in pairs, and run the Bayesian analysis on the mean difference.

1. From the menus choose:

Analyze > Bayesian Statistics > Related Samples Normal

2. Select the appropriate **Paired Variables** from the **Available Variables** list. At least one pair of source variables must be selected, and no more than two source variables can be selected for any given pair set.

Note: The available variables list provides all variables except for String variables.

3. Select the desired **Bayesian Analysis:**

- **Characterize Posterior Distribution:** When selected, the Bayesian inference is made from a perspective that is approached by characterizing posterior distributions. You can investigate the marginal posterior distribution of the parameter(s) of interest by integrating out the other nuisance parameters, and further construct credible intervals to draw direct inference. This is the default setting.
- **Estimate Bayes Factor:** When selected, estimating Bayes factors (one of the notable methodologies in Bayesian inference) constitutes a natural ratio to compare the marginal likelihoods between a null and an alternative hypothesis.

Bayes Factor	Evidence Category	Bayes Factor	Evidence Category	Bayes Factor	Evidence Category
>100	Extreme Evidence for H1	1-3	Anecdotal Evidence for H1	1/30-1/10	Strong Evidence for H0
30-100	Very Strong Evidence for H1	1	No Evidence	1/100-1/30	Very Strong Evidence for H0
10-30	Strong Evidence for H1	1/3-1	Anecdotal Evidence for H0	1/100	Extreme Evidence for H0

Table 5. Commonly used thresholds to define significance of evidence (continued)

Bayes Factor	Evidence Category	Bayes Factor	Evidence Category	Bayes Factor	Evidence Category
3-10	Moderate Evidence for H1	1/10-1/3	Moderate Evidence for H0		

H0: Null Hypothesis

H1: Alternative Hypothesis

7

8

- **Use Both Methods:** When selected, both the **Characterize Posterior Distribution** and **Estimate Bayes Factor** inference methods as used.
4. Select and/or enter the appropriate **Data Variance and Hypothesis Values** settings. The table reflects the variable pairs that are currently in the **Paired Variables** list. As variable pairs are added or removed from the **Paired Variables** list, the table automatically adds or removes the same variable pairs from its variable pair columns.

- When one or more variable pairs are in the **Paired Variables** list, the **Variance Known**, and **Variance Value** columns are enabled.

Variance Known

Select this option for each variable when the variance is known.

Variance Value

An optional parameter that specifies the variance value, if known, for observed data.

- When one or more variable pairs are in the **Paired Variables** list, and **Characterize Posterior Distribution** is not selected, the **Null Test Value** and **g Value** columns are enabled.

Null Test Value

A required parameter that specifies the null value in the Bayes factor estimation. Only one value is allowed, and 0 is the default value.

g Value

Specifies the value to define $\psi^2 = g\sigma_x^2$ in the Bayes factor estimation. When the **Variance Value** is specified, the **g Value** defaults to 1. When the **Variance Value** is not specified, you can specify a fixed **g** or omit the value to integrate it out.

5. You can optionally click **Criteria** to specify “[Bayesian One Sample Inference: Criteria](#)” on page 103 settings (credible interval percentage, missing values options, and numerical method settings), or click **Priors** to specify “[Bayesian One Sample Inference: Binomial/Poisson Priors](#)” on page 107 settings (conjugate or custom prior distributions).

Bayesian Independent - Sample Inference

This feature requires SPSS Statistics Standard Edition or the Advanced Statistics option.

The Bayesian Independent - Sample Inference procedure provides options for using a group variable to define two unrelated groups, and make Bayesian inference on the difference of the two group means. You can estimate the Bayes factors by using different approaches, and also characterize the desired posterior distribution either assuming the variances are known or unknown.

1. From the menus choose:

Analyze > Bayesian Statistics > Independent Samples Normal

⁷ Lee, M.D., and Wagenmakers, E.-J. 2013. *Bayesian Modeling for Cognitive Science: A Practical Course*. Cambridge University Press.

⁸ Jeffreys, H. 1961. *Theory of probability*. Oxford University Press.

2. Select the appropriate **Test Variables** from the source variables list. At least one source variable must be selected.
3. Select the appropriate **Grouping Variable** from the **Available Variables** list. A grouping variable defines two groups for the unpaired *t*-test. The selected grouping variable can be either a numeric or a string variable.
4. Select the desired **Bayesian Analysis**:
 - **Characterize Posterior Distribution**: When selected, the Bayesian inference is made from a perspective that is approached by characterizing posterior distributions. You can investigate the marginal posterior distribution of the parameter(s) of interest by integrating out the other nuisance parameters, and further construct credible intervals to draw direct inference. This is the default setting.
 - **Estimate Bayes Factor**: When selected, estimating Bayes factors (one of the notable methodologies in Bayesian inference) constitutes a natural ratio to compare the marginal likelihoods between a null and an alternative hypothesis.

Table 6. Commonly used thresholds to define significance of evidence

Bayes Factor	Evidence Category	Bayes Factor	Evidence Category	Bayes Factor	Evidence Category
>100	Extreme Evidence for H1	1-3	Anecdotal Evidence for H1	1/30-1/10	Strong Evidence for H0
30-100	Very Strong Evidence for H1	1	No Evidence	1/100-1/30	Very Strong Evidence for H0
10-30	Strong Evidence for H1	1/3-1	Anecdotal Evidence for H0	1/100	Extreme Evidence for H0
3-10	Moderate Evidence for H1	1/10-1/3	Moderate Evidence for H0		

H0: Null Hypothesis

H1: Alternative Hypothesis

9

10

- **Use Both Methods**: When selected, both the **Characterize Posterior Distribution** and **Estimate Bayes Factor** inference methods as used.
5. Use the **Define Groups** options to define two groups for the *t* test by specifying two values (for string variables), or two values, a midpoint, or a cut point (for numeric variables).

Note: The specified values must exist in the variable, otherwise an error message displays to indicate that at least one of the groups is empty.

For numeric variables:

- **Use specified values.** Enter a value for Group 1 and another value for Group 2. Cases with any other values are excluded from the analysis. Numbers need not be integers (for example, 6.25 and 12.5 are valid).

⁹ Lee, M.D., and Wagenmakers, E.-J. 2013. *Bayesian Modeling for Cognitive Science: A Practical Course*. Cambridge University Press.

¹⁰ Jeffreys, H. 1961. *Theory of probability*. Oxford University Press.

- **Use midpoint value.** When selected, the groups are separated into $<$ and \geq midpoint values.
- **Use cut point.**
 - **Cutpoint.** Enter a number that splits the values of the grouping variable into two sets. All cases with values that are less than the cutpoint form one group, and cases with values that are greater than or equal to the cutpoint form the other group.

For string grouping variables, enter a string for Group 1 and another value for Group 2, such as *yes* and *no*. Cases with other strings are excluded from the analysis.

6. You can optionally click **Criteria** to specify “Bayesian Independent-Sample Inference: Criteria” on page 112 settings (credible interval percentage, missing values options, and adaptive quadrature method settings), click **Priors** to specify “Bayesian Independent-Sample Inference: Prior Distribution” on page 113 settings (data variance, prior on variance, and prior on mean conditional on variance), or click **Estimate Bayes Factor** to specify “Bayesian Independent - Sample Inference: Estimate Bayes Factor” on page 114 settings.

Bayesian Independent - Sample Inference Define Groups (numeric)

For numeric grouping variables, define the two groups for the *t* test by specifying two values, a midpoint, or a cut point.

Note: The specified values must exist in the variable, otherwise an error message displays to indicate that at least one of the groups is empty.

- **Use specified values.** Enter a value for Group 1 and another value for Group 2. Cases with any other values are excluded from the analysis. Numbers need not be integers (for example, 6.25 and 12.5 are valid).
- **Use midpoint value.** When selected, the groups are separated into $<$ and \geq midpoint values.
- **Use cut point.**
 - **Cutpoint.** Enter a number that splits the values of the grouping variable into two sets. All cases with values that are less than the cutpoint form one group, and cases with values that are greater than or equal to the cutpoint form the other group.

Bayesian Independent - Sample Inference Define Groups (string)

For string grouping variables, enter a string for Group 1 and another value for Group 2, such as *yes* and *no*. Cases with other strings are excluded from the analysis.

Note: The specified values must exist in the variable, otherwise an error message displays to indicate that at least one of the groups is empty.

Bayesian Independent-Sample Inference: Criteria

You can specify the following analysis criteria for your Bayesian Independent-Sample Inference:

Credible interval percentage %

Specify the significance level for computing credible intervals. The default level is 95%.

Missing Values

Specify the method in which to control missing values.

Exclude cases pairwise

This is the default setting and excludes records with missing values on a analysis by analysis basis. Records that include missing values, for a field that is used for a specific test, are omitted from the test.

Exclude cases listwise

This setting excludes records that include missing values listwise. Records that include missing values for any field that is named on any subcommand are excluded from all analysis.

Note: The following options are available only when either the **Estimate Bayes Factor** or **Use Both Methods** option is selected for **Bayesian Analysis**.

Adaptive Quadrature Method

Specify the tolerance and maximum iteration values for the Adaptive Quadrature Quadrature method.

Tolerance

Specify the tolerance value for the numerical methods. The default setting is 0.000001.

Maximum iterations

Specify the maximum number of Adaptive Quadrature method iterations. The value must be a positive integer. The default setting is 500.

Bayesian Independent-Sample Inference: Prior Distribution

You can specify the following prior distribution criteria for your Bayesian Independent-Sample Inference:

Note: Many applied researchers may question the need to specify a prior. Reference priors minimize the concern where the prior is generally overwhelmed as the data increases. When informative prior information is specified, Bayesian methods can effectively use the information. The requirement to specify a prior should not be viewed as a deterrent to using Bayesian analysis.

Data Variance

Provides options for defining data variance settings.

Variance known

When selected, allows you to enter two known group variances. Both values must be > 0 .

Group 1 variance

Enter the first known group variance value.

Group 2 variance

Enter the second known group variance value.

Assume equal variance

Controls whether or not the two group variances are assumed to be equal. By default, it is assumed that group variances are unequal. This setting is ignored when values are entered for the two group variances.

Assume unequal variance

Controls whether or not the two group variances are assumed to be unequal. By default, it is assumed that group variances are unequal. This setting is ignored when values are entered for the two group variances.

Prior on variance

Specify the prior distribution for the two equal variances.

Jeffreys

When selected, a non-informative (objective) prior distribution for a parameter space is used.

Inverse-ChiSquare

Specifies the continuous probability distribution of a positive-valued random variable and the parameters for inverse- $\chi^2(v_0, \sigma^2_0)$, where $v_0 > 0$ is the degree of freedom, and $\sigma^2_0 > 0$ is the scale parameter.

Degrees of freedom

Specify a value for the number of values in the final calculation that are free to vary.

Scale Parameter

Specify the scale parameter $\sigma^2_0 > 0$ for inverse- $\chi^2(v_0, \sigma^2_0)$. You must enter a single value that is greater than 0. The larger the scale parameter, the more spread out the distribution.

Prior on mean conditional on variance

Provides options for specifying the prior distribution for the two group means.

Note: The **Diffuse** and **Normal** options are available only when the **Variance known** option is selected.

Diffuse

The default setting. Specifies the diffuse prior.

Normal

When selected, you must specify location and scale parameters for the defined group means.

Location Parameter

Enter a numeric values that specifies the location parameters for the group distributions.

Scale Parameter

Specify the scale parameter $\sigma^2_0 > 0$ for inverse- $\chi^2(v_0, \sigma^2_0)$. For each group, you must enter a single value that is greater than 0. The larger the scale parameter, the more spread out the distribution.

Bayesian Independent - Sample Inference: Estimate Bayes Factor

You can specify the method that is used to estimate the Bayes factor.

Rouder's method

When selected, invokes the Rouder's approach. This is the default setting

Gonen's method

When selected, invokes the Gonen approach and you must specify the following effect size settings:

Mean for effect size

Enter a value that specifies the mean difference between the two groups.

Variance for effect size

Enter a value that specifies the variance for the two groups. The value must be > 0 .

Hyper-Prior method

When selected, invokes the hyper-g approach where you are required to specify a single value. Enter a value between -1 and -0.5 in the **Shape Parameter** field. The default value is -0.75.

Bayesian Inference about Pearson Correlation

This feature requires SPSS Statistics Standard Edition or the Advanced Statistics option.

Pearson correlation coefficient measures the linear relation between two scale variables jointly following a bivariate normal distribution. The conventional statistical inference about the correlation coefficient has been broadly discussed, and its practice has long been offered in IBM SPSS Statistics. The design of the Bayesian inference about Pearson correlation coefficient allows users to draw Bayesian inference by estimating Bayes factors and characterizing posterior distributions.

1. From the menus choose:

Analyze > Bayesian Statistics > Pearson Correlation

2. Select the appropriate **Test Variables** to use for pairwise correlation inference from the **Available Variables** list. At least two source variables must be selected. When more than two variables are selected, the analysis is run on all of the selected variables' pairwise combinations.

3. Select the desired **Bayesian Analysis**:

- **Characterize Posterior Distribution:** When selected, the Bayesian inference is made from a perspective that is approached by characterizing posterior distributions. You can investigate the marginal posterior distribution of the parameter(s) of interest by integrating out the other nuisance parameters, and further construct credible intervals to draw direct inference. This is the default setting.
- **Estimate Bayes Factor:** When selected, estimating Bayes factors (one of the notable methodologies in Bayesian inference) constitutes a natural ratio to compare the marginal likelihoods between a null and an alternative hypothesis.

Table 7. Commonly used thresholds to define significance of evidence

Bayes Factor	Evidence Category	Bayes Factor	Evidence Category	Bayes Factor	Evidence Category
>100	Extreme Evidence for H1	1-3	Anecdotal Evidence for H1	1/30-1/10	Strong Evidence for H0
30-100	Very Strong Evidence for H1	1	No Evidence	1/100-1/30	Very Strong Evidence for H0
10-30	Strong Evidence for H1	1/3-1	Anecdotal Evidence for H0	1/100	Extreme Evidence for H0
3-10	Moderate Evidence for H1	1/10-1/3	Moderate Evidence for H0		

H0: Null Hypothesis

H1: Alternative Hypothesis

11

12

- **Use Both Methods:** When selected, both the **Characterize Posterior Distribution** and **Estimate Bayes Factor** inference methods as used.
- Specify the **Maximum number of plots** to see in the output. A set of plots can contain 3 plots on the same pane. The plots are generated in order from the first variable versus the remaining variables, then the second variable versus the remaining variables, and so on. The defined integer value must be between 0 and 50. By default, 10 sets of plots are output to accommodate five variables. This option is not available when **Estimate Bayes Factor** is selected.
 - You can optionally click **Criteria** to specify “[Bayesian Pearson Correlation: Criteria](#)” on page 115 settings (credible interval percentage, missing values options, and numerical method settings), click **Priors** to specify “[Bayesian Pearson Correlation: Prior Distribution](#)” on page 116 settings (value c for the prior $p(\rho) \propto (1 - \rho^2)^c$, or click **Bayes Factor** to specify “[Bayesian Independent - Sample Inference: Estimate Bayes Factor](#)” on page 114 settings.

Bayesian Pearson Correlation: Criteria

You can specify the following analysis criteria for Bayesian Pearson Correlation Inference (pairwise).

Credible interval percentage %

Specify the significance level for computing credible intervals. The default level is 95%.

Missing Values

Specify the method in which to control missing values.

Exclude cases pairwise

This setting excludes records that include missing values pairwise.

Exclude cases listwise

This setting excludes records that include missing values listwise. Records that include missing values for any field that is named on any subcommand are excluded from all analysis.

¹¹ Lee, M.D., and Wagenmakers, E.-J. 2013. *Bayesian Modeling for Cognitive Science: A Practical Course*. Cambridge University Press.

¹² Jeffreys, H. 1961. *Theory of probability*. Oxford University Press.

Note: The following options are available only when either the **Estimate Bayes Factor** or **Use Both Methods** option is selected for **Bayesian Analysis**.

Numerical Method

Specify the numerical method that is used to estimate the integral.

Set custom seed

When selected, you can specify a custom seed value in the **Seed** field.

Tolerance

Specify the tolerance value for the numerical methods. The default setting is 0.000001.

Maximum iterations

Specify the maximum number of method iterations. The value must be a positive integer. The default setting is 2000.

Number of Monte Carlo Samples

Specify the number of points that are sampled for the Monte Carlo approximation. The value must be a positive integer. The default value is 10000.

Samples Simulated for Posterior Distribution

Specify the number of samples that are used to draw the desired posterior distribution. The default value is 10000.

Bayesian Pearson Correlation: Prior Distribution

You can specify the value c for the prior $p(\rho) \propto (1-\rho^2)^c$.

Note: Many applied researchers may question the need to specify a prior. Reference priors minimize the concern where the prior is generally overwhelmed as the data increases. When informative prior information is specified, Bayesian methods can effectively use the information. The requirement to specify a prior should not be viewed as a deterrent to using Bayesian analysis.

Uniform (c = 0)

When selected the uniform prior is used.

Jeffreys (c = -1.5)

When selected, a non-informative prior distribution is used.

Set custom c value

When selected, you can specify a custom **c value**. Any single real number is allowed.

Bayesian Pearson Correlation: Bayes Factor

You can specify the method that is used to estimate the Bayes factor. The following options are available only when either the **Estimate Bayes Factor** or **User Both Methods** Bayesian Analysis option is selected.

JZS Bayes factor

When selected, invokes the Zellner-Siow's approach. This is the default setting.

Fractional Bayes factor

When selected, you can specify the fractional Bayes factor and null hypothesis value. For the fractional Bayes factor, you must specify a value $\epsilon \in (0,1)$. The default value is 0.5.

Bayesian Inference about Linear Regression Models

This feature requires SPSS Statistics Standard Edition or the Advanced Statistics option.

Regression is a statistical method that is broadly used in quantitative modeling. Linear regression is a basic and standard approach in which researchers use the values of several variables to explain or predict values of a scale outcome. Bayesian univariate linear regression is an approach to linear regression where the statistical analysis is undertaken within the context of Bayesian inference.

You can invoke the regression procedure and define a full model.

1. From the menus choose:

Analyze > Bayesian Statistics > Linear Regression

2. Select a single, non-string, dependent variable from the **Available Variables** list. You must select one non-string variable.
3. Select one or more categorical factor variables for the model from the **Available Variables** list.
4. Select one or more, non-string, covariate scale variables from the **Available Variables** list.

Note: Both of the **Factor(s)** and **Covariate(s)** lists cannot be empty. You must select at least one **Factor(s)** or **Covariate(s)** variable.

5. Optionally, select a single, non-string, variable to serve as the regression weight from the **Available Variables** list.
6. Select the desired **Bayesian Analysis:**
 - **Characterize Posterior Distribution:** When selected, the Bayesian inference is made from a perspective that is approached by characterizing posterior distributions. You can investigate the marginal posterior distribution of the parameter(s) of interest by integrating out the other nuisance parameters, and further construct credible intervals to draw direct inference. This is the default setting.
 - **Estimate Bayes Factor:** When selected, estimating Bayes factors (one of the notable methodologies in Bayesian inference) constitutes a natural ratio to compare the marginal likelihoods between a null and an alternative hypothesis.

Table 8. Commonly used thresholds to define significance of evidence

Bayes Factor	Evidence Category	Bayes Factor	Evidence Category	Bayes Factor	Evidence Category
>100	Extreme Evidence for H1	1-3	Anecdotal Evidence for H1	1/30-1/10	Strong Evidence for H0
30-100	Very Strong Evidence for H1	1	No Evidence	1/100-1/30	Very Strong Evidence for H0
10-30	Strong Evidence for H1	1/3-1	Anecdotal Evidence for H0	1/100	Extreme Evidence for H0
3-10	Moderate Evidence for H1	1/10-1/3	Moderate Evidence for H0		

H0: Null Hypothesis

H1: Alternative Hypothesis

13

14

- **Use Both Methods:** When selected, both the **Characterize Posterior Distribution** and **Estimate Bayes Factor** inference methods as used.

Optionally, you can:

- Click **Criteria** to specify the credible interval percentage and numerical method settings.
- Click **Priors** to define reference and conjugate prior distribution settings.

¹³ Lee, M.D., and Wagenmakers, E.-J. 2013. *Bayesian Modeling for Cognitive Science: A Practical Course*. Cambridge University Press.

¹⁴ Jeffreys, H. 1961. *Theory of probability*. Oxford University Press.

- Click **Bayes Factor** to specify Bayes factor settings.
- Click **Save** to identify which items to save, and save model information to an XML file.
- Click **Predict** to specify regressors for Bayesian prediction.
- Click **Plots** to plot the posterior distributions of the regression parameters, the variance of error terms, and the predicted values.
- Click **F-tests** to compare statistical models in order to identify the model that best fits the population from which is was sampled.

Bayesian Linear Regression Models: Criteria

You can specify the following analysis criteria for Bayesian Linear Regression models.

Credible interval percentage %

Specify the significance level for computing credible intervals. The default level is 95%.

Note: The following options are available only when either the **Estimate Bayes Factor** or **Use Both Methods** option is selected for **Bayesian Analysis**.

Numerical Method

Specify the numerical method that is used to estimate the integral.

Tolerance

Specify the tolerance value for the numerical methods. The default setting is 0.000001.

Maximum iterations

Specify the maximum number of method iterations. The value must be a positive integer. The default setting is 2000.

Bayesian Linear Regression Models: Priors Distributions

You can specify the following prior distribution settings for the regression parameters and the variance of the errors. The following options are available only when the **Characterize Posterior Distribution** option is selected for **Bayesian Analysis**.

Note: Many applied researchers may question the need to specify a prior. Reference priors minimize the concern where the prior is generally overwhelmed as the data increases. When informative prior information is specified, Bayesian methods can effectively use the information. The requirement to specify a prior should not be viewed as a deterrent to using Bayesian analysis.

Reference

When selected, reference analysis produces objective Bayesian inference. Inferential statements depend only on the assumed model and the available data, and the prior distribution that is used to make an inference is the least informative. This is the default setting.

Conjugate

Provides options for defining conjugate prior distributions. Conjugate priors assume the Normal-Inverse-Gamma joint distribution. Although conjugate priors are not required when performing Bayesian updates, they aid the calculation processes.

Note: In order to specify conjugate priors for a linear regression model, set your expected mean of regression parameters in the **Priors on variance of errors** table. You can also choose to use the **Variance of covariance matrix** settings to specify the prior variance-covariance.

Priors on variance of errors

Shape Parameter

Specify the shape parameter a_0 for Inverse-Gamma distribution. You must enter a single value that is greater than 0.

Scale Parameter

Specify the scale parameter b_0 for Inverse-Gamma distribution. You must enter a single value that is greater than 0. The larger the scale parameter, the more spread out the distribution.

The table lists the mean of regression parameters (including intercept), which specifies the mean vector θ_0 for the defined regression parameters. The number of values must meet the number of regression parameters, including the intercept term.

The first variable name is always INTERCEPT. From the second row, the **Variables** column is automatically populated with the variables that are specified by Factor(s) and Covariate(s). The **Mean** column does not include any default values.

Click **Reset** to clear the values.

Variance of covariance matrix: σ^2x

Specify V_0 the values in the lower triangle in the variance-covariance matrix for the multivariate normal prior. Note that V_0 must be semi-positive definite. The last value of each row must be positive. The next row should have one more value than the previous row. No values are specified for reference categories (if any).

Click **Reset** to clear the values.

Use identity matrix

When selected, the scaled identity matrix is used. You cannot specify V_0 values in the lower triangle in the variance-covariance matrix for the multivariate normal prior.

Bayesian Linear Regression Models: Bayes Factor

You can specify the model design for the analysis, including the approach that is used to estimate the Bayes factor for the Bayesian Linear Regression Models. The following options are available only when either the **Estimate Bayes Factor** or **Use Both Methods** Bayesian Analysis option is selected.

Null Model

When selected, the estimated Bayes factors are based on the null model. This is the default setting.

Full Model

When selected, the estimated Bayes factors are based on the full model and you can select variables to use and additional factors and covariates.

Variables

Lists all variables available for the full model.

Additional factor(s)

Select variables from the **Variables** list to use as additional factors.

Additional covariate(s)

Select variables from the **Variables** list to use as additional covariates.

Computation

Specify the approach to estimate Bayes factors. JZS method is the default setting.

JZS method

When selected, invokes the Zellner-Siow's approach. This is the default setting.

Zellner's method

When selected, invokes the Zellner's approach and you are required specify a single g prior value > 0 (there is no default value).

Hyper-Prior method

When selected, invokes the hyper- g approach and you are required to specify a shape parameter a_0 for Inverse-Gamma distribution. You must specify a single value > 0 (the default value is 3).

Rouder's method

When selected, invokes the Rouder's approach and you are required to specify a scale parameter b_0 for Inverse-Gamma distribution. You must specify a single value > 0 (the default value is 1).

Bayesian Linear Regression Models: Save

This dialog allows you specify which statistics are scored for the Bayesian prediction distribution and export the model results to an XML file.

Posterior predictive statistics

You can score the following statistics that are derived from Bayesian predictions.

Means

Mean of the posterior predictive distribution.

Variiances

Variance of the posterior predictive distribution.

Modes

Mode of the posterior predictive distribution.

Credible interval lower limit

Lower bound of the credible interval of the posterior predictive distribution.

Credible interval upper limit

Upper bound of the credible interval of the posterior predictive distribution.

Note: You can assign corresponding variable names for each statistic.

Export model information to XML file

Enter an XML file name and location to export the scored parameter variance-covariance matrix.

Bayesian Linear Regression Models: Predict

You can specify the regressors to generate predictive distributions.

Regressors for Bayesian Prediction

The table lists all available regressors. The **Regressors** column is automatically populated by certain Factor and Covariate variables. Specify the observed vectors with the values for the regressors. Each regressor can be assigned one value or string and are allowed to predict only one case. For factors, both values and strings are allowed.

Either all or none of the regressor values must be specified in order to run the prediction (by clicking **Run Analysis**).

When a Factor or Covariate variable is removed, the corresponding regressor row is removed from the table.

For covariates, only numerical values can be specified. For factors, both numerical values and strings are allowed.

Note: Click **Reset** to clear the defined values.

Bayesian Linear Regression Models: Plots

You can control the plots that are output.

Covariates

Lists the currently defined covariates.

Plot covariate(s)

Select the covariates to be plotted from the **Covariates** list and add them to the **Plot covariates** list.

Factors

Lists the currently defined factors.

Plot factor(s)

Select the factors to be plotted from the **Factors** list and add them to the **Plot factors** list.

Maximum categories to be plotted

Select the maximum number of categories to be plotted (single, positive integer). The setting applies to all factors. By default, the first 2 levels are plotted for each factor.

Include plots of

Intercept term

When selected, the intercept term is plotted. The setting is deselected by default.

Variance of error terms

When selected, the variance of errors is plotted. The setting is deselected by default.

Bayesian predicted distribution

When selected, the predictive distribution is plotted. The setting is deselected by default. The setting can be selected only when valid regressors values are selected.

Bayesian Linear Regression Models: F-tests

You can create one or more partial F-tests. An F-test is any statistical test in which the test statistic has an F-distribution under the null hypothesis. F-tests are commonly used when comparing statistical models that have been fitted to a data set, in order to identify the model that best fits the population from which the data were sampled.

Available variables

Lists the factor and covariate variables that are selected from the main Bayesian Linear Regression dialog. When factor and covariate variables are added or removed from the main dialog, the list is updated accordingly.

Test variable(s)

Select the factor/covariate variables to test from the **Available variables** list and add them to the **Testing variable(s)** list.

Note: The **Include intercept term** option must be selected when no test factors or covariates are selected.

Testing variable(s) and value(s)

Specify the values to be tested. The number of values must match the number of parameters in the original model. When values are specified, the first value must be specified for the intercept term (assume all values are 0 when not explicitly defined).

Include intercept term

When selected, the intercept terms are included in the test. By default, the setting is not selected.

When enabled, use the **Testing value** field to specify a value.

Test label (optional)

You can optionally specify a label for each test. You can specify a string value with a maximum length of 255 bytes. Only one label per each F-test is allowed.

Bayesian One-way ANOVA

This feature requires SPSS Statistics Standard Edition or the Advanced Statistics option.

The One-Way ANOVA procedure produces a one-way analysis of variance for a quantitative dependent variable by a single factor (independent) variable. Analysis of variance is used to test the hypothesis that several means are equal. SPSS Statistics supports Bayes-factors, conjugate priors and noninformative priors.

1. From the menus choose:

Analyze > Bayesian Statistics > One-way ANOVA

2. Select a single, numeric **Dependent** variable from the **Available Variables** list. You must select at least one variable.

3. Select a single **Factor** variable for the model from the **Available Variables** list. You must select at least one **Factor** variable.

4. Select a single, non-string, variable to serve as the regression **Weight** from the **Available Variables** list. The **Weight** variable field can be empty.

5. Select the desired **Bayesian Analysis**:

- **Characterize Posterior Distribution:** When selected, the Bayesian inference is made from a perspective that is approached by characterizing posterior distributions. You can investigate the marginal posterior distribution of the parameter(s) of interest by integrating out the other nuisance parameters, and further construct credible intervals to draw direct inference. This is the default setting.
- **Estimate Bayes Factor:** When selected, estimating Bayes factors (one of the notable methodologies in Bayesian inference) constitutes a natural ratio to compare the marginal likelihoods between a null and an alternative hypothesis.

Table 9. Commonly used thresholds to define significance of evidence

Bayes Factor	Evidence Category	Bayes Factor	Evidence Category	Bayes Factor	Evidence Category
>100	Extreme Evidence for H1	1-3	Anecdotal Evidence for H1	1/30-1/10	Strong Evidence for H0
30-100	Very Strong Evidence for H1	1	No Evidence	1/100-1/30	Very Strong Evidence for H0
10-30	Strong Evidence for H1	1/3-1	Anecdotal Evidence for H0	1/100	Extreme Evidence for H0
3-10	Moderate Evidence for H1	1/10-1/3	Moderate Evidence for H0		

H0: Null Hypothesis

H1: Alternative Hypothesis

15

16

- **Use Both Methods:** When selected, both the **Characterize Posterior Distribution** and **Estimate Bayes Factor** inference methods as used.

Optionally, you can:

- Click **Criteria** to specify the credible interval percentage and numerical method settings.
- Click **Priors** to define reference and conjugate prior distribution settings.
- Click **Bayes Factor** to specify Bayes factor settings.
- Click **Plots** to control the plots that are output.

Bayesian One-way ANOVA: Criteria

You can specify the following analysis criteria for Bayesian One-way ANOVA models.

Credible interval percentage %

Specify the significance level for computing credible intervals. The default level is 95%.

Note: The following options are available only when either the **Estimate Bayes Factor** or **Use Both Methods** option is selected for **Bayesian Analysis**.

¹⁵ Lee, M.D., and Wagenmakers, E.-J. 2013. *Bayesian Modeling for Cognitive Science: A Practical Course*. Cambridge University Press.

¹⁶ Jeffreys, H. 1961. *Theory of probability*. Oxford University Press.

Numerical Method

Specify the numerical method that is used to estimate the integral.

Tolerance

Specify the tolerance value for the numerical methods. The default setting is 0.000001.

Maximum iterations

Specify the maximum number of method iterations. The value must be a positive integer. The default setting is 2000.

Bayesian One-way ANOVA: Priors

You can specify the following prior distribution settings for the regression parameters and the variance of the errors. The following options are available only when the **Characterize Posterior Distribution** option is selected for **Bayesian Analysis**.

Note: Many applied researchers may question the need to specify a prior. Reference priors minimize the concern where the prior is generally overwhelmed as the data increases. When informative prior information is specified, Bayesian methods can effectively use the information. The requirement to specify a prior should not be viewed as a deterrent to using Bayesian analysis.

Reference

When selected, reference analysis produces objective Bayesian inference. Inferential statements depend only on the assumed model and the available data, and the prior distribution that is used to make an inference is the least informative. This is the default setting.

Conjugate

Provides options for defining conjugate prior distributions. Conjugate priors assume the Normal-Inverse-Gamma joint distribution. Although conjugate priors are not required when performing Bayesian updates, they aid the calculation processes.

Priors on variance of errors

Shape Parameter

Specify the shape parameter a_0 for Inverse-Gamma distribution. You must enter a single value that is greater than 0.

Scale Parameter

Specify the scale parameter b_0 for Inverse-Gamma distribution. You must enter a single value that is greater than 0. The larger the scale parameter, the more spread out the distribution.

Priors on regression parameters

Specify the mean vector β_0 for the group means. The number of values must meet the number of regression parameters, including the intercept term.

The **Variables** column is automatically populated with the levels of the Factor. The **Mean** column does not include any default values.

Click **Reset** to clear the values.

Variance of covariance matrix: $\sigma^2\mathbf{x}$

Specify V_0 the values in the lower triangle in the variance-covariance matrix for the multivariate normal prior. Note that V_0 must be semi-positive definite. Only the lower triangle of the table must be specified.

The rows and columns are automatically populated with the levels of the Factor. All of the diagonal values are 1; all of the off-diagonal values are 0.

Click **Reset** to clear the values.

Use identity matrix

When selected, the identity matrix is used. You cannot specify V_0 values in the lower triangle in the variance-covariance matrix for the multivariate normal prior.

Bayesian One-way ANOVA: Bayes Factor

You can specify the approach that is used to estimate the Bayes factor for the Bayesian One-way ANOVA models. The following options are available only when either the **Estimate Bayes Factor** or **Use Both Methods** Bayesian Analysis option is selected.

Computation

Specify the approach to estimate Bayes factors. JZS method is the default setting.

JZS method

When selected, invokes the Zellner-Siow's approach. This is the default setting.

Zellner's method

When selected, invokes the Zellner's approach and you are required specify a single g prior value > 0 (there is no default value).

Hyper-Prior method

When selected, invokes the hyper- g approach and you are required to specify a shape parameter a_0 for Inverse-Gamma distribution. You must specify a single value > 0 (the default value is 3).

Rouder's method

When selected, invokes the Rouder's approach and you are required to specify a scale parameter b_0 for Inverse-Gamma distribution. You must specify a single value > 0 (the default value is 1).

Bayesian One-way ANOVA: Plots

You can control the plots that are output.

Plot group(s)

Specify the subgroups to be plotted. Plot the likelihood, prior, and posterior for the means of the specified groups. The **Groups** list is a subset of the categories of the factor variable, so the format should be consistent with the factor's data type and actual values.

Variance of error terms

When selected, the variance of errors is plotted. The setting is deselected by default. This option is not available when **Estimate Bayes Factor** is selected as the Bayesian Analysis.

Bayesian Loglinear Models

This feature requires SPSS Statistics Standard Edition or the Advanced Statistics option.

The design for testing the independence of two factors requires two categorical variables for the construction of a contingency table, and makes Bayesian inference on the row-column association. You can estimate the Bayes factors by assuming different models, and characterize the desired posterior distribution by simulating the simultaneous credible interval for the interaction terms.

1. From the menus choose:

Analyze > Bayesian Statistics > Loglinear Models

2. Select a single, non-scale, row variable from the **Available variables** list. You must select at least one non-scale variable.
3. Select a single, non-scale, column variable from the **Available variables** list. You must select at least one non-scale variable.

4. Select the desired **Bayesian Analysis**:

- **Characterize Posterior Distribution:** When selected, the Bayesian inference is made from a perspective that is approached by characterizing posterior distributions. You can investigate the marginal posterior distribution of the parameter(s) of interest by integrating out the other nuisance parameters, and further construct credible intervals to draw direct inference. This is the default setting.
- **Estimate Bayes Factor:** When selected, estimating Bayes factors (one of the notable methodologies in Bayesian inference) constitutes a natural ratio to compare the marginal likelihoods between a null and an alternative hypothesis.

Table 10. Commonly used thresholds to define significance of evidence

Bayes Factor	Evidence Category	Bayes Factor	Evidence Category	Bayes Factor	Evidence Category
>100	Extreme Evidence for H1	1-3	Anecdotal Evidence for H1	1/30-1/10	Strong Evidence for H0
30-100	Very Strong Evidence for H1	1	No Evidence	1/100-1/30	Very Strong Evidence for H0
10-30	Strong Evidence for H1	1/3-1	Anecdotal Evidence for H0	1/100	Extreme Evidence for H0
3-10	Moderate Evidence for H1	1/10-1/3	Moderate Evidence for H0		

H0: Null Hypothesis

H1: Alternative Hypothesis

17

18

- **Use Both Methods:** When selected, both the **Characterize Posterior Distribution** and **Estimate Bayes Factor** inference methods as used.

Optionally, you can:

- Click **Criteria** to specify the credible interval percentage and numerical method settings.
- Click **Bayes Factor** to specify Bayes factor settings.
- Click **Print** specify how the contents display in the output tables.

Bayesian Loglinear Models: Criteria

You can specify the following analysis criteria for Bayesian Loglinear models.

Credible interval percentage %

Specify the significance level for computing credible intervals. The default level is 95%.

Numerical Method

Specify the numerical method that is used to estimate the integral.

Set custom seed

When selected, you can specify a custom seed value in the **Seed** field. Specify a random seed set value. The value must be a positive integer. By default, a random seed value is assigned.

Note: The following options are available only when either the **Estimate Bayes Factor** or **Use Both Methods** option is selected for **Bayesian Analysis**.

Tolerance

Specify the tolerance value for the numerical methods. The default setting is 0.000001.

Maximum iterations

Specify the maximum number of method iterations. The value must be a positive integer. The default setting is 2000.

¹⁷ Lee, M.D., and Wagenmakers, E.-J. 2013. *Bayesian Modeling for Cognitive Science: A Practical Course*. Cambridge University Press.

¹⁸ Jeffreys, H. 1961. *Theory of probability*. Oxford University Press.

Samples simulated to Posterior Distribution

Specify the number of samples that are used to draw the desired posterior distribution. The default value is 10000.

Format

Select whether categories are displayed in **Ascending** or **Descending** order. Ascending is the default setting.

Bayesian Loglinear Models: Bayes Factor

You can specify the model assumed for the observed data (Poisson, Multinomial, or Nonparametric). Multinomial distribution is the setting by default. The following options are available only when either the **Estimate Bayes Factor** or **Use Both Methods** Bayesian Analysis option is selected.

Poisson Model

When selected, the Poisson model is assumed for the observed data.

Multinomial Model

When selected, the Multinomial model is assumed for the observed data. This is the default setting.

Fixed Margins

Select **Grand Total**, **Row Sum**, or **Column Sum** to specify the fixed marginal totals for the contingency table. **Grand Total** is the default setting.

Prior Distribution

Specify the prior distribution type when estimating the Bayes factor.

Conjugate

Select to specify a conjugate prior distribution. Use the **Shape Parameters** table to specify the shape parameters a_{rs} for Gamma distribution. You must specify the shape parameters when **Conjugate** is selected as the prior distribution type.

When a single value is specified, all a_{rs} 's are assumed to be equal to this value. $a_{rs} = 1$ is the default setting. If you need to specify more than one value, you can separate the values with blank spaces.

The number of numerical values that are specified in each row and each column must match the dimension of the contingency table. All of the specified values must be > 0 .

Click **Reset** to clear the values.

Scale Parameter

Specify the scale parameter b for Gamma distribution. You must specify a single value > 0 .

Mixture Dirichlet

Select to specify a mixture Dirichlet prior distribution.

Intrinsic

Select to specify an intrinsic prior distribution.

Nonparametric Model

When selected, the Nonparametric model is assumed for the observed data.

Fixed Margins

Select **Row Sum** or **Column Sum** to specify the fixed marginal totals for the contingency table. **Row Sum** is the default setting.

Prior Distribution

Specify the parameters for the Dirichlet priors. You must specify the **Prior Distribution** parameters when **Nonparametric Model** is selected. When a single value is specified, all λ_s are assumed to be equal to this value. $\lambda_s = 1$ is the setting by default. If you need to specify more than one value, you can separate the values with blank spaces. All of the specified values must be > 0 . The number of specified, numerical values must match the dimension of the row or column that is not fixed for the contingency table.

Click **Reset** to clear the values.

Bayesian Loglinear Models: Print

You can specify how the contents display in the output tables.

Table Design

Suppress Table

When selected, the contingency table is not included in the output. The setting is not enabled by default.

Note: The following settings have no affect when the **Suppress Table** setting is enabled.

Statistics

Specify the statistics for testing independence.

Chi-square

Select to compute the Pearson Chi-Square statistic, degrees of freedom, and 2-sided asymptotic significance. For a 2 by 2 contingency table, this setting also computes the Yates continuity corrected statistics, degrees of freedom, and associated 2-sided asymptotic significance. For a 2 by 2 contingency table, with at least one expected cell count < 5 , this setting also computes the 2-sided and 1-sided exact significance of the Fisher's exact test.

Likelihood ratio

Select to compute the likelihood ratio test statistic, degrees of freedom, and associated 2-sided asymptotic significance.

Counts

Specify which count types are included in the contingency table.

Observed

Select to include observed cell counts in the contingency table.

Expected

Select to include expected cell counts in the contingency table.

Percentages

Specify which percentage types are included in the contingency table.

Row

Select to include row percentages in the contingency table.

Column

Select to include column percentages in the contingency table.

Total

Select to include total percentages in the contingency table.

Bayesian One-way Repeated Measures ANOVA Models

This feature requires SPSS Statistics Standard Edition or the Advanced Statistics option.

In Bayesian one-way analysis of variance (ANOVA) models, it is assumed that there is a single measurement per subject. However, this assumption is not always true. It is not uncommon that a study design aims to investigate mean responses over multiple time points or conditions. The Bayesian One-way Repeated Measures ANOVA procedure measures one factor from the same subject at each distinct time point or condition, and allows subjects to be crossed within the levels. It is assumed that each subject has a single observation for each time point or condition (as such, the subject-treatment interaction is not accounted for).

1. From the menus choose:

Analyze > Bayesian Statistics > One-way Repeated Measures ANOVA

2. Select at least two **Repeated measures** variables from the **Available Variables** list.
3. Optionally, select a single variable to serve as the regression **Weight** from the **Available Variables** list. The **Weight** variable field can be empty.

Note: The available variables list provides all variables except for String variables.

4. Select the desired **Bayesian Analysis:**

- **Characterize Posterior Distribution:** When selected, the Bayesian inference is made from a perspective that is approached by characterizing posterior distributions. You can investigate the marginal posterior distribution of the parameter(s) of interest by integrating out the other nuisance parameters, and further construct credible intervals to draw direct inference. This is the default setting.
- **Estimate Bayes Factor:** When selected, estimating Bayes factors (one of the notable methodologies in Bayesian inference) constitutes a natural ratio to compare the marginal likelihoods between a null and an alternative hypothesis.

Table 11. Commonly used thresholds to define significance of evidence

Bayes Factor	Evidence Category	Bayes Factor	Evidence Category	Bayes Factor	Evidence Category
>100	Extreme Evidence for H1	1-3	Anecdotal Evidence for H1	1/30-1/10	Strong Evidence for H0
30-100	Very Strong Evidence for H1	1	No Evidence	1/100-1/30	Very Strong Evidence for H0
10-30	Strong Evidence for H1	1/3-1	Anecdotal Evidence for H0	1/100	Extreme Evidence for H0
3-10	Moderate Evidence for H1	1/10-1/3	Moderate Evidence for H0		

H0: Null Hypothesis

H1: Alternative Hypothesis

19

20

- **Use Both Methods:** When selected, both the **Characterize Posterior Distribution** and **Estimate Bayes Factor** inference methods as used.

Optionally, you can:

- Click **Criteria** to specify the credible interval percentage and numerical method settings.
- Click **Bayes Factor** to specify Bayes factor settings.
- Click **Plots** to plot the posterior distributions of the group means.

Bayesian One-way Repeated Measures ANOVA: Criteria

You can specify the following analysis criteria for Bayesian One-way Repeated Measures ANOVA models.

Credible interval percentage %

Specify the significance level for computing credible intervals. The default level is 95%.

Numerical Method

Specify the numerical method that is used to estimate the integral.

¹⁹ Lee, M.D., and Wagenmakers, E.-J. 2013. *Bayesian Modeling for Cognitive Science: A Practical Course*. Cambridge University Press.

²⁰ Jeffreys, H. 1961. *Theory of probability*. Oxford University Press.

Set custom seed

When selected, you can specify a custom seed value in the **Seed** field. The default value is 2,000,000. The value must be a positive integer between 1 and 2,147,483,647. By default, a random seed value is assigned.

Number of Monte Carlo Samples

Specify the number of points that are sampled for the Monte Carlo approximation. The value must be a positive integer between 10^3 and 10^6 . The default value is 30,000.

Bayesian One-way Repeated Measures ANOVA: Bayes Factor

You can specify the approach that is used to estimate the Bayes factor for the Bayesian One-way Repeated Measures ANOVA models. The following options are available only when either the **Estimate Bayes Factor** or **Use Both Methods** Bayesian Analysis option is selected.

Bayesian information criteria (BIC)

Uses an extension of the BIC approximation to the repeated measures design for estimating Bayes factors. The setting derives the effective sample size accounting for repeated measures correlation, and suggests an improved penalty term when estimating the BIC for the selection between two competing models. This is the default setting.

Rouder's mixed design

Uses the multivariate generalizations of the Cauchy distribution as the prior for standardized effect size, and a non-informative prior for variance.

Note: The global frequency weight setting and the regression weight are ignored when this option is selected.

Bayesian One-way Repeated Measures ANOVA: Plots

You can control the plots that are output to illustrate the posterior distributions of the group means. The table lists all variables that are selected as repeated measures on the Variables dialog. Select the repeated measures variables to plot

Kernel Ridge Regression

Kernel Ridge Regression is an extension procedure that uses the Python **sklearn.kernel_ridge.KernelRidge** class to estimate kernel ridge regression models. Kernel ridge regression models are nonparametric regression models that are capable of modeling linear and nonlinear relationships between predictor variables and outcomes. Results can be highly sensitive to choices of model hyperparameters. Kernel Ridge Regression facilitates choice of hyperparameter values through k-fold cross-validation on specified grids of values using the **sklearn.model_selection.GridSearchCV** class.

Example

Statistics

Additive_CHI2, CHI2, Cosine, Laplacian, Linear, Polynomial, RBF, Sigmoid, Alpha, Gamma, Coef0, Degree, crossvalidation, observed versus predicted, residuals versus predicted, dual weight coefficients, kernel space weight coefficients.

Data considerations

Data

- You can specify any or all of the eight different kernel functions.
- The selected kernel function determines which hyperparameters are active.
- Hyperparameters include alpha for ridge regularization that are common to all kernels plus as many as three other hyperparameters for each specific kernel function.

- When multiple kernel subcommands are specified, or more than one value for any parameter is specified, a grid search with cross-validation to evaluate models is performed, and the best fitting model that is based on held out data is selected.
- The extension accepts split variables from the Split File procedure and weights using the Weight Cases procedure.
- When weights are included, they are used in creating fitted values in all analyses. Due to limitations in the score method in the `sklearn.model_selection.GridSearchCV` class, crossvalidation evaluations that are used for model selection are not weighted.

Assumptions

Obtaining a Kernel Ridge Regression

1. From the menus choose:

Analyze > Regression > Kernel Ridge...

2. Select a **Dependent** variable.
3. Select one or more **Independent(s)** variables.
4. The default **Single model** setting is used when only one value for each kernel function parameter is specified. When the **Single model** setting is selected, you cannot specify additional **Kernel(s)** functions and weights are fully applied throughout the analysis, evaluation, and scoring of results. You can also use the up and down arrow controls to rearrange the kernel functions.

Optionally, select **Model selection** from the **Mode** list.

When **Model selection** is selected from the **Mode** list, you can add multiple kernel functions to the **Kernel(s)** list.

- a. Click the add control (+) to include additional kernel functions.
- b. Click the empty cell in the **Kernel** column to select a kernel function.
- c. Double-click any kernel function row cell to specify kernel function parameter values for the corresponding column (**Alpha**, **Gamma**, **Coef0**, **Degree**). For more information, see [“Kernel Parameters” on page 131](#). The default kernel function tuning parameters are listed below.

Additive_CHI2

ALPHA=1 GAMMA=1

CHI2

ALPHA=1 GAMMA=1

Cosine

ALPHA=1

Laplacian

ALPHA=1 GAMMA=1/p

Linear

The default kernel function. ALPHA=1

Polynomial

ALPHA=1 GAMMA=1/p COEF0=1 DEGREE=3

RBF

ALPHA=1 GAMMA=1/p

Sigmoid

ALPHA=1 GAMMA=1/p COEF0=1

Note: When more than one value for any kernel function parameter is specified, a grid search with cross-validation to evaluate models is performed, and the best fitting model that is based on held out data is selected.

5. Optionally, click **Options** to specify the number of crossvalidation folds, display options, plot settings, and items to save. For more information, see [“Kernel Ridge Regression: Options” on page 131](#).

6. Click **OK**.

Kernel Parameters

The **Kernel Parameters** dialog provides options for specifying single kernel function parameter values and for specifying that model selection is performed using a grid search over the combinations of kernels and specified grid parameter values.

Specify single parameters

Enable the setting to specify values for the selected kernel function parameter.

- Enter a value and click **Add** to include the value in the kernel function parameter.
- Select a parameter value and click **Change** to update the value.
- Select a parameter value and click **Remove** to delete the value.

Specify grid parameters

Enable the setting to specify that model selection is performed using a grid search over the combinations of kernels and specified grid parameter values.

Kernel Ridge Regression: Options

The **Plots** dialog provides options for specifying the number of crossvalidation folds, display options, plot settings, and items to save.

Number of crossvalidation folds

The number of splits or folds in crossvalidation with grid search for model selection. Enter an integer value larger than 1. The default value is 5. The setting is available only when **Model selection** is chosen as the **Mode** on the primary **Kernel Ridge Regression** dialog.

Display

Provides options for specifying which output to display when crossvalidation is in effect.

Best

The default setting displays only basic results for the chosen best model.

Compare

Displays basic results for all evaluated models.

Compare models and folds

Displays full results for each split or fold for each evaluated model.

Plot

Provides options for specifying plots of observed or residual values versus predicted values.

Observed vs. Predicted

Displays a scatterplot of observed versus predicted values for the specified or best model.

Residuals vs. Predicted

Displays a scatterplot of residuals versus predicted values for the specified or best model.

Save

The table provides options for specifying variables to save to the active dataset.

Predicted values

Saves predicted values from the specified or best model to the active dataset. An optional variable name can be included.

Residuals

Saves residuals from the specified or best model predictions to the active dataset. An optional variable name can be included.

Dual coefficients

Saves dual or kernel space weight coefficients from the specified model to the active dataset. An optional variable name can be included. The setting is not available when **Model selection** is chosen as the **Mode** on the primary **Kernel Ridge Regression** dialog.
