The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the ZR audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. R Read of an object
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
ACCESS_TYPE	INTEGER	Type of access. See Numeric codes for access types for a list of the codes for access types.
ACCESS_TYPE_DETAIL	VARCHAR(50)	Descriptive text that corresponds to ACCESS_TYPE.
LIBRARY_NAME	VARCHAR(10)	The name of the library. Contains the null value if there is no library name.
OBJECT_NAME	VARCHAR(10)	The name of the object. Contains the null value if there is no object name.
OBJECT_TYPE	VARCHAR(7)	The type of object. Contains the null value if there is no object type.
MEMBER_NAME	VARCHAR(10)	The member name for a *FILE object. Contains the null value if OBJECT_TYPE is not *FILE or if there is no member name.
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the object resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs. Contains the null value if there is no ASP information.
OBJECT_ASP_NUMBER	INTEGER	The number of the ASP device. 1 indicates the system ASP. Contains the null value if there is no ASP information.
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The path name of the object. Contains the null value if the path name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PATH_NAME_INDICATOR	VARCHAR(3)	Path name indicator: NO The PATH_NAME column does not contain an absolute path name for the object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name. YES The PATH_NAME column contains the absolute path name for the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the object identified in the PATH_NAME column. Contains the null value when PATH_NAME_INDICATOR is YES, or if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	The name of the object. Contains the null value if the object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
OBJECT_FILE_ID	BINARY(16)	The file ID of the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.

Table 193. AUDIT_JOURNAL_ZR table function (continued)

Column Name	Data Type	Description
PARENT_FILE_ID	BINARY(16)	The file ID of the parent directory. Contains the null value if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
IMGCLGE_ACCESS_TYPE	VARCHAR(10)	Access type for the image catalog entry. READ The file containing the image catalog entry is read-only. READ WRITE The file containing the image catalog entry is read/write capable. Contains the null value if the operation was against an image catalog or the object type is not *IMGCLG.
IMGCLGE_INDEX_NUMBER	INTEGER	Index number of the image catalog entry. Contains the null value if the operation was against an image catalog or the object type is not *IMGCLG.
IMGCLGE_VOLUME_ID	VARCHAR(32)	Volume ID of the image catalog entry. Can contain the special value *GEN. Contains the null value if the operation was against an image catalog or the object type is not *IMGCLG.
IMGCLGE_WRITE_PROTECTION	VARCHAR(3)	The write protection for the image catalog entry. NO The file containing the image catalog entry is not write protected. YES The file containing the image catalog entry is write protected.. Contains the null value if the operation was against an image catalog or the object type is not *IMGCLG.
IMGCLGE_VIRTUAL_DEVICE	VARCHAR(10)	The name of the virtual device for the image catalog entry. Contains the null value if the operation was against an image catalog, the image catalog is not in Ready status, or the object type is not *IMGCLG.

Example

- List objects in APPLIB that were read in the last 2 days.

```
SELECT COUNT(*), LIBRARY_NAME, OBJECT_NAME, OBJECT_TYPE FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_ZR(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 2 DAYS
  )
)
WHERE LIBRARY_NAME = 'APPLIB'
GROUP BY LIBRARY_NAME, OBJECT_NAME, OBJECT_TYPE;
```

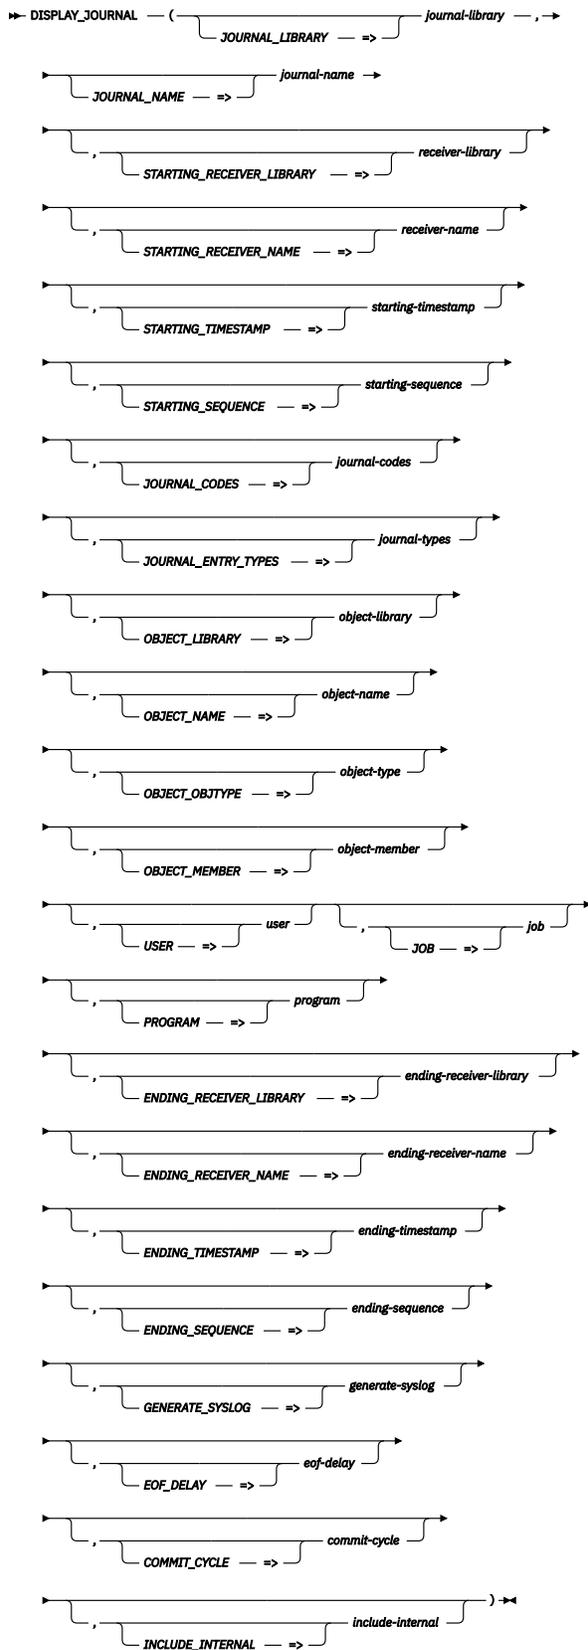

DISPLAY_JOURNAL table function

The DISPLAY_JOURNAL table function returns information about journal entries. It returns information similar to what is returned by the Display Journal (DSPJRN) CL command and the Retrieve Journal Entries (QjoRetrieveJournalEntries) API.

Authorization:

- The caller must have *USE authority to the journal and *EXECUTE authority to the library containing the journal.
- The caller must have *USE authority to every requested journal receiver and *EXECUTE authority to the library containing the journal receiver.
- *OBJEXIST authority is required to the journal if *object-name* is omitted or if *object-name* specifies an object that no longer exists.

- If *object-name* is *ALL, the caller must be authorized to every object associated with a journal entry.
 - The caller must have:
 - *USE authority to the object, and
 - *EXECUTE authority to the library containing the object.

The schema is QSYS2.

journal-library A character or graphic string expression that identifies the name of the library containing the journal. The name cannot be *LIBL or *CURLIB.

journal-name	A character or graphic string expression that identifies the name of the journal.
receiver-library	A character or graphic string expression that identifies the name of the starting journal receiver library. The name can be *LIBL or *CURLIB.
receiver-name	A character or graphic string expression that identifies the name of the starting journal receiver. If one of the special values is specified, the <i>receiver-library</i> value will be ignored. Otherwise, the <i>receiver-name</i> and <i>receiver-library</i> must identify a valid journal receiver. If no journal receiver is specified, *CURRENT is used.
*CURRENT	The journal receiver that is currently attached when starting to convert journal entries is used.
*CURCHAIN	The journal receiver chain that includes the journal receiver that is currently attached when starting to convert journal entries is used. This receiver chain does not cross a break in the chain. If there is a break in the chain, the receiver range is from the most recent break in the chain through the receiver that is attached when starting to convert journal entries.
*CURAVLCHN	The journal receiver chain that includes the journal receiver that is attached when starting to convert journal entries is used. This receiver chain does not cross a break in the chain. If there is a break in the chain, the receiver range is from the most recent break in the chain through the receiver that is attached when starting to convert journal entries. If journal receivers exist in the receiver chain that are not available because they were saved with the storage freed option, those journal receivers will be ignored and entries will be converted starting with the first available journal receiver in the chain.
*CURSEQCHN	The journal receiver chain that includes the journal receiver that is attached when starting to convert journal entries is used, starting with the most recent journal receiver in which the journal sequence number was reset if the journal sequence number was reset in the receiver chain. This receiver chain does not cross a break in the chain. If there is a break in the chain, the receiver range is from the most recent break in the chain through the receiver that is attached when starting to convert journal entries. If journal receivers exist in the receiver chain that are not available because they were saved with the storage freed option, those journal receivers will be ignored and entries will be converted starting with the first available journal receiver in the chain.
starting-timestamp	A timestamp value that specifies the starting timestamp to use ² . A value cannot be specified for both <i>starting-timestamp</i> and <i>starting-sequence</i> . If no starting timestamp is specified, the earliest timestamp in the receiver range is used.
starting-sequence	A decimal expression that identifies the starting sequence number to use. If the <i>starting-sequence</i> value is not found in the receiver range, an error is returned. A value cannot be specified for both <i>starting-timestamp</i> and <i>starting-sequence</i> . If no starting sequence is specified, the first sequence number in the receiver range is used.

² The accuracy of the entry timestamp stored in journal receivers is only accurate to 16 microseconds. Hence, a value passed as a *starting_timestamp* and *ending_timestamp* will be truncated such that the actual timestamps being searched for may be from 0 to 15 microseconds less than the specified value.

journal-codes	<p>A character or graphic string expression that lists the journal codes to return. The string can contain the special values of *ALL or *CTL, or it can be a list of one or more journal codes. Journal codes in the string can be separated by one or more separators. Separators are blank and comma. For example, a valid string can be 'RJ' or 'R J' or 'R,J' or 'R, J'.</p> <p>If no string is provided, *ALL is used.</p>
journal-types	<p>A character or graphic string expression that lists the journal entry types to return. The string can contain the special values of *ALL or *RCD, or it can be a list of one or more journal entry types. Journal entry types in the string can be separated by one or more separators. Separators are blank and comma. For example, a valid string can be 'JFCT' or 'JF CT' or 'JF,CT' or 'JF, CT'.</p> <p>If no string is provided, *ALL is used.</p>
object-library	<p>A character or graphic string expression that identifies the name of an object library. The values *LIBL and *CURLIB are allowed.</p>
object-name	<p>A character or graphic string expression that contains up to 300 object names. Multiple names can be separated by one or more separators. Separators are blank and comma.</p> <p>If <i>object-name</i> is the special value of *ALL, <i>object-library</i> must contain a library name and <i>object-type</i> must contain a valid object type. Otherwise, each object name must identify a valid object using the same <i>object-library</i>, <i>object-type</i>, and <i>object-member</i> parameters.</p> <p>If no object name is provided, a value of *ALLFILE is used for the journaled file name on the API interface.</p>
object-type	<p>A character or graphic string expression that identifies the system object type for the object. The value must be *DTAARA, *DTAQ, *FILE, or *LIB.</p>
object-member	<p>A character or graphic string expression that identifies the name of a member. It can be a special value of *FIRST, *ALL, or *NONE or a valid member name. If the object type is not *FILE, the member name is ignored.</p>
user	<p>A character or graphic string expression that identifies the user profile name for the current user of the job. If <i>user</i> is not specified, *ALL is used.</p>
job	<p>A character or graphic string expression that identifies the name of a job. Two forms of a job name are supported.</p> <ol style="list-style-type: none"> 1. A fully qualified job name in the form <i>job-number/job-user/job-name</i>. 2. The first 10 characters are the job name, the second 10 characters are the user name, and the last 6 characters are the job number. <p>If <i>job</i> is not specified, *ALL is used.</p>
program	<p>A character or graphic string expression that identifies the name of a program. If <i>program</i> is not specified, *ALL is used.</p>
ending-receiver-library	<p>A character or graphic string expression that identifies the name of the ending journal receiver library. The name can be *LIBL or *CURLIB. If <i>ending-receiver-name</i> is not *CURRENT, a value for <i>ending-receiver-library</i> must be specified.</p> <p>The value of this parameter is ignored if <i>eof-delay</i> is greater than zero.</p>
ending-receiver-name	<p>A character or graphic string expression that identifies the name of the ending journal receiver. If the special value *CURRENT is specified, the <i>ending-receiver-library</i> value will be ignored. Otherwise, the <i>ending-receiver-name</i> and <i>ending-receiver-library</i> must identify a valid journal receiver.</p> <p>If <i>ending-receiver-name</i> is not specified, *CURRENT is used.</p> <p>The value of this parameter is ignored if <i>eof-delay</i> is greater than zero.</p>

ending-timestamp A timestamp value that specifies the ending timestamp to use².
 A value cannot be specified for both *ending-timestamp* and *ending-sequence*. This parameter cannot be specified if *eof-delay* is greater than zero.
 If no ending timestamp is specified, the latest timestamp in the receiver range is used.

ending-sequence A decimal expression that identifies the ending sequence number to use. If the *ending-sequence* value is not found in the receiver range, an error is returned.
 A value cannot be specified for both *ending-timestamp* and *ending-sequence*. This parameter cannot be specified if *eof-delay* is greater than zero.
 If no ending sequence is specified, the last sequence number in the receiver range is used.
 When *ending-sequence* is used, the query results will end when the first ending sequence value is encountered. If the journal has had its sequence numbers reset, *ending-sequence* will only return results through the first match of *ending-sequence*.

generate-syslog A character or graphic string expression that indicates whether to transform journal entries into syslog formatted detail. Values are:

- NO** No syslog information will be returned. The SYSLOG_EVENT, SYSLOG_FACILITY, SYSLOG_SEVERITY, and SYSLOG_PRIORITY columns will contain the null value.
- RFC3164** Values will be returned for the SYSLOG_EVENT, SYSLOG_FACILITY, SYSLOG_SEVERITY, and SYSLOG_PRIORITY columns if syslog information is defined for the journal entry. The SYSLOG_EVENT column will contain a syslog header that matches the RFC3164 format as described by the Internet Engineering Task Force (IETF) Request For Comments (RFC) 3164.
- RFC5424** Values will be returned for the SYSLOG_EVENT, SYSLOG_FACILITY, SYSLOG_SEVERITY, and SYSLOG_PRIORITY columns if syslog information is defined for the journal entry. The SYSLOG_EVENT column will contain a syslog header that matches the RFC5424 format as described by the Internet Engineering Task Force (IETF) Request For Comments (RFC) 5424.

DISPLAY_JOURNAL only returns syslog information for the audit journal. If RFC3164 or RFC5424 is specified, *journal-library* must be QSYS and *journal-name* must be QAUDJRN.
 If *generate-syslog* is not specified or is the null value, NO is used.

eof-delay An integer expression that specifies the number of seconds to sleep when all audit journal entries have been read. This delay allows the caller to establish a polling service that will continually return rows, sleeping for the specified interval whenever all entries have been processed.
 A value of zero indicates no delay is used and a finite set of rows will be returned. A value greater than zero indicates that the table function will sleep, as needed, to wait for new audit journal entries and never end. If *eof-delay* is not specified or is the null value, zero is used.
 If this parameter has a value greater than zero, the *generate-syslog* parameter must be RFC3164 or RFC5424, the *ending-receiver-library* and *ending-receiver-name* are ignored, and the *ending-timestamp* and *ending-sequence* parameters cannot be specified with a value other than their default values.
 When using a non-zero *eof-delay* parameter, avoid using query clauses that depend on returning a finite number of rows. For example, using the FETCH FIRST n ROWS clause can cause the query to end when the requested number of rows has been satisfied. A query using the DISPLAY_JOURNAL function with a non-zero *eof-delay* parameter does

not allow data to be copied (ALWCPYDTA(*NO)). This means that a query requiring a copy of data, such as one using an ORDER BY clause or UNION DISTINCT, will issue an error and not be allowed. When using *eof-delay*, consider using a simple query to avoid blocking of rows. When rows are blocked for data transport efficiency, rows won't be returned until the block is full. Therefore, you should decide whether you favor data transport efficiency or moving events as soon as they occur.

commit-cycle

A decimal expression that identifies the commit cycle identifier to use.

If *commit-cycle* is not specified, *ALL is used.

include-internal

A character or graphic string expression that indicates whether to return hidden journal entries. Hidden entries are generated and used by the system. When hidden entries are returned, it is possible to display all journal entries so all sequence numbers are accounted for.

NO Internal entries are not returned.

YES Internal entries are returned.

If *include-internal* is not specified, NO is used.

The special values supported for the function arguments are the same as for the Display Journal (DSPJRN) CL command.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 194. DISPLAY_JOURNAL table function

Column Name	Data Type	Description
ENTRY_TIMESTAMP	TIMESTAMP	The system date and time when the journal entry was added to the journal receiver ² .
SEQUENCE_NUMBER	DECIMAL(21,0)	A number assigned by the system to each journal entry.
JOURNAL_CODE	CHAR(1)	The primary category of the journal entry.
JOURNAL_ENTRY_TYPE	CHAR(2)	Further identifies the type of user-created or system-created entry.
COUNT_OR_RRN	BIGINT	Contains either the relative record number (RRN) of the record that caused the journal entry or a count that is pertinent to the specific type of journal entry.
ENTRY_DATA	BLOB(2G)	The entry specific data returned for this journal entry. See Notes section for row and column access control considerations.
NULL_VALUE_INDICATORS	VARCHAR(8000)	The null value indicators returned for this journal entry.
OBJECT	VARCHAR(30)	The name of the object for which the journal entry was added.
OBJECT_TYPE	VARCHAR(10)	The type of object in the entry.
OBJECT_TYPE_INDICATOR	CHAR(1)	An indicator with respect to the information in the object field.
FILE_TYPE_INDICATOR	CHAR(1)	Identifies whether or not this journal entry is associated with a logical file.
JOURNAL_IDENTIFIER	VARCHAR(10)	The journal identifier (JID) for the object.
USER_NAME	VARCHAR(10)	The name of the effective user profile under which the job was running when the entry was created. This value is identical to what is returned in the CURRENT_USER column.
JOB_NAME	VARCHAR(10)	The name of the job that added the entry.
JOB_USER	VARCHAR(10)	The user profile name of the user that started the job.
JOB_NUMBER	VARCHAR(6)	The job number of the job that added the entry.
THREAD	BIGINT	Identifies the thread within the process that added the journal entry.
PROGRAM_NAME	VARCHAR(10)	The name of the program that added the entry.
PROGRAM_LIBRARY	VARCHAR(10)	The name of the library that contains the program that added the journal entry.
PROGRAM_LIBRARY_ASP_DEVICE	VARCHAR(10)	The name of the ASP device that contains the program.

Table 194. DISPLAY_JOURNAL table function (continued)

Column Name	Data Type	Description
PROGRAM_LIBRARY_ASP_NUMBER	INTEGER	The number for the auxiliary storage pool that contains the program that added the journal entry. 1 indicates the system ASP.
COMMIT_CYCLE	DECIMAL(21,0)	A number that identifies the commit cycle.
NESTED_COMMIT_LEVEL	BIGINT	Indicates the nesting level of the commit cycle that was open when a journal entry representing an object level change was deposited.
XID	VARCHAR(140)	The transaction identifier, as defined by the Open Group's XA specification, for commit cycles related to an XA transaction branch.
LUW	VARCHAR(39)	The logical unit of work identifies entries to be associated with a given unit of work.
REMOTE_PORT	INTEGER	The port number of the remote address associated with this journal entry.
REMOTE_ADDRESS	VARCHAR(46)	The remote address associated with the journal entry.
SYSTEM_NAME	VARCHAR(8)	The name of the system on which the entry is being retrieved.
SYSTEM_SEQUENCE_NUMBER	DECIMAL(21,0)	The system sequence number indicates the relative sequence of when this journal entry was deposited into the journal.
REFERENTIAL_CONSTRAINT	CHAR(1)	Whether this entry was recorded for actions that occurred on records that are part of a referential constraint.
TRIGGER	CHAR(1)	Whether this entry was created as result of a trigger program.
IGNORE_ON_APPLY	CHAR(1)	Whether this entry is ignored during an Apply Journalized Changes (APYJRNCHG) or Remove Journalized Changed (RMVJRNCHG) command.
MINIMIZED_ENTRY_DATA	CHAR(1)	Whether this entry has minimized entry specific data as a result of the journal having specified MINENTDTA for the object type of the entry.
MINIMIZED_ON_FIELD_BOUNDARY	CHAR(1)	Whether this entry has minimized entry specific data on field boundaries as a result of the journal having been specified with MINENTDTA(*FLDBDY).
INDICATOR_FLAG	CHAR(1)	An indicator for the operation.
RECEIVER_NAME	VARCHAR(10)	The name of the receiver holding the journal entry.
RECEIVER_LIBRARY	VARCHAR(10)	The name of the library containing the receiver holding the journal entry.
RECEIVER_ASP_DEVICE	VARCHAR(10)	The name of the ASP device containing the receiver holding the journal entry.
RECEIVER_ASP_NUMBER	INTEGER	The number for the auxiliary storage pool containing the receiver holding the journal entry. 1 indicates the system ASP.
ARM_NUMBER	INTEGER	The number of the disk arm that contains the journal entry.
OBJECT_ASP_DEVICE	VARCHAR(10)	ASP device name.
OBJECT_ASP_NUMBER	INTEGER	ASP number. 1 indicates the system ASP.
PARENT_FILE_ID	BINARY(16)	File ID for parent directory.
OBJECT_FILE_ID	BINARY(16)	File ID for object.
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	File ID of directory containing object in PATH_NAME.
OBJECT_FILE_NAME	VARGRAPHIC(2002) CCSID 1200	Object name.
PATH_NAME	DBCLOB(16M) CCSID 1200	Name of integrated file system path.
DLO_NAME	VARCHAR(12)	DLO name.
FOLDER_PATH	VARCHAR(63)	DLO folder path.
CURRENT_USER	VARCHAR(10)	The name of the effective user profile under which the job was running when the entry was created. This value is identical to what is returned in the USER_NAME column.

Table 194. DISPLAY_JOURNAL table function (continued)

Column Name	Data Type	Description
SYSLOG_EVENT	VARGRAPHIC(2048) CCSID 1200	<p>The Common Event Format (CEF) syslog event for the journal entry preceded with a header of the requested type. If a header-type of RFC3164 is requested, the maximum length is 1024 characters. If a header-type of RFC5424 is requested, the maximum length is 2048 characters. The string will be truncated with no warning if it exceeds the maximum length.</p> <p>The audit journal entry types that generate syslog information and the key names returned for journal entries are listed in the Notes section.</p> <p>Contains the null value if there is no syslog event defined for the journal entry or if NO was specified for the GENERATE_SYSLOG parameter.</p>
SYSLOG_FACILITY	INTEGER	<p>The syslog facility assigned to the event.</p> <p>4 Security/authorization messages. This value is returned for all T and U audit journal entries.</p> <p>Contains the null value if there is no syslog event defined for the journal entry or if NO was specified for the GENERATE_SYSLOG parameter.</p>
SYSLOG_SEVERITY	INTEGER	<p>The syslog severity assigned to the event.</p> <p>2 Critical condition</p> <p>4 Warning condition</p> <p>5 Notice: A normal but significant condition</p> <p>6 Informational message</p> <p>The severity assigned to each journal entry is listed in the Notes section.</p> <p>Contains the null value if there is no syslog event defined for the journal entry or if NO was specified for the GENERATE_SYSLOG parameter.</p>
SYSLOG_PRIORITY	INTEGER	<p>The syslog priority number assigned to the event.</p> <p>Contains the null value if there is no syslog event defined for the journal entry or if NO was specified for the GENERATE_SYSLOG parameter.</p>

Notes

Row and column access control: This table function recognizes whether ROW ACCESS CONTROL or COLUMN ACCESS CONTROL exists and is activated for the target table. If any row or column access control is active for the table, the rule text logic defined for the row permissions and/or column masks is applied before returning the value in ENTRY_DATA. When the rule text for a row permission determines that the user invoking the function should not see the row, the ENTRY_DATA column contains the text NOT AUTHORIZED. If the user is allowed to see the row and a column mask exists, the rule text for the column mask determines the value returned for ENTRY_DATA.

LOB data considerations: For journal code R (any entry type) and code F (IZ entry type), when a LOB data type is encountered that is not a zero-length string, 16 'Q's are placed in the Entry Specific Data, followed by the LOB data.

Filtering considerations: When using DISPLAY_JOURNAL to review journal activity for specific objects, there are some considerations to ensure complete results are returned.

- When querying the audit journal (JOURNAL_LIBRARY => 'QSYS' and JOURNAL_NAME => 'QAUDJRN'), do not use the object filters because they will result in no entries being returned. For an audit journal, use a WHERE clause to limit the rows returned.
- When querying a data journal, consider whether it's possible that the Journal Identifier (JID) has changed for the object. The object filters use the JID found in the object and will not return any entries with a different JID. If the JID for the object might have changed, avoid using the object filters. In this case, use a WHERE clause to limit the rows returned.

Syslog information: Syslog information is returned for all audit journal entries with T and U journal codes. Syslog information is also available for history log messages. See [HISTORY_LOG_INFO table function](#) for more details.

The following audit journal entries with T journal codes generate syslog information:

AD	Auditing changes
AF	Authority failure
AP	Obtaining adopted authority
AU	Attribute changes
AX	Row and column access control
CA	Authority changes
CD	Command string audit
CO	Create object
CP	User profile changed, created, or restored
CQ	Change of *CRQD object
CU	Cluster operations
CV	Connection verification
CY	Cryptographic configuration
DI	Directory server
DO	Delete object
DS	DST security password reset
EV	System environment variables
GR	Generic record
GS	Socket description was given to another job
IM	Intrusion monitor
IP	Interprocess communication
IR	IP rules actions
IS	Internet security management
JD	Change to user parameter of a job description
JS	Actions that affect jobs
KF	Key ring file
LD	Link, unlink, or look up directory entry
ML	Office services mail actions
M0	Db2 Mirror setup tools
M6	Db2 Mirror communication services
M7	Db2 Mirror replication services
M8	Db2 Mirror product services
M9	Db2 Mirror replication state
NA	Network attribute changed
ND	APPN directory search filter violation
NE	APPN end point filter violation
OM	Object move or rename
OR	Object restore

	OW	Object ownership changed
	O1	Optical access
	O2	Optical access
	O3	Optical access
	PA	Program changed to adopt authority
	PF	PTF operations
	PG	Change of an object's primary group
	PO	Printed output
	PS	Profile swap
	PU	PTF object changes
	PW	Invalid password
	RA	Authority change during restore
	RJ	Restoring job description with user profile specified
	RO	Change of object owner during restore
	RP	Restoring adopted authority program
	RQ	Restoring a *CRQD object
	RU	Restoring user profile authority
	RZ	Changing a primary group during restore
	SD	Changes to system distribution directory
	SE	Subsystem routing entry changed
	SF	Actions to spooled files
	SG	Asynchronous signals
	SK	Sockets connections
	SM	Systems management changes
	SO	Server security user information actions
	ST	Use of service tools
	SV	System value changed
	VO	Validation list actions
	VP	Network password error
	XD	Directory server extension
	X0	Network authentication
	X1	Identity token
	X2	Query manager profile changes
	YC	DLO object accessed (change)
	YR	DLO object accessed (read)
	ZC	Object accessed (change)
	ZR	Object accessed (read)

| Audit journal entries with the U journal code are assigned a SYSLOG_SEVERITY of 6. The audit journal entries with T journal codes are assigned a SYSLOG_SEVERITY value in the following way:

- Severity 2 Critical condition
 - SV - System value when QAUDCTL is changed to *NONE
- – AF - Authority failure
- – DI - Directory server (operation type 'AF')
- – GR - Generic record, when function usage was checked and failed for a function name with a prefix of QIBM_DB_
- – IM - Intrusion monitor
- – IP - Interprocess communication (entry type 'F')
- Severity 5 Notice: A normal but significant condition
 - AD - Auditing changes
 - AX - Row and column access control
 - CA - Authority changes
 - CP - User profile changed, created, or restored
 - DI - Directory server (operation types 'AD', 'CA', 'CP', 'OM', 'OW', and 'PW')
 - DS - DST security password reset
 - IP - Interprocess communication (entry type 'A')
 - JD - Change to user parameter of a job description
 - JS - Actions that affect jobs (entry types 'M' and 'T')
 - OM - Object move or rename
 - OW - Object ownership changed
 - O3 - Optical access (entry type 'L')
 - PG - Change of an object's primary group
 - PS - Profile swap
 - PW - Invalid password
 - RA - Authority change during restore
 - RO - Change of object owner during restore
 - RU - Restoring user profile authority
 - RZ - Change a primary group during restore
 - SO - Server security user information actions
 - VO - Validation list actions (entry type 'U')
 - VP - Network password error
 - X0 - Network authentication (entry types '2' - '6', '8', '9' and 'A' - 'F')
 - X1 - Identity token (entry types 'F' and 'U')
 - X2 - Query manager profile changes
- Severity 6 Informational message
 - AP - Obtaining adopted authority
 - AU - Attribute changes
 - CD - Command string audit
 - CO - Create object
 - CQ - Change of *CRQD object
 - CU - Cluster operations
 - CV - Connection verification
 - CY - Cryptographic configuration

- DI - Directory server (all operation types other than 'AD', 'AF', 'CA', 'CP', 'OM', 'OW', and 'PW')
- DO - Delete object
- EV - System environment variables
- GR - Generic record, except for the Severity 4 case where function usage was checked and failed
- GS - Socket description was given to another job
- IP - Interprocess communication (all entry types other than 'A' and 'F')
- IR - IP rules actions
- IS - Internet security management
- JS - Actions that affect jobs (all entry types other than 'M' and 'T')
- KF - Key ring file
- LD - Link, unlink, or look up directory entry
- ML - Office services mail actions
- M0 - Db2 Mirror setup tools
- M6 - Db2 Mirror communication services
- M7 - Db2 Mirror replication services
- M8 - Db2 Mirror product services
- M9 - Db2 Mirror replication state
- NA - Network attribute changed
- ND - APPN directory search filter violation
- NE - APPN end point filter violation
- OR - Object restore
- O1 - Optical access
- O2 - Optical access
- O3 - Optical access (all entry types other than 'L')
- PA - Program changed to adopt authority
- PF - PTF operations
- PO - Printed output
- PU - PTF object changes
- RJ - Restoring job description with user profile specified
- RP - Restoring adopted authority program
- RQ - Restoring a *CRQD object
- SD - Changes to system distribution directory
- SE - Subsystem routing entry changed
- SF - Actions to spooled files
- SG - Asynchronous signals
- SK - Sockets connections
- SM - Systems management changes
- ST - Use of service tools
- SV - System value changed, except for QAUDCTL severity 2 case
- VO - Validation list actions (all entry types other than 'U')
- XD - Directory server extension
- X0 - Network authentication (all entry types other than '2' - '6', '8', '9' and 'A' - 'F')
- X1 - Identity token (all entry types other than 'F' and 'U')

- YC - DLO object accessed (change)
- YR - DLO object accessed (read)
- ZC - Object accessed (change)
- ZR - Object accessed (read)

The Common Event Format key names that are generated within the SYSLOG_EVENT column are:

<i>Table 195. Common Event Format key names</i>	
Common Event Format key name	Description
attrName	Attribute name (extracted from ENTRY_DATA column)
attrValue	Attribute value (extracted from ENTRY_DATA column)
deviceExternalId	Device name (extracted from ENTRY_DATA column)
dloName	Document Library Object name (DLO_NAME column)
dloPath	Document Library Object folder path (FOLDER_PATH column)
dproc	Destination job (process) name (extracted from ENTRY_DATA column)
dpt	Destination port number (extracted from ENTRY_DATA column)
dst	Destination IP address (extracted from ENTRY_DATA column)
duser	Destination user name (extracted from ENTRY_DATA column)
filePath	Integrated file system stream file path (PATH_NAME column)
fileType	Object type (OBJECT_TYPE column)
fname	Integrated file system stream file name (OBJECT_FILE_NAME column)
msg	Additional information from the audit record not included in other keys (extracted from ENTRY_DATA column)
objName	Object name (OBJECT column)
oldAttrValue	Attribute value (before change) (extracted from ENTRY_DATA column)
oldDloName	Document Library Object name (before rename) (extracted from ENTRY_DATA column)
oldDloPath	Document Library Object folder path (before rename) (extracted from ENTRY_DATA column)
oldFileName	Integrated file system stream file name (before rename) (extracted from ENTRY_DATA column)

Table 195. Common Event Format key names (continued)

Common Event Format key name	Description
oldFilePath	Integrated file system stream file path (before rename) (extracted from ENTRY_DATA column)
oldObjName	Object name (before rename) (extracted from ENTRY_DATA column)
reason	Text description of the audit journal entry
shost	Source system (host) name (SYSTEM_NAME column)
sproc	Source job (process) name (JOB_NAME, JOB_USER, JOB_NUMBER columns)
spt	Source port number (REMOTE_PORT column)
src	Source IP address (REMOTE_ADDRESS column)
suser	Source user name (USER_NAME column)

Examples

- Select all entries from the *CURRENT receiver of journal TESTLIB/QSQJRN.

```
SELECT * FROM TABLE (
    QSYS2.DISPLAY_JOURNAL( 'TESTLIB', 'QSQJRN')) AS JT;
```

- Find all changes made by SUPERUSER against the PRODDATA/SALES table. The first two arguments are passed without names since they correspond with the first two parameters for the function. The other four arguments are passed using the parameter name syntax to avoid specifying a value for the parameters that are not needed.

```
SELECT journal_code, journal_entry_type, object, object_type, X.*
FROM TABLE (
    QSYS2.Display_Journal(
        'PRODDATA', 'QSQJRN', -- Journal library and name
        OBJECT_LIBRARY=>'PRODDATA', OBJECT_NAME=>'SALES',
        OBJECT_OBJTYPE=>'*FILE', OBJECT_MEMBER=>'SALES'
    ) ) AS X
WHERE journal_entry_type in ('DL', 'PT', 'PX', 'UP') AND "CURRENT_USER" = 'SUPERUSER'
ORDER BY entry_timestamp DESC;
```

- Review audit journal entries for the REQUESTS file in MYCO library. For an audit journal, a predicate is used to designate the object name.

```
SELECT journal_code, journal_entry_type, object, object_type, X.*
FROM TABLE (QSYS2.Display_Journal('QSYS', 'QAUDJRN') ) AS X
WHERE LEFT(OBJECT,20) = CHAR('REQUESTS', 10) CONCAT CHAR('MYCO', 10)
ORDER BY entry_timestamp DESC;
```

- Review changes from the last hour for the REQUESTS file in MYCO library using the current JID. This query will only find entries where the JID of MYCO/REQUESTS *FILE is an exact match to the entry. It filters for the following three journal codes:

- D** Database File Operation
- F** Database File Member Operation
- R** Operation on Specific Record

```
SELECT journal_code, journal_entry_type, object, object_type, X.*
FROM TABLE (QSYS2.Display_Journal('MYCO', 'QSQJRN',
    JOURNAL_CODES => 'D,F,R',
    STARTING_RECEIVER_NAME => '*CURCHAIN',
```

```

OBJECT_OBJTYPE=>'*FILE',
OBJECT_LIBRARY=>'MYCO',
OBJECT_NAME=>'REQUESTS',
OBJECT_MEMBER=>'*ALL'
) ) AS X
WHERE entry_timestamp > CURRENT_TIMESTAMP - 1 HOUR
ORDER BY entry_timestamp DESC ;

```

- Review all changes from the last hour for the REQUESTS file in MYCO library, including any that might have a different Journal ID (JID). To see entries for all JIDs, a predicate is used to designate the object name.

```

SELECT journal_code, journal_entry_type, hex( journal_identifier ),
       object, object_type, X.*
FROM TABLE (QSYS2.Display_Journal('MYCO', 'QSQJRN',
                                JOURNAL_CODES => 'D,F,R',
                                STARTING_RECEIVER_NAME => '*CURCHAIN'
                                ) ) AS X
WHERE LEFT(OBJECT,20) = CHAR('REQUESTS', 10) CONCAT CHAR('MYCO', 10)
      and entry_timestamp > CURRENT_TIMESTAMP - 1 HOUR
ORDER BY entry_timestamp DESC ;

```

- Select entries from the audit journal that return syslog information and format them with an RFC5424 header.

```

SELECT syslog_facility, syslog_severity, syslog_event
FROM TABLE (QSYS2.DISPLAY_JOURNAL('QSYS', 'QAUDJRN',
                                GENERATE_SYSLOG => 'RFC5424'
                                ) ) AS X
WHERE syslog_event IS NOT NULL;

```

JOURNAL_INFO view

The JOURNAL_INFO view contains information about journals, including remote journals.

The values returned for the columns in the view are closely related to the values returned by the Retrieve Journal Information (QJORJRN) API. Refer to the API for more detailed information.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the journal, and
- *OBJOPR and some data authority other than *EXECUTE to the journal

The following table describes the columns in the view. The system name is JRNINFO. The schema is QSYS2.

Table 196. JOURNAL_INFO view

Column Name	System Column Name	Data Type	Description
JOURNAL_NAME	JRNNAME	VARCHAR(10)	The name of the journal.
JOURNAL_LIBRARY	SYS_DNAME	VARCHAR(10)	The name of the library that contains the journal.
ASP_NUMBER	ASPNUMBER	INTEGER	The number of the auxiliary storage pool to which storage for the journal is allocated. 1 indicates the system ASP.
JOURNAL_ASPPGRP	JRNASPPGRP	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the journal resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs.
ATTACHED_JOURNAL_RECEIVER_NAME	ATTRCVNAME	VARCHAR(10) Nullable	The name of the journal receiver that is currently attached to this journal. Contains the null value when there is no attached receiver.
ATTACHED_JOURNAL_RECEIVER_LIBRARY	ATTRCVLIB	VARCHAR(10) Nullable	The name of the library that contains the attached journal receiver. Contains the null value when there is no attached receiver.
MESSAGE_QUEUE	MSGQNAME	VARCHAR(10)	The name of the message queue that is associated with this journal.

Table 196. JOURNAL_INFO view (continued)

Column Name	System Column Name	Data Type	Description
MESSAGE_QUEUE_LIBRARY	MSGQLIB	VARCHAR(10)	The name of the library that contains the message queue.
DELETE_RECEIVER_OPTION	DLTRCVOPT	VARCHAR(3)	<p>Indicates whether the system deletes detached journal receivers that are associated with this journal when they are no longer needed for IPL or IASP vary on recovery.</p> <p>NO Detached journal receivers that are associated with this journal are not deleted when they are no longer needed for IPL or IASP vary on recovery.</p> <p>YES Detached journal receivers that are associated with this journal are deleted when they are no longer needed for IPL or IASP vary on recovery.</p>
DELETE_RECEIVER_DELAY	DLTRCVDLY	INTEGER Nullable	<p>The delay time (in minutes) between attempts to delete journal receivers associated with this journal.</p> <p>Contains the null value when DELETE_RECEIVER_OPTION is NO.</p>
JOURNAL_TYPE	TYPE	VARCHAR(10)	<p>The scope of the journal and some of its characteristics.</p> <p>*LOCAL This is a local journal.</p> <p>*REMOTE This is a remote journal.</p>
JOURNAL_STATE	STATE	VARCHAR(10)	<p>An indication as to whether journal entries are currently being sent to a journal. For a remote journal, this is whether the journal is actively receiving journal entries from the source system journal.</p> <p>*ACTIVE If this is a local journal, this means journal entries can be deposited to this journal. If this is a remote journal, this means journal entries can be received from a source journal.</p> <p>*CTLINACT The remote journal is in the process of a controlled inactivate.</p> <p>*FAILED If this is a remote journal, this means journal entries cannot be received from a source journal due to a remote journal function failure. Does not apply to local journals.</p> <p>*INACTIVE If this is a remote journal, this means journal entries cannot be received from a source journal.</p> <p>*INACTPEND If this is a remote journal, this means a request is being processed to set the journal state to *INACTIVE. Does not apply to local journals.</p> <p>*PENDING The remote journal is transitioning from an *INACTIVE state to an *ACTIVE state.</p> <p>*STANDBY If this is a local journal, this means that most journal entries are not deposited into the journal and there will be no errors indicating that the entry was not deposited. Does not apply to remote journals.</p>
NUMBER_JOURNAL_RECEIVERS	NUMJRNRVCV	INTEGER	The total number of journal receivers that are associated with the journal.

Table 196. JOURNAL_INFO view (continued)

Column Name	System Column Name	Data Type	Description
TOTAL_SIZE_JOURNAL_RECEIVERS	SIZJRRCV	BIGINT	The total size of the journal receivers (in kilobytes) associated with the journal.
NUMBER_REMOTE_JOURNALS	RMTJRNS	INTEGER	The total number of remote journals that are directly downstream of this journal.
REDIRECTED_RECEIVER_LIBRARY	RDRRCVLIB	VARCHAR(10) Nullable	For a local or *TYPE1 remote journal, the redirected receiver library name that is currently in place on this journal's local journal for any downstream journal receivers associated with *TYPE1 remote journals. Contains *NONE if no *TYPE1 remote journals have been added or if no receiver library redirection was specified when *TYPE1 remote journals were added. Contains the redirected receiver library name that is currently in place on this remote journal if the specified journal is a *TYPE2 remote journal. Contains the null value if no *TYPE1 remote journals have been added.
MAXIMUM_REMOTE_JOURNALS_ENTRIES_BEHIND	MAXRMTENTB	INTEGER Nullable	The maximum number of entries that are waiting to be sent to the target system for any remote journal. Contains the null value if NUMBER_REMOTE_JOURNALS is 0 or if no attached remote journals are active with async delivery mode.
MAXIMUM_REMOTE_JOURNALS_TIME_BEHIND	MAXRMTSECB	BIGINT Nullable	The maximum value (in hundredths of seconds) that the source journal is behind in sending journal entries to the target system for any remote journal. Contains the null value if NUMBER_REMOTE_JOURNALS is 0 or if no attached remote journals are active with async delivery mode.
MAXIMUM_REMOTE_JOURNALS_RETRANSMISSIONS	MAXRMTRETR	BIGINT Nullable	The maximum value for any remote journal of the total number of times the local system retransmitted a segment because an acknowledgement was not received. Contains the null value if NUMBER_REMOTE_JOURNALS is 0 or if no attached remote journals are active using TCP/IP.
JOURNAL_TEXT	TEXT	VARCHAR(50) Nullable	The text description of the journal. Contains the null value if the journal has no text.
MANAGE_RECEIVER_OPTION	MNGRCVOPT	VARCHAR(10) Nullable	Indicates whether the system or user manages the changing of journal receivers. *SYSTEM The system manages the changing of journal receivers. *USER The user manages the changing of journal receivers. Contains the null value for a remote journal.
MANAGE_RECEIVER_DELAY	MNGRCVDLY	INTEGER Nullable	The delay time (in minutes) between attempts to attach new journal receivers to this journal. Contains the null value when MANAGE_RECEIVER_OPTION is *USER or the null value.
REMOVE_INTERNAL_ENTRIES	RMVINTENT	VARCHAR(3) Nullable	Handling of internal system entries. NO The internal system entries are not removed. YES The size of the attached receivers is reduced by automatic removal of the internal system entries. Contains the null value for a remote journal.

Table 196. JOURNAL_INFO view (continued)

Column Name	System Column Name	Data Type	Description
REMOVE_FIXED_LENGTH_DETAIL	MINFIXLEN	VARCHAR(3) Nullable	<p>Handling of fixed length details.</p> <p>NO Fixed length data is not removed.</p> <p>YES The size of the journal entries that are deposited into the attached journal receivers is reduced by the automatic removal of all fixed length data such as job name, machine sequence number, and so on.</p> <p>Contains the null value for a remote journal.</p>
RECEIVER_MAXIMUM_SIZE	MAXOPT	VARCHAR(10) Nullable	<p>The receiver size option that applies to this journal receiver.</p> <p>*MAXOPT1 The journal receivers attached to the journal can have a maximum receiver size of approximately one terabyte (1,099,511,627,776 bytes) and a maximum sequence number of 9,999,999,999. Additionally, the maximum size of the journal entry that can be deposited is 15,761,440 bytes.</p> <p>*MAXOPT2 The journal receivers attached to the journal can have a maximum receiver size of approximately one terabyte (1,099,511,627,776 bytes) and a maximum sequence number of 9,999,999,999. Additionally, the maximum size of the journal entry which can be deposited is 4,000,000,000 bytes.</p> <p>*MAXOPT3 The journal receivers attached to the journal can have a maximum receiver size of approximately one terabyte (1,099,511,627,776 bytes) and a maximum sequence number of 18,446,744,073,709,551,600. Additionally, the maximum size of the journal entry which can be deposited is 4,000,000,000 bytes.</p> <p>*NONE The journal receivers attached to the journal can have a maximum journal receiver size of approximately 1.9 gigabytes and a maximum sequence number of 2,147,483,136.</p> <p>Contains the null value for a remote journal.</p>
MINIMIZE_ESD_FOR_DATA_AREAS	MINDTAARA	VARCHAR(3) Nullable	<p>Indicates whether journal entries for data areas may have minimized entry specific data.</p> <p>NO Journal entries for data areas do not have minimized entry specific data.</p> <p>YES Journal entries for data areas have minimized entry specific data.</p> <p>Contains the null value for a remote journal.</p>

Table 196. JOURNAL_INFO view (continued)

Column Name	System Column Name	Data Type	Description
MINIMIZE_ESD_FOR_FILES	MINFILE	VARCHAR(19) Nullable	<p>Indicates whether journal entries for files may have minimized entry specific data.</p> <p>MINIMIZED Journal entries for files may have minimized entry specific data. The minimizing does not occur on field boundaries. Therefore, the entry specific data may not be viewable and may not be used for auditing purposes.</p> <p>MINIMIZED FOR AUDIT Journal entries for files may have minimized entry specific data. The minimizing occurs on field boundaries. Therefore, the entry specific data will be viewable and may be used for auditing purposes.</p> <p>NO Journal entries for files will have complete entry specific data.</p> <p>Contains the null value for a remote journal.</p>
JOURNAL_CACHE	JRNCACHE	VARCHAR(3) Nullable	<p>Specifies whether journal entries are cached before being written out to disk.</p> <p>NO Journal entries are not cached before being written out to disk.</p> <p>YES Journal entries are cached before being written out to disk.</p> <p>Contains the null value for a remote journal.</p>
FIXED_LENGTH_DATA_INCLUDES_JOB_NAME	FLDJOB	VARCHAR(3) Nullable	<p>Indicates whether the job name will be stored when journal entries are deposited.</p> <p>NO The job name will not be stored when journal entries are deposited.</p> <p>YES The job name will be stored when journal entries are deposited.</p> <p>Contains the null value for a remote journal.</p>
FIXED_LENGTH_DATA_INCLUDES_USER_NAME	FLDUSR	VARCHAR(3) Nullable	<p>Indicates whether the user name will be stored when journal entries are deposited.</p> <p>NO The user name will not be stored when journal entries are deposited.</p> <p>YES The user name will be stored when journal entries are deposited.</p> <p>Contains the null value for a remote journal.</p>
FIXED_LENGTH_DATA_INCLUDES_PROGRAM_NAME	FLDPGM	VARCHAR(3) Nullable	<p>Indicates whether the program name will be stored when journal entries are deposited.</p> <p>NO The program name will not be stored when journal entries are deposited.</p> <p>YES The program name will be stored when journal entries are deposited.</p> <p>Contains the null value for a remote journal.</p>
FIXED_LENGTH_DATA_INCLUDES_PROGRAM_LIBRARY	FLDPGLIB	VARCHAR(3) Nullable	<p>Indicates whether the program library name will be stored when journal entries are deposited.</p> <p>NO The program library name will not be stored when journal entries are deposited.</p> <p>YES The program library name will be stored when journal entries are deposited.</p> <p>Contains the null value for a remote journal.</p>

Table 196. JOURNAL_INFO view (continued)

Column Name	System Column Name	Data Type	Description
FIXED_LENGTH_DATA_INCLUDES_SYSTEM_SEQUENCE_NUMBER	FLDSYSSEQ	VARCHAR(3) Nullable	Indicates whether the system sequence number will be stored when journal entries are deposited. NO The system sequence number will not be stored when journal entries are deposited. YES The system sequence number will be stored when journal entries are deposited. Contains the null value for a remote journal.
FIXED_LENGTH_DATA_INCLUDES_REMOTE_ADDRESS	FLDRMTADR	VARCHAR(3) Nullable	Indicates whether the remote address will be stored when journal entries are deposited. NO The remote address will not be stored when journal entries are deposited. YES The remote address will be stored when journal entries are deposited. Contains the null value for a remote journal.
FIXED_LENGTH_DATA_INCLUDES_THREAD_ID	FLDTHD	VARCHAR(3) Nullable	Indicates whether the thread identifier will be stored when journal entries are deposited. NO The thread identifier will not be stored when journal entries are deposited. YES The thread identifier will be stored when journal entries are deposited. Contains the null value for a remote journal.
FIXED_LENGTH_DATA_INCLUDES_LOGICAL_UNIT_OF_WORK_ID	FLDLUW	VARCHAR(3) Nullable	Indicates whether the logical unit of work identifier will be stored when journal entries are deposited. NO The logical unit of work identifier will not be stored when journal entries are deposited. YES The logical unit of work identifier will be stored when journal entries are deposited. Contains the null value for a remote journal.
FIXED_LENGTH_DATA_INCLUDES_TRANSACTION_ID	FLDXID	VARCHAR(3) Nullable	Indicates whether the transaction identifier will be stored when journal entries are deposited. NO The transaction identifier will not be stored when journal entries are deposited. YES The transaction identifier will be stored when journal entries are deposited. Contains the null value for a remote journal.
JOURNALED_OBJECT_LIMIT	JRNOBJLMT	VARCHAR(10) Nullable	The number of objects that can be journaled to the journal. *MAX250K The maximum number of objects that can be journaled to the journal is 250,000. *MAX10M The maximum number of objects that can be journaled to the journal is 10,000,000. Contains the null value for a remote journal.
JOURNALED_OBJECTS	JRNALL	INTEGER Nullable	Total of all objects journaled to the journal. This count includes explicitly journaled objects such as files, file members, access paths, data areas, data queues, libraries, and integrated file system objects. This count also includes implicitly journaled objects such as journal receivers, commitment definitions, and objects journaled for system recovery purposes. Contains the null value for a remote journal.

Table 196. JOURNAL_INFO view (continued)

Column Name	System Column Name	Data Type	Description
JOURNALED_FILES	JRNFILE	INTEGER Nullable	The total number of files that are currently being journaled to this journal. Contains the null value for a remote journal.
JOURNALED_MEMBERS	JRNMBR	INTEGER Nullable	The total number of file members that are currently being journaled to this journal. Contains the null value for a remote journal.
JOURNALED_DATA_AREAS	JRNDAARA	INTEGER Nullable	The total number of data areas that are currently being journaled to this journal. Contains the null value for a remote journal.
JOURNALED_DATA_QUEUES	JRNDAQ	INTEGER Nullable	The total number of data queues that are currently being journaled to this journal. Contains the null value for a remote journal.
JOURNALED_IFS_OBJECTS	JRNIFS	INTEGER Nullable	The total number of integrated file system objects of type *DIR, *STMF, and *SYMLNK that are currently being journaled to this journal. Contains the null value for a remote journal.
JOURNALED_ACCESS_PATHS	JRNAP	INTEGER Nullable	The total number of access paths that are currently being journaled to this journal. Contains the null value for a remote journal.
JOURNALED_COMMITMENT_DEFINITIONS	JRNCMTDFN	INTEGER Nullable	The total number of commitment definitions that are currently being implicitly journaled to this journal. Contains the null value for a remote journal.
JOURNALED_LIBRARIES	JRNLIB	INTEGER Nullable	The total number of libraries that are currently being journaled to this journal. Contains the null value for a remote journal.
JOURNAL_RECOVERY_COUNT	JRNRCYCNT	INTEGER Nullable	The approximate number of journaled changes that would need to be recovered during journal synchronization for this journal in the event of an abnormal IPL or vary on. Contains the null value for a local journal with the value *SYSDFT or for a remote journal.
REMOTE_JOURNAL_TYPE	RMTJRNTYPE	VARCHAR(10) Nullable	The type of remote journal. Values are *TYPE1 and *TYPE2. Contains the null value for a local journal.
JOURNAL_DELIVERY_MODE	DELIVMODE	VARCHAR(10) Nullable	The journal delivery mode that is being used to replicate journal entries to this journal. *ASYNC Journal entries are being delivered or replicated asynchronously. *ASYNCPEND Journal entries are to be delivered or replicated asynchronously, but the journal is currently in catch-up mode. *SYNC Journal entries are being delivered or replicated synchronously. *SYNCPEND Journal entries are to be delivered or replicated synchronously, but the journal is currently in catch-up mode. Contains the null value for a local journal or a remote journal whose JOURNAL_STATE field is not *ACTIVE or *CTLINACT.

Table 196. JOURNAL_INFO view (continued)

Column Name	System Column Name	Data Type	Description
LOCAL_JOURNAL_NAME	LCLJRNAME	VARCHAR(10) Nullable	The journal name of the local journal. The local journal is the journal that is the initiator of the original journal deposit that has been replicated downstream to this journal. Contains the null value for a local journal.
LOCAL_JOURNAL_LIBRARY	LCLJRNLIB	VARCHAR(10) Nullable	The library name of the local journal. Contains the null value for a local journal.
LOCAL_JOURNAL_SYSTEM	LCLJRNSYS	VARCHAR(8) Nullable	The name of the system for the local journal. Contains *UNKNOWN if journal is a remote journal and does not have an attached receiver. Contains the null value for a local journal.
LOCAL_JOURNAL_ASPGRP	LCLASPGRP	VARCHAR(10) Nullable	The name of the independent auxiliary storage pool (ASP) group of the local journal. *SYSBAS is used to indicate the system ASP and all basic user ASPs. Contains *UNKNOWN if journal is a remote journal and does not have an attached receiver. Contains the null value for a local journal.
SOURCE_JOURNAL_NAME	SRCJRNAME	VARCHAR(10) Nullable	The journal name of the source journal. The source journal is the journal that is directly upstream of this journal. Contains *UNKNOWN if journal is a remote journal and does not have an attached receiver. Contains the null value for a local journal.
SOURCE_JOURNAL_LIBRARY	SRCJRNLIB	VARCHAR(10) Nullable	The library name of the source journal. Contains *UNKNOWN if journal is a remote journal and does not have an attached receiver. Contains the null value for a local journal.
SOURCE_JOURNAL_SYSTEM	SRCJRNSYS	VARCHAR(8) Nullable	The name of the system for the source journal. Contains *UNKNOWN if journal is a remote journal and does not have an attached receiver. Contains the null value for a local journal.
SOURCE_JOURNAL_ASPGRP	SRCASPGRP	VARCHAR(10) Nullable	The name of the independent auxiliary storage pool (ASP) group of the source journal. Contains *UNKNOWN if journal is a remote journal and does not have an attached receiver. Contains the null value for a local journal.
LOCAL_RECEIVER_SYSTEM	LCLRCVSY	VARCHAR(8) Nullable	If this journal receiver is associated with a remote journal, the name of the system for the local journal. Contains *UNKNOWN if journal is a remote journal and does not have an attached receiver. Contains the null value for a local journal.
SOURCE_RECEIVER_SYSTEM	SRCRCVSY	VARCHAR(8) Nullable	If this journal receiver is associated with a remote journal, the name of the system for the source journal. Contains *UNKNOWN if journal is a remote journal and does not have an attached receiver. Contains the null value for a local journal.
ACTIVATION_TIME	ACTDT	TIMESTAMP Nullable	If the journal is a remote journal and it is currently active, the date and time the journal was activated. Contains the null value for a local journal or a remote journal whose JOURNAL_STATE field is not *ACTIVE or *CTLINACT.

Table 196. JOURNAL_INFO view (continued)

Column Name	System Column Name	Data Type	Description
ESTIMATED_TIME_BEHIND	ESTBEHIND	BIGINT Nullable	If the journal is an active remote journal and the delivery mode is asynchronous, this is the estimated amount of time, in milliseconds, between when the journal entries are written to disk on the source system and when they are received on the target system. Contains the null value for a local journal or a remote journal whose JOURNAL_STATE field is not *ACTIVE or *CTLINACT.
MAXIMUM_TIME_BEHIND	MAXBEHIND	BIGINT Nullable	The maximum value of ESTIMATED_TIME_BEHIND since the journal was activated. Contains the null value for a local journal or a remote journal whose JOURNAL_STATE field is not *ACTIVE or *CTLINACT.
MAXIMUM_BEHIND_TIMESTAMP	MAXBHNDTIM	TIMESTAMP Nullable	The date and time that the ESTIMATED_TIME_BEHIND occurred. Contains the null value for a local journal or a remote journal whose JOURNAL_STATE field is not *ACTIVE or *CTLINACT.
JOURNAL_ENTRY_FILTERING	FILTER	VARCHAR(3) Nullable	Indicates whether or not journal entry filtering is active for this journal. NO Journal entry filtering is not active for this journal. YES Journal entry filtering is active for this journal. Contains the null value for a local journal or a remote journal whose JOURNAL_STATE field is not *ACTIVE or *CTLINACT.

Examples

- List all journals that are falling behind sending entries to one or more remote journals:

```
SELECT JOURNAL_NAME, JOURNAL_LIBRARY,
       MAXIMUM_REMOTE_JOURNALS_ENTRIES_BEHIND,
       MAXIMUM_REMOTE_JOURNALS_TIME_BEHIND, MAXIMUM_REMOTE_JOURNALS_RETRANSMISSIONS
FROM QSYS2.JOURNAL_INFO
WHERE MAXIMUM_REMOTE_JOURNALS_ENTRIES_BEHIND > 0
ORDER BY MAXIMUM_REMOTE_JOURNALS_ENTRIES_BEHIND DESC
```

- Find any remote journals that are not currently active:

```
SELECT * FROM QSYS2.JOURNAL_INFO
WHERE JOURNAL_TYPE = '*REMOTE'
      AND JOURNAL_STATE <> '*ACTIVE'
ORDER BY JOURNAL_LIBRARY, JOURNAL_NAME,
```

- For security auditing reasons, find any journals that are not recording remote address info:

```
SELECT * FROM QSYS2.JOURNAL_INFO
WHERE REMOVE_FIXED_LENGTH_DETAIL = 'YES'
      OR FIXED_LENGTH_DATA_INCLUDES_REMOTE_ADDRESS = 'NO'
```

JOURNAL_RECEIVER_INFO view

The JOURNAL_RECEIVER_INFO view contains information about all journal receivers on the system.

The values returned for the columns in the view are closely related to the values returned by the Retrieve Journal Receiver Information (QjorTvJrnReceiverInformation) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the journal receiver, and

- *OBJOPR authority and some data authority other than *EXECUTE to the journal receiver.

If the journal receiver is associated with a journal, the caller requires:

- *EXECUTE authority to the library containing the journal, and
- *OBJOPR authority to the journal.

The following table describes the columns in the view. The system name is JRNRCV_INF. The schema is QSYS2.

Table 197. JOURNAL_RECEIVER_INFO view

Column Name	System Column Name	Data Type	Description
JOURNAL_RECEIVER_LIBRARY	JRNRCV_LIB	VARCHAR(10)	The name of the library that contains the journal receiver.
JOURNAL_RECEIVER_NAME	JRNRCV	VARCHAR(10)	The name of the journal receiver.
DESCRIPTIVE_TEXT	TEXT	VARCHAR(50) Nullable	The text description of the journal receiver.
JOURNAL_RECEIVER_ASP_NUMBER	RCV_ASPNUM	INTEGER	The number of the auxiliary storage pool to which storage for the journal receiver is allocated. 1 indicates the system ASP.
JOURNAL_RECEIVER_ASP_NAME	RCV_ASPNAM	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the journal receiver resides. A value of *SYSBAS indicates the system ASP or a basic user ASP.
JOURNAL_LIBRARY	JRN_LIB	VARCHAR(10) Nullable	The name of the library that contains the journal. Contains the null value if the receiver has never been attached to a journal.
JOURNAL_NAME	JOURNAL	VARCHAR(10) Nullable	The name of the journal that the journal receiver is attached to or used to be attached to. Contains the null value if the receiver has never been attached to a journal.
THRESHOLD	THRESHOLD	INTEGER Nullable	An auxiliary disk storage space threshold value (in kilobytes) for the journal receiver. If the threshold value is exceeded during journaling and the journal has the MNGRCV(*USER) attribute, a message (CPF7099) is sent to the message queue that is specified on the Create Journal (CRTJRN) or the Change Journal (CHGJRN) command. If the journal has the MNGRCV(*SYSTEM) attribute, the system creates and attaches a new journal receiver, detaches the old journal receiver when the threshold is reached, and sends message CPF7020 to the journal message queue. Contains the null value for remote journal receivers.
SIZE	SIZE	INTEGER	The number of kilobytes of auxiliary disk storage used by this journal receiver.

Table 197. JOURNAL_RECEIVER_INFO view (continued)

Column Name	System Column Name	Data Type	Description
STATUS	STATUS	VARCHAR(8)	<p>The status of the journal receiver.</p> <p>ATTACHED The journal receiver is currently attached to the journal.</p> <p>ONLINE The journal receiver is online. The journal receiver has not been saved, and it has been detached from the journal.</p> <p>SAVED The journal receiver was saved after it was detached. The journal receiver storage was not freed when it was saved.</p> <p>FREED The journal receiver was saved after it was detached. The journal receiver storage was freed when it was saved.</p> <p>PARTIAL The journal receiver status is partial for one of the following reasons:</p> <ul style="list-style-type: none"> • It was restored from a version that was saved while it was attached to the journal. Additional journal entries may have been written that were not restored. • It is associated with a remote journal and it does not contain all the journal entries that are in the associated journal receiver attached to the source journal. <p>EMPTY The journal receiver has never been attached to a journal.</p>
NUMBER_OF_JOURNAL_ENTRIES	ENTRIES	DECIMAL(20,0) Nullable	<p>The number of journal entries that are contained in this journal receiver.</p> <p>Contains the null value if STATUS is EMPTY.</p>
FIRST_SEQUENCE_NUMBER	FIRST_SEQ	DECIMAL(21,0) Nullable	<p>The journal sequence number of the first journal entry in this journal receiver.</p> <p>Contains the null value if STATUS is EMPTY.</p>
LAST_SEQUENCE_NUMBER	LAST_SEQ	DECIMAL(21,0) Nullable	<p>The journal sequence number of the last journal entry in this journal receiver.</p> <p>Contains the null value if STATUS is EMPTY.</p>
MAXIMUM_ENTRY_SPECIFIC_DATA_LENGTH	MAX_ESD	DECIMAL(20,0) Nullable	<p>The length in bytes of the longest entry-specific data among all journal entries in this journal receiver.</p> <p>Contains the null value if STATUS is EMPTY.</p>
MAXIMUM_NULL_VALUE_INDICATORS	MAX_NVI	INTEGER Nullable	<p>The maximum number of null value indicators among all journal entries in this journal receiver.</p> <p>Contains the null value if STATUS is EMPTY.</p>
ATTACH_TIMESTAMP	ATTACHED	TIMESTAMP(0) Nullable	<p>The date and time that this journal receiver was attached to the journal. For a journal receiver attached to a remote journal, this is the date and time that the journal receiver was attached on the local system.</p> <p>Contains the null value if STATUS is EMPTY.</p>
DETACH_TIMESTAMP	DETACHED	TIMESTAMP(0) Nullable	<p>The date and time that this journal receiver was detached from the journal. For a journal receiver attached to a *REMOTE journal, this is the date and time that the journal receiver was detached on the local system.</p> <p>Contains the null value if STATUS is EMPTY, ATTACHED, or PARTIAL.</p>

Table 197. JOURNAL_RECEIVER_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SAVE_TIMESTAMP	SAVED	TIMESTAMP(0) Nullable	The date and time that the journal receiver was last saved. This value reflects when the receiver was saved from the system it exists on (either the source or target system time). Contains the null value if the journal receiver was never saved.
PREVIOUS_JOURNAL_RECEIVER_LIBRARY	PREV_RCVL	VARCHAR(10) Nullable	The name of the library of the previous journal receiver that is associated with the same journal. Contains the null value if STATUS is EMPTY, if there was no journal receiver attached to the journal prior to this journal receiver, or if it is currently associated with a remote journal.
PREVIOUS_JOURNAL_RECEIVER	PREV_RCV	VARCHAR(10) Nullable	The name of the previous journal receiver that is associated with the same journal. Contains the null value if STATUS is EMPTY, if there was no journal receiver attached to the journal prior to this journal receiver, or if it is currently associated with a remote journal.
NEXT_JOURNAL_RECEIVER_LIBRARY	NEXT_RCVL	VARCHAR(10) Nullable	The name of the library of the next journal receiver that is associated with the same journal. v
NEXT_JOURNAL_RECEIVER	NEXT_RCV	VARCHAR(10) Nullable	The name of the next journal receiver that is associated with the same journal. v

Table 197. JOURNAL_RECEIVER_INFO view (continued)

Column Name	System Column Name	Data Type	Description
RECEIVER_MAXIMUM_SIZE	MAXOPT	pendin VARCHAR(8) Nullable	<p>The journal receiver sequence number and size option for this journal receiver. If this journal receiver is attached to a remote journal, the value is determined by the local journal.</p> <p>*NONE The journal receiver has a maximum journal receiver size of approximately 1.9 gigabytes and a maximum sequence number of 2,147,483,136.</p> <p>*MAXOPT1 The journal receiver has a maximum journal receiver size of approximately one terabyte (1,099,511,627,776 bytes) and a maximum sequence number of 9,999,999,999. Additionally, the maximum size of the journal entry that can be deposited is 15,761,440 bytes. This occurs if this receiver was attached when RCVSIZOPT(*MAXOPT1) was in effect for the journal.</p> <p>*MAXOPT2 The journal receiver has a maximum journal receiver size of approximately one terabyte (1,099,511,627,776 bytes) and a maximum sequence number of 9,999,999,999. This occurs if this receiver was attached when RCVSIZOPT(*MAXOPT2) was in effect for the journal. Additionally, the maximum size of the journal entry which can be deposited is 4,000,000,000 bytes.</p> <p>*MAXOPT3 The journal receiver has a maximum journal receiver size of approximately one terabyte (1,099,511,627,776 bytes) and a maximum sequence number of 18,446,744,073,709,551,600. This occurs if this receiver was attached when RCVSIZOPT(*MAXOPT3) was in effect for the journal. Additionally, the maximum size of the journal entry which can be deposited is 4,000,000,000 bytes.</p> <p>Contains the null value if STATUS is EMPTY.</p>
MINIMIZE_ESD_FOR_DATA_AREAS	MINDTAARA	VARCHAR(3) Nullable	<p>Whether the entry-specific data for data areas is minimized. If this journal receiver is attached to a remote journal, the value for is determined by the local journal.</p> <p>NO Journal entries for data areas have complete entry specific data.</p> <p>YES Journal entries for data areas may have minimized entry specific data.</p> <p>Contains the null value if STATUS is EMPTY.</p>

Table 197. JOURNAL_RECEIVER_INFO view (continued)

Column Name	System Column Name	Data Type	Description
MINIMIZE_ESD_FOR_FILES	MINFILE	VARCHAR(6) Nullable	<p>Whether the entry-specific data for files is minimized. If this journal receiver is attached to a remote journal, the value is determined by the local journal.</p> <p>FLDBDY Journal entries for files may have minimized entry specific data. The minimizing occurs on field boundaries. Therefore, the entry specific data will be viewable and may be used for auditing purposes.</p> <p>NO Journal entries for files have complete entry specific data.</p> <p>YES Journal entries for files may have minimized entry specific data. The minimizing does not occur on field boundaries. Therefore, the entry specific data may not be viewable and may not be used for auditing purposes.</p> <p>Contains the null value if STATUS is EMPTY.</p>
FIXED_LENGTH_DATA_INCLUDES_JOB_NAME	FLDJOB	VARCHAR(3) Nullable	<p>Indicates whether the job name is stored when journal entries are deposited.</p> <p>NO The job name is not stored when journal entries are deposited.</p> <p>YES The job name is stored when journal entries are deposited.</p> <p>Contains the null value if STATUS is EMPTY.</p>
FIXED_LENGTH_DATA_INCLUDES_USER_NAME	FLDUSR	VARCHAR(3) Nullable	<p>Indicates whether the user name is stored when journal entries were deposited.</p> <p>NO The user name is not stored when journal entries are deposited.</p> <p>YES The user name is stored when journal entries are deposited.</p> <p>Contains the null value if STATUS is EMPTY.</p>
FIXED_LENGTH_DATA_INCLUDES_PROGRAM_NAME	FLDPGM	VARCHAR(3) Nullable	<p>Indicates whether the program name is stored when journal entries were deposited.</p> <p>NO The program name is not stored when journal entries are deposited.</p> <p>YES The program name is stored when journal entries are deposited.</p> <p>Contains the null value if STATUS is EMPTY.</p>
FIXED_LENGTH_DATA_INCLUDES_PROGRAM_LIBRARY	FLDPGMLIB	VARCHAR(3) Nullable	<p>Indicates whether the program library name is stored when journal entries were deposited.</p> <p>NO The program library name is not stored when journal entries are deposited.</p> <p>YES The program library name is stored when journal entries are deposited.</p> <p>Contains the null value if STATUS is EMPTY.</p>
FIXED_LENGTH_DATA_INCLUDES_SYSTEM_SEQUENCE_NUMBER	FLDSYSSEQ	VARCHAR(3) Nullable	<p>Indicates whether the system sequence number is stored when journal entries were deposited.</p> <p>NO The system sequence number is not stored when journal entries are deposited.</p> <p>YES The system sequence number is stored when journal entries are deposited.</p> <p>Contains the null value if STATUS is EMPTY.</p>

Table 197. JOURNAL_RECEIVER_INFO view (continued)

Column Name	System Column Name	Data Type	Description
FIXED_LENGTH_DATA_INCLUDES_REMOTE_ADDRESS	FLDRMTADR	VARCHAR(3) Nullable	<p>Indicates whether the remote address is stored when journal entries were deposited.</p> <p>NO The remote address is not stored when journal entries are deposited.</p> <p>YES The remote address is stored when journal entries are deposited.</p> <p>Contains the null value if STATUS is EMPTY.</p>
FIXED_LENGTH_DATA_INCLUDES_THREAD_ID	FLDTHD	VARCHAR(3) Nullable	<p>Indicates whether the thread identifier is stored when journal entries were deposited.</p> <p>NO The thread identifier is not stored when journal entries are deposited.</p> <p>YES The thread identifier is stored when journal entries are deposited.</p> <p>Contains the null value if STATUS is EMPTY.</p>
FIXED_LENGTH_DATA_INCLUDES_LOGICAL_UNIT_OF_WORK_ID	FLDLUW	VARCHAR(3) Nullable	<p>Indicates whether the logical unit of work identifier is stored when journal entries were deposited.</p> <p>NO The logical unit of work identifier is not stored when journal entries are deposited.</p> <p>YES The logical unit of work identifier is stored when journal entries are deposited.</p> <p>Contains the null value if STATUS is EMPTY.</p>
FIXED_LENGTH_DATA_INCLUDES_TRANSACTION_ID	FLDXID	VARCHAR(3) Nullable	<p>Indicates whether the transaction identifier is stored when journal entries were deposited.</p> <p>NO The transaction identifier is not stored when journal entries are deposited.</p> <p>YES The transaction identifier is stored when journal entries are deposited.</p> <p>Contains the null value if STATUS is EMPTY.</p>
PENDING_TRANSACTIONS	PEND_TRANS	VARCHAR(3) Nullable	<p>Whether the journal receiver contains journal entries for commitment control transactions that have not yet been committed or rolled back.</p> <p>NO The journal receiver does not contain entries for pending commitment control transactions.</p> <p>YES The journal receiver contains entries for pending commitment control transactions.</p> <p>Contains the null value if STATUS is EMPTY or the journal receiver was attached to a remote journal.</p>
REMOTE_JOURNAL_TYPE	RMT_TYPE	VARCHAR(6) Nullable	<p>If this journal receiver was attached to a remote journal, this is the remote journal type for that journal when this journal receiver was attached. Values are *TYPE1 and *TYPE2.</p> <p>Contains the null value if the journal receiver was not attached to a remote journal.</p>
LOCAL_JOURNAL_SYSTEM	LCLJRNSYS	VARCHAR(8) Nullable	<p>The system name of the local journal. The local journal is the journal that is the initiator of the original journal deposit that has been replicated downstream to this journal.</p> <p>Contains the null value if the journal receiver was not attached to a remote journal.</p>
LOCAL_JOURNAL_LIBRARY	LCLJRNLIB	VARCHAR(10) Nullable	<p>The library name of the local journal.</p> <p>Contains the null value if the journal receiver was not attached to a remote journal.</p>

Table 197. JOURNAL_RECEIVER_INFO view (continued)

Column Name	System Column Name	Data Type	Description
LOCAL_JOURNAL_NAME	LCLJRNAME	VARCHAR(10) Nullable	The name of the local journal. The local journal is the journal that is the initiator of the original journal deposit that has been replicated downstream to this journal. Contains the null value if the journal receiver was not attached to a remote journal.
LOCAL_JOURNAL_ASP_GROUP	LCLASPGRP	VARCHAR(10) Nullable	The independent auxiliary storage pool (IASP) group of the local journal. Contains the null value if the journal receiver was not attached to a remote journal.
LOCAL_JOURNAL_RECEIVER_LIBRARY	LCLRCVLIB	VARCHAR(10) Nullable	The library name of the journal receiver that is associated with the local journal. Contains the null value if the journal receiver was not attached to a remote journal.
SOURCE_JOURNAL_SYSTEM	SRCJRNSYS	VARCHAR(8) Nullable	The system name of the source journal. Contains the null value if the journal receiver was not attached to a remote journal.
SOURCE_JOURNAL_LIBRARY	SRCJRNLIB	VARCHAR(10) Nullable	The library name of the source journal. Contains the null value if the journal receiver was not attached to a remote journal.
SOURCE_JOURNAL_NAME	SRCJRNAME	VARCHAR(10) Nullable	The name of the source journal. The source journal is the journal that is directly upstream of this remote journal. Contains the null value if the journal receiver was not attached to a remote journal.
SOURCE_JOURNAL_ASP_GROUP	SRCASPGRP	VARCHAR(10) Nullable	The independent auxiliary storage pool (IASP) group of the source journal. Contains the null value if the journal receiver was not attached to a remote journal.
SOURCE_JOURNAL_RECEIVER_LIBRARY	SRCRCVLIB	VARCHAR(10) Nullable	The library name of the journal receiver that is associated with the source journal. Contains the null value if the journal receiver was not attached to a remote journal.
REDIRECTED_RECEIVER_LIBRARY	REDIR_LIB	VARCHAR(10) Nullable	The *TYPE1 receiver library redirection that was in effect when this journal receiver was attached. Contains the null value if the journal receiver was not attached to a remote journal or REMOTE_JOURNAL_TYPE is not *TYPE1.
FILTER_BY_OBJECT	FTR_OBJECT	VARCHAR(4) Nullable	Specifies whether journal entries sent to the remote journal will be filtered by object. *NO Journal entries sent to the remote journal will not be filtered by object. *YES Journal entries deposited for objects that indicated remote journal filtering at the time they were deposited will not be sent to the remote journal. Contains the null value if the journal receiver was not attached to a remote journal.
FILTER_IMAGES	FTR_IMAGE	VARCHAR(7) Nullable	Specifies whether before images will be sent to the remote journal. *NONE All journal entries will be sent to the remote journal, unless they are filtered by the Filter by object or Filter by program specifications. *BEFORE Before images will not be sent to the remote journal. Contains the null value if the journal receiver was not attached to a remote journal.

Table 197. JOURNAL_RECEIVER_INFO view (continued)

Column Name	System Column Name	Data Type	Description
FILTER_PROGRAMS	FTR_PGM	INTEGER Nullable	The number of programs for which journal entries sent on behalf of these programs were filtered when sent to this journal receiver. These programs are listed in the FILTER_PROGRAM_ARRAY and FILTER_PROGRAM_JSON columns. Contains the null value if the journal receiver was not attached to a remote journal.
FILTER_PROGRAM_ARRAY	FTR_ARRAY	VARCHAR(219) Nullable	An array of up to 20 names of 22 characters apiece. The first 10 of each is a program name, followed by a blank, followed by 10 characters for the program library name. One comma separates the entries. The program library name can be *ALL. Journal entries sent on behalf of these programs will not be sent to the remote journal. Contains the null value if the journal receiver was not attached to a remote journal or FILTER_PROGRAMS is zero.
FILTER_PROGRAM_JSON	FTR_LISTJ	VARCHAR(498) CCSID 1208 Nullable	A list of programs and libraries. Journal entries sent on behalf of these programs were filtered when sent to this journal receiver. The program's library name may be *ALL. This list is returned as an array within a JSON object. Each entry in the JSON array contains two JSON objects: <ul style="list-style-type: none"> • An object with a name of "LIBRARY" and a value of the library name containing the program • An object with a name of "PROGRAM" and a value of the program name Contains the null value if the journal receiver was not attached to a remote journal or FILTER_PROGRAMS is zero.

Examples

- Return a list of journal receivers that have not been saved.

```
SELECT JOURNAL_RECEIVER_LIBRARY, JOURNAL_RECEIVER_NAME, STATUS
FROM QSYS2.JOURNAL_RECEIVER_INFO
WHERE STATUS = 'ONLINE';
```

- Return the length of time, in seconds, that journal receivers in RCVLIB were attached.

```
SELECT JOURNAL_RECEIVER_LIBRARY, JOURNAL_RECEIVER_NAME, TIMESTAMPDIF (SECOND,
DETACH_TIMESTAMP, ATTACH_TIMESTAMP), SIZE
FROM QSYS2.JOURNAL_RECEIVER_INFO
WHERE DETACH_TIMESTAMP IS NOT NULL AND
JOURNAL_RECEIVER_LIBRARY = 'RCVLIB';
```

- Return a list of programs contained in the FILTER_PROGRAMS_JSON column related to journal receiver RCV1 in RCVLIB.

```
SELECT j.*, r.*
FROM QSYS2.JOURNAL_RECEIVER_INFO r,
JSON_TABLE(FILTER_PROGRAM_JSON, 'lax $.PROGRAM_LIST'
COLUMNS(LIBRARY VARCHAR(10),
PROGRAM VARCHAR(10))) j
WHERE JOURNAL_RECEIVER_LIBRARY = 'RCVLIB' AND JOURNAL_RECEIVER_NAME = 'RCV1';
```

JOURNALED_OBJECTS view

The JOURNALED_OBJECTS view returns information about journaled objects. Only information about external objects is returned. Internal objects such as commit blocks and access paths are not included.

The values returned for the columns in the view are closely related to the values returned by the Retrieve Journal Information (QjoRetrieveJournalInformation) API and the Work with Journal Attributes (WRKJRNA) CL command.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the journal, and
- *OBJOPR authority and some data authority other than *EXECUTE to the journal.

The following table describes the columns in the view. The system name is JRN_OBJC. The schema is QSYS2.

Table 198. JOURNALED_OBJECTS view

Column Name	System Column Name	Data Type	Description
JOURNAL_LIBRARY	JRNLIB	VARCHAR(10)	The name of the library that contains the journal.
JOURNAL_NAME	JRNNAME	VARCHAR(10)	The name of the journal.
IASP_NUMBER	IASPNUMBER	INTEGER	The number of the auxiliary storage pool to which storage for the journal is allocated. 1 indicates the system ASP.
IASP_NAME	IASP_NAME	VARCHAR(10)	The device description name of the independent auxiliary storage pool (IASP). The special value of *SYSBAS indicates SYSBASE, which includes the system ASP (ASP 1) and the basic user ASPs (ASPs 2-32).
OBJECT_TYPE	OBJ_TYPE	VARCHAR(7)	Type of object. *DIR Directory *DTAARA Data area *DTAQ Data queue *FILE Database file *JRNRCV Journal receiver *LIB Library *STMF Stream file *SYMLNK Symbolic link
OBJECT_LIBRARY	OBJ_LIB	VARCHAR(10) Nullable	The name of the library that contains the object. Contains the null value if OBJECT_TYPE is *DIR, *STMF, or *SYMLNK.
OBJECT_NAME	OBJ_NAME	VARCHAR(10) Nullable	The name of the object. Contains the null value if OBJECT_TYPE is *DIR, *STMF, or *SYMLNK.
FILE_TYPE	FILE_TYPE	VARCHAR(8) Nullable	The type of file that is journaled. LOGICAL Logical file PHYSICAL Physical file Contains the null value if OBJECT_TYPE is not *FILE.
PATH_NAME	PATH_NAME	DBCLOB(16M) CCSID 1200 Nullable	The path name of an integrated file system object. Contains the null value if OBJECT_TYPE is not *DIR, *STMF, or *SYMLNK.
FILE_IDENTIFIER	FILE_ID	BINARY(16) Nullable	The identifier associated with the integrated file system object. Contains the null value if OBJECT_TYPE is not *DIR, *STMF, or *SYMLNK.

Table 198. JOURNALED_OBJECTS view (continued)

Column Name	System Column Name	Data Type	Description
JOURNAL_IMAGES	IMAGES	VARCHAR(6) Nullable	<p>Specifies the kinds of images written to the journal for this object.</p> <p>*AFTER Only after images are written to the journal.</p> <p>*BOTH Both before and after images are written to the journal.</p> <p>Contains the null value if OBJECT_TYPE is *JRNRCV.</p>
OMIT_JOURNAL_ENTRY	OMIT_ENTRY	VARCHAR(10) Nullable	<p>Specifies the journal entries that are omitted.</p> <p>*NONE No entries are omitted.</p> <p>*OPNCLO Open and close entries are omitted. Open and close operations on the specified file members do not create open and close journal entries. Using this option prevents the use of TOJOB0 and TOJOB C entries on the Apply Journalized Changes (APYJRNCHG) and Remove Journalized Changes (RMVJRNCHG) commands, but it saves some storage space in the attached receivers.</p> <p>*OPNCLOSYN Open, close, and force entries are omitted. Open, close, and force operations on the specified objects do not generate open, close and force journal entries. Using this option prevents the use of TOJOB0 and TOJOB C entries on the Apply Journalized Changes (APYJRNCHG) command, but it saves some storage space in the journal receivers.</p> <p>Contains the null value if OBJECT_TYPE is *JRNRCV.</p>
INHERIT	INHERIT	VARCHAR(4) Nullable	<p>Specifies whether new objects created within this journalized directory or library, moved into this journalized directory or library, or restored into this journalized directory or library should inherit the journal state of the parent directory or library.</p> <p>*NO New objects will not inherit the journal state of the parent.</p> <p>*YES New objects will inherit the journal state of the parent.</p> <p>Contains the null value if OBJECT_TYPE is not *DIR or *LIB.</p>
REMOTE_JOURNAL_FILTER	RMT_FILTER	VARCHAR(4) Nullable	<p>Specifies whether the journal entries deposited for objects that inherit the journal state of the directory or library are eligible for remote journal filtering by object.</p> <p>*NO Journal entries deposited for objects will not be eligible for remote journal filtering by object.</p> <p>*YES Journal entries deposited for objects will be eligible for remote journal filtering by object. When using remote journal filtering by object, journal entries for the object will not be sent to the target system.</p> <p>Contains the null value if OBJECT_TYPE is *JRNRCV.</p>

Example

- Review all the objects journaled to APPLIB/APPJRN.

```
SELECT *
FROM QSYS2.JOURNALED_OBJECTS
WHERE OBJECT_LIBRARY = 'APPLIB' AND JOURNAL_NAME = 'APPJRN'
ORDER BY OBJECT_TYPE, OBJECT_LIBRARY, OBJECT_NAME, PATH_NAME;
```

MANAGE_AUDIT_JOURNAL_DATA_MART procedure

The MANAGE_AUDIT_JOURNAL_DATA_MART procedure populates a table with audit journal data for a specific audit journal entry type from a specified time period, or deletes an existing data mart table.

The table is created in the specified library with the name AUDIT_JOURNAL_XX where XX corresponds to the specified audit journal entry type. For example, when creating a data mart for the PW (Password) audit journal entry, a table named AUDIT_JOURNAL_PW is created. The procedure uses “Audit journal entry services” on page 664 to populate the table. The result of the call to the procedure, including any failure message, is returned by the QSYS2.AUDIT_JOURNAL_DATA_MART_INFO view.

Authorization:

To call this procedure when *data-mart-action* is ADD, the caller must have:

- *AUDIT special authority
- *USE authority to the library that contains the audit journal data mart
- *OBJOPR, *READ, and *ADD authority to the AUDIT_JOURNAL_XX table
- *USE and *OBJEXIST authority to the audit journal
- *USE authority to all requested journal receivers

To call this procedure when *data-mart-action* is CREATE, the caller must have:

- *AUDIT special authority.
- *OBJOPR, *READ, *ADD, and *EXECUTE authority to the library that contains the audit journal data mart
- *USE and *OBJEXIST authority to the audit journal
- *USE authority to all requested journal receivers

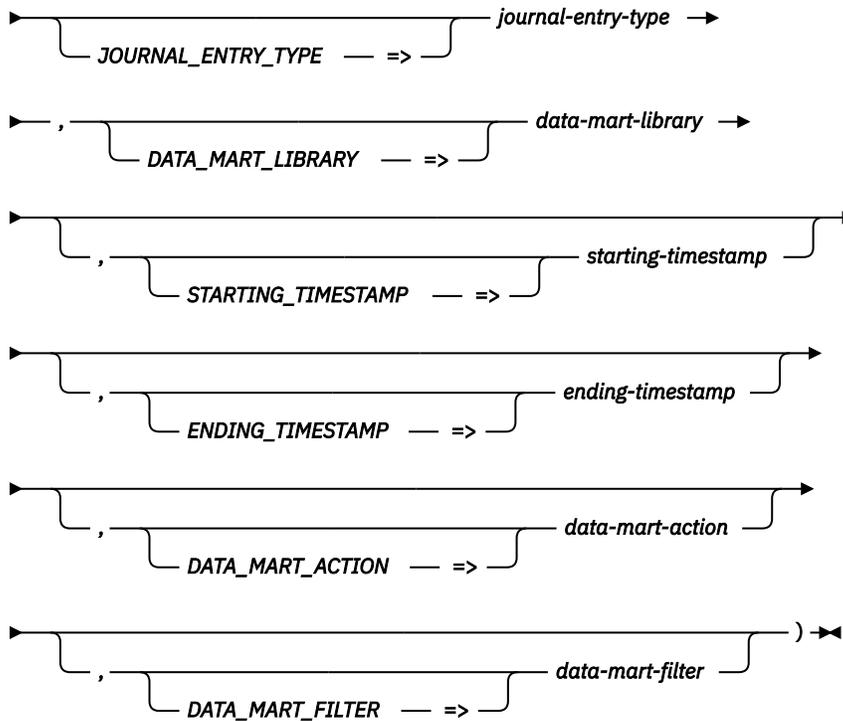

To call this procedure when *data-mart-action* is DROP, the caller must have:

- *AUDIT special authority
- *USE authority to the library that contains the audit journal data mart
- *OBJOPR and *OBJEXIST authority to the AUDIT_JOURNAL_XX table

To call this procedure when *data-mart-action* is REPLACE, the caller must have:

- *AUDIT special authority
- *OBJOPR, *READ, *ADD, and *EXECUTE authority to the library that will contain the audit journal data mart
- *OBJOPR, *OBJMGT, *OBJEXIST, *READ, *ADD, and *DLT authority to the AUDIT_JOURNAL_XX table
- *USE and *OBJEXIST authority to the audit journal
- *USE authority to all requested journal receivers

➤➤ `MANAGE_AUDIT_JOURNAL_DATA_MART` (→

The schema is QSYS2.

journal-entry-type

A character or graphic string expression that identifies the journal entry type to include in the data mart. Only journal entry types that have corresponding “[Audit journal entry services](#)” on page 664 are supported.

data-mart-library

A character or graphic string expression that identifies the library that contains the data mart table or where the data mart table is to be created.
data-mart-library must exist.

starting-timestamp

A character or graphic string expression that identifies the starting timestamp to use. If no timestamp is provided,

- *CONTINUE is used when *data-mart-action* is ADD.
- *FIRST is used when *data-mart-action* is CREATE or REPLACE.
- *starting-timestamp* will be ignored when *data-mart-action* is DROP.

***CONTINUE** A timestamp just after the last value for ENTRY_TIMESTAMP in the AUDIT_JOURNAL_xx table is used.

***FIRST** The attach time for the oldest, attached journal receiver is used.

ending-timestamp

A timestamp value that specifies the ending timestamp to use. If no timestamp is provided,

- the current timestamp will be used when *data-mart-action* is ADD, CREATE, or REPLACE.
- *ending-timestamp* will be ignored when *data-mart-action* is DROP.

data-mart-action

A character or graphic string expression that indicates the type of action to perform. If no string is provided, CREATE is used.

- ADD** Inserts data into an existing data mart table and adds an entry for this *data-mart-library* and *journal-entry-type* to the AUDIT_JOURNAL_DATA_MART_INFO table. It uses the value of *data-mart-filter* that was specified when the *data-mart-action* of CREATE or REPLACE was run.
If the table does not exist, an error is returned.
- CREATE** Creates and populates a new data mart table and adds an entry for this *data-mart-library* and *journal-entry-type* to the AUDIT_JOURNAL_DATA_MART_INFO table.
If the table exists, an error is returned.
- DROP** Deletes the data mart table and removes the corresponding entry from the AUDIT_JOURNAL_DATA_MART_INFO table.
If the table does not exist, an error is returned. If there is an entry in the AUDIT_JOURNAL_DATA_MART_INFO table, it is removed.
- REPLACE** Creates and populates a new data mart table and adds an entry for this *data-mart-library* and *journal-entry-type* to the AUDIT_JOURNAL_DATA_MART_INFO table.
If the table exists, the current rows will be deleted.
If the table does not exist, it is created.

data-mart-filter A character or graphic string expression up to 1000 characters long that limits the rows added to the data mart table. The string must consist of one or more predicates that will be appended to the SQL request to return data from the AUDIT_JOURNAL_XX table function. The predicate string is not validated in any way. If it is incorrect, an SQL syntax error will be returned. Columns referenced in the predicate must exist as return columns from the AUDIT_JOURNAL_XX table function.
If this parameter is omitted all information for the audit journal type with timestamps in the specified timestamp range will be added to the data mart table.
This parameter is ignored when *data-mart-action* is ADD or DROP.

Notes

The resulting AUDIT_JOURNAL_XX table will have the same format as the corresponding “Audit journal entry services” on page 664 table function. The table is owned by the caller who first creates the table and *PUBLIC is configured with *EXCLUDE authority. The system name of the table is AJ_XX. The table is not managed by the system. It is up to the user to grant access to other users and to maintain the table.

To view an AUDIT_JOURNAL_XX table, the caller must have:

- *USE authority to the library that contains the AUDIT_JOURNAL_XX table.
- *OBJOPR and *READ authority to the AUDIT_JOURNAL_XX table.

Examples

- Build a data mart for PW audit journal entries from the last month in the DMARTLIB library.

```
CALL QSYS2.MANAGE_AUDIT_JOURNAL_DATA_MART(JOURNAL_ENTRY_TYPE => 'PW',
                                           DATA_MART_LIBRARY => 'DMARTLIB',
                                           STARTING_TIMESTAMP => CURRENT DATE - 1 MONTH,
                                           ENDING_TIMESTAMP => CURRENT_TIMESTAMP);
```

- Build a data mart for AF audit journal entries from the last month in the DMARTLIB library. Only include A (not authorized to object) entries that are for objects not in a library that starts with Q.

```
CALL QSYS2.MANAGE_AUDIT_JOURNAL_DATA_MART(JOURNAL_ENTRY_TYPE => 'AF',
                                           DATA_MART_LIBRARY => 'DMARTLIB',
                                           STARTING_TIMESTAMP => CURRENT DATE - 1 MONTH,
```

```

        ENDING_TIMESTAMP => CURRENT_TIMESTAMP,
        DATA_MART_FILTER => 'VIOLATION_TYPE = 'A' AND OBJECT_LIBRARY NOT
LIKE 'Q%'');

```

- Add journal data for PW entries to the existing data mart in DMARTLIB.

```

CALL QSYS2.MANAGE_AUDIT_JOURNAL_DATA_MART(JOURNAL_ENTRY_TYPE => 'PW',
        DATA_MART_LIBRARY => 'DMARTLIB',
        STARTING_TIMESTAMP => '*CONTINUE',
        ENDING_TIMESTAMP => CURRENT_TIMESTAMP,
        DATA_MART_ACTION => 'ADD'
);

```

- Drop the DMARTLIB.AUDIT_JOURNAL_PW table.

```

CALL QSYS2.MANAGE_AUDIT_JOURNAL_DATA_MART(JOURNAL_ENTRY_TYPE => 'PW',
        DATA_MART_LIBRARY => 'DMARTLIB',
        DATA_MART_ACTION => 'DROP'
);

```

REMOTE_JOURNAL_INFO view

The REMOTE_JOURNAL_INFO view returns information about every remote journal defined for a local or remote journal on the IBM i where this view is referenced. The remote journals returned by this service exist on a different IBM i, as noted by the remote database (RDB) name.

This information is similar to what is returned by the Retrieve Journal Information (QjoRetrieveJournalInformation) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the journal, and
- *OBJOPR authority and some data authority other than *EXECUTE to the journal.

The following table describes the columns in the view. The system name is RMT_JRNS. The schema is QSYS2.

Table 199. REMOTE_JOURNAL_INFO view

Column Name	System Column Name	Data Type	Description
SOURCE_JOURNAL_LIBRARY	SRC_JRNLIB	VARCHAR(10)	The library that contains SOURCE_JOURNAL.
SOURCE_JOURNAL	SRC_JRN	VARCHAR(10)	The name of the journal that has the remote journal defined.
REMOTE_DATABASE_NAME	RMT_RDB	VARCHAR(18)	The name of the remote database that is the target and contains the remote journal.
REMOTE_JOURNAL_LIBRARY	RMT_JRNLIB	VARCHAR(10)	The library that contains REMOTE_JOURNAL.
REMOTE_JOURNAL	RMT_JRN	VARCHAR(10)	The name of the remote journal that is the target for remote journaling.
REMOTE_JOURNAL_RECEIVER_LIBRARY	RMT_RCVLIB	VARCHAR(10)	The library name of the remote journal receiver that is the target for remote journaling. The special value of *SRCRCVLIB indicates the journal receivers are created on the target system in the same library as they exist on the source system.

Table 199. REMOTE_JOURNAL_INFO view (continued)

Column Name	System Column Name	Data Type	Description
REMOTE_JOURNAL_STATE	RMT_STATE	VARCHAR(8)	<p>The state of the remote journaling.</p> <p>ACTIVE The remote journal is ready to receive any journal entries from its source journal.</p> <p>CTLINACT The remote journal is in the process of a controlled inactivate. Therefore, the remote journal will be receiving those journal entries that were already queued for replication when the Change Remote Journal (CHGRMTJRN) command or the Change Journal State (QjoChangeJournalState) API requested to inactivate the remote journal. However, no entries deposited after that request will be replicated to the remote journal.</p> <p>FAILED The remote journal is not ready to receive any journal entries from its source journal due to a remote journal function failure, for example, a communications failure. You will need to inactivate the remote journal by using the Change Remote Journal (CHGRMTJRN) command or by calling the Change Journal State (QjoChangeJournalState) API.</p> <p>INACTIVE The remote journal is not ready to receive any journal entries from its source journal.</p> <p>PENDING The remote journal is transitioning from an INACTIVE state to an ACTIVE state.</p>
REMOTE_JOURNAL_TYPE	RMT_JTYPE	VARCHAR(6)	<p>The type of remote journal that was created. The type influences characteristics of the remote journal such as journal receiver restore options, redirection capabilities, and remote journal association support.</p> <p>*TYPE1 Type 1 remote journal</p> <p>*TYPE2 Type 2 remote journal</p>
DELIVERY_MODE	DELIVERY	VARCHAR(10) Nullable	<p>The remote journal delivery mode that is being used to replicate journal entries to the remote journal.</p> <p>*ASYNC Journal entries are being delivered or replicated asynchronously.</p> <p>*ASYNCPEND Journal entries are to be delivered or replicated asynchronously, but the remote journal is currently in catch-up mode.</p> <p>*SYNC Journal entries are being delivered or replicated synchronously.</p> <p>*SYNCPEND Journal entries are to be delivered or replicated synchronously, but the remote journal is currently in catch-up mode.</p> <p>Contains the null value if REMOTE_JOURNAL_STATE is not ACTIVE or CTLINACT.</p>

Table 199. REMOTE_JOURNAL_INFO view (continued)

Column Name	System Column Name	Data Type	Description
DATA_PORT_SERVICES_NODE_ID	NODE_ID	VARCHAR(8) Nullable	The node identifier being used by data port services to identify the target system in a cluster environment. If a node identifier and at least one internet address is retrieved, then data port services is being used as an alternate communication method to the target system. Contains the null value if the remote journal is not configured for data port services.
DATA_PORT_SERVICES_ADDRESS_1	IP_ADDR1	VARCHAR(45) Nullable	The first internet address being used by data port services to communicate to the target system. Contains the null value if the remote journal is not configured for data port services.
DATA_PORT_SERVICES_ADDRESS_2	IP_ADDR2	VARCHAR(45) Nullable	The second internet address being used by data port services to communicate to the target system. Contains the null value if the remote journal is not configured for data port services or there are less than two internet addresses being used.
DATA_PORT_SERVICES_ADDRESS_3	IP_ADDR3	VARCHAR(45) Nullable	The third internet address being used by data port services to communicate to the target system. Contains the null value if the remote journal is not configured for data port services or there are less than three internet addresses being used.
DATA_PORT_SERVICES_ADDRESS_4	IP_ADDR4	VARCHAR(45) Nullable	The fourth internet address being used by data port services to communicate to the target system. Contains the null value if the remote journal is not configured for data port services or there are less than four internet addresses being used.
VALIDITY_CHECKING	VALID_CHK	VARCHAR(9) Nullable	The validity checking status. When communications validity checking is turned on, the remote journal environment provides additional checking to verify that the data which is received by the target system matches the data that was sent from the source system. If the data does not match, the data will not be written to the target system, the remote journal environment will be inactivated, and messages indicating the communications failure will be issued to the journal message queue and QHST. *DISABLED Communications validity checking is turned off for this remote journal environment. *ENABLED Communications validity checking is turned on for this remote journal environment. Contains the null value if REMOTE_JOURNAL_STATE is not ACTIVE or CTLINACT.
SENDING_TASK_PRIORITY	PRIORITY	INTEGER Nullable	The priority of the sending task on the source system. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE or DELIVERY_MODE is not *ASYNC or *ASYNCPEND.
SYNCHRONOUS_SENDING_TIME_OUT	TIME_OUT	INTEGER Nullable	The maximum amount of time, in seconds, to wait for a response from the remote system when a response is required in a synchronous remote journal environment. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE or DELIVERY_MODE is not *SYNC or *SYNCPEND.

Table 199. REMOTE_JOURNAL_INFO view (continued)

Column Name	System Column Name	Data Type	Description
MAXIMUM_RESTART_ATTEMPTS	MAXRESTART	INTEGER Nullable	The number of times the operating system will attempt to reactivate the remote journal after a recoverable failure. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE.
RESTART_DELAY_TIME	RESTARTDLY	INTEGER Nullable	The number of seconds between attempts to reactivate the remote journal after a recoverable failure. Contains the null value if MAXIMUM_RESTART_ATTEMPTS is null or 0.
FILTER_BY_OBJECT	FTR_OBJECT	VARCHAR(4) Nullable	Specifies whether journal entries sent to the remote journal will be filtered by object. *NO Journal entries sent to the remote journal will not be filtered by object. *YES Journal entries deposited for objects that indicated remote journal filtering at the time they were deposited will not be sent to the remote journal. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE.
FILTER_IMAGES	FTR_IMAGE	VARCHAR(7) Nullable	Specifies whether before images will be sent to the remote journal. *NONE All journal entries will be sent to the remote journal, unless they are filtered by the Filter by object or Filter by program specifications. *BEFORE Before images will not be sent to the remote journal. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE.
FILTER_PROGRAMS	FTR_PGM	INTEGER Nullable	The number of programs returned in FILTER_PROGRAM_ARRAY. Journal entries sent on behalf of these programs will not be sent to the remote journal. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE.
FILTER_PROGRAM_ARRAY	FTR_ARRAY	VARCHAR(219) Nullable	An array of up to 20 names of 22 characters each. The first 10 of each is a program name, followed by a blank, followed by 10 characters for the program library name. One comma separates the entries. The program library name can be *ALL. Journal entries sent on behalf of these programs will not be sent to the remote journal. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE or FILTER_PROGRAMS is zero.
FILTER_PROGRAM_JSON	FTR_LISTJ	VARCHAR(498) CCSID 1208 Nullable	A list of programs and libraries. Journal entries sent on behalf of these programs were filtered when sent to this journal receiver. The program's library name may be *ALL. This list is returned as an array within a JSON object. Each entry in the JSON array contains two JSON objects: <ul style="list-style-type: none"> An object with a name of "LIBRARY" and a value of the library name containing the program An object with a name of "PROGRAM" and a value of the program name Contains the null value if the journal receiver was not attached to a remote journal or FILTER_PROGRAMS is zero.

Table 199. REMOTE_JOURNAL_INFO view (continued)

Column Name	System Column Name	Data Type	Description
BUNDLES_SENT	BUNDLES	BIGINT Nullable	The number of bundles that have been sent to the target system since the source journal transitioned to an active state. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE.
MAXIMUM_BUNDLE_SIZE	BUNDLE_SIZ	BIGINT Nullable	The number of bytes in the largest bundle that has been sent to the target system since the source journal transitioned to an active state. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE.
MAXIMUM_BUNDLE_SIZE_TIME	BUNDLE_TIM	TIMESTAMP Nullable	The date and time that the maximum bundle size was sent to the target system. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE or MAXIMUM_BUNDLE_SIZE is 0.
SUPER_BUNDLE_MODE_COUNT	SUPER_CNT	BIGINT Nullable	The number of times that the remote journal environment has automatically gone into super bundling mode. Super bundling mode helps the remote journal environment keep up with the local journal when the local journal has a high rate of journal entry deposits. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE or DELIVERY_MODE is not *ASYNC or *ASYNCPEND.
ENTRIES_BEHIND	BEHIND	BIGINT Nullable	The number of entries that are waiting to be sent to the target system. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE or DELIVERY_MODE is not *ASYNC or *ASYNCPEND.
MAXIMUM_ENTRIES_BEHIND	MBEHIND	BIGINT Nullable	The maximum number of entries that were waiting to be sent to the target system since the source journal transitioned to an active state. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE or DELIVERY_MODE is not *ASYNC or *ASYNCPEND.
MAXIMUM_ENTRIES_BEHIND_TIME	MBEHINDT	TIMESTAMP Nullable	The date and time that MAXIMUM_ENTRIES_BEHIND occurred. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE or DELIVERY_MODE is not *ASYNC or *ASYNCPEND or MAXIMUM_ENTRIES_BEHIND is 0.
TIME_BEHIND	TBEHIND	BIGINT Nullable	The value, in hundredths of seconds, that the source journal is behind in sending journal entries to the target system. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE or DELIVERY_MODE is not *ASYNC or *ASYNCPEND.
MAXIMUM_TIME_BEHIND	MTBEHIND	BIGINT Nullable	The maximum value, in hundredths of seconds, that the source journal was behind in sending journal entries to the target system. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE or DELIVERY_MODE is not *ASYNC or *ASYNCPEND.
MAXIMUM_TIME_BEHIND_TIME	MTBEHINDT	TIMESTAMP Nullable	The date and time that MAXIMUM_TIME_BEHIND occurred. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE or DELIVERY_MODE is not *ASYNC or *ASYNCPEND or MAXIMUM_TIME_BEHIND is 0.

Table 199. REMOTE_JOURNAL_INFO view (continued)

Column Name	System Column Name	Data Type	Description
RETRANSMISSIONS	RETRANS	BIGINT Nullable	The total number of times the local system retransmitted a segment because an acknowledgement was not received. This is a cumulative count of all segments resent since the remote journal was last activated. A value greater than zero may indicate a problem with the network. Contains the null value if this information is not available
LAST_CATCHUP_TIME	LAST_CATCH	TIMESTAMP Nullable	The date and time that the remote journal environment last transitioned to DELIVERY_MODE *ASYNCPEND or *SYNCPEND. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE.
LAST_ACTIVE_TIME	LAST_ACT	TIMESTAMP Nullable	The date and time that the remote journal environment last transitioned from DELIVERY_MODE *ASYNCPEND or *SYNCPEND to DELIVERY_MODE *ASYNCPEND or *SYNCPEND. Contains the null value if REMOTE_JOURNAL_STATE is INACTIVE
CONTROLLED_INACTIVATE_SEQUENCE_NUMBER	INACT_SEQ	DECIMAL(21,0) Nullable	The sequence number of the last journal entry that was queued for replication before the Change Remote Journal (CHGRMTJRN) command or the Change Journal State (QjoChangeJournalState) API was called to start a controlled inactivate of the remote journal. Contains the null value if REMOTE_JOURNAL_STATE is not CTLINACT.
CONTROLLED_INACTIVATE_JOURNAL_RECEIVER_LIBRARY	INACTJRCVL	VARCHAR(10) Nullable	The library of the journal receiver that contains the CONTROLLED_INACTIVATE_SEQUENCE_NUMBER. Contains the null value if REMOTE_JOURNAL_STATE is not CTLINACT.
CONTROLLED_INACTIVATE_JOURNAL_RECEIVER	INACTJRCV	VARCHAR(10) Nullable	The name of the journal receiver that contains the CONTROLLED_INACTIVATE_SEQUENCE_NUMBER. Contains the null value if REMOTE_JOURNAL_STATE is not CTLINACT.
SOURCE_JOURNAL_IASP_NUMBER	SRC_ASPNUM	INTEGER	The number of the auxiliary storage pool to which storage for the journal that has the remote journal defined is allocated. 1 indicates the system ASP.
SOURCE_JOURNAL_IASP_NAME	SRC_ASPNAM	VARCHAR(10)	The device description name of the independent auxiliary storage pool (IASP). The special value of *SYSBAS indicates SYSBASE, which includes the system ASP (ASP 1) and the basic user ASPs (ASPs 2-32).

Example

- Return information about remote journals defined for system RMTSYS1.

```
SELECT * FROM QSYS2.REMOTE_JOURNAL_INFO
WHERE REMOTE_DATABASE_NAME = 'RMTSYS1';
```

SMAPP_ACCESS_PATHS view

The SMAPP_ACCESS_PATHS view returns a list of access paths which are monitored by System-Managed Access Path Protection (SMAPP).

Some access paths are ineligible for SMAPP protection. See [How the system chooses access paths to protect](#) for more details.

Authorization: The caller must have *JOBCTL special authority.

The following table describes the columns in the view. The system name is SMAPP_AP. The schema is QSYS2.

Table 200. SMAPP_ACCESS_PATHS view

Column Name	System Column Name	Data Type	Description
SYSTEM_TABLE_SCHEMA	LIB_NAME	VARCHAR(10)	The library containing the database file associated with the access path.
SYSTEM_TABLE_NAME	FILE_NAME	VARCHAR(10)	The database file associated with the access path.
ASP_NUMBER	ASPNUMBER	INTEGER	The number of the auxiliary storage pool containing the access path. 1 indicates the system ASP.
IASP_NAME	IASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool containing the access path. The special value of *SYSBAS is returned if ASP_NUMBER is not greater than or equal to 33.
STATUS	STATUS	VARCHAR(11)	The eligibility and protection status of the access path. INELIGIBLE This access path is not eligible to be protected by the system and may need to be rebuilt during an initial program load (IPL) or during the vary on of an independent ASP after an abnormal system end. PROTECTED This access path is protected by the system. UNPROTECTED This access path is not protected by the system and may need to be rebuilt during an initial program load (IPL) or during the vary on of an independent ASP after an abnormal system end.
INELIGIBLE_REASON	INELIG_RSN	VARCHAR(17) Nullable	The reason that the access path is not eligible for access protection. MULTIPLE JOURNALS The access path is built over physical files which are journaled to separate journals. JOURNAL STANDBY The access path is built over a physical file which is journaled to a journal whose journal state is currently *STANDBY. Contains the null value if STATUS is not *INELIGIBLE.
ESTIMATED_RECOVERY	EST_RECOV	BIGINT	The estimated amount of time, in seconds, that the system would take to recover the access path during an initial program load (IPL) or during the vary on of an independent ASP after an abnormal system end if the access path is not chosen for protection.

Example

- List all the access paths in APPLIB that are not currently protected.

```
SELECT * FROM QSYS2.SMAPP_ACCESS_PATHS
WHERE LIB_NAME = 'APPLIB' AND STATUS <> 'PROTECTED'
ORDER BY ESTIMATED_RECOVERY DESC;
```

Librarian Services

These services provide object and library list information.

JOURNAL_INHERIT_RULES view

The JOURNAL_INHERIT_RULES view returns the journal inherit rules for libraries.

The rules define which objects created in a library, moved into a library, or restored into a library should inherit the journal state of the library and the inherited journal attributes.

Each rule defines object types, object names, and operations that the rule applies to. Multiple rules can be defined for the same set of objects. If multiple rules are defined for the same object and operation, the last rule defined for that object will be applied.

This information is similar to the journal inherit rules returned by the Retrieve Library Description (QLIRLIBD) API.

Authorization: The caller must have *READ authority to the library.

The following table describes the columns in the view. The system name is LIB_JRN. The schema is QSYS2.

Table 201. JOURNAL_INHERIT_RULES view

Column Name	System Column Name	Data Type	Description
LIBRARY_NAME	LIBRARY	VARCHAR(10)	The name of the library for this rule.
JOURNALED	JOURNALED	VARCHAR(3)	The current journaling status of the library. Rules are only in effect when the library is journaled. NO The library is not currently journaled. YES The library is currently journaled.
IASP_NUMBER	IASPNUMBER	INTEGER	The number of the auxiliary storage pool (ASP) from which the system allocates storage for the library. 1 indicates the system ASP.
IASP_NAME	IASP_NAME	VARCHAR(10)	The device description name of the independent auxiliary storage pool (IASP). The special value of *SYSBAS indicates SYSBASE, which includes the system ASP (ASP 1) and the basic user ASPs (ASPs 2-32).
ORDINAL_POSITION	ORDINAL	INTEGER	The order this rule was added for this library. The number starts at one for each library and increments by one for every additional rule for that library. If more than one rule is defined for any object, the one with the higher number will be used.
OBJECT_TYPE	TYPE	VARCHAR(7)	Specifies the object type of the objects that are identified by this rule. *ALL This rule applies to all object types that can be journaled. *DTAARA This rule applies to data areas. *DTAQ This rule applies to data queues. *FILE This rule applies to database physical files.

Table 201. JOURNAL_INHERIT_RULES view (continued)

Column Name	System Column Name	Data Type	Description
OPERATION	OPERATION	VARCHAR(10)	<p>The operations performed on the object type for which journaling is to be started if other criteria specified for the object type are also satisfied.</p> <p>*ALLOPR Journaling is started for all objects created in, moved into, or restored into the library. This is a combination of the values *CREATE, *MOVE, and *RESTORE.</p> <p>*CREATE Journaling is started for all objects created in the library.</p> <p>*MOVE Journaling is started for all objects moved into the library if they are not already journaled.</p> <p>*RESTORE If an object is restored over a currently existing object, the restored object will retain the same journal options and journal state of the object it was restored over. If an object was never journaled when it was saved, journaling is started for the object when it is restored into the library. If an object was journaled when it was saved, it will first attempt to start journaling to the journal it was journaled to when it was saved, with the same journal options it had when it was saved. If that journal does not exist, the object will start journaling to the same journal the library is journaled to, with the journal options defined by this rule.</p> <p>*RSTOVRJRN If an object is restored over a currently existing object, the restored object will retain the same journal options and journal state of the object it was restored over. Otherwise, journaling is started for all objects restored into the library, regardless of the journal options and journal state of the object when it was saved.</p>
RULE_ACTION	ACTION	VARCHAR(8)	<p>Indicates whether the objects that match the object type and operation in this rule will be included or omitted from the list of objects that inherit the journal options and journal state of the library.</p> <p>*INCLUDE All objects that match the object type and operation of this rule will inherit the journal options and journal state of the library.</p> <p>*OMIT All objects that match the object type and operation of this rule will not inherit any journaling attributes or state from the library. This overrides a *INCLUDE rule and therefore can be used to omit a subset of a previously defined *INCLUDE rule.</p>
NAME_FILTER	NAMEFILTER	VARCHAR(10) Nullable	<p>The object names of the objects that are identified by this rule.</p> <p>name This rule applies to all objects that match the other criteria and match the specified name.</p> <p>generic-name This rule applies to all objects that match the other criteria and match the specified generic name.</p> <p>A generic name is specified as a string that contains one or more characters followed by an asterisk (*). If a generic name is specified, then all objects that have names with the same prefix as the generic object name are selected.</p> <p>*ALL This rule applies to all objects that match the other criteria.</p>

Table 201. JOURNAL_INHERIT_RULES view (continued)

Column Name	System Column Name	Data Type	Description
JOURNAL_IMAGES	IMAGES	VARCHAR(7) Nullable	<p>The kinds of journal images that are written to the journal receiver for changes to objects that inherit the journal options and journal state from the library.</p> <p>*AFTER Only after images are journaled for an object for which journaling is started because it inherits the journaling attributes from the library.</p> <p>*BOTH Both before and after images are journaled for an object for which journaling is started because it inherits the journal option from the library. This value is only valid for data area (*DTAARA) and database file (*FILE) objects. If this value is specified and *ALL is specified for object type, the system will generate both before and after images for data areas and database files and the system will only generate after images for all other object types.</p> <p>*OBJDFT The default value for each object type will be used for this journal option when an object inherits the journaling attributes from the library. Database files (*FILE) will have both before and after images generated by the system. All other object types will have only after images generated by the system.</p> <p>Contains the null value if RULE_ACTION is *OMIT.</p>
OMIT_JOURNAL_ENTRY	OMIT_ENTRY	VARCHAR(7) Nullable	<p>The journal entries that are not to be written for changes to objects that inherit the journaling options and state of the library.</p> <p>*NONE No journal entries will be omitted for objects that inherit the journal options and journal state from the library.</p> <p>*OBJDFT The default value for each object type will be used for this journal option when an object inherits the journal options and journal state from the library. Open and close entries will be omitted for database files (*FILE). No other object types will omit journal entries.</p> <p>*OPNCLO Open and close entries are omitted for database file (*FILE) objects that inherit the journal options and journal state from the library.</p> <p>This prevents the use of TOJOB0 and TOJOB0C entries on the Apply Journalized Changes (APYJRNCHG) and Remove Journalized Changes (RMVJRNCHG) commands, but it saves some storage space in the journal receivers.</p> <p>This value is only valid for object type *FILE. If this value is specified and *ALL is specified for object type, database files will omit the entries. All other object types will not omit any journal entries.</p> <p>Contains the null value if RULE_ACTION is *OMIT.</p>

Table 201. JOURNAL_INHERIT_RULES view (continued)

Column Name	System Column Name	Data Type	Description
REMOTE_JOURNAL_FILTER	RMT_FILTER	VARCHAR(7) Nullable	Specifies whether the journal entries written for the objects that inherit the journal state of the library should be eligible for remote journal filtering by object. *NO Journal entries deposited for the objects that inherit the journal state of the library will not be eligible for remote journal filtering by object. *OBJDFT The default value for each object type will be used for this journaling attribute when an object inherits the journal state of the library. For all object types, journal entries deposited for the objects that inherit the journal state of the library will not be eligible for remote journal filtering by object. *YES Journal entries deposited for the objects that inherit the journal state of the library will be eligible for remote journal filtering by object. When using remote journal filtering by object, most journal entries for the object will not be sent to the target system.

Example

- Retrieve the journal inherit rules for library APPLIB.

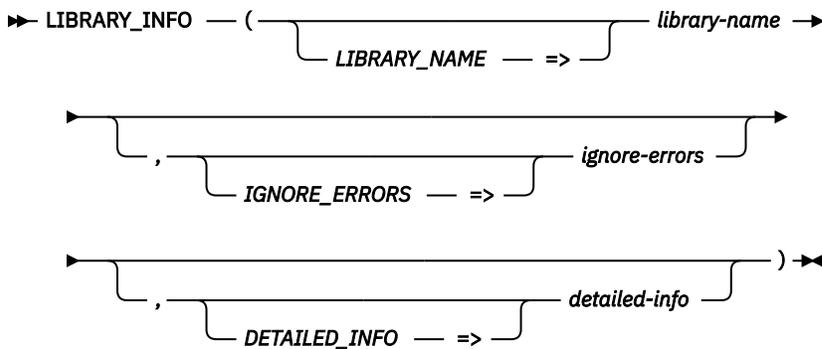

```
SELECT * FROM QSYS2.JOURNAL_INHERIT_RULES
WHERE LIBRARY_NAME = 'APPLIB';
```

LIBRARY_INFO table function

The LIBRARY_INFO table function returns a result table that contains information about a specific library.

This information is similar to what is returned by the Retrieve Library Description (QLIRLIBD) API and the Retrieve Library Description (RTVLIBD) command

Authorization: The caller must have *READ authority to the library. The null value is returned for the OBJECT_AUDIT_CREATE column unless the caller has *ALLOBJ or *AUDIT special authority.

The schema is QSYS2.

library-name An expression that contains the name of a library.

ignore-errors A character or graphic string expression that identifies what to do when an error is encountered.

NO An error is returned.

YES A warning is returned.

No row is returned when an error is encountered. This is the default.

detailed-info A character or graphic string expression that indicates which columns should be returned.

LIBRARY_SIZE All the columns including the LIBRARY_SIZE column are returned. For a library with a large number of objects, LIBRARY_SIZE can be a time consuming calculation. This is the default.

NO Null is returned for the LIBRARY_SIZE column.

The result of the function is a table containing one row with the format shown in the following table. All the columns are nullable.

Table 202. LIBRARY_INFO table function

Column Name	Data Type	Description
OBJECT_COUNT	INTEGER	The total number of external objects in the specified library. The count includes objects to which you may not be authorized.
LIBRARY_SIZE	BIGINT	The size of the library, in bytes, which includes the size of the objects in the library plus the size of the library object itself. This value will be a rounded value for a library larger than 1 000 000 000 bytes. Contains the null value if <i>detailed-info</i> is NO.
LIBRARY_SIZE_COMPLETE	VARCHAR(3)	Whether LIBRARY_SIZE includes all objects in the library. NO Some objects in the library were omitted because they were locked, or the user does not have any authority to the object. YES The size of all the objects in the library was used in determining the total library size. Contains the null value if <i>detailed-info</i> is NO.
LIBRARY_TYPE	CHAR(4)	The library type. PROD The library is a production library. Database files in production libraries cannot be opened for updating if a user, while in debug mode, requested that production libraries be protected. TEST The library is a test library. All objects in a test library can be updated during a test. See the Start Debug (STRDBG) command in the on-line help for more details.
TEXT_DESCRIPTION	VARCHAR(50)	The user-defined text that briefly describes the library and its function. Contains the null value if the library has no descriptive text.
IASP_NAME	VARCHAR(10)	The auxiliary storage pool (ASP) device name where the library is stored. If the library is in the system ASP or one of the basic user ASPs, contains *SYSBAS. Contains the null value if the name of the ASP device cannot be determined.
IASP_NUMBER	INTEGER	The number of the auxiliary storage pool (ASP) from which the system allocates storage for the library. 1 indicates the system ASP.

Table 202. LIBRARY_INFO table function (continued)

Column Name	Data Type	Description
CREATE_AUTHORITY	VARCHAR(10)	<p>The default public authority for an object created into the library. This is the authority given to a user who does not have specific authority to the object, who is not on an authorization list specified for the object, and whose user groups have no specific authority to the object. When you create an object into the library, the AUT parameter on the create command for the object determines the public authority for the object. If the AUT value on the create command for the object is *LIBCRTAUT, which is the default, the public authority for the object is set to the CRTAUT value for the library.</p> <p>*ALL The user can perform all authorized operations on an object created in this library.</p> <p>*CHANGE The user can read the object description and has read, add, update, and delete authority to an object created in this library.</p> <p>*EXCLUDE The user is prevented from accessing an object created in this library.</p> <p>*SYSVAL The default authority for an object created in this library is determined by the value specified by the QCRTAUT system value.</p> <p>*USE The user can read the object and its description but cannot change them for an object created in this library.</p> <p>Authorization list name The name of the authorization list that secures an object created in this library. The default public authority is taken from the authorization list, and the public authority for the object is specified as *AUTL.</p>
OBJECT_AUDIT_CREATE	VARCHAR(7)	<p>The auditing value for objects created in this library.</p> <p>*ALL All change or read access to the object is logged.</p> <p>*CHANGE All change access to the object by all users is logged.</p> <p>*NONE Use or change access to the object is not logged (no audit entry is sent to the security journal).</p> <p>*SYSVAL The value specified in the system value QCRTOBJAUD is used.</p> <p>*USRPRF The user profile of the user who accesses the object is used to determine if an audit record is sent for this access. The OBJAUD parameter of the Change User Auditing (CHGUSRAUD) command is used to turn auditing on for a specific user.</p> <p>Contains the null value if caller does not have either all object (*ALLOBJ) or audit (*AUDIT) special authority.</p>
JOURNALED	VARCHAR(3)	<p>Identifies the current journaling status of the library.</p> <p>NO The library is not currently journaled.</p> <p>YES The library is currently journaled.</p>
JOURNAL_LIBRARY	VARCHAR(10)	<p>The name of the library that contains the journal that receives the journaled changes to the library, if the library is currently journaled. If the library was previously journaled but is not currently journaled, contains the name of the library that contains the last journal to which the library was journaled.</p> <p>Contains the null value if journaling has never been started for this library.</p>
JOURNAL_NAME	VARCHAR(10)	<p>The name of the journal that receives the journaled changes to the library, if the library is currently journaled. If the library was previously journaled but is not currently journaled, contains the name of the last journal to which the library was journaled.</p> <p>Contains the null value if journaling has never been started for this library.</p>

Table 202. LIBRARY_INFO table function (continued)

Column Name	Data Type	Description
INHERIT_JOURNALING	VARCHAR(3)	Identifies whether new journal-eligible objects created into, moved into, or restored into this library should inherit journaling from the library according to the journal inherit rules. NO The new journal-eligible objects will not inherit journaling from the library. YES The new journal-eligible objects will inherit journaling from the library according to the journal inherit rules.
JOURNAL_INHERIT_RULES	INTEGER	The number of inherit rules defined for this library. The rules can be listed using the QSYS2.JOURNAL_INHERIT_RULES view.
JOURNAL_START_TIMESTAMP	TIMESTAMP	The timestamp journaling was last started for this library. Contains the null value if journaling has never been started for this library.
APPLY_STARTING_RECEIVER_LIBRARY	VARCHAR(10)	Specifies the library name of the oldest journal receiver needed to successfully use the Apply Journalized Changes (APYJRNCHG) command. Contains the null value if the object has not been journaled or it has not been saved and restored since journaling was started.
APPLY_STARTING_RECEIVER	VARCHAR(10)	Specifies the name of the oldest journal receiver needed to successfully use the Apply Journalized Changes (APYJRNCHG) command. Contains the null value if the object has not been journaled or it has not been saved and restored since journaling was started.
APPLY_STARTING_RECEIVER_ASP	VARCHAR(10)	The auxiliary storage pool (ASP) device name where APPLY_STARTING_RECEIVER is stored. If APPLY_STARTING_RECEIVER is in the system ASP or one of the basic user ASPs, contains *SYSBAS. Contains the null value if the name of the ASP device cannot be determined.

Example

- Retrieve information about library APPLIB.

```
SELECT * FROM TABLE(QSYS2.LIBRARY_INFO('APPLIB'));
```

LIBRARY_LIST_INFO view

The LIBRARY_LIST_INFO view contains information about the current job's library list.

The information returned is similar to the detail available through the DSPLIBL (Display Library List) CL command.

Authorization: None required.

The following table describes the columns in the view. The system name is LIBLIST. The schema is QSYS2.

Table 203. LIBRARY_LIST_INFO view

Column Name	System Column Name	Data Type	Description
ORDINAL_POSITION	COLNO	INTEGER	Position of this entry in the library list.
SCHEMA_NAME	NAME	VARCHAR(128) Nullable	Name of the schema.
SYSTEM_SCHEMA_NAME	SYS_NAME	VARCHAR(10)	System name of the schema.

Table 203. LIBRARY_LIST_INFO view (continued)

Column Name	System Column Name	Data Type	Description
TYPE	TYPE	VARCHAR(15)	The portion of the library list containing the selected library. Possible values are: USER The library is in the user portion of the library list. SYSTEM The library is in the system portion of the library list. PRODUCT The library is a product library in the library list. CURRENT The library is the current library entry in the library list.
IASP_NUMBER	IASP	SMALLINT Nullable	The number of the auxiliary storage pool where storage is allocated for the library. 0 indicates the system ASP.
TEXT_DESCRIPTION	TEXT	VARGRAPHIC(50) CCSID 1200 Nullable	The text description of the library. Contains the null value if there is no text description.

Example

- See the current library list for your job

```
SELECT * FROM QSYS2.LIBRARY_LIST_INFO
```

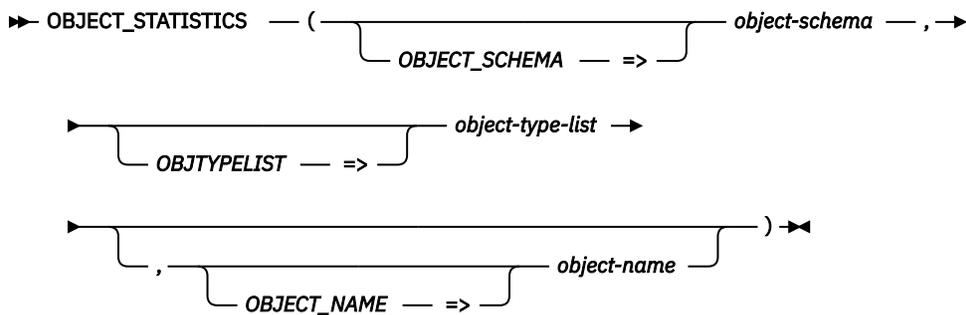

OBJECT_STATISTICS table function

The OBJECT_STATISTICS table function returns information about objects in a library.

Authorization:

- For an object that is not a user profile:
 - If the caller has *EXECUTE authority to the library,
 - If the caller has *OBJOPR and *READ authority to an object, full details are returned.
 - Otherwise, partial information is returned along with an SQL warning of '01548'.
 Otherwise, the object information is not returned.
- For a user profile object:
 - The caller must have at least one of the following:
 - Some authority to the user profile, or
 - Authorization to the QIBM_DB_SECADM function usage identifier.
 Otherwise, the user profile object information is not returned.

The caller must have *ALLOBJ or *AUDIT special authority to return values for the OBJECT_AUDIT column.

The schema is QSYS2.

object-schema A character or graphic string expression that identifies the name of a library. If the library's name is a delimited name, the delimited form of the name must be specified. It can be either a long or short library name.

The following special values are allowed for *object-schema*.

- *ALL** All libraries.
- *ALLAVL** All libraries in all available ASPs.
- *ALLUSR** All user libraries in *SYSBAS and the current thread's ASP group.
- *ALLUSRAVL** All user libraries in all available ASPs.
- *CURLIB** The job's current library.
- *LIBL** The library list.
- *USRLIBL** The job's current library and the user portion of the library list.

The following special value is allowed for *object-schema* when *object-type-list* is '*LIB' or 'LIB'.

- *ALLSIMPLE** The fastest approach to retrieving all user and system library names in *SYSBAS and the current thread's ASP group. Values are returned for the following columns: OBJNAME, OBJLONGNAME, OBJTYPE, OBJLIB, OBJLONGSCHEMA, IASP_NUMBER, and IASP_NAME. All other columns return NULL.

object-type-list A character or graphic string expression containing one or more system object types separated by either a blank or a comma. The object types can include or exclude the leading * character. The special value of '*ALL' or 'ALL' can be used to return all objects in the library *object-schema*.

object-name A character or graphic string expression that identifies the name of an object or a library. If the object's name is a delimited name, the delimited form of the name must be specified. It can be either a long or short object name. The name must be the valid system name for the object unless the object is a file or a library; for files and libraries the SQL name can be specified.

A generic name can be specified to find multiple system objects. If the last character in the name is an asterisk, the name is a generic name. For example, to return object names that start with 'EMP', specify an *object-name* value of 'EMP*'. When a generic name is specified, long SQL names are not included in the search.

If this parameter is specified, only objects with this name in *object-schema* corresponding to the object types in *object-type-list* are returned.

If this parameter is not specified, all objects in *object-schema* corresponding to the object types in *object-type-list* are returned.

If *object-schema* is *ALL, *ALLSIMPLE, *ALLAVL, *ALLUSR, or *ALLUSRAVL and *object-type* is *LIB or LIB, the *object-name* parameter is ignored.

The following special value is allowed for *object-name*.

***ALLSIMPLE** The fastest approach to retrieving the system names for objects in a library. All objects in *object-schema* corresponding to the object types in *object-type-list* are returned. Values are returned for the following columns: OBJNAME, OBJTYPE, OBJLIB, OBJLONGSCHEMA, IASP_NUMBER, and IASP_NAME. All other columns return NULL.

The result of the function is a table containing a row for each object with the format shown in the following table. All the columns are null capable.

Table 204. OBJECT_STATISTICS table function

Column Name	Data Type	Description
OBJNAME	VARCHAR(10)	System name of the object.
OBJTYPE	VARCHAR(8)	System type of the object.
OBJOWNER	VARCHAR(10)	The user profile that owns the object. Contains the null value if no owner is available.
OBJDEFINER	VARCHAR(10)	The user profile that created the object. Contains the null value if the object definer is not known.
OBJCREATED	TIMESTAMP	Timestamp of when the object was created.
OBJSIZE	DECIMAL(15,0)	Size of the object, in bytes.
OBJTEXT	VARCHAR(50)	The description of the object. Contains the null value if the object has no text.
OBJLONGNAME	VARCHAR(128)	The SQL name for the object. For an external procedure or an external function, the name will be returned when a single procedure or function exists for that *PGM or *SRVPGM object. Contains the null value if an SQL name could not be returned.
LAST_USED_TIMESTAMP	TIMESTAMP	The date the object was used last. The time portion of the timestamp will always be 0. Contains the null value if the object has not been used.
LAST_USED_OBJECT	VARCHAR(4)	Indicates whether the LAST_USED_TIMESTAMP value is meaningful for this object. NO The object does not maintain the LAST_USED_TIMESTAMP. YES The object maintains the LAST_USED_TIMESTAMP.
DAYS_USED_COUNT	INTEGER	The number of days an object has been used on the system.
LAST_RESET_TIMESTAMP	TIMESTAMP	The date when the days used count was last reset to zero. The time portion of the timestamp will always be 0. Contains the null value if the days used count has not been reset.
IASP_NUMBER	SMALLINT	The auxiliary storage pool (ASP) where storage is allocated for the object. 0 indicates the system ASP.
IASP_NAME	VARCHAR(10)	The device description name of the independent auxiliary storage pool (IASP). The special value of *SYSBAS indicates SYSBASE, which includes the system ASP (ASP 1) and the basic user ASPs (ASPs 2-32).
OBJATTRIBUTE	VARCHAR(10)	The attribute for this object's type, if any. Contains an empty string if no attribute.
OBJLONGSCHEMA	VARCHAR(128)	The SQL schema name for this object.
TEXT	VARGRAPHIC(50) CCSID 1200	The description of the object for *LIB objects. Contains the null value if OBJTYPE is not *LIB.

Table 204. OBJECT_STATISTICS table function (continued)

Column Name	Data Type	Description
SQL_OBJECT_TYPE	VARCHAR(9)	The SQL type of the object. Values are: <ul style="list-style-type: none"> • ALIAS • FUNCTION • INDEX • PACKAGE • PROCEDURE • ROUTINE • SEQUENCE • TABLE • TRIGGER • TYPE • VARIABLE • VIEW • XSR Contains the null value if the object is not an SQL object.
OBJLIB	VARCHAR(10)	System name of the schema.
CHANGE_TIMESTAMP	TIMESTAMP	The timestamp of the last time the object was changed.
USER_CHANGED	VARCHAR(3)	Indicates whether the object was modified by a user. Values are: <ul style="list-style-type: none"> NO The object was not modified by a user. YES The object was modified by a user. Contains the null value for certain objects that are installed as part of the operating system.
SOURCE_FILE	VARCHAR(10)	The name of the source file that was used to create the object. Contains the null value if a source file was not used.
SOURCE_LIBRARY	VARCHAR(10)	The name of the source file library that was used to create the object. Contains the null value if a source file was not used.
SOURCE_MEMBER	VARCHAR(10)	The name of the source file member that was used to create the object. Contains the null value if a source file was not used.
SOURCE_TIMESTAMP	TIMESTAMP	The last source update timestamp of the member in the source file at the time the object was created. Contains the null value if a source file was not used or if the source timestamp is not available.
CREATED_SYSTEM	VARCHAR(8)	The name of the system on which the object was created.
CREATED_SYSTEM_VERSION	VARCHAR(9)	The version of the operating system when the object was created. The field has a VxRxMx format where: <ul style="list-style-type: none"> Vx The character V is followed by a version number. Rx The character R is followed by a release level. Mx The character M is followed by a modification level.
LICENSED_PROGRAM	VARCHAR(7)	The name of the licensed program if the object is part of a licensed program. Contains the null value if the object is not a part of a licensed program.
LICENSED_PROGRAM_VERSION	VARCHAR(9)	The version number, release level, and modification level of the licensed program if the object is part of a licensed program. The field has a VxRxMx format where: <ul style="list-style-type: none"> Vx The character V is followed by a version number. Rx The character R is followed by a release level. Mx The character M is followed by a modification level. Contains the null value if the object is not a part of a licensed program.
COMPILER	VARCHAR(7)	The licensed program identifier of the compiler. Contains the null value if the object was not created with a compiler.

Table 204. OBJECT_STATISTICS table function (continued)

Column Name	Data Type	Description
COMPILER_VERSION	VARCHAR(9)	The licensed program version number, release level, and modification level of the compiler. The field has a VxRxMx format where: Vx The character V is followed by a version number. Rx The character R is followed by a release level. Mx The character M is followed by a modification level. Contains the null value if the object was not created with a compiler.
OBJECT_CONTROL_LEVEL	CHAR(8)	The object control level for the object. Contains the null value if there is no object control level.
PTF_NUMBER	CHAR(7)	The Program Temporary Fix that resulted in the creation of this object. Contains the null value for a user created object.
APAR_ID	CHAR(6)	The authorized program analysis report (APAR) with this identification number associated with the last change. Will contain the value CHGDFT for a command that is changed using CHGCMDDFT. The Change Object Description (QLICOBJD) API can change this field to any value. Contains the null value is no value is available.
USER_DEFINED_ATTRIBUTE	VARCHAR(10)	Further defines an object type. This field is set by the user by using the QLICOBJD API. Contains the null value if the attribute has not been set.
ALLOW_CHANGE_BY_PROGRAM	VARCHAR(3)	Identifies whether or not any changes other than the text or the days used count and reset date can be made to the object's description by the Change Object Description (QLICOBJD) API. NO The QLICOBJD API cannot be used to change fields in the object's description other than the text or the days used count and reset date. YES The QLICOBJD API can be used to change fields in the object's description.
CHANGED_BY_PROGRAM	VARCHAR(3)	Identifies whether the object has been modified by the Change Object Description (QLICOBJD) API. NO The object has not been modified by the QLICOBJD API. YES The object has been modified by the QLICOBJD API.
COMPRESSED	VARCHAR(4)	Indicates whether the object is compressed or decompressed. Values are: NO Permanently decompressed and compressible. YES Compressed. TEMP Temporarily decompressed. FREE Saved with storage freed; compression status cannot be determined. Contains the null value if the object is permanently decompressed and not compressible.
PRIMARY_GROUP	VARCHAR(10)	The name of the user profile that is the primary group for the object. Contains the null value if there is no primary group for the object.
STORAGE_FREED	VARCHAR(3)	The storage status of the object data. NO The storage for the object data has not been freed. YES The storage for the object data has been freed. See the SAVOBJ or SAVLIB command, STG parameter, for more details.
ASSOCIATED_SPACE_SIZE	INTEGER	The size, in bytes, of the primary associated space of the object. Contains the null value if the object has no primary associated space.

Table 204. OBJECT_STATISTICS table function (continued)

Column Name	Data Type	Description
OPTIMUM_SPACE_ALIGNMENT	VARCHAR(3)	Identifies whether the primary associated space for the object has been optimally aligned. Optimum alignment may allow for better performance of applications that manipulate the object. NO The space associated with the object has not been optimally aligned. YES The space associated with the object has been optimally aligned. Contains the null value if the object has no associated space.
OVERFLOW_STORAGE	VARCHAR(3)	Indicates if the object has overflowed the auxiliary storage pool it resides in. NO The object has not overflowed the auxiliary storage pool. YES The object has overflowed the auxiliary storage pool.
OBJECT_DOMAIN	VARCHAR(7)	The domain that contains the object. Values are: *SYSTEM The object is in the system domain. *USER The object is in the user domain.
OBJECT_AUDIT	VARCHAR(10)	The type of auditing for an object. Values are: *NONE No auditing occurs for this object when it is read or changed regardless of the user who is accessing the object. *USRPRF Audit this object only if the current user is being audited. The current user is tested to determine if auditing should be done for this object. The user profile can specify if only change access is audited or if both read and change accesses are audited for this object. *CHANGE Audit all change access to this object by all users on the system. *ALL Audit all access to this object by all users on the system. All access is defined as a read or change operation. Contains the null value if you do not have either all object (*ALLOBJ) or audit (*AUDIT) special authority.
OBJECT_SIGNED	VARCHAR(3)	Indicates whether the object has a digital signature. NO The object does not have a digital signature. YES The object has a digital signature.
SYSTEM_TRUSTED_SOURCE	VARCHAR(3)	Indicates whether the object is signed by a source that is trusted by the system. NO None of the object signatures came from a source that is trusted by the system. YES The object is signed by a source that is trusted by the system. If the object has multiple signatures, at least one of the signatures came from a source that is trusted by the system.
MULTIPLE_SIGNATURES	VARCHAR(3)	Indicates whether the object has more than one digital signature. NO The object has only one digital signature or does not have a digital signature. YES The object has more than one digital signature.
SAVE_TIMESTAMP	TIMESTAMP	The timestamp the object was last saved. Contains the null value if the object has not been saved.
RESTORE_TIMESTAMP	TIMESTAMP	The timestamp the object was last restored. Contains the null value if the object has not been restored.
SAVE_WHILE_ACTIVE_TIMESTAMP	TIMESTAMP	The timestamp at which the object was saved while active. Contains the null value if the object has not been saved while active.
SAVE_COMMAND	VARCHAR(10)	The command used to save the object. Contains the null value if the object has not been saved.

Table 204. OBJECT_STATISTICS table function (continued)

Column Name	Data Type	Description
SAVE_DEVICE	VARCHAR(5)	The type of the device to which the object was last saved. Valid values are: *OPT The object was saved to optical. *SAVF The object was saved to a save file. *TAP The object was saved to tape. Contains the null value if the object has not been saved.
SAVE_FILE_NAME	VARCHAR(10)	The save file used to save the object. Contains the null value if the object was not last saved to a save file.
SAVE_FILE_LIBRARY	VARCHAR(10)	The save file library used to save the object. Contains the null value if the object was not last saved to a save file.
SAVE_VOLUME	VARCHAR(71)	The tape or optical volumes used to save the object. A maximum of ten volumes is returned. The string contains one blank between volume identifiers. If more than ten volumes were used, an ellipsis (three periods) is returned to the right of the identifier of the tenth volume. Contains the null value if the object was not last saved to tape or optical.
SAVE_LABEL	VARCHAR(17)	The file label used when the object was saved to tape or optical. Contains the null value if the object was not last saved to tape or optical.
SAVE_SEQUENCE_NUMBER	DECIMAL(10,0)	The sequence number used to when the object was saved to tape. Contains the null value if the object was not last saved to tape.
LAST_SAVE_SIZE	DECIMAL(15,0)	The size of the object in bytes at the time of the last save. This value defines the amount of storage that is required if the object is restored. Contains the null value if the object has not been saved.
JOURNALED	VARCHAR(3)	Identifies the current journaling status of the object. Valid values are: NO The object is not currently journaled. YES The object is currently journaled.
JOURNAL_NAME	VARCHAR(10)	The name of journal that receives the journaled changes or the name of the last journal if the object is not currently journaled. Contains the null value if the object has not been journaled.
JOURNAL_LIBRARY	VARCHAR(10)	The name of journal library that receives the journaled changes or the name of the last journal library if the object is not currently journaled. Contains the null value if the object has not been journaled.
JOURNAL_IMAGES	VARCHAR(6)	Specifies the kinds of images that are generated for changes to the object. Valid values are: *AFTER Only after images are generated for changes to the object. *BOTH Both before and after images are generated for changes to the object. Contains the null value if the object has not been journaled.
OMIT_JOURNAL_ENTRY	VARCHAR(7)	Specifies the journal entries that are omitted. Valid values are: *NONE No journal entries are omitted. *OPNCLO Open and close entries are omitted. Open and close operations on the specified file members do not create open and close journal entries. Contains the null value if the object has not been journaled.
REMOTE_JOURNAL_FILTER	VARCHAR(3)	The remote journal filter value for the object. Valid values are: NO The journal entries deposited for the object will not be eligible for remote journal filtering. YES The journal entries deposited for the object will be eligible for remote journal filtering. Contains the null value if the object has not been journaled.

Table 204. OBJECT_STATISTICS table function (continued)

Column Name	Data Type	Description
JOURNAL_START_TIMESTAMP	TIMESTAMP	The timestamp journaling was last started. Contains the null value if the object has not been journaled.
APPLY_STARTING_RECEIVER	VARCHAR(10)	Specifies the name of the oldest journal receiver needed to successfully use the Apply Journaled Changes (APYJRNCHG) or Remove Journaled Changes (RMVJRNCHG) command. Contains the null value if the object has not been journaled or it has not been saved and restored since journaling was started.
APPLY_STARTING_RECEIVER_LIBRARY	VARCHAR(10)	Specifies the library name of the oldest journal receiver needed to successfully use the Apply Journaled Changes (APYJRNCHG) or Remove Journaled Changes (RMVJRNCHG) command. Contains the null value if the object has not been journaled or it has not been saved and restored since journaling was started.
AUTHORITY_COLLECTION_VALUE	VARCHAR(10)	Specifies the authority collection value used for the object when authority collection for objects is active on the partition. Valid values are: *NONE No authority information will be collected for this object when authority collection for objects is active on the partition. A value of *NONE will be returned if the object type is not supported by authority collection. *OBJINF Authority information will be collected for this object when authority collection for objects is active on the partition. The authority checking information is collected for each unique instance of the object level information associated with the authority check.

Example

- Find all journals in library MJATST.

```
SELECT * FROM TABLE (QSYS2.OBJECT_STATISTICS('MJATST ', 'JRN') ) AS X
```

or

```
SELECT * FROM TABLE (QSYS2.OBJECT_STATISTICS('MJATST ', '*JRN') ) AS X
```

- Find all journals and journal receivers in library MJATST.

```
SELECT * FROM TABLE (QSYS2.OBJECT_STATISTICS('MJATST ', 'JRN JRNRCV') ) AS X
```

or

```
SELECT * FROM TABLE (QSYS2.OBJECT_STATISTICS('MJATST ', '*JRN *JRNRCV') ) AS X
```

- Find all programs and service programs in library MYLIB. Use *ALLSIMPLE to return the list quickly, omitting the detail information.

```
SELECT * FROM TABLE (QSYS2.OBJECT_STATISTICS('MYLIB', 'PGM SRVPGM', '*ALLSIMPLE')) X
```

- Find any CL commands that have had their parameter defaults changed.

```
SELECT * FROM TABLE(QSYS2.OBJECT_STATISTICS('QSYS', '*CMD'))  
WHERE APAR_ID = 'CHGDFT';
```

SYSTEM_OBJECT_TYPES table

The SYSTEM_OBJECT_TYPES table returns a list of external object types found on IBM i.

Additional information about object types is available at this link: [External object types](#)

Authorization: None required.

The following table describes the columns in the table. The system name is OBJ_TYPES. The schema is QSYS2.

Table 205. SYSTEM_OBJECT_TYPES table

Column Name	System Column Name	Data Type	Description
OBJECT_TYPE	OBJTYPE	VARCHAR(7)	System object type.
TEXT_DESCRIPTION	TEXT	VARCHAR(60)	Description of the object type.
CATEGORY	CATEGORY	VARCHAR(7)	Category of object type. IFS The object type resides in the integrated file system (IFS). LIBRARY The object type resides in a library.

Example

List all the system object types that are found in libraries:

```
SELECT * FROM QSYS2.SYSTEM_OBJECT_TYPES
WHERE CATEGORY = 'LIBRARY';
```

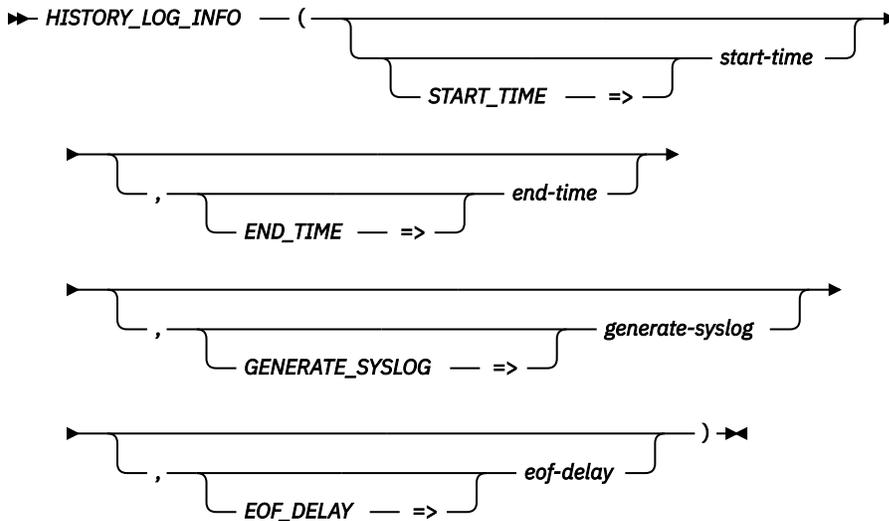

Message Handling Services

These views and functions provide system message information.

HISTORY_LOG_INFO table function

The HISTORY_LOG_INFO table function returns one row for each message in the history log based on the timestamp range specified. It returns information similar to what is returned by the Display Log (DSPLOG) CL command and the Open List of History Log Messages (QMHOHST) API.

Authorization: None required.

The schema is QSYS2.

start-time A timestamp expression that indicates the starting timestamp to use when returning history log information.

If this parameter is omitted, the default of CURRENT DATE - 1 DAY is used.

end-time A timestamp expression that indicates the ending timestamp to use when returning history log information.

If this parameter is omitted, the default of '9999-12-30-00.00.00.000000' is used.

generate-syslog

A character or graphic string expression that indicates whether to transform history log messages into syslog formatted detail. Values are:

- NO** No syslog information will be returned. The SYSLOG_EVENT, SYSLOG_FACILITY, SYSLOG_SEVERITY, and SYSLOG_PRIORITY columns will contain the null value.
- RFC3164** Values will be returned for the SYSLOG_EVENT, SYSLOG_FACILITY, SYSLOG_SEVERITY, and SYSLOG_PRIORITY columns for each history log message. The SYSLOG_EVENT column will contain a syslog header that matches the RFC3164 format as described by the Internet Engineering Task Force (IETF) Request For Comments (RFC) 3164.
- RFC5424** Values will be returned for the SYSLOG_EVENT, SYSLOG_FACILITY, SYSLOG_SEVERITY, and SYSLOG_PRIORITY columns for each history log message. The SYSLOG_EVENT column will contain a syslog header that matches the RFC5424 format as described by the Internet Engineering Task Force (IETF) Request For Comments (RFC) 5424.

If *generate-syslog* is not specified or is the null value, NO is used.

eof-delay

An integer expression that specifies the number of seconds to sleep when all history log messages have been read. This delay allows the caller to establish a polling service that will continually return rows, sleeping for the specified interval whenever all messages have been processed.

A value of zero indicates no delay is used and a finite set of rows will be returned. A value greater than zero indicates that the table function will sleep, as needed, to wait for new history log messages and never end. If *eof-delay* is not specified or is the null value, zero is used.

If this parameter has a value greater than zero, the *generate-syslog* parameter must be RFC3164 or RFC5424, and the *end-time* parameter cannot be specified with a value other than its default value.

When using a non-zero *eof-delay* parameter, avoid using query clauses that depend on returning a finite number of rows. For example, using the FETCH FIRST n ROWS clause can cause the query to end when the requested number of rows has been satisfied. A query using the HISTORY_LOG_INFO function with a non-zero *eof-delay* parameter does not allow data to be copied (ALWCPYDTA(*NO)). This means that a query requiring a copy of data, such as one using an ORDER BY clause or UNION DISTINCT, will issue an error and not be allowed. When using *eof-delay*, consider using a simple query to avoid blocking of rows. When rows are blocked for data transport efficiency, rows won't be returned until the block is full. Therefore, you should decide whether you favor data transport efficiency or moving events as soon as they occur.

The result of the function is a table containing multiple rows with the format shown in the following table. All the columns are nullable.

Table 206. HISTORY_LOG_INFO table function

Column Name	Data Type	Description
ORDINAL_POSITION	INTEGER	A unique number for each row that indicates the time order of messages in the job log. The first (oldest) message returned from the history log will have a value of 1. Subsequent messages will have a value one greater than the previous message. Since these values are assigned when this catalog is queried, there will be no gaps in values.
MESSAGE_ID	VARCHAR(7)	The message ID for this message. Contains the null value if this is an impromptu message or MESSAGE_TYPE is REPLY.

Table 206. HISTORY_LOG_INFO table function (continued)

Column Name	Data Type	Description
MESSAGE_TYPE	VARCHAR(13)	Type of message. <ul style="list-style-type: none"> • COMPLETION • DIAGNOSTIC • ESCAPE • INFORMATIONAL • INQUIRY • NOTIFY • REPLY • REQUEST • SENDER
MESSAGE_SUBTYPE	VARCHAR(22)	Subtype of message. The values returned for REPLY messages: <ul style="list-style-type: none"> • FROM EXIT PROGRAM • FROM SYSTEM REPLY LIST • MESSAGE DEFAULT USED • NOT VALIDITY CHECKED • SYSTEM DEFAULT USED • VALIDITY CHECKED The value returned for some REQUEST messages: <ul style="list-style-type: none"> • WITH PROMPTING Contains the null value for other message types.
SEVERITY	SMALLINT	The severity assigned to the message.
MESSAGE_TIMESTAMP	TIMESTAMP	The timestamp when the message was sent.
FROM_USER	VARCHAR(10)	The current user of the job when the message was sent.
FROM_JOB	VARCHAR(28)	The qualified job name when the message was sent.
FROM_JOB_NAME	VARCHAR(10)	The name of the job when the message was sent.
FROM_JOB_USER	VARCHAR(10)	The user profile that started the job when the message was sent.
FROM_JOB_NUMBER	VARCHAR(6)	The job number of the job when the message was sent.
FROM_PROGRAM	VARCHAR(10)	The program that sent the message.
MESSAGE_LIBRARY	VARCHAR(10)	The name of the library containing the message file. Contains the null value if MESSAGE_ID is null.
MESSAGE_FILE	VARCHAR(10)	The message file containing the message. Contains the null value if MESSAGE_ID is null.
MESSAGE_TOKENS	VARCHAR(4096) FOR BIT DATA	The message token string. If the value is longer than 4096 characters, it will be truncated with no warning. Contains the null value if there are no message tokens.
MESSAGE_TEXT	VARGRAPHIC(1024) CCSID 1200	The first level text of the message including tokens, or the impromptu message text. Contains the null value if MESSAGE_ID is null or if the message file could not be accessed.
MESSAGE_SECOND_LEVEL_TEXT	VARGRAPHIC(4096) CCSID 1200	The second level text of the message including tokens. Contains the null value if MESSAGE_ID is null or if the message has no second level text or if the message file could not be accessed.

Table 206. HISTORY_LOG_INFO table function (continued)

Column Name	Data Type	Description
SYSLOG_EVENT	VARGRAPHIC(2048) CCSID 1200	<p>The Common Event Format (CEF) syslog event for the message preceded by a header of the requested type. If a header-type of RFC3164 is requested, the maximum length is 1024 characters. If a header-type of RFC5424 is requested, the maximum length is 2048 characters. The string will be truncated with no warning if it exceeds the maximum length.</p> <p>The key names returned for history log information are listed in the Notes section.</p> <p>Contains the null value if NO was specified for the GENERATE_SYSLOG parameter.</p>
SYSLOG_FACILITY	INTEGER	<p>The syslog facility assigned to the event.</p> <ul style="list-style-type: none"> 1 user-level messages 4 security/authorization messages <p>The facility assigned is defined in the Notes section.</p> <p>Contains the null value if NO was specified for the GENERATE_SYSLOG parameter.</p>
SYSLOG_SEVERITY	INTEGER	<p>The syslog severity assigned to the event.</p> <ul style="list-style-type: none"> 1 Alert: Action must be taken immediately 3 Error condition 4 Warning condition 5 Notice: A normal but significant condition 6 Informational message 7 Debug level message <p>The severity assigned is listed in the Notes section.</p> <p>Contains the null value if NO was specified for the GENERATE_SYSLOG parameter.</p>
SYSLOG_PRIORITY	INTEGER	<p>The syslog priority number assigned to the event.</p> <p>Contains the null value if NO was specified for the GENERATE_SYSLOG parameter.</p>

Notes

Syslog information: Syslog information is returned for all messages in the history log. Syslog information is also available for audit journal entries. See [DISPLAY_JOURNAL table function](#) for more details.

All history log messages return a SYSLOG_FACILITY value of 1 except as noted below. Messages are assigned a SYSLOG_SEVERITY value in the following way:

- Severity 1 Alert: Action must be taken immediately
 - MESSAGE_TYPE contains a value of INQUIRY, NOTIFY, or REPLY
- Severity 3 Error condition
 - MESSAGE_ID contains a value of CPF1164 with a job ending code value in the MESSAGE_TEXT column of 30 or higher
 - MESSAGE_TYPE contains a value of ESCAPE when the SEVERITY column contains a value of 50 or greater
- Severity 4 Warning condition
 - MESSAGE_ID contains a value of CPF1393. The SYSLOG_FACILITY column is set to 4.
 - MESSAGE_ID contains a value of CPF1164 with a job ending code value in the MESSAGE_TEXT column of 20
 - MESSAGE_TYPE contains a value of ESCAPE when the SEVERITY column contains a value of 30 or greater but less than 50

- Severity 5 Notice: A normal but significant condition
 - MESSAGE_ID contains a value of CPF1164 with a job ending code value in the MESSAGE_TEXT column of 10
 - MESSAGE_TYPE contains a value of INFORMATIONAL, COMPLETION, DIAGNOSTIC, or REQUEST when the SEVERITY column contains a value of 50 or greater
- Severity 6 Informational message
 - MESSAGE_ID contains a value of CPF1164 with a job ending code value in the MESSAGE_TEXT column of 0
 - MESSAGE_TYPE contains a value of ESCAPE when the SEVERITY column contains a value less than 30
 - MESSAGE_TYPE contains a value of SENDER
 - MESSAGE_TYPE contains a value of INFORMATIONAL, COMPLETION, DIAGNOSTIC, or REQUEST when the SEVERITY column contains a value less than 50
- Severity 7 Debug level message
 - MESSAGE_ID contains a value of CPF9897 or CPF9898 (regardless of severity or message type)

The Common Event Format key names that are generated within the SYSLOG_EVENT column are:

<i>Table 207. Common Event Format key names</i>	
Common Event Format key name	Description
msg	The message text (MESSAGE_TEXT column) from the history log message
reason	Text description of the history log message
sproc	The qualified job name (FROM_JOB column) from the history log message
suser	Current user name (FROM_USER column) from the history log message

Examples

- Return a list of history log messages for all of yesterday and today.

```
SELECT * FROM TABLE(QSYS2.HISTORY_LOG_INFO()) X
```

- Return a list of all history log messages for the last 24 hours.

```
SELECT * FROM TABLE(QSYS2.HISTORY_LOG_INFO(CURRENT_TIMESTAMP - 1 DAY)) X
```

- Return history log information since the last IPL, assuming that the last IPL timestamp is in a global variable named LAST_IPL_TIME.

```
SELECT * FROM TABLE(QSYS2.HISTORY_LOG_INFO(LAST_IPL_TIME, CURRENT_TIMESTAMP)) A
```

- Return syslog information formatted with an RFC3164 header for all history log messages from the start of today forward into the future. When all history log messages have been returned to the caller, the query will pause for 5 minutes (300 seconds) before checking again for messages.

```
SELECT syslog_facility, syslog_severity, syslog_event
FROM TABLE (QSYS2.HISTORY_LOG_INFO(START_TIME => CURRENT DATE,
                                   GENERATE_SYSLOG => 'RFC3164',
                                   EOF_DELAY => 300
                                   ) ) AS X;
```

Table 208. JOBLLOG_INFO table function (continued)

Column Name	Data Type	Description
MESSAGE_TYPE	VARCHAR(13)	Type of message. Values are: <ul style="list-style-type: none"> • COMMAND • COMPLETION • DIAGNOSTIC • ESCAPE • INFORMATIONAL • INQUIRY • NOTIFY • REPLY • REQUEST • SCOPE • SENDER
MESSAGE_SUBTYPE	VARCHAR(22)	Subtype of message. Values for NOTIFY or ESCAPE messages are: <ul style="list-style-type: none"> • EXCEPTION HANDLED • EXCEPTION NOT HANDLED Values for REPLY messages are: <ul style="list-style-type: none"> • FROM EXIT PROGRAM • FROM SYSTEM REPLY LIST • MESSAGE DEFAULT USED • NOT VALIDITY CHECKED • SYSTEM DEFAULT USED • VALIDITY CHECKED Contains the null value for other message types.
SEVERITY	SMALLINT	The severity assigned to the message.
MESSAGE_TIMESTAMP	TIMESTAMP	The timestamp for when the message was issued.
FROM_LIBRARY	VARCHAR(10)	The library containing the program or service program that sent the message.
FROM_PROGRAM	VARCHAR(256)	The program or service program name that sent the message.
FROM_MODULE	VARCHAR(10)	The module that sent the message.
FROM_PROCEDURE	VARCHAR(4096)	The procedure that sent the message.
FROM_INSTRUCTION	VARCHAR(10)	The instruction that sent the message.
TO_LIBRARY	VARCHAR(10)	The library containing the program or service program that received the message
TO_PROGRAM	VARCHAR(10)	The program or service program name that received the message.
TO_MODULE	VARCHAR(10)	The module that received the message.
TO_PROCEDURE	VARCHAR(4096)	The procedure that received the message.
TO_INSTRUCTION	VARCHAR(10)	The instruction that received the message.
FROM_USER	VARCHAR(10)	The userid of the job when the message was sent.
MESSAGE_FILE	VARCHAR(10)	The message file containing the message.
MESSAGE_LIBRARY	VARCHAR(10)	The name of the library containing the message file.
MESSAGE_TOKEN_LENGTH	SMALLINT	The length of the MESSAGE_TOKENS string.
MESSAGE_TOKENS	VARCHAR(12000) FOR BIT DATA	The message token string. If the value is longer than 12000 characters, it will be truncated with no warning.
MESSAGE_TEXT	VARGRAPHIC(1024) CCSID 1200	The first level text of the message including tokens.
MESSAGE_SECOND_LEVEL_TEXT	VARGRAPHIC(4096) CCSID 1200	The second level text of the message including tokens.
MESSAGE_KEY	BINARY(4)	The key assigned to the message. The key is assigned by the command or API that sends the message.

Table 208. JOBLLOG_INFO table function (continued)

Column Name	Data Type	Description
QUALIFIED_JOB_NAME	VARCHAR(28)	The qualified name of the job for this job log.

Examples

- Return joblog information for job 347117/QUSER/QZDASOINIT.

```
SELECT * FROM TABLE(QSYS2.JOBLLOG_INFO('347117/QUSER/QZDASOINIT')) A
```

- Extract the last command entered by the user.

```
SELECT MESSAGE_TEXT FROM TABLE(QSYS2.JOBLLOG_INFO('817029/QUSER/QPADEV0004')) A
WHERE A.MESSAGE_TYPE = 'REQUEST'
ORDER BY ORDINAL_POSITION DESC
FETCH FIRST 1 ROW ONLY
```

MESSAGE_FILE_DATA view

The MESSAGE_FILE_DATA view returns one row for each message in a message file.

The information is similar to what is returned by the Display Message Description (DSPMSGD) CL command and the Retrieve Message (QMHRTVM) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the message file, and
- *USE authority to the message file.

The following table describes the columns in the view. The system name is MSGF_DATA. The schema is QSYS2.

Table 209. MESSAGE_FILE_DATA view

Column Name	System Column Name	Data Type	Description
MESSAGE_FILE_LIBRARY	MSGF_LIB	VARCHAR(10)	The library containing the message file.
MESSAGE_FILE	MSGF	VARCHAR(10)	The message file.
MESSAGE_ID	MSGID	CHAR(7)	The message identifier.
MESSAGE_TEXT	MSG_TEXT	VARGRAPHIC(132) CCSID 1200	The text of the message.
MESSAGE_SECOND_LEVEL_TEXT	SECLVL	VARGRAPHIC(300) 0) CCSID 1200 Nullable	The second-level message text of the message. Contains the null value if no second-level text is defined.
SEVERITY	SEVERITY	INTEGER	The severity of the message.
MESSAGE_DATA_COUNT	MSGDATAcnt	INTEGER	The number of variables defined in MESSAGE_DATA.
MESSAGE_DATA	MSGDATA	VARCHAR(2078) Nullable	A string containing all the message data fields, also referred to as substitution variables, for the message. The format of the string is described following this table. Contains the null value if no message data fields are defined.
LOG_PROBLEM	LOGPRB	VARCHAR(4)	The log problem value for the message. *NO Problems are not logged. *YES Problems are logged.
CREATION_DATE	CRT_DATE	DATE	The date the message was created.
CREATION_LEVEL	CRT_LEVEL	INTEGER	The level number of the message. This is a value from 1 to 99.
MODIFICATION_DATE	MOD_DATE	DATE	The date the message was modified.
MODIFICATION_LEVEL	MOD_LEVEL	INTEGER	The modification level number of the message. This is a value from 1 to 99.

Table 209. MESSAGE_FILE_DATA view (continued)

Column Name	System Column Name	Data Type	Description
CCSID	CCSID	INTEGER	The CCSID that applies to the stored values of MESSAGE_TEXT and MESSAGE_SECOND_LEVEL_TEXT.
DEFAULT_PROGRAM_LIBRARY	DFT_PGMLIB	VARCHAR(10) Nullable	The library specified for the default program. Can contain the following special values: *CURLIB The current library is used. *LIBL The program is found using the library list. Contains the null value if no default program is defined.
DEFAULT_PROGRAM	DFT_PGM	VARCHAR(10) Nullable	The name of the program called to take default action if this message is sent as an escape message to a program or procedure that is not monitoring for it. Contains the null value if no default program is defined.
REPLY_TYPE	REPLY_TYPE	VARCHAR(6) Nullable	The type of valid values that can be made to an inquiry or notify message. *ALPHA Only an alphabetic string is valid. Blanks are not allowed. *CHAR Any character string is valid. If it is a quoted character string, the apostrophes are passed as part of the character string. *DEC Only a decimal number is a valid reply. *NAME Only a simple name is a valid reply. The name does not have to be an object name, but it must start with an alphabetic character; the remaining characters must be alphanumeric. Contains the null value if there is no reply type.
REPLY_LENGTH	REPLY_LEN	INTEGER Nullable	The maximum length of a reply to an inquiry or notify message. Contains the null value if there is no reply type.
REPLY_DECIMAL_POSITIONS	REPLY_DEC	INTEGER Nullable	The maximum number of decimal positions allowed in the message reply. Contains the null value if there is no reply type or if REPLY_TYPE is not *DEC.
DEFAULT_REPLY	DFT_REPLY	VARCHAR(132) Nullable	The default reply for the message. Contains the null value if no default reply is defined.
VALID_REPLY_VALUES_COUNT	REPLY_CNT	INTEGER	The number of entries returned in VALID_REPLY_VALUES.
VALID_REPLY_VALUES	REPLY_VALS	VARCHAR(659) Nullable	The list of valid reply values. Each value is a character string with a length of 32. One blank separates values. Contains the null value if no valid reply values are defined.
VALID_REPLY_LOWER_LIMIT	LOWERLIMIT	VARCHAR(32) Nullable	The lower value limit for a valid reply. Contains the null value if no range values for replies are defined.
VALID_REPLY_UPPER_LIMIT	UPPERLIMIT	VARCHAR(32) Nullable	The upper value limit for a valid reply. Contains the null value if no range values for replies are defined.
VALID_REPLY_RELATIONSHIP_OPERATOR	REL_OP	CHAR(3) Nullable	The relational operator for a relational test entry. *EQ Equal to *GE Greater than or equal to *GT Greater than *LE Less than or equal to *LT Less than *NE Not equal to Contains the null value if no relationship for valid replies is defined.

Table 209. MESSAGE_FILE_DATA view (continued)

Column Name	System Column Name	Data Type	Description
VALID_REPLY_RELATIONSHIP_VALUE	REL_VALUE	VARCHAR(32) Nullable	The value to be compared to the reply entered for a relational test entry. Contains the null value if no relationship for valid replies is defined.
SPECIAL_REPLY_VALUES_COUNT	SPECIALCNT	INTEGER	The number of entries returned in SPECIAL_REPLY_VALUES.
SPECIAL_REPLY_VALUES	SPECIALVAL	VARCHAR(1319) Nullable	The list of special reply values. Each pair of values consists of the <i>from-value</i> followed by a colon (:) followed by the <i>to-value</i> . One blank separates each pair of values. Contains the null value if no special reply values are defined.
DUMP_LIST_COUNT	DUMP_COUNT	INTEGER	The number of entries returned in DUMP_LIST.
DUMP_LIST	DUMP_LIST	VARCHAR(815) Nullable	The list of data items to be dumped when the message is sent as an escape message to a program that is not monitoring for it. The list contains entries separated by a single blank. 1-99 The number of the message data field that is to be dumped. *JOB The job information produced by the Display Job (DSPJOB) command is printed. *JOBDMPI The data areas of the job are dumped as specified by the Dump Job (DMPJOB) command. *JOBINT The internal machine data structures related to the machine process in which the job is running are dumped to the machine error log. Contains the null value if there is no dump list for this message.
ALERT_OPTION	ALERTOPT	VARCHAR(9)	Whether an alert is sent for the message. *DEFER An alert is sent after local problem analysis. *IMMED An alert is sent immediately when the message is sent to a message queue that has the allow alerts attribute set to *YES. *NO No alert is sent. *UNATTEND An alert is sent immediately when the system is running in unattended mode.
ALERT_INDEX	ALERTINDEX	INTEGER Nullable	The number of the message data field that is passed with the alert. Contains the null value if no alert is sent or no message data field is passed with the alert.

The MESSAGE_DATA column contains all of the substitution variables formatted as follows. A single blank separates each variable attribute. There is one blank between each variable definition. The order of the attributes is:

1. Variable identifier, such as &1.
2. Data type of the variable.

- *BIN** A binary value formatted in the message as a signed decimal value.
- *CCHAR** A convertible character string.
- *CHAR** A character string formatted without enclosing apostrophes.
- *DEC** A packed decimal number that is formatted in the message as a signed decimal value with a decimal point.
- *DTS** An 8-byte field that contains a system date/time stamp and is formatted in the message as the date followed by one blank and then the time.
- *HEX** A string of bytes formatted as a hexadecimal value.

- *ITV** An 8-byte binary field that contains the time interval (in seconds) for wait time-out conditions.
- *QTDCHAR** A character string formatted with enclosing apostrophes.
- *SPP** A 16-byte space pointer to data in a space object.
- *SYP** A 16-byte system pointer to a system object.
- *UBIN** A binary value formatted in the message as an unsigned decimal value
- *UTC** An 8-byte field that contains a system date/time stamp in Coordinated Universal Time (UTC) and is formatted in the message as the date followed by one blank and then the time. Before the output formatting the date/time stamp is adjusted from UTC using the time zone specified for the job.
- *UTCD** An 8-byte field that contains a system date/time stamp in Coordinated Universal Time (UTC) and is formatted in the message as a date with no time. Before the output formatting the date/time stamp is adjusted from UTC using the time zone specified for the job.
- *UTCT** An 8-byte field that contains a system date/time stamp in Coordinated Universal Time (UTC) and is formatted in the message as a time with no date. Before the output formatting the date/time stamp is adjusted from UTC using the time zone specified for the job.

3. Length, if applicable.

- *VARY or the length of the substitution variable.

4. Additional length information, if applicable.

- Fractional digits for a *DEC variable
- 2 or 4 when the length is *VARY

For example, when there are two substitution variables, one a varying character and one a four byte integer, the string might look like this.

```
&1 *CHAR *VARY 2 &2 *BIN 4
```

Example

Find any messages in the APPLIB/APPMSGs message file that contain the word VALUE in upper case, lower case, or mixed case in either the message text or the second level message text.

```
SELECT * FROM QSYS2.MESSAGE_FILE_DATA
WHERE MESSAGE_FILE_LIBRARY = 'APPLIB' AND MESSAGE_FILE = 'APPMSGs' AND
  (UPPER(MESSAGE_TEXT) LIKE '%VALUE%' OR
   UPPER(MESSAGE_SECOND_LEVEL_TEXT) LIKE '%VALUE%');
```

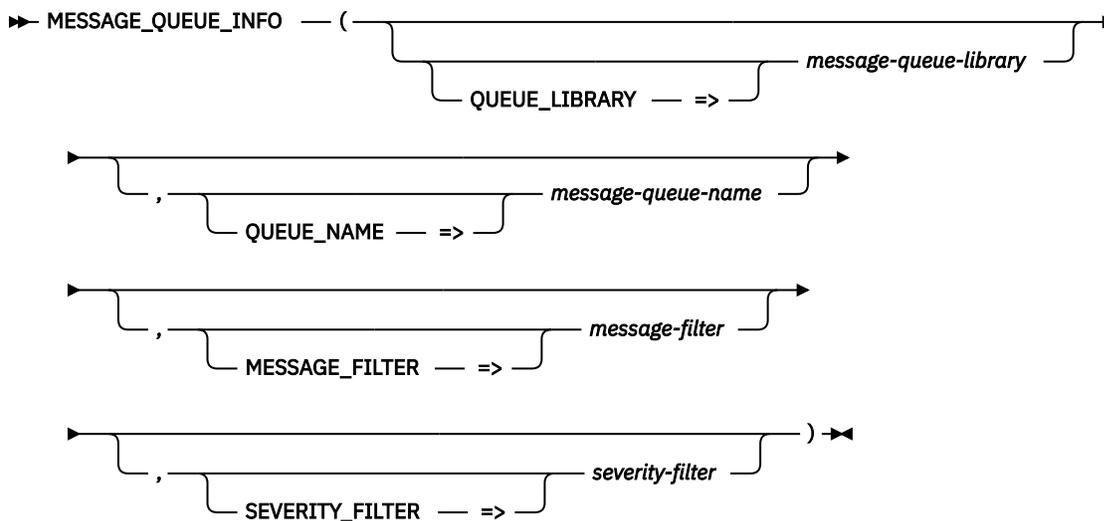

MESSAGE_QUEUE_INFO table function

The MESSAGE_QUEUE_INFO table function returns one row for each message in a specific message queue. It returns information similar to what is returned by the Display Messages (DSPMSG) CL command and the Receive Nonprogram Message (QMHRVCV) and Open List of Messages (QGYOLMSG) APIs.

This table function does not change the contents of the message queue. The message is kept in the message queue without changing its new or old designation.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the message queue, and
- *USE authority to the message queue

The schema is QSYS2.

message-queue-library A character or graphic string expression that contains the name of the library containing *message-queue-name*. If omitted, the default is QSYS.

message-queue-name A character or graphic string expression that contains the name of a message queue. If omitted, the default is QSYSOPR.

message-filter A character or graphic string expression that indicates the type of messages to be returned. The string can contain one or more of the following values separated by blanks. Specifying 'COMPLETE INQUIRY SENDER' is the same as specifying ALL.

ALL All messages are returned. This is the default.

COMPLETE Only messages that do not require a reply are returned.

INQUIRY Only inquiry messages that require a reply are returned.

SENDER Only copies of the inquiry messages that were sent to other message queues and still require a reply are returned.

severity-filter An integer value indicating the minimum severity of messages to be returned. The value must be from 0 to 99. The default is 0, indicating all messages are to be returned.

The result of the function is a table containing multiple rows with the format shown in the following table. All the columns are nullable.

Table 210. MESSAGE_QUEUE_INFO table function

Column Name	Data Type	Description
MESSAGE_ID	VARCHAR(7)	The message ID for this message. Contains the null value if this is an impromptu message or MESSAGE_TYPE is REPLY.
MESSAGE_TYPE	VARCHAR(13)	Type of message. Values are: <ul style="list-style-type: none"> • COMPLETION • DIAGNOSTIC • ESCAPE • INFORMATIONAL • INQUIRY • NOTIFY • REPLY • REQUEST • SENDER

Table 210. MESSAGE_QUEUE_INFO table function (continued)

Column Name	Data Type	Description
MESSAGE_SUBTYPE	VARCHAR(22)	<p>Subtype of message.</p> <p>The values returned for REPLY messages:</p> <ul style="list-style-type: none"> FROM EXIT PROGRAM FROM SYSTEM REPLY LIST MESSAGE DEFAULT USED NOT VALIDITY CHECKED SYSTEM DEFAULT USED VALIDITY CHECKED <p>The value returned for some REQUEST messages:</p> <ul style="list-style-type: none"> WITH PROMPTING <p>Contains the null value for other message types.</p>
MESSAGE_TEXT	VARGRAPHIC(1024) CCSID 1200	<p>The first level text of the message including tokens, or the impromptu message text.</p> <p>Contains the null value if MESSAGE_TYPE is REPLY or if the message file could not be accessed.</p>
SEVERITY	SMALLINT	The severity assigned to the message.
MESSAGE_TIMESTAMP	TIMESTAMP	The timestamp when the message was sent.
MESSAGE_KEY	BINARY(4)	<p>The key assigned to the message.</p> <p>The key is assigned by the command or API that sends the message. For details, see Message Types and Message Keys in the Qmhrvcvm API</p>
ASSOCIATED_MESSAGE_KEY	BINARY(4)	<p>For MESSAGE_TYPE of REPLY, contains the associated inquiry or notify message key.</p> <p>Contains the null value for other message types.</p>
FROM_USER	VARCHAR(10)	The current user of the thread when the message was sent.
FROM_JOB	VARCHAR(28)	The qualified job name of the job that sent the message.
FROM_PROGRAM	VARCHAR(10)	The program that sent the message.
MESSAGE_FILE_LIBRARY	VARCHAR(10)	<p>The name of the library containing the message file.</p> <p>Contains the null value if MESSAGE_ID is null or if the message file could not be accessed.</p>
MESSAGE_FILE_NAME	VARCHAR(10)	<p>The message file containing the message.</p> <p>Contains the null value if MESSAGE_ID is null.</p>
MESSAGE_TOKENS	VARCHAR(4096) FOR BIT DATA	<p>The message token string. If the value is longer than 4096 characters, it will be truncated with no warning.</p> <p>Contains the null value if there are no tokens.</p>
MESSAGE_SECOND_LEVEL_TEXT	VARGRAPHIC(4096) CCSID 1200	<p>The second level text of the message including tokens.</p> <p>Contains the null value if MESSAGE_ID is null or if the message has no second level text or if the message file could not be accessed.</p>

Example

- Return a list of inquiry messages in QSYSOPR that have not been replied to

```
SELECT MESSAGE_ID, MESSAGE_TEXT, MESSAGE_TIMESTAMP
FROM TABLE(QSYS2.MESSAGE_QUEUE_INFO(MESSAGE_FILTER => 'INQUIRY'));
```

MESSAGE_QUEUE_INFO view

The MESSAGE_QUEUE_INFO view returns one row for each message in a message queue. It returns information similar to what is returned by the Display Messages (DSPMSG) CL command and the Receive Nonprogram Message (QMHRVCV) API.

This view does not change the contents of the message queue. The message is kept in the message queue without changing its new or old designation. The view does not utilize the wait time parameter as described in the QMHRVCV API. A wait time of 0 is used.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the message queue, and
- *USE authority to the message queue

The following table describes the columns in the view. The system name is MSGQ_INFO. The schema is QSYS2.

Table 211. MESSAGE_QUEUE_INFO view

Column Name	System Column Name	Data Type	Description
MESSAGE_QUEUE_LIBRARY	MSGQ_LIB	VARCHAR(10)	The name of the library containing the message queue.
MESSAGE_QUEUE_NAME	MSGQ_NAME	VARCHAR(10)	The name of the message queue containing the message.
MESSAGE_ID	MSGID	VARCHAR(7) Nullable	The message ID for this message. Contains the null value if this is an impromptu message or MESSAGE_TYPE is REPLY.
MESSAGE_TYPE	MSG_TYPE	VARCHAR(13)	Type of message. Values are: <ul style="list-style-type: none"> • COMPLETION • DIAGNOSTIC • ESCAPE • INFORMATIONAL • INQUIRY • NOTIFY • REPLY • REQUEST • SENDER
MESSAGE_SUBTYPE	MSG_SUBTYP	VARCHAR(22) Nullable	Subtype of message. The values returned for REPLY messages: <ul style="list-style-type: none"> • FROM EXIT PROGRAM • FROM SYSTEM REPLY LIST • MESSAGE DEFAULT USED • NOT VALIDITY CHECKED • SYSTEM DEFAULT USED • VALIDITY CHECKED The value returned for some REQUEST messages: <ul style="list-style-type: none"> • WITH PROMPTING Contains the null value for other message types.
MESSAGE_TEXT	MSG_TEXT	VARGRAPHIC(1024) CCSID 1200 Nullable	The first level text of the message including tokens, or the impromptu message text. Contains the null value if the message file could not be accessed.
SEVERITY	SEVERITY	SMALLINT	The severity assigned to the message.
MESSAGE_TIMESTAMP	MSG_TIME	TIMESTAMP	The timestamp when the message was sent.
MESSAGE_KEY	MSG_KEY	BINARY(4)	The key assigned to the message. The key is assigned by the command or API that sends the message. For details, see Message Types and Message Keys in the Qmhrvcv API

Table 211. MESSAGE_QUEUE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
ASSOCIATED_MESSAGE_KEY	ASSOC_KEY	BINARY(4) Nullable	For MESSAGE_TYPE of REPLY, contains the associated inquiry or notify message key. Contains the null value for other message types.
FROM_USER	FROM_USER	VARCHAR(10)	The current user of the thread when the message was sent.
FROM_JOB	FROM_JOB	VARCHAR(28)	The qualified job name of the job that sent the message.
FROM_PROGRAM	FROM_PGM	VARCHAR(10)	The program that sent the message.
MESSAGE_FILE_LIBRARY	MSGF_LIB	VARCHAR(10) Nullable	The name of the library containing the message file. Contains the null value if MESSAGE_ID is null or if the message file could not be accessed.
MESSAGE_FILE_NAME	MSGF_NAME	VARCHAR(10) Nullable	The message file containing the message. Contains the null value if MESSAGE_ID is null.
MESSAGE_TOKENS	MSG_TOKENS	VARCHAR(4096) FOR BIT DATA Nullable	The message token string. If the value is longer than 4096 characters, it will be truncated with no warning. Contains the null value if there are no tokens.
MESSAGE_SECOND_LEVEL_TEXT	MSG_TEXT2	VARGRAPHIC(4096) CCSID 1200 Nullable	The second level text of the message including tokens. Contains the null value if MESSAGE_ID is null or if the message has no second level text or if the message file could not be accessed.

Example

- Examine all inquiry messages and their responses.

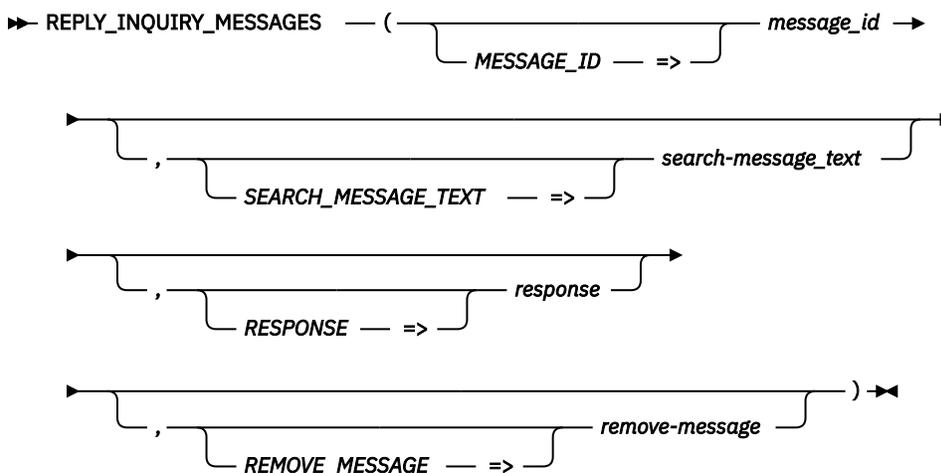

```
SELECT a.message_timestamp, a.message_text, a.from_user,
       b.message_timestamp, b.message_text, b.from_user
FROM qsys2.message_queue_info a INNER JOIN qsys2.message_queue_info b
  ON a.message_key = b.associated_message_key
WHERE a.message_type = 'INQUIRY' AND
      b.message_type = 'REPLY'
ORDER BY b.message_timestamp DESC;
```

REPLY_INQUIRY_MESSAGES scalar function

The REPLY_INQUIRY_MESSAGES scalar function replies to one or more inquiry messages in the QSYSOPR message queue.

This function extends what can be done by the Send Reply (SNDRPY) CL command.

Authorization: See Note below.

The schema is SYSTOOLS.

- message-id** A character string containing the message identifier of the inquiry message. The special value *IMMED can be specified to indicate the message has no message identifier.
- search-message-text** A character string containing a string that must exist in the message text in order for the inquiry message to be selected. The comparison is case insensitive.
When *message-id* is *IMMED, a value must be specified. Otherwise, a value is optional.
- response** A character string containing the response to be provided to any inquiry messages that meet the *message-id* and *search-string* criteria.
If *response* is omitted or contains the value *DFT, the default reply stored in the message description of the inquiry message is sent as the reply, or the system default reply of *N is used.
- remove-message** A character string that indicates whether the inquiry message and its reply are removed from the message queue.
- NO** The message will not be removed.
- YES** The message will be removed. This is the default.

The result of the function is an integer that indicates the number of inquiry messages that were responded to.

Note

This function is provided in the SYSTOOLS schema as an example of how to respond to inquiry messages in the QSYSOPR message queue using an SQL scalar function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Examples

- Respond to any inquiry messages for message identifier CPA7025. Leave the messages in the message queue.

```
VALUES SYSTOOLS.REPLY_INQUIRY_MESSAGES(  
    MESSAGE_ID => 'CPA7025',  
    RESPONSE => 'I',  
    REMOVE_MESSAGE => 'NO'  
);
```

- Respond to any impromptu inquiry messages containing the text string 'restore'.

```
VALUES SYSTOOLS.REPLY_INQUIRY_MESSAGES(  
    MESSAGE_ID => '*IMMED',  
    SEARCH_MESSAGE_TEXT => 'restore',  
    RESPONSE => 'CONTINUE',  
    REMOVE_MESSAGE => 'YES'  
);
```

REPLY_LIST_INFO view

The REPLY_LIST_INFO view contains information about the current job's reply list entries.

The information returned is similar to the detail available through the Work with Reply List Entries (WRKRPYLE) CL command.

Authorization: None required.

The following table describes the columns in the view. The system name is REPLYLIST. The schema is QSYS2.

Table 212. REPLY_LIST_INFO view

Column Name	System Column Name	Data Type	Description
SEQUENCE_NUMBER	SEQNO	SMALLINT	The number that specifies the search order of the entries in the reply list.
MESSAGE_ID	MSGID	VARCHAR(7)	The identifier of the inquiry message for which automatic system action is to be taken. A value of ANY indicates that this reply list entry matches any message identifier. Unless comparison data is specified for this reply list entry, all reply list entries with a sequence number greater than this one are ignored.
MESSAGE_REPLY	REPLY	VARCHAR(32)	When an inquiry message is received with a matching message identifier, this value defines whether an automatic reply to the message is given. DEFAULT The default reply to the inquiry message is sent. REQUIRED The inquiry message requires an explicit reply. character string The character string to be sent as the reply to the inquiry message.
COMPARISON_DATA	COMPDATA	VARGRAPHIC(28) CCSID 1200 Nullable	The character string that is compared with the message data of the inquiry message. Contains the null value if there is no comparison data.
COMPARISON_DATA_OFFSET	OFFSET	SMALLINT Nullable	The position in the message data of the inquiry message at which the comparison with the COMPARISON_DATA starts. Contains the null value if there is no comparison data.
DUMP_JOB	DUMPJOB	VARCHAR(3)	Specifies whether the job that sent the inquiry message is to be dumped. NO The job is not dumped. YES The job is dumped before control returns to the program that is sending the message.

Example

- See the reply list entries for your job

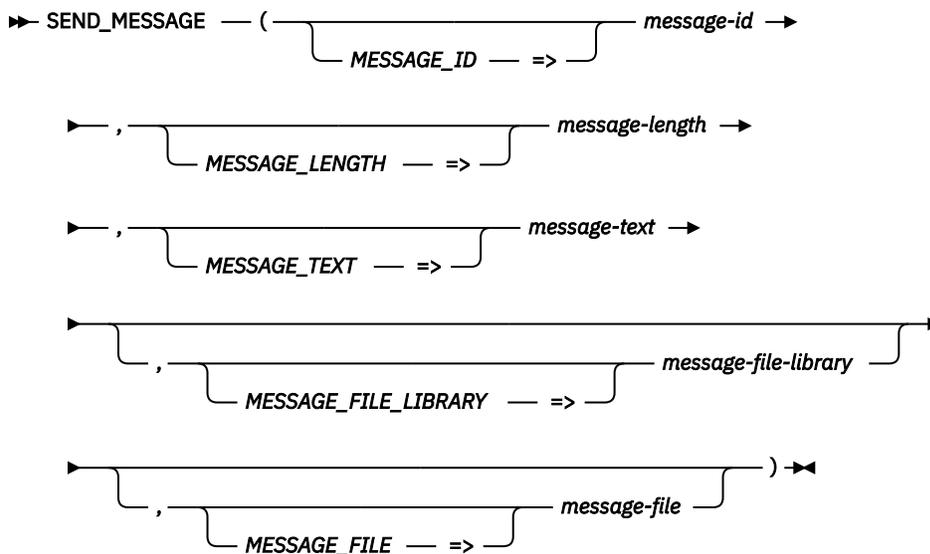

```
SELECT * FROM QSYS2.REPLY_LIST_INFO
```

SEND_MESSAGE procedure

The SEND_MESSAGE procedure sends an informational message to the QSYSOPR message queue.

Authorization: The caller must have:

- *OBJOPR and *ADD authorities to the QSYSOPR message queue,
- *EXECUTE authority to the library containing the message file, and
- *USE authority to the message file.

The schema is QSYS2.

- message-id** A character string expression that identifies the message ID to send to the QSYSOPR message queue.
- message-length** An integer value that defines the length of *message-text*.
- message-text** The message text for the message.
- message-file-library** The library that contains *message-file*. Can contain the special value *LIBL. The default is QSYS.
- message-file** The message file that contains *message-id*. The default is QSQLMSG.

Notes

This procedure is designed to send a predefined message to the QSYSOPR message queue. The message is expected to have one substitution variable defined as *CHAR *VARY 2.

When sending a message from a Query Supervisor exit program, SQL7064 in the QSYS/QSQLMSG message file is defined for this purpose. When sending a message in other situations, it is recommended that a different message should be used.

Example

- Send a message to the QSYSOPR message queue when a critical error is diagnosed.

```
CALL QSYS2.SEND_MESSAGE('APP1234', 31, 'Unexpected error in MYLIB/PGM2.' ,
                        'APPLIB', 'MYMSGF');
```

Performance Services

These services provide information related to system performance.

COLLECTION_SERVICES_INFO view

The COLLECTION_SERVICES_INFO view returns the configuration properties for Collection Services.

The values returned for the columns in the view are closely related to the values returned by the Configure Perf Collection (CFGPFRCOL) CL command and the Retrieve Collection Services Attributes (QypsRtvColSrvAttributes) API.

Authorization: The caller must have *USE authority on the QSYS/QYPSCOLL service program or be authorized through the QPMCCFCN authorization list.

The following table describes the columns in the view. The system name is CS_INFO. The schema is QSYS2.

Table 213. COLLECTION_SERVICES_INFO view

Column Name	System Column Name	Data Type	Description
ACTIVE_COLLECTION_LIBRARY	CURCOL_LIB	VARCHAR(10) Nullable	The name of the library where the currently active management collection object is stored. Contains the null value if there is no active collection.
ACTIVE_COLLECTION_NAME	CURCOL	VARCHAR(10) Nullable	The name of the current management collection object. Contains the null value if there is no active collection.
ACTIVE_COLLECTION_PROFILE	CURCOL_PRF	VARCHAR(10) Nullable	The name of the collection profile being used by the active collection. The collection profile defines which categories of data to collect. *CUSTOM A profile where both the categories to collect and category interval times may be customized. *ENHCPCPLN Enhanced Capacity Planning. Same as *STANDARDP plus the PEX Data - Processor Efficiency category. *MINIMUM The minimum set of categories required to support basic performance reporting functions. *STANDARD All categories that are typically used for performance reporting except for communications protocol related data. *STANDARDP Same as *STANDARD but communications protocol categories are included. Contains the null value if there is no active collection.
ACTIVE_COLLECTION_START_TIME	START_TIME	TIMESTAMP Nullable	The UTC timestamp when the current (active) collection was started. Contains the null value if there is no active collection.
COLLECTION_LIBRARY	LIB	VARCHAR(10)	The name of the library where performance data is stored.
COLLECTION_PROFILE	DFTCOLPRF	VARCHAR(10)	The name of the configured collection profile. The collection profile defines which categories of data to collect. *CUSTOM A profile where both the categories to collect and category interval times may be customized. *ENHCPCPLN Enhanced Capacity Planning. Same as *STANDARDP plus the PEX Data - Processor Efficiency category. *MINIMUM The minimum set of categories required to support basic performance reporting functions. *STANDARD All categories that are typically used for performance reporting except for communications protocol related data. *STANDARDP Same as *STANDARD but communications protocol categories are included.
DEFAULT_COLLECTION_INTERVAL	INTERVAL	INTEGER Nullable	The default interval, in seconds, used when collecting data for a category. Values are: 15, 30, 60, 300, 900, 1800, or 3600 seconds. Contains the null value if not collecting on an interval.
MGTCOL_RETENTION_PERIOD	RETPERIOD	INTEGER Nullable	The management collection (*MGTCOL) object retention period, in hours. *MGTCOL objects in the configured collection library that are older than the retention period are automatically deleted when Collection Services is started or cycled. Contains the null value for permanent retention.
CYCLE_TIME	CYCTIME	INTEGER	The number of minutes past midnight when the first cycle is to occur. The maximum value is 1439 minutes (which is one minute less than 24 hours).
CYCLE_INTERVAL	CYCITV	INTEGER	The number of hours between cycles. The cycle time can range from a minimum value of one hour to a maximum value of 24 hours.

Table 213. COLLECTION_SERVICES_INFO view (continued)

Column Name	System Column Name	Data Type	Description
CREATE_STANDARD_DB_FILES	CRTDBF	VARCHAR(3)	<p>Whether the standard database file collection is created by Collection Services while performance data is being collected.</p> <p>NO Collection Services will not create the standard database file collection.</p> <p>YES Collection Services will create the standard database file collection. A batch job named CRTPFRTA is submitted to process the data in the current management collection object as it is collected. The collection name (begins with a "Q") is the same as the name of the *MGTCOL the data was exported from.</p>
RETENTION_DAYS	STDDTARET	INTEGER Nullable	<p>This retention period, in days, used to determine how long standard database file collections should be retained on the system. When Collection Services is started or cycled, the Collection Services server job (QYSPFRCOL) will automatically delete standard database file collections in the configured collection library that are older than the current retention period.</p> <p>Contains the null value for permanent retention.</p>
CREATE_SUMMARY_DB_FILES	CRTPFRSUM	VARCHAR(3)	<p>Whether additional logical files are created as supported by the CRTPFRSUM command.</p> <p>NO Summary file data is not generated.</p> <p>YES Summary file data is generated.</p>
CREATE_SYSTEM_MONITOR_DB_FILES	CRTSYSMON	VARCHAR(3)	<p>Whether additional system monitor database files should be created by Collection Services while performance data is being collected.</p> <p>NO Collection Services will not create the system monitor database files for the standard database file collection.</p> <p>YES Collection Services will create the system monitor database files for the standard database file collection. The batch job named CRTPFRTA will populate the system monitor database files using the data in the current management collection object as it is collected.</p>
ENABLE_SYSTEM_MONITORING	ENBSYSMON	VARCHAR(3)	<p>Whether Collection Services is configured to collect and produce data for system monitors.</p> <p>NO System monitor support is not enabled.</p> <p>YES System monitor support is enabled. Collection Services will collect certain data categories more frequently than the configured default collection interval. A batch job named CRTPFRTA2 is submitted to produce a system monitor database file collection with the same name as the management collection object except it begins with an 'R'.</p>
SYSTEM_MONITOR_DB_FILE_RETENTION	SYSMONRET	INTEGER Nullable	<p>This retention period, in days, used to determine how long system monitor database file collections should be retained on the system. When Collection Services is started or cycled, the Collection Services server job (QYSPFRCOL) will automatically delete system monitor database file collections in the configured collection library that are older than the retention period.</p> <p>Contains the null value for permanent retention.</p>
CATEGORY_LIST_COUNT	CGY_COUNT	INTEGER	The number of entries in CATEGORY_LIST.
CATEGORY_LIST	SYSMONCGY	VARCHAR(2000) CCSID 1208 Nullable	<p>A list of collection categories that are included in the system monitor collection. Each category can have an independent collection interval. This list is returned as an array within a JSON object.</p> <p>Each entry in the JSON array contains two JSON objects:</p> <ul style="list-style-type: none"> An object with a name of "category" and a value of the category name An object with a name of "interval" and a value of the category's collection interval, in seconds <p>Contains the null value if CATEGORY_LIST_COUNT is 0.</p>
EXCLUDED_LINE_COUNT	EXC_COUNT	INTEGER	The number of entries in EXCLUDED_LINE_LIST.

Table 213. COLLECTION_SERVICES_INFO view (continued)

Column Name	System Column Name	Data Type	Description
EXCLUDED_LINE_LIST	EXC_LIST	VARCHAR(598) Nullable	A list of communication line names that are excluded from the calculation of communication line protocol metrics. Each entry is ten characters long with a comma and space separating entries. Contains the null value if EXCLUDED_LINE_COUNT is 0.
CREATE_HISTORICAL_DATA	CRTPFHST	VARCHAR(3)	Whether historical data will be created when Collection Services is cycled. NO Collection Services will not create historical data. YES Collection Services will create historical data by processing management collection objects that exist in the configured collection library. A batch job named QYSPFRHST is submitted by Collection Services at cycle time.
HISTORICAL_DATA_INTERVAL	HSTITV	INTEGER	The time interval, in seconds, used to create historical data.
HISTORICAL_SUMMARY_DATA_RETENTION	HSTSUMRET	INTEGER	The historical summary data retention period, in months, that determines how long Collection Services historical summary data is to exist. Historical summary data is stored in files beginning with QAPMHMxxxx. Historical summary data older than the retention period is deleted.
CREATE_HISTORICAL_DETAILED_DATA	CRTHSTDTL	VARCHAR(3)	Whether historical detailed data will be created when Collection Services is cycled. Creating historical detailed data will allow detailed data for the top contributors of various metrics to be stored in the historical collection to be used as drill-down data. The number of top contributors is determined by the value of the historical detailed data filter. NO Collection Services will not create historical detailed data. YES Collection Services will create historical detailed data when processing management collection objects that exist in the configured collection library. A batch job named QYSPFRHST is submitted by Collection Services at cycle time.
HISTORICAL_DETAILED_DATA_RETENTION	HSTDTLRET	INTEGER	The historical detailed data retention period, in days, that determines how long Collection Services historical detailed data is to exist. Historical detailed data is stored in files beginning with QAPMHDxxxx. Historical detailed data older than the retention period is deleted.
HISTORICAL_DETAILED_DATA_FILTER	HSTFILTER	INTEGER Nullable	The number of top contributors for each metric to be stored in the historical data collection to be used as detailed drill-down data. Contains the null value if all detailed data is kept.

Example

- Return the Collection Services configuration properties.

```
SELECT * FROM QSYS2.COLLECTION_SERVICES_INFO;
```

PowerHA Services

These table functions and views provide information about PowerHA.

[PowerHA SQL Services](#)

Product Services

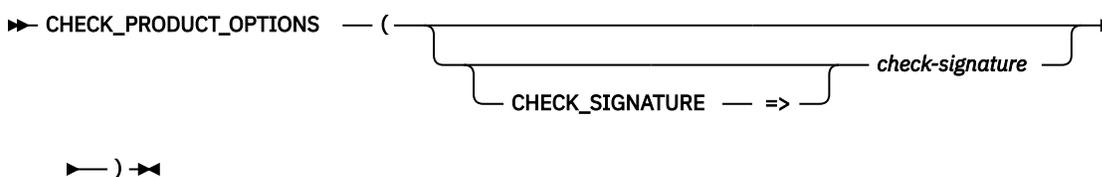

These services provide information about licensed products.

CHECK_PRODUCT_OPTIONS table function

The CHECK_PRODUCT_OPTIONS table function reports differences between the correct structure and the actual structure of all installed software products.

This service combines the QSYS2.SOFTWARE_PRODUCT_INFO view and the Check Product Option (CHKPRDOPT) CL command to check all the installed products and options on the system.

Authorization: See Note below.

The schema is SYSTOOLS.

check-signature An expression that indicates whether the digital signatures of objects are to be checked.

- *ALL** All objects that can be digitally signed will have the signature verified. Any object that can be signed but has no signature will be identified in a message but the product will not be set to be in error. Any signed object with a signature that is not valid will be identified in a message. If an invalid signature is found, the product will be set to be in an erroneous state.
- *NONE** Digital signatures of objects will not be checked.
- *SIGNED** Objects with digital signatures are checked. Any object that has been signed will have the signature verified. Objects with invalid signatures will be identified in a message and the product will be set to be in an erroneous state. This is the default.

The result of the function is a table containing multiple rows with the format shown in the following table. All the columns are nullable.

Table 214. CHECK_PRODUCT_OPTIONS table function

Column Name	Data Type	Description
PRODUCT_ID	VARCHAR(7)	The product ID.
PRODUCT_OPTION	VARCHAR(5)	The product option of the product. Can contain the following special value: *BASE The base part of the product.
LOAD_ID	VARCHAR(4)	The load ID of the product load .
RELEASE_LEVEL	VARCHAR(10)	The release level of the product.
CHECK_SUCCESSFUL	VARCHAR(3)	Whether the check was successful. NO A message was returned for this product option. YES No message was returned for this product option.
FAILURE_MESSAGE_ID	CHAR(7)	The message ID of the failure when CHECK_SUCCESSFUL has a value of NO. Examine the job log for additional message details. The CL command listed in the CHKPRDOPT_COMMAND column can be used to run the check again. Contains the null value if CHECK_SUCCESSFUL is YES.
FAILURE_MESSAGE_TEXT	VARGRAPHIC(1024) CCSID 1200	The message text for the failure when CHECK_SUCCESSFUL has a value of NO. Contains the null value if CHECK_SUCCESSFUL is YES.
CHKPRDOPT_COMMAND	VARCHAR(1000)	The CL command string used to check this product option.

Note

This function is provided in the SYSTOOLS schema as an example of how to return information that has been written to the joblog. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

- List any potential problems with all installed software products.

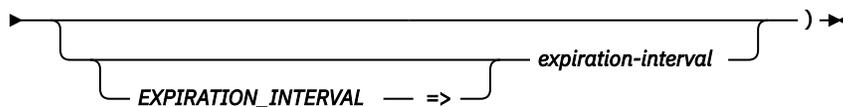

```
SELECT * FROM TABLE(SYSTOOLS.CHECK_PRODUCT_OPTIONS( ));
```

LICENSE_EXPIRATION_CHECK procedure

The LICENSE_EXPIRATION_CHECK procedure sends a message to the QSYSOPR message queue for every license that corresponds to an installed product that has already expired or is set to expire within the specified number of days.

Authorization: See Note below.

►► LICENSE_EXPIRATION_CHECK — (→

The schema is SYSTOOLS.

expiration-interval An integer value that indicates the number of days to use as the threshold for checking license information. If not specified, 30 will be used.

Note

This procedure is provided in the SYSTOOLS schema as an example of how to work with license information using an SQL procedure. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar procedures, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

- Send an informational message to the system operator message queue, QSYS/QSYSOPR, for every installed product with a license that will expire in the next 10 days.

```
CALL SYSTOOLS.LICENSE_EXPIRATION_CHECK(10);
```

LICENSE_INFO view

The LICENSE_INFO view contains information about all products or features that contain license information.

The values returned for the columns in the view are similar to the values returned by the Work with License Information (WRKLICINF) CL command or [Retrieve License Information \(QLZARTV\) API](#). Refer to the API for more detailed information.

Authorization: None required.

The following table describes the columns in the view. The system name is LIC_INFO. The schema is QSYS2.

Table 215. LICENSE_INFO view

Column Name	System Column Name	Data Type	Description
PRODUCT_ID	LICPGM	VARCHAR(7)	The identifier of the product.
LICENSE_TERM	LIC_TERM	VARCHAR(6)	The license term indicates whether the authorized usage limit for a product exists until the next version, next release, or next modification level of the product. <ul style="list-style-type: none"> Vx or vv for products licensed by version. VxRy or vvrr for products licensed by release. VxRyMz or vvrrmm for products licensed by modification.
RELEASE_LEVEL	RLS_LVL	VARCHAR(6)	The version, release, and modification level of the product in either VxRyMz or vvrrmm format.
FEATURE_ID	FEATURE	VARCHAR(4)	The feature number of the product.
INSTALLED	INSTALLED	VARCHAR(3)	Indicates whether this feature number of the product is installed. <p>NO The feature is not installed.</p> <p>YES The feature is installed.</p>
PROCESSOR_GROUP	PROC_GROUP	VARCHAR(3)	The processor group of this system.
PRODUCT_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	The description of the product or feature. Contains null if there is no description text.
USAGE_LIMIT	USG_LIMIT	INTEGER Nullable	The usage limit of the product or feature that contains license information. Values are 0-999999 indicating the number of users allowed to access the product. Contains null if there is no usage limit.
USAGE_LIMIT_UPDATED	USG_UPDATE	TIMESTAMP(0) Nullable	The timestamp when the usage limit was last updated. Contains null if the usage limit has never been updated.
USAGE_TYPE	USAGE_TYPE	VARCHAR(11)	The usage type of the license. <p>*CONCURRENT The usage type is concurrent, meaning the usage limit is for the number of uses held by unique jobs using the product or feature at the same time.</p> <p>*REGISTERED The usage type is registered, meaning the usage limit is for the number of uses held by license users registered to use the product or feature.</p> <p>*PROCESSOR The usage type is processor, meaning the usage limit is for the number of processors on system partitions where this product or feature is in use.</p>
USAGE_COUNT	USG_COUNT	DECIMAL(8,2)	The current usage count for the product or feature. Valid values are 0 through 999999. If the product is using processor usage type, the usage count value is rounded up to the next whole number.
GLOBAL_COUNT	GLOB_COUNT	DECIMAL(8,2)	The number of jobs currently using this product or feature across all system partitions.
LICENSED_USER_COUNT	LIC_COUNT	INTEGER	The number of current license users.

Table 215. LICENSE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
THRESHOLD	THRESHOLD	DECIMAL(10,2) Nullable	The usage limit threshold for this product or feature. Contains null if there is no usage limit threshold.
PEAK_USAGE	PEAK_USAGE	DECIMAL(10,2)	For concurrent usage, the maximum number of uses held by license users of the product or feature at one time. For registered usage, the maximum number of uses that have been registered through license users for the product or feature. For processor usage, the maximum number of processors configured for this system partition while this product or feature was in use.
LAST_PEAK	LAST_PEAK	TIMESTAMP(0) Nullable	The timestamp when the peak usage of the product or feature last occurred since the peak usage was reset to zero. Contains null if the product has not been used since the peak usage was reset to zero.
COMPLIANCE_TYPE	COMP_TYPE	VARCHAR(10)	The compliance type of the program determines the action taken when the usage limit of the product or feature is exceeded. *OPRACTION License requests are denied and failure messages are sent. *WARNING A warning message is sent. *KEYED Requests for licenses over the usage limit are allowed for the number of days in the product's grace period. Once the grace period ends, the license users holding uses over the usage limit will be released and no requests for uses over the limit will be granted until a new license key is received from the software provider. The expiration date is the date the license will expire. After the expiration date is reached, the default usage limit is in effect. When a request for a license is received after the usage limit has been reached, the system sends a warning message to the system operator message queue and to any additional message queues defined for the product.
LOG_VIOLATION	LOG	VARCHAR(3)	Specifies whether or not requests exceeding the usage limit are logged in the QUSRSYS/QLZALOG journal. NO The requests for a license when the usage count is greater than or equal to the usage limit will not be logged. YES The requests for a license when the usage count is greater than or equal to the usage limit will be logged.
LICENSE_EXPIRATION	EXPIR_DATE	DATE Nullable	The date the license will expire. After the expiration date is reached, the usage limit is reset to the default usage limit. Contains null if the license has no expiration date.
GRACE_PERIOD	GRACE_PRD	INTEGER	The number of days a user has to obtain a new license key after a product or feature exceeds its usage limit.
GRACE_END	GRACE_END	DATE Nullable	The date the grace period expires. When a request for license uses exceeds the usage limit for a product or feature, the date the grace period expires is determined by adding the number of days in the grace period to the current date. Contains null if there is no grace period or the grace period has expired.
VENDOR_DATA	VENDOR	VARCHAR(8)	Information the vendor defined when the key was added using the Add License Key Information (ADDLICENSE) command.

Table 215. LICENSE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
MESSAGE_QUEUE1	MESSAGE_1	VARCHAR(10) Nullable	The name of the first message queue to which messages will be sent. Each of these message queues, in addition to the system operator message queue, will be sent a messages if one of the following occurs: <ul style="list-style-type: none"> The usage count threshold is met. A license request is made, and the usage count is equal to or greater than the usage limit. The usage limit is changed. The messages sent include: <ul style="list-style-type: none"> CPI9E10 - License usage limit changed for product &1. CPI9E19 - Usage limit threshold exceeded. CPI9E75 - Grace period will expire on &3. CPI9E76 - Expiration date will be reached on &3. Contains null if there is no first message queue.
MESSAGE_QUEUE_LIBRARY1	LIBRARY_1	VARCHAR(10) Nullable	The library containing the first message queue. Contains null if there is no first message queue.
MESSAGE_QUEUE2	MESSAGE_2	VARCHAR(10) Nullable	The name of the second message queue to which messages will be sent. Contains null if there is no second message queue.
MESSAGE_QUEUE_LIBRARY2	LIBRARY_2	VARCHAR(10) Nullable	The library containing the second message queue. Contains null if there is no second message queue.
MESSAGE_QUEUE3	MESSAGE_3	VARCHAR(10) Nullable	The name of the third message queue to which messages will be sent. Contains null if there is no third message queue.
MESSAGE_QUEUE_LIBRARY3	LIBRARY_3	VARCHAR(10) Nullable	The library containing the third message queue. Contains null if there is no third message queue.
MESSAGE_QUEUE4	MESSAGE_4	VARCHAR(10) Nullable	The name of the fourth message queue to which messages will be sent. Contains null if there is no fourth message queue.
MESSAGE_QUEUE_LIBRARY4	LIBRARY_4	VARCHAR(10) Nullable	The library containing the fourth message queue. Contains null if there is no fourth message queue.
MESSAGE_QUEUE5	MESSAGE_5	VARCHAR(10) Nullable	The name of the fifth message queue to which messages will be sent. Contains null if there is no fifth message queue.
MESSAGE_QUEUE_LIBRARY5	LIBRARY_5	VARCHAR(10) Nullable	The library containing the fifth message queue. Contains null if there is no fifth message queue.

Example

Return information about all licensed products and features that will expire within the next 2 weeks.

```
SELECT * FROM QSYS2.LICENSE_INFO
WHERE LICENSE_EXPIRATION <= CURRENT DATE + 14 DAYS;
```

SOFTWARE_PRODUCT_INFO view

The SOFTWARE_PRODUCT_INFO view returns information about software products.

The values returned for the columns in the view are closely related to the values returned by the Display Software Resources (DSPSFWRSC) command and the Retrieve Product Information (QSZRTVPR) API.

Authorization: None required.

The following table describes the columns in the view. The system name is SFW_PROD. The schema is QSYS2.

Table 216. SOFTWARE_PRODUCT_INFO view

Column Name	System Column Name	Data Type	Description
PRODUCT_ID	PRODUCT_ID	VARCHAR(7)	The product ID.
PRODUCT_OPTION	PROD_OPT	VARCHAR(5)	The product option of the product. Can contain the following special value: *BASE The base part of the product.
LOAD_ID	LOAD_ID	VARCHAR(4)	The load ID of the product load for which information was returned.
LOAD_TYPE	LOAD_TYPE	VARCHAR(8)	The type of load. CODE The load is a code load. LANGUAGE The load is a language load.
RELEASE_LEVEL	RELEASE	VARCHAR(10)	The release level of the product selected.
INSTALLED	INSTALLED	VARCHAR(3)	Whether the code load for this product option is installed. A load is installed if a product load (*PRDLOD) object is loaded on the system by the Restore Licensed Program (RSTLICPGM) command. NO The code load for this product option is not installed. YES The code load for this product option is installed.
SYMBOLIC_LOAD_STATE	SYM_STATE	VARCHAR(9)	The symbolic state of the load for which information was returned. This value, in conjunction with the LOAD_ERROR column, can be used to determine if the load is installed correctly. CREATED The product load object for this load exists. DAMAGED If this is for an option other than the base option or for a language load for the base option, the product load object has been damaged. If this is for the code load for the base option, one of the following happened: <ul style="list-style-type: none"> The product definition for this product ID and release level has been damaged. The product load object has been damaged. DEFINED The load is defined. The product load object for this load does not exist. INSTALLED The product load (*PRDLOD) object for this load was loaded onto the system by the RSTLICPGM command. LOADED Indicates one of the following: <ul style="list-style-type: none"> A restore licensed program function is in progress. A delete licensed program function is in progress. PACKAGED The product load object for this load has been packaged with the PKGPRDOPT command.

Table 216. SOFTWARE_PRODUCT_INFO view (continued)

Column Name	System Column Name	Data Type	Description
LOAD_ERROR	LOAD_ERROR	VARCHAR(3)	<p>Whether there is a known error for this load.</p> <p>NO No error was found the last time that the state of this load was checked or updated.</p> <p>YES An error was found the last time that the state of this load was checked or updated.</p>
LOAD_STATE	LOAD_STATE	CHAR(2)	<p>The state of the load for which information was returned.</p> <p>10 The load is defined.</p> <p>20 The product load object for this load exists.</p> <p>30 The product load object for this load has been packaged with the PKGPRDOPT command or the QSZPKGPO API.</p> <p>32 The product load object for this load has been packaged with the PKGPRDOPT command or the QSZPKGPO API. Either a development library or folder was renamed, but the product does not allow dynamic naming, or the product definition or product load for a packaged load was renamed or moved to another library.</p> <p>33 The product load object for this load has been packaged with the PKGPRDOPT command or the QSZPKGPO API. However, an object was found to be damaged the last time that the CHKPRDOPT command or SAVLICPGM command was used for this load.</p> <p>34 The product load object for this load has been packaged with the PKGPRDOPT command or the QSZPKGPO API. Either an attempt was made to delete the product load using the delete licensed program function and the function failed, or a packaged object was missing the last time that the CHKPRDOPT command or SAVLICPGM command was used for this load.</p> <p>35 A RSTLICPGM command is in progress. The product being replaced had been packaged, but not installed.</p> <p>38 A DLTLICPGM command is in progress. The product being deleted had been packaged, but not installed.</p> <p>3E A RSTLICPGM command did not complete successfully. A preoperation exit program failed. The product being replaced had been packaged, but not installed.</p> <p>3F A RSTLICPGM command failed. A preoperation exit program did not fail. The product being replaced had been packaged, but not installed.</p> <p>50 A RSTLICPGM command is in progress. The product being replaced had been installed.</p> <p>53 A DLTLICPGM command is in progress. The product being deleted had been installed.</p> <p>59 This product is an IBM-supplied product, and it is not compatible with the currently installed release level of the operating system.</p>

Table 216. SOFTWARE_PRODUCT_INFO view (continued)

Column Name	System Column Name	Data Type	Description
LOAD_STATE (continued)			<p>60 The product load object for this load was loaded onto the system by the RSTLICPGM command.</p> <p>61 The product load object for this load was loaded onto the system by the RSTLICPGM command, but a postoperation exit program failed.</p> <p>62 An installed library or folder was renamed, but the product does not allow dynamic naming.</p> <p>63 The product load object for this load was installed by the RSTLICPGM command, but an object is damaged.</p> <p>64 The product load object for this load was installed by the RSTLICPGM command, but an object was found to be missing when CHKPRDOPT or SAVLICPGM was used, or an error occurred while DLTICPGM was being used.</p> <p>67 The CHKPRDOPT command was used for this product load, but the postoperation exit program failed or indicated that an error was found.</p> <p>6E A RSTLICPGM command did not complete successfully.</p> <p>6F A RSTLICPGM command failed.</p> <p>90 The product load was installed successfully. If an object was missing or was damaged, and the problem was corrected, using the CHKPRDOPT command sets the state back to 90.</p>
SUPPORTED	SUPPORTED	VARCHAR(3)	<p>Whether this load is currently supported. A load can be supported by using the Work with Supported Products (WRKSPTPRD) command in the System Manager for IBM i licensed program.</p> <p>NO This load is not currently supported.</p> <p>YES This load is currently supported.</p>
COMPATIBLE	COMPATIBLE	VARCHAR(3) Nullable	<p>Indicates whether this IBM product is compatible with the current release.</p> <p>NO The product is not compatible.</p> <p>YES The product is compatible.</p> <p>Contains the null value if this product does not have a compatibility value.</p>
PRODUCT_LIBRARY_COUNT	LIB_COUNT	INTEGER	The number of product libraries included in the PRODUCT_LIBRARIES column.
PRODUCT_LIBRARIES	PROD_LIB	VARCHAR(120) Nullable	<p>The list of product load libraries. Each library name entry is ten characters long with one blank separating entries.</p> <p>Contains the null value if PRODUCT_LIBRARY_COUNT is 0.</p>
PRODUCT_DIRECTORY_COUNT	DIR_COUNT	INTEGER	The number of product directories included in the PRODUCT_DIRECTORIES column.
PRODUCT_DIRECTORIES	PROD_DIR	DBCLOB(5M) CCSID 1200 Nullable	<p>The list of product directories. Directory entries are separated by the string '--' (a blank, two minus signs, and a blank).</p> <p>Contains the null value if PRODUCT_DIRECTORY_COUNT is 0.</p>

Table 216. SOFTWARE_PRODUCT_INFO view (continued)

Column Name	System Column Name	Data Type	Description
TEXT_DESCRIPTION	TEXT	VARCHAR(132) Nullable	Text description for this product option. Contains the null value if there is no text description or the text description is not available.
PRIMARY_LANGUAGE_LOAD_ID	LANG_ID	CHAR(4) Nullable	For code loads, this field contains the primary language of the product option. Contains the null value for language loads and for code loads when no language is installed in the libraries for the code load.
RELEASE_DATE	REL_DATE	DATE Nullable	Indicates the value specified for the release date when the product definition for this product load was created. Contains the null value if no release date was specified.
MINIMUM_TARGET_RELEASE	MIN_TGTRLS	CHAR(6)	The minimum release of the operating system to which the Save Licensed Program (SAVLICPGM) command will allow the product to be saved.
MINIMUM_VRM_BASE	MIN_BASE	CHAR(6) Nullable	The minimum release level that is allowed for the *BASE option that will run with the current level of the option for the product. Can containing the following special value: *MATCH The release of the option matches that of the *BASE. Contains the null value for Licensed Internal Code.
REQUIREMENTS_MET	REQ_MET	INTEGER	The reason why the release requirements between the base and option may or may not be in error. 0 There is not enough information available to determine if the release requirements have been met. This value if always returned for a load type of *LANG. 1 The releases of the *BASE and option meet all requirements. 2 The release of the option is too old compared to the *BASE. 3 The release of the *BASE is too old compared to the option.
MIXED_RELEASES	MIXED_REL	VARCHAR(3)	Product allows mixed releases. NO The *BASE option and other options of this product cannot be at different release levels. YES The *BASE option and other options of this product can be at different release levels.
LEVEL_ID	LEVEL_ID	CHAR(3) Nullable	The level identifier of the product for which information was returned. The format is Lxx. Contains the null value for all products other than the operating system and Licensed Internal Code.
REGISTRATION_TYPE	REG_TYPE	CHAR(2)	The registration type associated with the product. The registration type and registration value together make up the registration ID for the product.
REGISTRATION_VALUE	REG_VALUE	VARCHAR(14)	The registration value associated with the product.

Example

- List any licensed programs that are in an error state.

```
SELECT *
FROM QSYS2.SOFTWARE_PRODUCT_INFO
WHERE LOAD_ERROR = 'YES';
```

PTF Services

These views provide PTF information.

DEFECTIVE_PTF_CURRENCY view

The DEFECTIVE_PTF_CURRENCY is a view which returns a list of defective PTFs on the system that do not have the corrective PTF applied.

The data returned by this view is the same data that is returned by GO QMGTOOLS/MG option 24 (PTF Menu), then taking option 3 (Compare DEFECTIVE PTFs from IBM). This information is generally refreshed one time each week.

Authorization: See Note below.

The following table describes the columns in the view. The system name is DEFPTF_CUR. The schema is SYSTOOLS.

Table 217. DEFECTIVE_PTF_CURRENCY view

Column name	System column name	Data type	Description
PARTITION_NAME	PART_NAME	VARGRAPHIC(255) CCSID 1200	The name of the partition as it is known to the HMC.
HOST_NAME	HOST_NAME	VARCHAR(256)	Name of the system.
SERIAL_NUMBER	SERIAL	CHAR(8)	The machine serial number.
OS_RELEASE_LEVEL	OS_RELEASE	VARCHAR(10)	The operating system release level in VxRxMx format.
DEFECTIVE_PTF	DEF_PTF	CHAR(7)	The PTF identifier of the defective PTF.
APAR_ID	APAR_ID	VARCHAR(8)	The APAR associated with the fixing PTF.
PRODUCT_ID	LICPGM	CHAR(7)	The product ID.
FIXING_PTF	FIXING_PTF	CHAR(7)	The PTF identifier of the corrective PTF. Returns the value UNKNOWN if the corrective PTF cannot be determined.

Note

This view is provided in the SYSTOOLS schema as an example of how to retrieve live data from a service using SQL. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar interfaces, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

List any defective PTFs on the current system that have not had the corrective PTF installed.

```
SELECT * FROM SYSTOOLS.DEFECTIVE_PTF_CURRENCY;
```

ELECTRONIC_SERVICE_AGENT_INFO view

The ELECTRONIC_SERVICE_AGENT_INFO view returns detailed information about the Electronic Service Agent (ESA) connections.

The Electronic Service Agent must be configured and activated before this view can successfully return results. See [Electronic Service Agent](#) for information about ESA.

The values returned for the columns in the view are closely related to the detail generated by the VFYSRVAGT TYPE(*DETAIL) CL command.

When the ESA_CONNECTION column contains the null value, there is no connectivity. RESULT_BY_IP_ADDRESS and RESULT_BY_HOSTNAME will both return a value of FAILURE, and partial information will be returned in the other columns.

Authorization: The caller must have *ALLOBJ special authority.

The following table describes the columns in the view. The system name is ESA_INFO. The schema is QSYS2.

Table 218. ELECTRONIC_SERVICE_AGENT_INFO view

Column Name	System Column Name	Data Type	Description
ESA_STATUS	STATUS	VARCHAR(9)	The ESA status. ACTIVATED ESA has been activated on this system INACTIVE ESA has not been activated
ESA_CONNECTION	CONNECTION	VARCHAR(18) Nullable	The type of connection between the IBM i and IBM support servers. DIRECT LAN CONNECT A direct LAN connection is configured HTTP PROXY A connection through an HTTP/HTTPS proxy is configured Contains the null value if the type of connection is not available.
PROXY_HOST_OR_IP	PROXY_HOST	VARCHAR(256) Nullable	The proxy hostname or proxy IP address, depending on the configuration. Contains the null value if ESA_CONNECTION is DIRECT LAN CONNECT.
PROXY_PORT	PROXY_PORT	INTEGER Nullable	The proxy port. Contains the null value if ESA_CONNECTIVITY is DIRECT LAN CONNECT.
PROXY_ID	PROXY_ID	VARCHAR(16) Nullable	The proxy user ID. Contains the null value if the HTTP proxy is a non-authenticated HTTP proxy, if the proxy ID is not configured, or if ESA_CONNECTIVITY is DIRECT LAN CONNECT.
RESULT_BY_IP_ADDRESS	RESULT_IP	VARCHAR(7)	Connection status using IP address. SUCCESS Returned successful status FAILURE Returned failure status UNKNOWN No response If either RESULT_BY_IP_ADDRESS or RESULT_BY_HOSTNAME has a value of SUCCESS, ESA has a working connection.

Table 218. ELECTRONIC_SERVICE_AGENT_INFO view (continued)

Column Name	System Column Name	Data Type	Description
RESULT_BY_HOSTNAME	RESULT_HST	VARCHAR(7)	<p>Connection status using hostname.</p> <p>SUCCESS Returned successful status</p> <p>FAILURE Returned failure status</p> <p>UNKNOWN No response</p> <p>If either RESULT_BY_IP_ADDRESS or RESULT_BY_HOSTNAME has a value of SUCCESS, ESA has a working connection.</p>
SERVER_TYPE	SERV_TYPE	VARCHAR(25)	<p>The type of IBM support server.</p> <p>The following values are returned when using traditional path (Non-Edge) support. If using simplified path (Edge), the values are prefixed with EDGE. For example, EDGE BULK DATA.</p> <p>Appended at the end of the value is a blank followed by a number to make the value unique.</p> <p>BULK DATA Handles bulk data requests</p> <p>CONFIGURATION Handles service provider configuration requests</p> <p>FIX REPOSITORY Handles fix requests</p> <p>GATEWAY Distributes requests to the corresponding servers</p> <p>INVENTORY REPORT Handles inventory report requests</p> <p>PROBLEM REPORT Handles problem call home requests</p> <p>PROFILE Handles profile create/edit/delete requests</p> <p>STATUS REPORT Handles status requests</p> <p>UPDATE ORDER Handles PTF download requests</p>
SERVER_HOSTNAME	SERV_HOST	VARCHAR(30)	The hostname of the server. When using Edge, SERVER_HOSTNAME will be ESUPPORT.IBM.COM .
SERVER_IP_ADDRESS	SERV_IP	VARCHAR(45)	The IP address of the server.
SERVER_PORT	SERV_PORT	INTEGER	The port of the server. The default port is 443.

Example

- Return the connection information for the Electronic Service Agent.

```
SELECT * FROM QSYS2.ELECTRONIC_SERVICE_AGENT_INFO;
```

FIRMWARE_CURRENCY view

The FIRMWARE_CURRENCY view implements a live comparison of the firmware fix level installed on the partition against the level available through a feed from the Fix Level Recommendation Tool (FLRT).

When queried, the view uses Display Hardware Resources (DSPHDWRSC) and Display Firmware Status (DSPFMWSTS) commands and the JSON_TABLE and HTTPGETCLOB functions to consume a live JSON feed from the Fix Level Recommendation Tool. When querying this view, the job CCSID cannot be 65535 or the query will fail.

The result of the query shows the firmware fix level installed on the partition and the firmware latest fix levels made available by IBM. It also returns the general information shown by the DSPFMWSTS command.

Authorization: See Note below.

The following table describes the columns in the view. The system name is FWCUR. The schema is SYSTOOLS.

Table 219. FIRMWARE_CURRENCY view

Column name	System column name	Data type	Description
FW_CURRENCY	FW_CRNCY	VARCHAR(28)	A description of the firmware status. Values returned are: INSTALLED LEVEL IS CURRENT The firmware fix level installed matches the most current available from IBM UPDATE AVAILABLE An update is available from IBM UPGRADE AVAILABLE An upgrade is available from IBM UPDATE AND UPGRADE AVAILABLE Both an update and an upgrade are available from IBM
FW_CURRENT_FIXPACK	FW_FIXPACK	VARCHAR(20)	The current fix level on the partition.
FW_RELEASE_DATE	FW_GA	DATE	The general availability date of the firmware on the partition.
FW_MACHINE_TYPE_MODEL	FW_MTM	VARCHAR(20)	The machine type model of the partition.
FW_RECOMMENDED_UPDATE	FW_RUPD	VARCHAR(20) Nullable	The update fix level of the firmware. Contains the null value if no update version is available.
FW_RECOMMENDED_UPGRADE	FW_RUPG	VARCHAR(20) Nullable	The upgrade fix level of the firmware. Contains the null value if no upgrade version is available.
FW_UPDATE_ACCESS_KEY_EXPIRATION	KEY_EXP	DATE Nullable	The expiration date of the Update access key. Server firmware fix packs with a later date are not activated until a valid Update access key expiration date is detected. Contains the null value if the update access key expiration date is not available.
FW_SERVICE_PARTITION	SVC_PART	VARCHAR(3)	Indicates whether the logical partition is operating as a service partition. NO The logical partition is not operating as a service partition. YES The logical partition is operating as a service partition.
FW_UPDATE_POLICY	UPD_POLICY	VARCHAR(5)	Indicates how changes are made to the server firmware. HMC The server firmware is managed by a Hardware Management Console (HMC). The operating system is not allowed to make changes to the server firmware. OPSYS The server firmware is managed by the operating system using Program Temporary Fixes (PTFs) for the specified server firmware product ID/release (FW_PRODUCT_ID and FW_PRODUCT_RELEASE).

Table 219. FIRMWARE_CURRENCY view (continued)

Column name	System column name	Data type	Description
FW_IPL_SOURCE	IPL_SRC	VARCHAR(9)	The copy of the server firmware that was used on the previous server IPL. PERMANENT The last server IPL used the permanent copy of the server firmware. TEMPORARY The last server IPL used the temporary copy of the server firmware.
FW_IPL_REQUIRED	IPL_REQD	VARCHAR(3)	Whether an IPL is required to activate PTFs for the server firmware product. NO PTFs are active. YES PTFs are applied but are not active.
FW_PRODUCT_ID	PRODUCT_ID	VARCHAR(7) Nullable	The IBM i product that matches the level of the server firmware on the system. Managing the server firmware level is performed by applying or removing PTFs for this product. Contains the null value if no product ID exists for the active server firmware.
FW_PRODUCT_RELEASE	RELEASE	VARCHAR(6) Nullable	The release corresponding to FW_PRODUCT_ID. Contains the null value if no product ID exists for the active server firmware.
FW_TEMPFIXPACK	FW_TEMPFP	VARCHAR(20)	The temporary copy of the server firmware. It has been downloaded to the server and is available to be active but might not be currently active.
FW_PERMFIXPACK	FW_PERMFP	VARCHAR(20)	The permanent copy of the server firmware.

Notes

- The view requires the system to have access to the internet with the ability to access the FLRT website. The FLRT website is:

```
https://esupport.ibm.com/customer care/flrt/liteTable?prodKey=fw&format=json
```

- If the FLRT website is relocated, this view can be updated by the user. Use the Insert Generated SQL feature in ACS to extract the source for the SYSTOOLS.FLRT_FW_INFO table function. Update the link and recreate the table function.
- If any of the CL commands or SQL functions used by the view encounter an error, an error will be returned to indicate the failure. The job log can be examined to determine the root cause of the problem.
- This view is provided in the SYSTOOLS schema as an example of how to retrieve live data using an SQL view and table function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar interfaces, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

Examine the firmware fix level information for the partition.

```
SELECT * FROM SYSTOOLS.FIRMWARE_CURRENCY;
```

GROUP_PTF_CURRENCY view

The GROUP_PTF_CURRENCY is a view containing a query which implements a live comparison of the PTF Groups installed on the partition against the service levels listed on the IBM Preventive Service Planning website. The information is generally updated once a week.

When queried, the view uses the XMLTABLE and HTTPGETBLOB table functions to consume a live XML feed from IBM Preventive Service Planning (PSP). If the partition cannot connect to the PSP website, the PTF_GROUP_CURRENCY column will contain PSP INFORMATION NOT AVAILABLE. When querying this view, the job CCSID cannot be 65535 or the query will fail.

The results of the query show which PTF Groups installed on the partition match the latest level made available by IBM and those which have a more recent version available.

Authorization: See Note below.

The following table describes the columns in the view. The system name is GRPPTFCUR. The schema is SYSTOOLS.

Table 220. GROUP_PTF_CURRENCY view

Column name	System column name	Data type	Description
PTF_GROUP_CURRENCY	GRP_CRNCY	VARCHAR(46) Nullable	A description of the PTF group's status. Values returned are: INSTALLED LEVEL IS CURRENT Indicates that the PTF Group level installed matches the most current level available from IBM CURRENT AT THE NEXT IPL Indicates that the most current PTF Group level available from IBM is ready to be applied when the next IPL occurs. UPDATE AVAILABLE Indicates that a more recent PTF Group level is available from IBM PSP INFORMATION NOT AVAILABLE Indicates that the query is unable to connect to the external IBM PSP PTF Group level feed. Returns the null value if not applicable to this PTF group.
PTF_GROUP_ID	GRP_ID	CHAR(7) Nullable	The name of the PTF group.
PTF_GROUP_TITLE	GRP_TITLE	VARCHAR(1000) Nullable	The descriptive name of the PTF group.
PTF_GROUP_LEVEL_INSTALLED	GRP_LVL	INTEGER Nullable	The most recent level of this PTF Group installed on the partition.
PTF_GROUP_LEVEL_AVAILABLE	GRP_IBMLVL	INTEGER Nullable	The PTF Group level which is available from IBM PSP.
LAST_UPDATED_BY_IBM	GRP_UPDATE	DATE Nullable	The date that IBM made the latest PTF Group level available.
PTF_GROUP_RELEASE	GRP_RLS	VARCHAR(6) Nullable	The release level of the PTF Group. For example, 'R730' indicates IBM i 7.3 release level.
PTF_GROUP_STATUS_ON_SYSTEM	GRP_SYSSTS	VARCHAR(20) Nullable	This column will always contain the value 'INSTALLED'.
PTF_GROUP_LAST_UPDATED_BY_IBM	GRP_LSTUPD	CHAR(10) Nullable	The date that IBM made the latest PTF Group level available. This is the character form of the date formatted as MM/DD/YYYY.

Notes

- The PSP website is:

```
https://public.dhe.ibm.com/services/us/igsc/PSP/xmldoc.xml
```

To determine the IP address for your geography, ping www.ibm.com.

- If the PSP website is relocated, this view can be updated by the user. Use the Insert Generated SQL feature in ACS to extract the source for the SYSTOOLS.GROUP_PTF_CURRENCY view. Update the link and recreate the view.
- The PTF_GROUP_STATUS_ON_SYSTEM column is included in this view to demonstrate that it would be possible to create your own version of this query or view which includes information about PTF Groups that are loaded, but not installed.
- This view is provided in the SYSTOOLS schema as an example of how to retrieve live data using an SQL view and table function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar interfaces, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

Compare the PTF Group service level detail, ordering the results from furthest behind to current.

```
SELECT * FROM SYSTOOLS.GROUP_PTF_CURRENCY
ORDER BY PTF_GROUP_LEVEL_AVAILABLE - PTF_GROUP_LEVEL_INSTALLED DESC
```

Related reference

SYSTOOLS

SYSTOOLS is a set of Db2 for IBM i supplied examples and tools.

GROUP_PTF_DETAILS view

The GROUP_PTF_DETAILS is a view containing a query which implements a live comparison of the PTFs within PTF Groups installed on the partition against the service levels listed on the IBM Preventive Service Planning website.

When queried, the view uses the XMLTable() and HTTPGETBLOB() table functions to consume a live XML feed from IBM Preventive Service Planning (PSP). If the partition cannot connect to the PSP website, the query will fail with an SQL4302. When querying this view, the job CCSID cannot be 65535 or the query will fail.

The results of the query show which PTFs from all PTF Groups installed on the partition match the latest level made available by IBM and those which have a more recent version available.

Authorization: See Note below.

The following table describes the columns in the view. The system name is GRPPTFDL. The schema is SYSTOOLS.

Table 221. GROUP_PTF_DETAILS view

Column name	System column name	Data type	Description
PTF_GROUP_DESCRIPTION	GRPDESC	VARCHAR(100)	Description of the PTF group.
PTF_GROUP_NAME	GRPNAME	CHAR(7)	Name of the PTF group.

Table 221. GROUP_PTF_DETAILS view (continued)

Column name	System column name	Data type	Description
PTF_STATUS	PTF_STATUS	VARCHAR(11)	Status of the PTF. PTF APPLIED The PTF has been loaded and applied. PTF LOADED The PTF has been loaded but not applied. PTF MISSING The PTF does not exist on this partition.
PTF_PRODUCT_ID	LICPGM	VARCHAR(7)	The licensed program for this PTF.
PTF_IDENTIFIER	PTFID	VARCHAR(7)	The identifier of the PTF.
APAR_NAME	APAR_NAME	VARCHAR(8)	The APAR name associated with the PTF.
INCLUDED_IN_GROUP	INCLUDED	DATE	The date that this PTF was first made available in a group PTF.
PTF_CUM_PACKAGE	PTF_CUMPKG	VARCHAR(8)	The identifier of the cumulative PTF package containing this PTF.
PTF_PRODUCT_DESCRIPTION	PRODESC	VARCHAR(132) Nullable	Product description.
PTF_RELEASE_LEVEL	PTFRLS	VARCHAR(6) Nullable	The release level of the PTF.
PTF_PRODUCT_LOAD	PRODLOAD	VARCHAR(4) Nullable	The load ID of the product load for the PTF.
PTF_LOADED_STATUS	LOADSTAT	VARCHAR(19) Nullable	The current loaded status of the PTF. NOT LOADED The PTF has never been loaded. LOADED The PTF has been loaded. APPLIED The PTF has been applied. PERMANENTLY APPLIED The PTF has been applied permanently. PERMANENTLY REMOVED The PTF has been permanently removed. DAMAGED The PTF is damaged. An error occurred while applying the PTF. It needs to be reloaded and applied. SUPERSEDED The PTF is superseded. A PTF will have a status of superseded when one of the following situations occurs: <ul style="list-style-type: none"> Another PTF with a more recent correction for the problem has been loaded on the system. The PTF ID that has been loaded can be found in the PTF_SUPERSEDED_BY_PTF column. The PTF save file for another PTF with a more recent correction for the problem has been logged into *SERVICE on the system.
PTF_SAVE_FILE	SAVF	VARCHAR(3) Nullable	Indicates whether a save file exists for the PTF. NO The PTF has no save file. YES The PTF has a save file.
PTF_COVER_LETTER	COVER	VARCHAR(3) Nullable	Indicates whether a cover letter exists for the PTF. NO The PTF has no cover letter. YES The PTF has a cover letter.

Table 221. GROUP_PTF_DETAILS view (continued)

Column name	System column name	Data type	Description
PTF_ON_ORDER	ONORD	VARCHAR(3) Nullable	Indicates whether the PTF has been ordered. NO The PTF has not been ordered or has already been received. YES The PTF has been ordered.
PTF_IPL_ACTION	IPLACT	VARCHAR(19) Nullable	The action to be taken on this PTF during the next unattended IPL. NONE No action occurs at the next IPL. TEMPORARILY APPLIED The PTF is temporarily applied at the next IPL. TEMPORARILY REMOVED The PTF is temporarily removed at the next IPL. PERMANENTLY APPLIED The PTF is permanently applied at the next IPL. PERMANENTLY REMOVED The PTF is permanently removed at the next IPL.
PTF_ACTION_PENDING	ACTPEND	VARCHAR(3) Nullable	Indicates whether a required action has yet to be performed to make this PTF active. NO No required actions are pending for this PTF. YES A required action needs to occur for this PTF to be active. Check the Activation Instructions section of the cover letter to determine what the action is. If the PTF_ACTION_REQUIRED column is set to IPL and the activation instructions have been performed, then the PTF is active. However, this column will not be updated until the next IPL.
PTF_ACTION_REQUIRED	ACTREQ	VARCHAR(12) Nullable	Indicates whether an action is required to make this PTF active when it is applied. See the cover letter to determine what action needs to be taken. NONE No activation instructions are needed for this PTF. EXIT PROGRAM This PTF was shipped with activation instructions in the cover letter. This value is returned for all PTFs that have an exit program to update the status of the PTF after the activation instructions have been performed. IPL This PTF was shipped with activation instructions in the cover letter. No exit program exists to verify the activation instructions were performed.
PTF_IPL_REQUIRED	IPLREQ	VARCHAR(9) Nullable	Indicates whether an IPL is required to apply this PTF. DELAYED The PTF is delayed. The PTF must be applied during an IPL. IMMEDIATE The PTF is immediate. No IPL is needed to apply the PTF. UNKNOWN The type of the PTF is not known.
PTF_IS_RELEASED	RELEASED	VARCHAR(3) Nullable	Indicates whether the PTF save file is available for distribution to another system. This is set to YES only when the System Manager for IBM i licensed program is on the system and the product is supported. The PTF_SAVE_FILE column must have a value of YES before using the value in this column. NO The PTF save file cannot be distributed. YES The PTF save file is released and can be distributed to another system.

Table 221. GROUP_PTF_DETAILS view (continued)

Column name	System column name	Data type	Description
PTF_MINIMUM_LEVEL	MINLVL	VARCHAR(2) Nullable	The indicator of the lowest level of the product to which this PTF can be applied. The level can be AA to 99. Contains the null value if the product does not have a level.
PTF_MAXIMUM_LEVEL	MAXLVL	VARCHAR(2) Nullable	The indicator of the highest level of the product to which this PTF can be applied. The level can be AA to 99. Contains the null value if the product does not have a level.
PTF_STATUS_TIMESTAMP	STATTIME	TIMESTAMP Nullable	The date and time that the PTF status was last changed. Contains the null value when the status date and time is not available.
PTF_SUPERSEDED_BY_PTF	SUPERSEDE	VARCHAR(7) Nullable	The identifier of the PTF that has replaced this PTF. This field will be blank when the PTF is not superseded or when the superseding PTF has not been loaded on the system.
PTF_CREATION_TIMESTAMP	CRTTIME	TIMESTAMP Nullable	The date and time that the PTF was created. Contains the null value when the creation date and time cannot be determined.
PTF_INCLUDED_IN_GROUP_DATE	PTF_DATE	VARCHAR(10)	The date that this PTF was first made available in a group PTF. Contains the character form of a date formatted as MM/DD/YY.

Notes

The PSP websites used by this service are found based upon the PTF groups that are currently installed on the partition. For each distinct PTF group, a unique PSP XML feed is accessed:

```
https://public.dhe.ibm.com/services/us/igsc/PSP/<PTF-Group-Name>.xml
```

For example, the JAVA PTF group details can be accessed using:

```
https://public.dhe.ibm.com/services/us/igsc/PSP/SF99572.xml
```

To determine the IP address for your geography, ping www.ibm.com.

This view is provided in the SYSTOOLS schema as an example of how to retrieve live data using an SQL view and table function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar interfaces, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

- Review the details for the PTFs which have not yet been applied for the PTF groups installed on this partition.

```
SELECT * FROM SYSTOOLS.GROUP_PTF_DETAILS
WHERE PTF_STATUS <> 'PTF APPLIED'
ORDER BY PTF_GROUP_NAME
```

Related reference

[SYSTOOLS](#)

SYSTOOLS is a set of Db2 for IBM i supplied examples and tools.

GROUP_PTF_INFO view

The GROUP_PTF_INFO view contains information about the group PTFs for the server.

The information returned is similar to the information available from [Work with PTF Groups \(WRKPTFGRP\)](#) CL command.

Authorization: The caller must have *USE authority to the Work with PTF Groups (WRKPTFGRP) command.

The following table describes the columns in the view. The system name is GRPPTFINFO. The schema is QSYS2.

Table 222. GROUP_PTF_INFO view

Column name	System column name	Data type	Description
COLLECTED_TIME	COLLE00001	TIMESTAMP	Date and time of when this row information was generated.
PTF_GROUP_NAME	PTF_G00001	VARCHAR(60) Nullable	Name of the PTF group.
PTF_GROUP_DESCRIPTION	PTF_G00002	VARCHAR(100) Nullable	Description of the PTF group.
PTF_GROUP_LEVEL	PTF_G00003	INTEGER Nullable	Level of the PTF group.
PTF_GROUP_TARGET_RELEASE	PTF_G00004	VARCHAR(6) Nullable	Release level for PTF group.

Table 222. GROUP_PTF_INFO view (continued)

Column name	System column name	Data type	Description
PTF_GROUP_STATUS	PTF_G00005	VARCHAR(20) Nullable	Status of the PTF group. UNKNOWN The PTF group status cannot be resolved because a related PTF group is either not found on the system or is in error. NOT APPLICABLE All PTFs in the PTF group and related PTF groups are for products that are not installed or supported on this system. SUPPORTED ONLY There are no PTFs in the PTF group or related PTF groups that are for installed products on this system. There is at least one PTF that is for a product, release, option, and load identifier that is supported on this system. NOT INSTALLED There is at least one PTF that is for an installed product on this system, and not all of the PTFs or their superseding PTFs are temporarily or permanently applied. INSTALLED All PTFs for products that are installed on this system are temporarily or permanently applied. If a PTF is superseded, a superseding PTF is either temporarily or permanently applied. ERROR The PTF group information is in error. Either delete the PTF group or replace the PTF group information that is currently on the system. APPLY AT NEXT IPL All PTFs for the installed products on the system are either set to be applied at the next IPL or are already temporarily or permanently applied. RELATED GROUP The PTF group does not have any PTFs for products installed or supported on the system. However, it is identified in another PTF group as a related PTF group. Deleting a PTF group in this status will cause the other PTF group to have a status of UNKNOWN. ON ORDER There is at least one PTF in the group that is on order and has not yet been installed on the system. It will be delivered on either physical or virtual media.

Example

Determine the level of the latest CUM PTF group installed on the system.

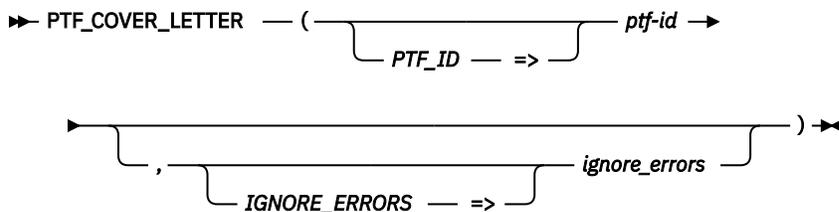

```
SELECT MAX(PTF_GROUP_LEVEL) AS CUM_LEVEL
FROM QSYS2.GROUP_PTF_INFO
WHERE PTF_GROUP_NAME IN ('SF99610', 'SF99710')
AND PTF_GROUP_STATUS = 'INSTALLED'
```

PTF_COVER_LETTER table function

The PTF_COVER_LETTER table function returns the cover letter content for a PTF.

The information returned is similar to what is returned by the Display PTF Cover Letter (DSPPTFCVR) command.

Authorization: See Note below.

The schema is SYSTOOLS.

ptf-id The PTF identifier for the cover letter to be returned.

ignore-errors A character string that identifies what to do when an error is encountered.

NO An error is returned.

YES A warning is returned.

No row is returned when an error is encountered. This is the default.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 223. PTF_COVER_LETTER table function

Column Name	Data Type	Description
LINE_NUMBER	INTEGER	The position of this row in the PTF cover letter. The first row has a value of 1.
PTF_COVER_LETTER_LINE	VARCHAR(80)	The data for this row in the PTF cover letter.

Note

This function is provided in the SYSTOOLS schema as an example of how to return PTF cover letter information from a system file by using an SQL table function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

Return cover letters for any PTFs that have been loaded but not applied.

```
WITH PTFS (PTF_ID) AS (  
  SELECT PTFID FROM QSYS2.PTF_INFO  
  WHERE PTF_COVER_LETTER = 'YES' AND  
        PTF_LOADED_STATUS = 'LOADED')  
SELECT PTF_ID, C.*  
FROM PTFS, TABLE (SYSTOOLS.PTF_COVER_LETTER(PTF_ID)) C  
ORDER BY 1, 2;
```

PTF_INFO view

The PTF_INFO view contains information about PTFs for the server.

The information returned is similar to [QpzListPTF API](#).

Authorization: The caller must have *USE authority to the Display Program Temporary Fix (DSPPTF) command.

The following table describes the columns in the view. The schema is QSYS2.

Table 224. PTF_INFO view

Column name	System column name	Data type	Description
PTF_PRODUCT_ID	LICPGM	VARCHAR(7) Nullable	Product identifier.
PTF_PRODUCT_OPTION	PRODOPT	VARCHAR(6) Nullable	Product option.
PTF_PRODUCT_OPTION_2	PRODOPT2	VARCHAR(6) Nullable	Product option. The column contains the optional part number or *BASE.
PTF_PRODUCT_RELEASE_LEVEL	PRODRLS	VARCHAR(6) Nullable	Product release level.
PTF_PRODUCT_DESCRIPTION	PRODESC	VARCHAR(132) Nullable	Product description.
PTF_IDENTIFIER	PTFID	VARCHAR(7) Nullable	The identifier of the PTF.
PTF_RELEASE_LEVEL	PTFRLS	VARCHAR(6) Nullable	The release level of the PTF.
PTF_PRODUCT_LOAD	PRODLOAD	VARCHAR(4) Nullable	The load ID of the product load for the PTF.
PTF_LOADED_STATUS	LOADSTAT	VARCHAR(19) Nullable	The current loaded status of the PTF. NOT LOADED The PTF has never been loaded. LOADED The PTF has been loaded. APPLIED The PTF has been temporarily applied. PERMANENTLY APPLIED The PTF has been applied permanently. PERMANENTLY REMOVED The PTF has been permanently removed. DAMAGED The PTF is damaged. An error occurred while applying the PTF. It needs to be reloaded and applied. SUPERSEDED The PTF is superseded. A PTF will have a status of superseded when one of the following situations occurs: <ul style="list-style-type: none"> Another PTF with a more recent correction for the problem has been loaded on the system. The PTF ID that has been loaded can be found in the PTF_SUPERSEDED_BY_PTF column. The PTF save file for another PTF with a more recent correction for the problem has been logged into *SERVICE on the system.
PTF_SAVE_FILE	SAVF	VARCHAR(3) Nullable	Indicates whether a save file exists for the PTF. NO The PTF has no save file. YES The PTF has a save file.

Table 224. PTF_INFO view (continued)

Column name	System column name	Data type	Description
PTF_COVER_LETTER	COVER	VARCHAR(3) Nullable	Indicates whether a cover letter exists for the PTF. NO The PTF has no cover letter. YES The PTF has a cover letter.
PTF_ON_ORDER	ONORD	VARCHAR(3) Nullable	Indicates whether the PTF has been ordered. NO The PTF has not been ordered or has already been received. YES The PTF has been ordered.
PTF_IPL_ACTION	IPLACT	VARCHAR(19) Nullable	The action to be taken on this PTF during the next unattended IPL. NONE No action occurs at the next IPL. TEMPORARILY APPLIED The PTF is temporarily applied at the next IPL. TEMPORARILY REMOVED The PTF is temporarily removed at the next IPL. PERMANENTLY APPLIED The PTF is permanently applied at the next IPL. PERMANENTLY REMOVED The PTF is permanently removed at the next IPL.
PTF_ACTION_PENDING	ACTPEND	VARCHAR(3) Nullable	Indicates whether a required action has yet to be performed to make this PTF active. NO No required actions are pending for this PTF. YES A required action needs to occur for this PTF to be active. Check the Activation Instructions section of the cover letter to determine what the action is. If the PTF_ACTION_REQUIRED column is set to IPL and the activation instructions have been performed, then the PTF is active. However, this column will not be updated until the next IPL.
PTF_ACTION_REQUIRED	ACTREQ	VARCHAR(12) Nullable	Indicates whether an action is required to make this PTF active when it is applied. See the cover letter to determine what action needs to be taken. NONE No activation instructions are needed for this PTF. EXIT PROGRAM This PTF was shipped with activation instructions in the cover letter. This value is returned for all PTFs that have an exit program to update the status of the PTF after the activation instructions have been performed. IPL This PTF was shipped with activation instructions in the cover letter. No exit program exists to verify the activation instructions were performed.
PTF_IPL_REQUIRED	IPLREQ	VARCHAR(9) Nullable	Indicates whether an IPL is required to apply this PTF. DELAYED The PTF is delayed. The PTF must be applied during an IPL. IMMEDIATE The PTF is immediate. No IPL is needed to apply the PTF. UNKNOWN The type of the PTF is not known.

Table 224. PTF_INFO view (continued)

Column name	System column name	Data type	Description
PTF_IS_RELEASED	RELEASED	VARCHAR(3) Nullable	Indicates whether the PTF save file is available for distribution to another system. This is set to YES only when the System Manager for IBM i licensed program is on the system and the product is supported. The PTF_SAVE_FILE column must have a value of YES before using the value in this column. NO The PTF save file cannot be distributed. YES The PTF save file is released and can be distributed to another system.
PTF_MINIMUM_LEVEL	MINLVL	VARCHAR(2) Nullable	The indicator of the lowest level of the product to which this PTF can be applied. The level can be AA to 99. Contains the null value if the product does not have a level.
PTF_MAXIMUM_LEVEL	MAXLVL	VARCHAR(2) Nullable	The indicator of the highest level of the product to which this PTF can be applied. The level can be AA to 99. Contains the null value if the product does not have a level.
PTF_STATUS_TIMESTAMP	STATTIME	TIMESTAMP Nullable	The date and time that the PTF status was last changed. Contains the null value when the status date and time is not available.
PTF_SUPERSEDED_BY_PTF	SUPERSEDE	VARCHAR(7) Nullable	The identifier of the PTF that has replaced this PTF. This field will be blank when the PTF is not superseded or when the superseding PTF has not been loaded on the system.
PTF_LATEST_SUPERSEDING_PTF	LATEST_PTF	VARCHAR(7) Nullable	The identifier of the most recent PTF that has superseded this PTF. Contains the null value when PTF_LOADED_STATUS is not PERMANENTLY APPLIED or SUPERSEDED.
PTF_CREATION_TIMESTAMP	CRTTIME	TIMESTAMP Nullable	The date and time that the PTF was created. Contains the null value when the creation date and time cannot be determined.
PTF_TECHNOLOGY_REFRESH_PTF	TRPTF	VARCHAR(3) Nullable	Indicates whether this is a technology refresh PTF. NO This is not a technology refresh PTF. YES This is a technology refresh PTF.
PTF_TEMPORARY_APPLY_TIMESTAMP	TMPTIME	TIMESTAMP Nullable	The date and time that the PTF was temporarily applied. Contains the null value if the PTF has not been temporarily applied.

Examples

- Find which PTFs will be impacted by the next IPL.

```
SELECT PTF_IDENTIFIER, PTF_IPL_ACTION, A.*
FROM QSYS2.PTF_INFO A
WHERE PTF_IPL_ACTION <> 'NONE'
```

- Find which PTFs are loaded but not applied.

```
SELECT PTF_IDENTIFIER, PTF_PRODUCT_DESCRIPTION, A.*
FROM QSYS2.PTF_INFO A
WHERE PTF_LOADED_STATUS = 'LOADED'
ORDER BY PTF_PRODUCT_ID
```

Security Services

These views, procedures, and functions provide security information.

ADD_VALIDATION_LIST_ENTRY scalar function

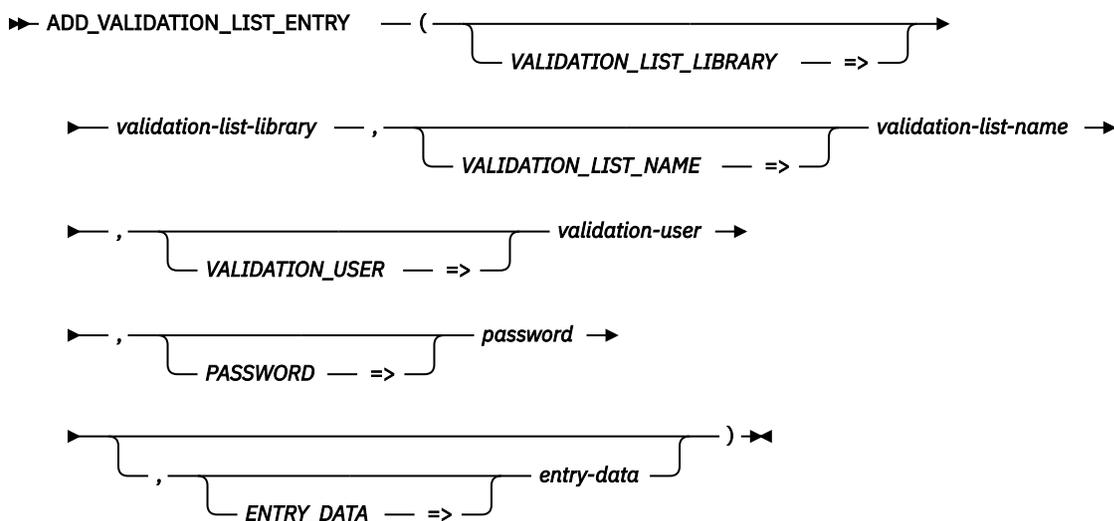

The ADD_VALIDATION_LIST_ENTRY scalar function adds an entry to the specified validation list.

The values in a validation list entry are used by specific interfaces that are controlled with validation lists. This function provides a way to add the entries but does not enforce any specific rules.

This function uses the [QsyAddValidationLstEntry\(\)](#)--Add Validation List Entry API to add the entry.

The function requires that Option 13 (System Openness Includes) of the IBM i operating system is installed.

Authorization: See Note below.

The schema is SYSTOOLS.

validation-list-library	A character string containing the name of the library that contains the validation list. Can contain the special values of *CURLIB or *LIBL.
validation-list-name	A character string containing the name of the validation list.
validation-user	A character string containing the name provided by a user when interacting with the IBM i. The name can be up to 100 characters long. This name does not need to correspond to an IBM i user profile name.
password	A character string containing the password that corresponds to <i>validation-user</i> . The password can be up to 600 characters long. The value will be encrypted when stored in the validation list.
entry-data	A character string containing additional data for the entry. The string can be up to 1000 characters long. This parameter is optional. If it is omitted, there is no additional data associated with <i>validation-user</i> .

The result of the function is an integer. If the add operation is successful, the function returns a value of 0. If the operation returns an error, the function returns the errno value from the API.

Note

This function is provided in the SYSTOOLS schema as an example of how a complex API can be simplified in an SQL scalar function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

Add an authentication entry for a user of an external interface. Use a global variable so the password is not visible in the function invocation. Wrap the invocation so a descriptive errno value is returned.

```
CREATE VARIABLE MYLIB.VLDL_PW VARCHAR(100);

SET MYLIB.VLDL_PW = 'password for my user access';

VALUES SYSTOOLS.ERRNO_INFO(SYSTOOLS.ADD_VALIDATION_LIST_ENTRY(
    VALIDATION_LIST_LIBRARY => 'APPLIB',
    VALIDATION_LIST_NAME    => 'APPVLDL',
    VALIDATION_USER        => 'my application user name',
    PASSWORD                => MYLIB.VLDL_PW));
```

AUTHORITY_COLLECTION views

The AUTHORITY_COLLECTION views returns information about the authority check for an object.

See [Authority collection views](#) for the description of the view.

AUTHORIZATION_LIST_INFO view

The AUTHORIZATION_LIST_INFO view returns a list of all objects secured by an authorization list.

The information returned is similar to the information available through the Display Authorization List Objects (DSPAUTLOBJ) CL command and the List Objects Secured by Authorization List (QSYLATLO) API.

Authorization: The caller must have:

- *READ authority to the authorization list, or
- Authorized to the QIBM_DB_SECADM function usage identifier.

The following table describes the columns in the view. The system name is AUTHL_INFO. The schema is QSYS2.

Table 225. AUTHORIZATION_LIST_INFO view

Column name	System column name	Data type	Description
AUTHORIZATION_LIST	AUTH_LIST	VARCHAR(10)	The authorization list for this object.
SYSTEM_OBJECT_SCHEMA	SYS_DNAME	VARCHAR(10) Nullable	The library that contains the object. Returns the null value if the object is not in the QSYS or QDLS file system.
SYSTEM_OBJECT_NAME	SYS_ONAME	VARCHAR(10) Nullable	The object that is secured by the authorization list. Returns the null value if the object is not in the QSYS or QDLS file system.
SYSTEM_OBJECT_TYPE	SYS_OTYPE	VARCHAR(8)	The system object type of the secured object.
OBJECT_ATTRIBUTE	OBJATTR	VARCHAR(5) Nullable	The attribute for the secured object's type. Returns the null value if the object has no attribute or if it is not in the QSYS or QDLS file system.
OBJECT_SCHEMA	OSHEMA	VARCHAR(128) Nullable	The SQL schema name for this object. Returns the null value if the object is not in the QSYS or QDLS file system.
OBJECT_NAME	ONAME	VARCHAR(128) Nullable	The SQL name of the object. For an external procedure or an external function, the name will be returned when a single procedure or function exists for that *PGM or *SRVPGM object. Contains the null value if an SQL name could not be returned.

Table 225. AUTHORIZATION_LIST_INFO view (continued)

Column name	System column name	Data type	Description
OBJECT_TYPE	OTYPE	VARCHAR(9) Nullable	<p>The SQL object type. The following values can be returned.</p> <p>ALIAS The object is an SQL alias.</p> <p>FUNCTION The object is an SQL function.</p> <p>INDEX The object is an SQL index.</p> <p>PACKAGE The object is an SQL package.</p> <p>PROCEDURE The object is an SQL procedure.</p> <p>ROUTINE The object is used in SQL by one or more external functions and/or external procedures.</p> <p>SEQUENCE The object is an SQL sequence.</p> <p>TABLE The object is an SQL table.</p> <p>TRIGGER The object is an SQL trigger.</p> <p>TYPE The object is an SQL type.</p> <p>VARIABLE The object is an SQL global variable.</p> <p>VIEW The object is an SQL view.</p> <p>XSR The object is an XML schema repository object.</p> <p>Returns the null value if the object is not an SQL object.</p>
OBJECT_OWNER	OWNER	VARCHAR(10)	The owner of the object.
PRIMARY_GROUP	GROUP	VARCHAR(10) Nullable	<p>The user who is the primary group for the object.</p> <p>Returns the null value if there is no primary group for the object.</p>
TEXT_DESCRIPTION	TEXT	VARCHAR(50) Nullable	<p>The descriptive text for the secured object.</p> <p>Returns the null value if the object is not in the QSYS or QDLS file system.</p>
ASPGRP	ASPGRP	VARCHAR(10)	The name of the ASP device containing the object. A value of *SYSBAS indicates the system ASP and all basic user ASPs.
AUTHORITY HOLDER	AUT HOLDER	VARCHAR(3)	<p>Indicates whether the object is an authority holder.</p> <p>NO The object is not an authority holder.</p> <p>YES The object is an authority holder.</p>
PATH_NAME	PATH_NAME	DBCLOB(16M) CCSID 1200 Nullable	<p>The path name for the object that is secured by the authorization list.</p> <p>Returns the null value if the object is in the QSYS or QDLS file system.</p>
DLO_NAME	DLO_NAME	VARCHAR(12) Nullable	<p>The document library object (DLO) name for the object.</p> <p>Returns the null value if OBJECT_TYPE is not *DOC (document) or *FLR (folder).</p>
FOLDER_PATH	FOLDER	VARCHAR(63) Nullable	<p>The name of the folder that contains the DLO object.</p> <p>Returns the null value if the object is not in a folder.</p>

Example

Return information about all the object secured by authorization list APP1.

```
SELECT * FROM QSYS2.AUTHORIZATION_LIST_INFO WHERE AUTHORIZATION_LIST = 'APP1' ;
```

AUTHORIZATION_LIST_USER_INFO view

The AUTHORIZATION_LIST_USER_INFO view returns a list of all authorization lists and their authorities.

The information returned is similar to the information available through the Display Authorization List (DSPAUTL) CL command.

Authorization: None required.

The following table describes the columns in the view. The system name is AUTL_USERS. The schema is QSYS2.

Table 226. AUTHORIZATION_LIST_USER_INFO view

Column name	System column name	Data type	Description
AUTHORIZATION_LIST	AUTL	VARCHAR(10)	The name of the authorization list.
AUTHORIZATION_NAME	USER_NAME	VARCHAR(10)	User profile name. Can contain the following special value. *PUBLIC This row contains the public authority for the object.
OBJECT_AUTHORITY	OBJ_AUTH	VARCHAR(12)	The authority that the user has to the object. Contains one of the following values: *ALL Allows all operations on the object except those that are limited to the owner or controlled by authorization list management authority. *CHANGE Allows all operations on the object except those that are limited to the owner or controlled by object existence authority, object alter authority, object reference authority, and object management authority. *EXCLUDE All operations on the object are prohibited. *USE Allows access to the object attributes and use of the object. The user cannot change the object. USER DEFINED The specific object authorities and data authorities do not match any of the predefined object authority levels.
AUTHORIZATION_LIST_MANAGEMENT	AUTL_MGMT	VARCHAR(3)	The authorization list management authority for AUTHORIZATION_NAME. NO The user does not have this authority. YES The user has this authority.
OWNER	OWNER	VARCHAR(10)	The owner of the authorization list.
OBJECT_OPERATIONAL	OBJOPER	VARCHAR(3)	The object operational authority for AUTHORIZATION_NAME. NO The user does not have this authority. YES The user has this authority.
OBJECT_MANAGEMENT	OBJMGT	VARCHAR(3)	The object management authority for AUTHORIZATION_NAME. NO The user does not have this authority. YES The user has this authority.

Table 226. AUTHORIZATION_LIST_USER_INFO view (continued)

Column name	System column name	Data type	Description
OBJECT_EXISTENCE	OBJEXIST	VARCHAR(3)	The object existence authority for AUTHORIZATION_NAME. NO The user does not have this authority. YES The user has this authority.
OBJECT_ALTER	OBJALTER	VARCHAR(3)	The object alter authority for AUTHORIZATION_NAME. NO The user does not have this authority. YES The user has this authority.
OBJECT_REFERENCE	OBJREF	VARCHAR(3)	The object reference authority for AUTHORIZATION_NAME. NO The user does not have this authority. YES The user has this authority.
DATA_READ	DATA_READ	VARCHAR(3)	The data read authority for AUTHORIZATION_NAME. NO The user does not have this authority. YES The user has this authority.
DATA_ADD	DATA_ADD	VARCHAR(3)	The data add authority for AUTHORIZATION_NAME. NO The user does not have this authority. YES The user has this authority.
DATA_UPDATE	DATA_UPD	VARCHAR(3)	The data update authority for AUTHORIZATION_NAME. NO The user does not have this authority. YES The user has this authority.
DATA_DELETE	DATA_DEL	VARCHAR(3)	The data delete authority for AUTHORIZATION_NAME. NO The user does not have this authority. YES The user has this authority.
DATA_EXECUTE	DATA_EXEC	VARCHAR(3)	The data execute authority for AUTHORIZATION_NAME. NO The user does not have this authority. YES The user has this authority.
TEXT_DESCRIPTION	TEXT	VARCHAR(50) Nullable	The descriptive text for the authorization list. Contains null if the authorization list has no text description.

Example

List the public security settings for all authorization lists.

```
SELECT *
FROM QSYS2.AUTHORIZATION_LIST_USER_INFO
WHERE AUTHORIZATION_NAME = '*PUBLIC';
```

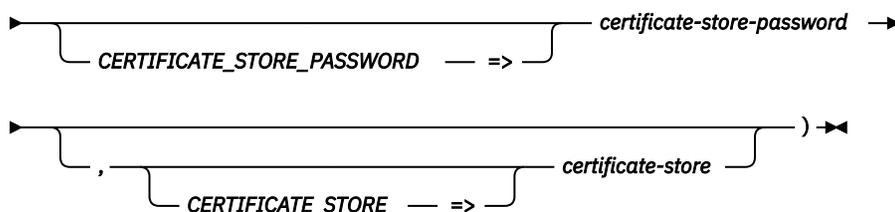

CERTIFICATE_INFO table function

The CERTIFICATE_INFO table function returns a result table that contains information about server or Certificate Authority (CA) certificates.

This information is similar to what is returned by the Retrieve Certificate Information (QYCURTVCI, QycuRetrieveCertificateInfo) API.

Authorization: The caller must provide the password for the certificate store. In addition, the caller must have *ALLOBJ and *SECADM special authorities.

►► CERTIFICATE_INFO — (→

The schema is QSYS2.

certificate-store-password An expression that contains the password for the specified certificate store. It is recommended that the password be passed as a variable, not as a string visible as clear text.

The following value can be used instead of specifying the password.

***NOPWD** The certificate store password will be retrieved from the stashed password file.

certificate-store A character or graphic string expression that indicates the certificate store from which a list of certificates is to be retrieved. The value can either be a fully qualified integrated file system directory path and file name of the certificate store, starting with a leading forward slash (/), or one of the following special values. If the file name does not identify a certificate store, no rows are returned. If *certificate-store* is not specified, *SYSTEM is the default.

***OBJECTSIGNING** The *OBJECTSIGNING certificate store.

***SIGNATUREVERIFICATION** The *SIGNATUREVERIFICATION certificate store.

***SYSTEM** The *SYSTEM certificate store.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 227. CERTIFICATE_INFO table function

Column Name	Data Type	Description
CERTIFICATE_LABEL	VARCHAR(256)	The label for the certificate.
SERIAL_NUMBER	VARCHAR(64)	Serial number.
VALIDITY_START	TIMESTAMP(0)	The beginning date of the validity period.
VALIDITY_END	TIMESTAMP(0)	The ending date of the validity period.
TRUSTED	VARCHAR(3)	Indicates if the certificate is trusted. NO The certificate is not trusted. YES The certificate is trusted.
KEY_SIZE	INTEGER	The size of the key, in bytes.

Table 227. CERTIFICATE_INFO table function (continued)

Column Name	Data Type	Description
PRIVATE_KEY	VARCHAR(3)	Indicates if the certificate has a private key. NO The certificate does not have a private key. YES The certificate has a private key.
PRIVATE_KEY_LABEL	VARCHAR(64)	The private key label. Contains the null value if PRIVATE_KEY is NO or if PRIVATE_KEY_STORAGE_LOCATION is SOFTWARE.
PRIVATE_KEY_STORAGE_LOCATION	VARCHAR(19)	Where the key is stored. HARDWARE The key is stored in hardware. HARDWARE ENCRYPTION The key is stored in hardware encryption. SOFTWARE The key is stored is software. Contains the null value if PRIVATE_KEY is NO.
DIGITAL_SIGNATURE	VARCHAR(3)	The certificate has the digital signature extension. NO The certificate does not have the digital signature extension. YES The certificate has the digital signature extension.
NONREPUDIATION	VARCHAR(3)	Indicates if the certificate has the nonrepudiation extension. NO The certificate does not have the nonrepudiation extension. YES The certificate has the nonrepudiation extension.
KEY_ENCIPHERMENT	VARCHAR(3)	Indicates if the certificate has the key encipherment extension. NO The certificate does not have the key encipherment extension. YES The certificate has the key encipherment extension.
DATA_ENCIPHERMENT	VARCHAR(3)	Indicates if the certificate has the data encipherment extension. NO The certificate does not have the data encipherment extension. YES The certificate has the data encipherment extension.
KEY_AGREEMENT	VARCHAR(3)	Indicates if the certificate has the key agreement extension NO The certificate does not have the key agreement extension. YES The certificate has the key agreement extension.
KEY_CERTIFICATE_SIGNATURE	VARCHAR(3)	Indicates if the certificate has the key certificate signature extension. NO The certificate does not have the key certificate signature extension. YES The certificate has the key certificate signature extension.
CRL_SIGNATURE	VARCHAR(3)	Indicates if the certificate has the Certificate Revocation List (CRL) signature extension. NO The certificate does not have the CRL signature extension. YES The certificate has the CRL signature extension.
CRL_LOCATION	VARCHAR(50)	The CRL location. Contains the null value if no value is available.
ENCIPHER_ONLY	VARCHAR(3)	Indicates if the certificate has the encipher only extension. NO The certificate does not have the encipher only extension. YES The certificate has the encipher only extension.
DECIPHER_ONLY	VARCHAR(3)	Indicates if the certificate has the decipher only extension. NO The certificate does not have the decipher only extension. YES The certificate has the decipher only extension.

Table 227. CERTIFICATE_INFO table function (continued)

Column Name	Data Type	Description
LDAP_SERVER_NAME	VARCHAR(900)	The LDAP server name. Contains the null value if no value is available.
IP_ADDRESS_COUNT	INTEGER	The number of addresses in the IP_ADDRESSES column. Currently, only one IP address is returned. Contains the null value if no IP addresses are available.
IP_ADDRESSES	VARCHAR(45)	The IP address. Contains the null value if no value is available.
DOMAIN_NAME_COUNT	INTEGER	The number of domain names in the DOMAIN_NAMES column. Currently, only one domain name is returned. Contains the null value if no domain names are available.
DOMAIN_NAMES	VARCHAR(256)	The domain name. Contains the null value if no value is available.
EMAIL_ADDRESS	VARCHAR(256)	The email address. Contains the null value if no value is available.
CRYPTOGRAPHIC_DEVICE_COUNT	INTEGER	The number of cryptographic devices.
CRYPTOGRAPHIC_DEVICES	VARCHAR(109)	A list of cryptographic device descriptions. Each entry is ten characters long. A single blank separates entries. Contains the null value if CRYPTOGRAPHIC_DEVICE_COUNT is 0.
SUBJECT_COMMON_NAME	VARCHAR(256)	The subject's common name. The SUBJECT set of columns define information about the end-entity that is being described for the certificate. Contains the null value if no value is available.
SUBJECT_ORGANIZATIONAL_UNIT	VARCHAR(256)	The subject's organizational unit. Contains the null value if no value is available.
SUBJECT_ORGANIZATION	VARCHAR(256)	The subject's organization. Contains the null value if no value is available.
SUBJECT_LOCALITY	VARCHAR(128)	The subject's locality. Contains the null value if no value is available.
SUBJECT_STATE_PROVINCE	VARCHAR(128)	The subject's state or province. Contains the null value if no value is available.
SUBJECT_POSTAL_CODE	VARCHAR(16)	The subject's postal code. Contains the null value if no value is available.
SUBJECT_COUNTRY_REGION	VARCHAR(3)	The subject's country or region. Contains the null value if no value is available.
ISSUER_COMMON_NAME	VARCHAR(256)	The issuer's common name. The ISSUER set of columns define information about the Certificate Authority that signed the end-entity certificate. Contains the null value if no value is available.
ISSUER_ORGANIZATIONAL_UNIT	VARCHAR(256)	The issuer's organizational unit. Contains the null value if no value is available.
ISSUER_ORGANIZATION	VARCHAR(256)	The issuer's organization. Contains the null value if no value is available.
ISSUER_LOCALITY	VARCHAR(128)	The issuer's locality. Contains the null value if no value is available.
ISSUER_STATE_PROVINCE	VARCHAR(128)	The issuer's state or province. Contains the null value if no value is available.
ISSUER_POSTAL_CODE	VARCHAR(16)	The issuer's postal code. Contains the null value if no value is available.

Table 227. CERTIFICATE_INFO table function (continued)

Column Name	Data Type	Description
ISSUER_COUNTRY_REGION	VARCHAR(3)	The issuer's country or region. Contains the null value if no value is available.

Example

Retrieve all the certificates for the *SYSTEM certificate store that will be expired within the next month. Use a password that has been set in a global variable.

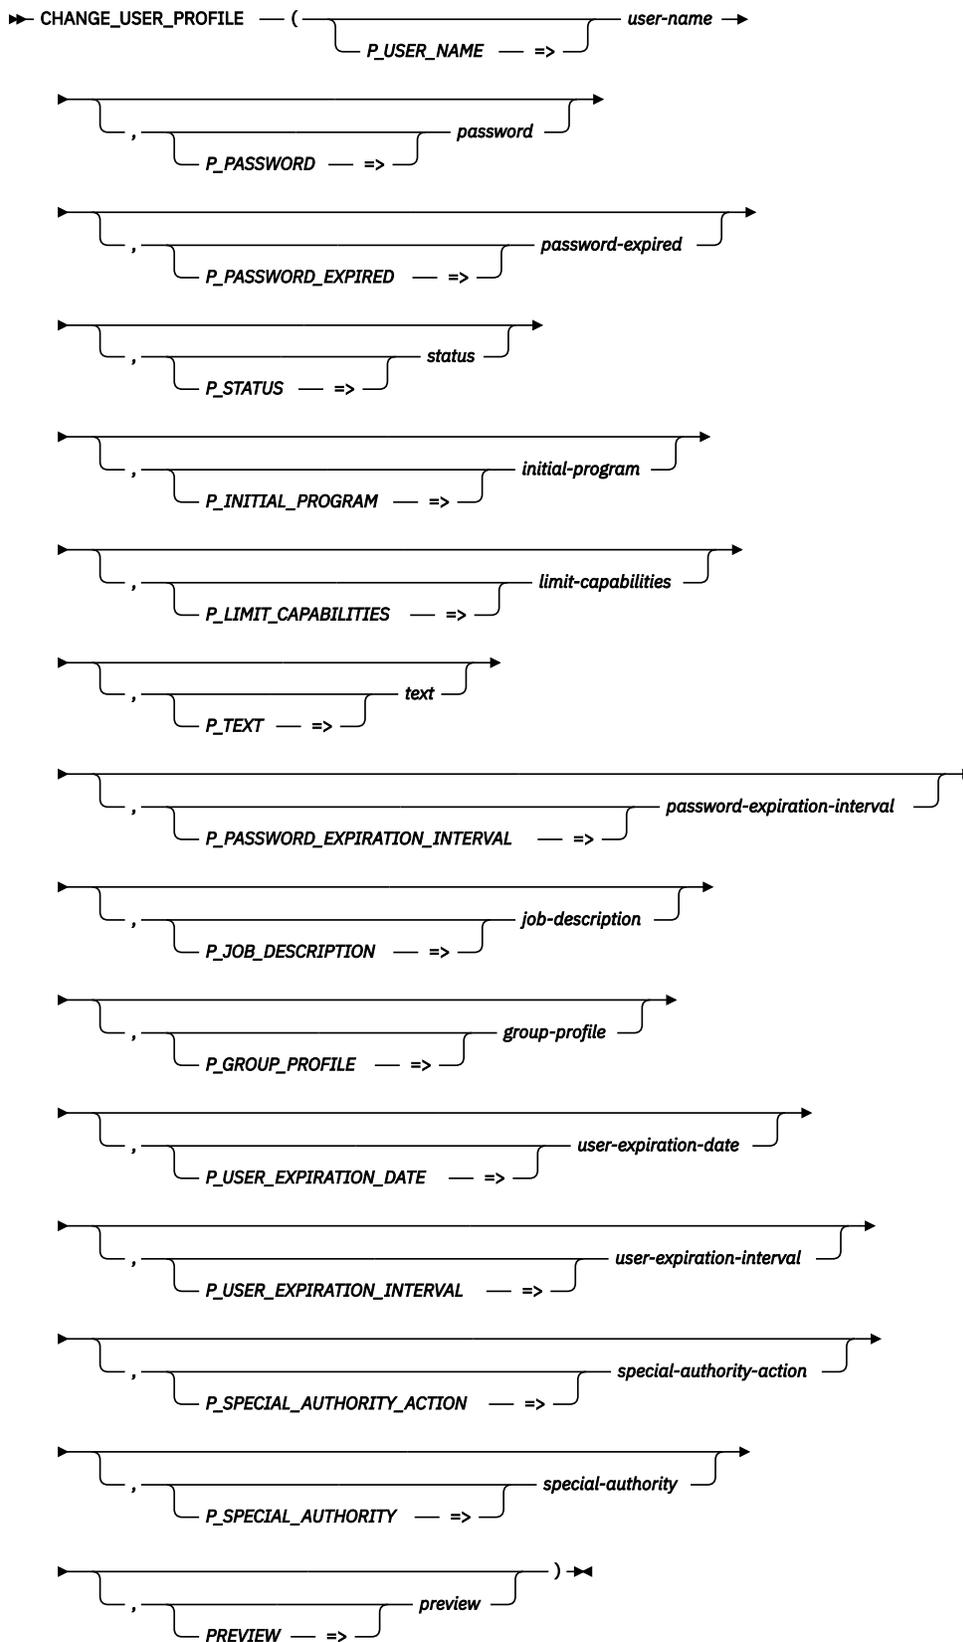

- ```
CREATE VARIABLE MYLIB.SYSTEM_CERT_PW VARCHAR(30);
SET MYLIB.SYSTEM_CERT_PW = 'cert_pwd';
SELECT * FROM TABLE(QSYS2.CERTIFICATE_INFO(CERTIFICATE_STORE_PASSWORD=> MYLIB.SYSTEM_CERT_PW))
WHERE VALIDITY_END < CURRENT DATE + 1 MONTH;
```

### CHANGE\_USER\_PROFILE table function

The CHANGE\_USER\_PROFILE table function changes a subset of user profile attributes.

For a detailed description of the parameters and their values, refer to [CHGUSRPRF CL command](#).

**Authorization:** See Note below.

The schema is SYSTOOLS.

***user-name*** A character string containing the name of the user profile whose values are to be changed.

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>password</b>                     | A character string containing a new password value for the user profile. This is the PASSWORD parameter. The default is *SAME.                                                                                                                                                                                                                                                                   |
| <b>password-expired</b>             | A character string that specifies whether the password for this user is set to expired. This is the PWDEXP parameter. The default is *SAME.                                                                                                                                                                                                                                                      |
| <b>status</b>                       | A character string that specifies the status of the user profile. This is the STATUS parameter. The default is *SAME.                                                                                                                                                                                                                                                                            |
| <b>initial-program</b>              | A character string that specifies the initial program to call. This is the INLPGM parameter. The default is *SAME.                                                                                                                                                                                                                                                                               |
| <b>limit-capabilities</b>           | A character string that specifies the capabilities for a user. This is the LMTCPB parameter. The default is *SAME.                                                                                                                                                                                                                                                                               |
| <b>text</b>                         | A character string that specifies the descriptive text for the user profile. This is the TEXT parameter. The default is *SAME.                                                                                                                                                                                                                                                                   |
| <b>password-expiration-interval</b> | A character string that specifies the password expiration interval, in days. This is the PWDEXPITV parameter. The default is *SAME.                                                                                                                                                                                                                                                              |
| <b>job-description</b>              | A character string that specifies the job description associated with this user profile. This is the JOBBD parameter. The default is *SAME.                                                                                                                                                                                                                                                      |
| <b>group-profile</b>                | A character string that specifies the group profile associated with this user profile. This is the GRPPRF parameter. The default is *SAME.                                                                                                                                                                                                                                                       |
| <b>user-expiration-date</b>         | A character string that specifies the date when the user profile expires and is automatically disabled. This is the USREXPDATE parameter. The default is *SAME.                                                                                                                                                                                                                                  |
| <b>user-expiration-interval</b>     | An integer value that specifies the expiration interval, in days, before the user profile is automatically disabled. This is the USREXPITV parameter. The default is NULL, meaning the value will not be changed.                                                                                                                                                                                |
| <b>special-authority-action</b>     | A character string that specifies the action that applies to the <i>special-authority</i> parameter. The default is *SAME.<br><br><b>*ADD</b> The special authority should be added to the user profile.<br><b>*REMOVE</b> The special authority should be removed from the user profile.                                                                                                        |
| <b>special-authority</b>            | A character string that specifies a single special authority value to be added to or removed from the user profile when the <i>special-authority-action</i> parameter has a value or *ADD or *REMOVE. This is the SPCAUT parameter. The default is NULL, meaning the value is not changed.                                                                                                       |
| <b>preview</b>                      | A character string that indicates whether the table function should execute the CHGUSRPRF command that has been constructed based upon the input parameters or whether only a preview of the potential action should be shown.<br><br><b>NO</b> The table function should change the user profiles<br><b>YES</b> The table function should return a preview of the changes. This is the default. |

The result of the function is a table containing a single row with the details about the user profile change. The columns of the result table are described in the following table. The result columns are nullable.

Table 228. CHANGE\_USER\_PROFILE table function

| Column Name | Data Type   | Description                                  |
|-------------|-------------|----------------------------------------------|
| USER_NAME   | VARCHAR(10) | The user profile being changed or previewed. |

Table 228. CHANGE\_USER\_PROFILE table function (continued)

| Column Name          | Data Type        | Description                                                                    |
|----------------------|------------------|--------------------------------------------------------------------------------|
| CHANGE_ATTEMPTED     | VARCHAR(3)       | Indicates whether the change was attempted.                                    |
|                      |                  | <b>NO</b> The change was not attempted                                         |
|                      |                  | <b>YES</b> The change was attempted                                            |
| CHANGE_SUCCESSFUL    | VARCHAR(3)       | Indicates whether the change was successful.                                   |
|                      |                  | <b>NO</b> The change was not successful                                        |
|                      |                  | <b>YES</b> The change was successful                                           |
|                      |                  | Contains the null value if CHANGE_ATTEMPTED is NO.                             |
| CHGUSRPRF_COMMAND    | VARCHAR(1000)    | The CHGUSRPRF command string.                                                  |
| FAILURE_MESSAGE_ID   | CHAR(7)          | The message ID.                                                                |
|                      |                  | Contains the null value if CHANGE_ATTEMPTED is NO or CHANGE_SUCCESSFUL is YES. |
| FAILURE_MESSAGE_TEXT | VARGRAPHIC(1024) | The text of the message.                                                       |
|                      | CCSID 1200       | Contains the null value if CHANGE_ATTEMPTED is NO or CHANGE_SUCCESSFUL is YES. |

## Note

This function is provided in the SYSTOOLS schema as a helper function to manage user profiles. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

## Example

Disable all enabled user profiles that have no password set.

Preview the list of profiles that will be affected.

```
SELECT * FROM QSYS2.USER_INFO,
 TABLE(SYSTOOLS.CHANGE_USER_PROFILE(
 P_USER_NAME => AUTHORIZATION_NAME,
 P_STATUS => '*DISABLED',
 PREVIEW => 'YES'))
WHERE STATUS = '*ENABLED' AND
 NO_PASSWORD_INDICATOR = 'YES';
```

Build and execute the CHGUSRPRF commands..

```
SELECT * FROM QSYS2.USER_INFO,
 TABLE(SYSTOOLS.CHANGE_USER_PROFILE(
 P_USER_NAME => AUTHORIZATION_NAME,
 P_STATUS => '*DISABLED',
 PREVIEW => 'NO'))
WHERE STATUS = '*ENABLED' AND
 NO_PASSWORD_INDICATOR = 'YES';
```

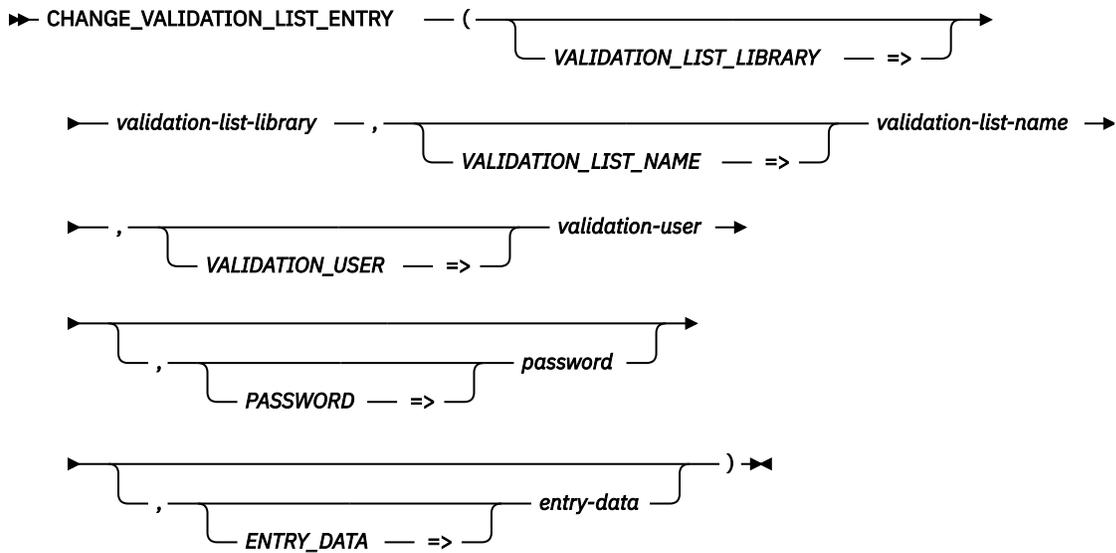

## CHANGE\_VALIDATION\_LIST\_ENTRY scalar function

The CHANGE\_VALIDATION\_LIST\_ENTRY scalar function changes an entry in the specified validation list.

This function uses the [QsyChangeValidationLstEntry\(\)--Change Validation List Entry API](#) to change the entry.

The function requires that Option 13 (System Openness Includes) of the IBM i operating system is installed.

**Authorization:** See Note below.

The schema is SYSTOOLS.

|                                |                                                                                                                                                                                                       |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>validation-list-library</b> | A character string containing the name of the library that contains the validation list. Can contain the special values of *CURLIB or *LIBL.                                                          |
| <b>validation-list-name</b>    | A character string containing the name of the validation list.                                                                                                                                        |
| <b>validation-user</b>         | A character string containing a name that exists in the specified validation list.                                                                                                                    |
| <b>password</b>                | A character string containing the password that corresponds to <i>validation-user</i> . The string can be up to 600 characters long. If this parameter is omitted, the password value is not changed. |
| <b>entry-data</b>              | A character string containing additional data for the entry. The string can be up to 1000 characters long. If this parameter is omitted, the additional data for the entry is not changed.            |

The result of the function is an integer. If the change operation is successful, the function returns a value of 0. If the operation returns an error, the function returns the errno value from the API.

## Note

This function is provided in the SYSTOOLS schema as an example of how a complex API can be simplified in an SQL scalar function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

## Example

Change the password for an existing authentication entry. Wrap the invocation so a descriptive errno value is returned.

```
CREATE VARIABLE MYLIB.VLDL_PW VARCHAR(100);
SET MYLIB.VLDL_PW = 'my new password';
```

```
VALUES SYSTOOLS.ERRNO_INFO(SYSTOOLS.CHANGE_VALIDATION_LIST_ENTRY(
 VALIDATION_LIST_LIBRARY => 'APPLIB',
 VALIDATION_LIST_NAME => 'APPVLDL',
 VALIDATION_USER => 'my application user name',
 PASSWORD => MYLIB.VLDL_PW));
```

## DRDA\_AUTHENTICATION\_ENTRY\_INFO view

The DRDA\_AUTHENTICATION\_ENTRY\_INFO view returns user server authentication entry information.

A server authentication entry defines a userid and password to send on a connect request over TCP/IP. A server authentication list is associated with every user profile on the system. The Add Server Authentication Entry (ADDSVRAUTE) command is used to add entries.

When a DRDA connection over TCP/IP is attempted without specifying a userid and password, and password authentication is required, the Db2 for i client checks the server authentication list for the user profile under which the client job is running. If it finds a match between the RDB name on the CONNECT statement and the server name in an authentication entry, or the server name is the special value QDDMDRDASERVER, the associated userid (and password if one exists) is used for the connection.

A server authentication entry can also be used to specify a userid and password to be used for a DDM connection over TCP/IP. When a DDM connection is attempted over TCP/IP, and password authentication is required, the Db2 for i client checks the server authentication list for the user profile under which the client job is running. If it finds a match between the RDB name specified in the DDM file and the server name in an authentication entry, or the server name is the special value QDDMDRDASERVER, the associated userid (and password if one exists) is used for the connection. If no RDB name is specified in the DDM file and the server name is either of the special values QDDMDRDASERVER or QDDMSERVER, the associated userid (and password if one exists) is used for the connection.

**Authorization:** The caller must have \*OBJOPR and \*READ authority to the \*USRPRF object.

The following table describes the columns in the view. The system name is DRDA\_AUTHE. The schema is QSYS2.

Table 229. DRDA\_AUTHENTICATION\_ENTRY\_INFO view

| Column Name               | System Column Name | Data Type                      | Description                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|--------------------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AUTHORIZATION_NAME        | USER_NAME          | VARCHAR(10)                    | The user profile on the client system.                                                                                                                                                                                                                                                                                                                                           |
| SERVER_NAME               | SRVR_NAME          | VARGRAPHIC(200)<br>CCSID 1200  | The target system for the authentication entry.<br><br>This is the name of the RDB or QDDMDRDASERVER that is used for connections made on behalf of RDB DDM files or DRDA connections. For a non-RDB DDM file that does not use the RDB directory, the value will be QDDMDRDASERVER or QDDMSERVER. See <a href="#">Client security in a TCP/IP network</a> for more information. |
| SERVER_AUTHORIZATION_NAME | SRVR_USER          | VARGRAPHIC(1000)<br>CCSID 1200 | The user profile on the target system.                                                                                                                                                                                                                                                                                                                                           |
| PASSWORD_STORED           | PW_STORED          | VARCHAR(3)                     | Indicates whether a password is stored for the authentication entry.<br><br><b>YES</b> A password is stored for the authentication entry.<br><b>NO</b> A password is not stored for the authentication entry.                                                                                                                                                                    |

## Example

For an auditor, generate a list of user profiles that have authentication entries on the system:

```
SELECT DISTINCT(AUTHORIZATION_NAME)
FROM QSYS2.DRDA_AUTHENTICATION_ENTRY_INFO
```

## FUNCTION\_INFO view

The FUNCTION\_INFO view contains details about function usage identifiers.

The values returned for the columns in the view are closely related to the values returned by the Display Function Usage (DSPFCNUSG) CL command.

**Authorization:** None required.

The following table describes the columns in the view. The system name is FCN\_INFO. The schema is QSYS2.

Table 230. FUNCTION\_INFO view

| Column Name                       | System Column Name | Data Type                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| FUNCTION_DESCRIPTION              | FCNDESC            | VARGRAPHIC(330)<br>CCSID(1200)<br>Nullable | The text for the function description.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| FUNCTION_PRODUCT_ID               | FCNPRDID           | VARCHAR(30)<br>Nullable                    | The ID of the product that the function is registered for.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| FUNCTION_GROUP_ID                 | FCNGRPID           | VARCHAR(30)<br>Nullable                    | The ID of the function group that the function is grouped with. If the function is not grouped with a function group, this field is set to *NONE.                                                                                                                                                                                                                                                                                                                                                                              |
| DEFAULT_USAGE                     | DFTUG              | VARCHAR(7)<br>Nullable                     | The default usage for the function.<br><br><b>DENIED</b> The default usage does not allow usage of the function.<br><b>ALLOWED</b> The default usage allows usage of the function.                                                                                                                                                                                                                                                                                                                                             |
| ALLOBJ_INDICATOR                  | ALLOBJ             | VARCHAR(8)<br>Nullable                     | Indicates whether a user with *ALLOBJ special authority can use the function.<br><br><b>NOT USED</b> The user, its groups, or default must allow usage of the function.<br><b>USED</b> A user with *ALLOBJ special authority is always allowed to use the function.                                                                                                                                                                                                                                                            |

Table 230. FUNCTION\_INFO view (continued)

| Column Name                 | System Column Name | Data Type              | Description                                                                                                                                                                                                        |
|-----------------------------|--------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| USAGE_INFORMATION_INDICATOR | USGINFO            | VARCHAR(3)<br>Nullable | Indicates whether there is usage information defined for the function.<br><br><b>NO</b> There is no usage information defined for the function.<br><b>YES</b> There is usage information defined for the function. |

## Example

Determine what function usage IDs exist and their default configuration.

```
SELECT * FROM QSYS2.FUNCTION_INFO ORDER BY FUNCTION_ID
```

## FUNCTION\_USAGE view

The FUNCTION\_USAGE view contains function usage configuration details.

The values returned for the columns in the view are closely related to the values returned by the Display Function Usage (DSPFCNUSG) CL command.

**Authorization:** The caller must have \*SECADM special authority.

The following table describes the columns in the view. The system name is FCN\_USAGE. The schema is QSYS2.

Table 231. FUNCTION\_USAGE view

| Column Name | System Column Name | Data Type   | Description                                                                                                                                                 |
|-------------|--------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FUNCTION_ID | FCNID              | VARCHAR(30) | The ID of the function.                                                                                                                                     |
| USER_NAME   | USER_NAME          | VARCHAR(10) | The name of the user profile that has a usage setting for this function                                                                                     |
| USAGE       | USAGE              | VARCHAR(7)  | Usage setting.<br><br><b>ALLOWED</b> The user profile is allowed to use the function.<br><b>DENIED</b> The user profile is not allowed to use the function. |
| USER_TYPE   | USER_TYPE          | VARCHAR(5)  | Type of user profile.<br><br><b>USER</b> The user profile is a user.<br><b>GROUP</b> The user profile is a group.                                           |

## Example

Determine what function usage has been granted or revoked.

```
SELECT * FROM QSYS2.FUNCTION_USAGE ORDER BY FUNCTION_ID, USER_NAME
```

## GROUP\_PROFILE\_ENTRIES view

The GROUP\_PROFILE\_ENTRIES view contains one row for each user profile that is part of a group profile.

Both group profile (GRPPRF) and supplemental group profile (SUPGRPPRF) information is considered for each user profile.

**Authorization:** The caller must have \*READ authority to the user profile.

The following table describes the columns in the view. The system name is GROUPLIST. The schema is QSYS2.

Table 232. GROUP\_PROFILE\_ENTRIES view

| Column Name        | System Column Name | Data Type               | Description                    |
|--------------------|--------------------|-------------------------|--------------------------------|
| GROUP_PROFILE_NAME | GROUPNAME          | VARCHAR(128)            | Group profile name             |
| USER_PROFILE_NAME  | USERNAME           | VARCHAR(128)            | User profile name              |
| USER_TEXT          | USER_TEXT          | VARCHAR(50)<br>Nullable | User profile text description. |

## OBJECT\_OWNERSHIP view

The OBJECT\_OWNERSHIP view returns ownership information for all objects.

The values returned for the columns in the view are closely related to the values returned by the WRKOBJOWN CL command and the List Objects User Is Authorized to, Owns, or Is Primary Group of (QSYLOBJA) API.

**Authorization:** The caller must have \*READ authority to the user profile that owns the object.

The following table describes the columns in the view. The system name is OBJ\_OWN. The schema is QSYS2.

Table 233. OBJECT\_OWNERSHIP view

| Column Name                   | System Column Name | Data Type                             | Description                                                                                                                                                                                                                                                                                            |
|-------------------------------|--------------------|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AUTHORIZATION_NAME            | USER_NAME          | VARCHAR(10)                           | User profile that owns the object.                                                                                                                                                                                                                                                                     |

## Examples

- Return a list of all objects owned by user FRANKDBA.

```
SELECT * FROM QSYS2.OBJECT_OWNERSHIP
WHERE AUTHORIZATION_NAME = 'FRANKDBA';
```

- Return a list of only objects in the integrated file system that are owned by user FRANKDBA.

```
SELECT * FROM QSYS2.OBJECT_OWNERSHIP
WHERE AUTHORIZATION_NAME = 'FRANKDBA'
AND PATH_NAME IS NOT NULL;
```

## OBJECT\_PRIVILEGES table function

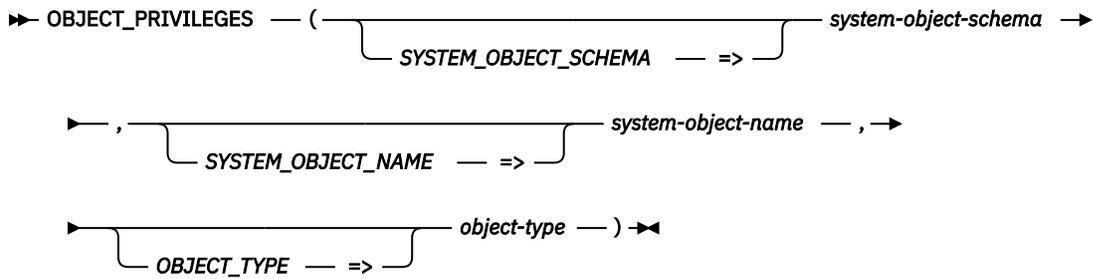

The OBJECT\_PRIVILEGES table function returns a row for every user authorized to the specified object, along with their associated object and data authorities.

The information returned is similar to the information available through the Display Object Authority (DSPOBJAUT) CL command.

**Authorization:** All authorized users are returned for an object when at least one of the following is true:

- The caller has \*OBJMGT authority.
- The caller is the owner of the object.
- The object is an authorization list.
- The caller is authorized to the QIBM\_DB\_SECADM function usage identifier.

Otherwise, only authorizations for the caller are returned.

The schema is QSYS2.

**system-object-schema** A character or graphic string expression that identifies the library that contains *system-object-name*.

**system-object-name** A character or graphic string expression that identifies the object.

**object-type** A character or graphic string expression that specifies the system object type of *system-object-name*.

The result of the function is a table containing rows with the format shown in the following table. All columns are nullable.

Table 234. `OBJECT_PRIVILEGES` table function

| Column name        | Data type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AUTHORIZATION_USER | VARCHAR(10) | User profile name. Can contain the following special value.<br><br><b>*PUBLIC</b> This row contains the public authority for the object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| OBJECT_AUTHORITY   | VARCHAR(12) | The authority that the user has to the object. Contains one of the following special values:<br><br><b>*ALL</b> Allows all operations on the object except those that are limited to the owner or controlled by authorization list management authority.<br><br><b>*AUTL</b> The public authority specified in the authorization list used by this object is used.<br><br><b>*CHANGE</b> Allows all operations on the object except those that are limited to the owner or controlled by object existence authority, object alter authority, object reference authority, and object management authority.<br><br><b>*EXCLUDE</b> All operations on the object are prohibited.<br><br><b>*USE</b> Allows access to the object attributes and use of the object. The user cannot change the object.<br><br><b>USER DEFINED</b> The specific object authorities and data authorities do not match any of the predefined object authority levels. |
| AUTHORIZATION_LIST | VARCHAR(10) | The name of the authorization list if the object is secured by an authorization list.<br><br>Contains null if the object is not secured by an authorization list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PRIMARY_GROUP      | VARCHAR(10) | The user who is the primary group for the object.<br><br>Returns the null value if there is no primary group for the object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Example

Return authority information for the file APPLIB/EMPLOYEE.

```
SELECT *
FROM TABLE(QSYS2.OBJECT_PRIVILEGES('APPLIB', 'EMPLOYEE', '*FILE'));
```

## OBJECT\_PRIVILEGES view

The OBJECT\_PRIVILEGES view returns a row for every user authorized to an object, along with their associated object and data authorities.

The information returned is similar to the information available through the Display Object Authority (DSPOBJAUT) CL command.

**Authorization:** All authorized users are returned for an object when at least one of the following is true:

- The caller has \*OBJMGT authority.
- The caller is the owner of the object.
- The object is an authorization list.
- The caller is authorized to the QIBM\_DB\_SECADM function usage identifier.

Otherwise, only authorizations for the caller are returned.

The following table describes the columns in the view. The system name is OBJ\_PRIV. The schema is QSYS2.

Table 235. OBJECT\_PRIVILEGES view

| Column name          | System column name | Data type                | Description                                                                                                                                                                                                                                                      |

Table 235. OBJECT\_PRIVILEGES view (continued)

| Column name      | System column name | Data type               | Description                                                                                                                                                                 |
|------------------|--------------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DATA_DELETE      | DATA_DEL           | VARCHAR(3)              | The data delete authority for AUTHORIZATION_NAME.<br><br><b>NO</b> The user does not have this authority.<br><b>YES</b> The user has this authority.                        |
| DATA_EXECUTE     | DATA_EXEC          | VARCHAR(3)              | The data execute authority for AUTHORIZATION_NAME.<br><br><b>NO</b> The user does not have this authority.<br><b>YES</b> The user has this authority.                       |
| TEXT_DESCRIPTION | TEXT               | VARCHAR(50)<br>Nullable | The descriptive text for this object.<br><br>Contains the null value if the object has no text description or if the user does not have sufficient authority to the object. |

## Example

Find user profiles that are publicly accessible.

```
SELECT *
FROM QSYS2.OBJECT_PRIVILEGES
WHERE SYSTEM_OBJECT_SCHEMA = 'QSYS' AND
OBJECT_TYPE = '*USRPRF' AND
AUTHORIZATION_NAME = '*PUBLIC' AND
OBJECT_AUTHORITY <> '*EXCLUDE';
```

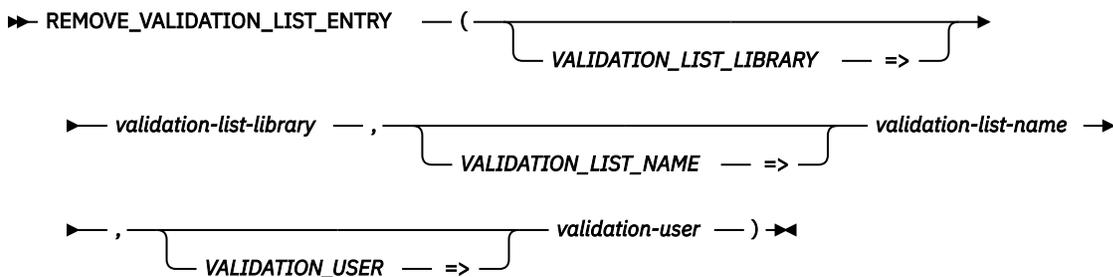

## REMOVE\_VALIDATION\_LIST\_ENTRY scalar function

The REMOVE\_VALIDATION\_LIST\_ENTRY scalar function removes an entry from the specified validation list.

This function uses the [QsyRemoveValidationLstEntry\(\)--Remove Validation List Entry API](#) to remove the entry.

The function requires that Option 13 (System Openness Includes) of the IBM i operating system is installed.

**Authorization:** See Note below.

The schema is SYSTOOLS.

**validation-list-library** A character string containing the name of the library that contains the validation list. Can contain the special values of \*CURLIB or \*LIBL.

**validation-list-name** A character string containing the name of the validation list.

**validation-user** A character string containing a name that exists in the specified validation list.

The result of the function is an integer. If the remove operation is successful, the function returns a value of 0. If the operation returns an error, the function returns the errno value from the API.

## Note

This function is provided in the SYSTOOLS schema as an example of how a complex API can be simplified in an SQL scalar function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

## Example

Remove an authentication entry for a specific user of an external interface. Wrap the invocation so a descriptive errno value is returned.

```
VALUES SYSTOOLS.ERRNO_INFO(SYSTOOLS.REMOVE_VALIDATION_LIST_ENTRY(
 VALIDATION_LIST_LIBRARY => 'APPLIB',
 VALIDATION_LIST_NAME => 'APPVLDL',
 VALIDATION_USER => 'my application user'));
```

## SECURITY\_INFO view

The SECURITY\_INFO view returns one row containing information about the IBM i security configuration.

The values returned for the columns in the view are closely related to the values returned by the Display Security Attributes (DSPSECA) and Display Security Auditing (DSPSECAUD) CL commands and by the Retrieve Security Attributes (QSRTVSA) API.

**Authorization:** The caller must have \*ALLOBJ or \*AUDIT special authority to see the system values for QAUDCTL, QAUDLVL, QAUDLVL2, and QCRTOBJAUD.

To see the AUDIT\_JOURNAL\_RECEIVER\_LIBRARY and AUDIT\_JOURNAL\_RECEIVER values, the caller must have:

- \*OBJOPR and some data authority other than \*EXECUTE to journal QSYS/QAUDJRN.

The following table describes the columns in the view. The system name is SEC\_INFO. The schema is QSYS2.

Table 236. SECURITY\_INFO view

| Column Name            | System Column Name | Data Type           | Description                                                                                                                                                                                                                                                                           |

| NEXT_GROUP_ID                       | NEXT_GID           | BIGINT     | The value that will be used the next time a group ID number (GID) is generated for a user profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### Example

- Return the security and password levels for the system.

```
SELECT SECURITY_LEVEL, PASSWORD_LEVEL FROM QSYS2.SECURITY_INFO;
```

### SET\_COLUMN\_ATTRIBUTE procedure

The SET\_COLUMN\_ATTRIBUTE procedure sets the SECURE attribute for a column so variable values used for the column cannot be seen in the database monitor or plan cache.

**Authorization:** The caller must have:

- \*EXECUTE authority to the library containing the table, and
- \*OBJOPR and \*OBJALTER authorities to the table.

►► SET\_COLUMN\_ATTRIBUTE — ( →

► *schema-name* — , — *table-name* — , — *column-name* — , — *attribute* — ) ►►

The schema is SYSPROC.

**schema-name** A character string expression containing the system name of a schema.

**table-name** A character string expression containing the system name of a table.

**column-name** A character string expression containing the system name of a column.

**attribute** A character string expression containing the attribute to set for the column.

Valid values are:

**SECURE NO** This column does not contain data that needs to be secured in a database monitor or plan cache

**SECURE YES** This column contains data that needs to be secured in a database monitor or plan cache.

All variable values for any query that references this column will not be visible in a database monitor or plan cache unless the security officer has started the database monitor or the security officer is accessing the plan cache. All host variable values will appear as \*SECURE when examined from the monitor and plan cache unless the user is the QSECOFR user.

The secure setting for a column is shown in the SECURE column of the QSYS2/SYSCOLUMNS2 catalog.

## Example

Set the credit card column in the ORDERS table so it is secure.

```
CALL SYSPROC.SET_COLUMN_ATTRIBUTE('LIB1', 'ORDERS', 'CCNBR', 'SECURE YES');
```

## SPECIAL\_AUTHORITY\_DATA\_MART table

The SPECIAL\_AUTHORITY\_DATA\_MART table is a data mart that contains information about special authorities for users. These authorities can come directly from a user profile or can be obtained through membership in a group profile.

This data mart is implemented as a materialized query table (MQT). The data in this table is only populated and refreshed when requested by a user. This is done by using the REFRESH TABLE SQL statement.

Gathering the special authority information can be a long running task. Consider running the refresh in a batch job.

**Authorization:** The table is shipped with public authority of \*EXCLUDE.

To refresh the table, the caller must have:

- \*EXECUTE authority to the SYSTOOLS library, and
- \*OBJMGT, \*OBJOPR, \*ADD, and \*DELETE authority to the SYSTOOLS/SPEC\_AUTH file.

To query the table, the caller must have:

- \*EXECUTE authority to the SYSTOOLS library, and
- \*OBJOPR and \*READ authority to the SYSTOOLS/SPEC\_AUTH file.

The following table describes the columns in the table. The system name is SPEC\_AUTH. The schema is SYSTOOLS.

Table 237. SPECIAL\_AUTHORITY\_DATA\_MART table

| Column Name        | System Column Name | Data Type   | Description              |
|--------------------|--------------------|-------------|--------------------------|
| AUTHORIZATION_NAME | USER_NAME          | VARCHAR(10) | User profile name.       |
| SPECIAL_AUTHORITY  | SPCAUT             | VARCHAR(9)  | Special authority value. |

Table 237. SPECIAL\_AUTHORITY\_DATA\_MART table (continued)

| Column Name        | System Column Name | Data Type               | Description                                                                                                                                                                                                                                   |
|--------------------|--------------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| GROUP_PROFILE_NAME | GROUP_NAME         | VARCHAR(10)<br>Nullable | The group profile that provided the special authority for this row.<br>Contains the null value if the special authority was obtained from the user profile.                                                                                   |
| STATUS             | STATUS             | VARCHAR(10)             | The status of the user profile.<br><br><b>*DISABLED</b> The user profile is disabled; therefore, the user cannot sign on.<br><b>*ENABLED</b> The user profile is enabled; therefore, the user is able to sign on.                             |
| TEXT_DESCRIPTION   | TEXT               | VARCHAR(50)<br>Nullable | The descriptive text for the user profile.<br>Contains the null value if the user profile has no text description.                                                                                                                            |
| LAST_USED_DATE     | LAST_USED          | DATE<br>Nullable        | The date the user profile was used last.<br>Contains the null value if the user profile has not been used.                                                                                                                                    |

## Examples

- Update the table to contain the current special authority values for all user profiles on the system.

```
REFRESH TABLE SYSTOOLS.SPECIAL_AUTHORITY_DATA_MART;
```

- Determine when the table was last refreshed.

```
SELECT REFRESH_TIME FROM QSYS2.SYSTABLES
WHERE TABLE_SCHEMA = 'SYSTOOLS' AND
 TABLE_NAME = 'SPECIAL_AUTHORITY_DATA_MART';
```

- List all the users who have \*ALLOBJ special authority, either directly from their user profile or as part of a group profile.

```
SELECT DISTINCT USER_NAME FROM SYSTOOLS.SPECIAL_AUTHORITY_DATA_MART
WHERE SPECIAL_AUTHORITY = '*ALLOBJ';
```

## SQL\_CHECK\_AUTHORITY scalar function

The SQL\_CHECK\_AUTHORITY scalar function returns an indication of whether the user is authorized to query the specified \*FILE object.

**Authorization:** None required.

►► SQL\_CHECK\_AUTHORITY — ( — *library-name* — , — *file-name* — ) ►►

The schema is QSYS2.

***library-name*** Library name containing the file.

***file-name*** File name for which authority will be examined.

The result of the function is a SMALLINT.

The returned value is:

- 0 The user does not have the special authority.
- 1 The user has the special authority.

## Example

- Check whether the current user has \*JOBCTL special authority.

```
VALUES QSYS2.SQL_CHECK_SPECIAL_AUTHORITY('*JOBCTL');
```

## USER\_INFO view

The USER\_INFO view contains information about user profiles.

The USER\_INFO\_BASIC view returns a subset of this information and is faster.

The values returned for the columns in the view are closely related to the values returned by [Retrieve User Information \(QSYRUSRI\) API](#). Refer to the API for more detailed information.

**Authorization:** The caller must have \*OBJOPR and \*READ authorities to the \*USRPRF. To see a non-null value for the USER\_DEFAULT\_PASSWORD column, the caller must have \*ALLOBJ and \*SECADM authorities.

The following table describes the columns in the view. The schema is QSYS2.

Table 238. USER\_INFO view

| Column Name                | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                 |
|----------------------------|--------------------|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AUTHORIZATION_NAME         | USER_NAME          | VARCHAR(10)<br>Nullable | User profile name.                                                                                                                                                                                                                                          |
| PREVIOUS_SIGNON            | PRVSIGNON          | TIMESTAMP<br>Nullable   | The date and time the user last signed on.<br>Contains null if the profile has never been used to sign on.                                                                                                                                                  |
| SIGN_ON_ATTEMPTS_NOT_VALID | SIGNONINV          | INTEGER<br>Nullable     | The number of sign-on attempts that were not valid since the last successful sign-on.                                                                                                                                                                       |
| STATUS                     | STATUS             | VARCHAR(10)<br>Nullable | The status of the user profile. Contains one of the following values:<br><br><b>*DISABLED</b> The user profile is disabled; therefore, the user cannot sign on.<br><br><b>*ENABLED</b> The user profile is enabled; therefore, the user is able to sign on. |
| NETSERVER_DISABLED         | NETSERVER          | VARCHAR(3)              | Whether this user profile is disabled for IBM i NetServer use.<br><br><b>NO</b> The user profile is not disabled for IBM i NetServer use.<br><br><b>YES</b> The user profile is disabled for IBM i NetServer use.                                           |
| PASSWORD_CHANGE_DATE       | PWDCHGDAT          | TIMESTAMP<br>Nullable   | The date the user's password was last changed.                                                                                                                                                                                                              |
| NO_PASSWORD_INDICATOR      | NOPWD              | VARCHAR(3)<br>Nullable  | Indicates whether *NONE is specified for the password in the user profile.<br><br><b>NO</b> The password in the user profile is not *NONE.<br><br><b>YES</b> The password in the user profile is *NONE.                                                     |

Table 238. USER\_INFO view (continued)

| Column Name                  | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------|--------------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PASSWORD_LEVEL_0_1           | PWD_0_1            | VARCHAR(3)<br>Nullable  | Indicates whether the user profile has a password that can be used for a system at QPWDLVL 0 or 1.<br><br><b>NO</b> The password cannot be used.<br><b>YES</b> The password can be used.<br><br>Contains the null value if NO_PASSWORD_INDICATOR has a value of YES.                                                                                            |
| PASSWORD_LEVEL_2_3           | PWD_2_3            | VARCHAR(3)<br>Nullable  | Indicates whether the user profile has a password that can be used for a system at QPWDLVL 2 or 3.<br><br><b>NO</b> The password cannot be used.<br><b>YES</b> The password can be used.<br><br>Contains the null value if NO_PASSWORD_INDICATOR has a value of YES.                                                                                            |
| PASSWORD_EXPIRATION_INTERVAL | PWDEXPITV          | SMALLINT<br>Nullable    | The number of days (from 1 through 366) the user's password can remain active before it must be changed. Can also be one of the following values:<br><br><b>0</b> The system value QPWDEXPITV is used to determine the user's password expiration interval.<br><br><b>-1</b> The user's password does not expire (*NOMAX).                                      |

If AUTHORIZATION_NAME is QSYS, this column contains the default shell path used for all user profiles that have not had a value explicitly set.<br><br>Returns the null value if a value has not been set using the QSYS2.SET_PASE_SHELL_INFO procedure.                                                                                                |

## Example

Determine which users are having trouble signing on.

```
SELECT * FROM QSYS2.USER_INFO
WHERE SIGN_ON_ATTEMPTS_NOT_VALID > 0
```

## USER\_INFO\_BASIC view

The USER\_INFO\_BASIC view contains information about user profiles.

This view returns a subset of columns that are returned by the USER\_INFO view. It does not return: USER\_OWNER, USER\_CREATOR, SIZE, CREATION\_TIMESTAMP, LAST\_USED\_TIMESTAMP, DAYS\_USED\_COUNT, or LAST\_RESET\_TIMESTAMP. USER\_INFO\_BASIC typically performs much better than USER\_INFO.

The values returned for the columns in the view are closely related to the values returned by [Retrieve User Information \(QSYRUSRI\) API](#). Refer to the API for more detailed information.

**Authorization:** The caller must have \*OBJOPR and \*READ authorities to the \*USRPRF. To see a non-null value for the USER\_DEFAULT\_PASSWORD column, the caller must have \*ALLOBJ and \*SECADM authorities.

The following table describes the columns in the view. The system name is USER\_INFOB. The schema is QSYS2.

Table 239. USER\_INFO\_BASIC view

| Column Name                | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                 |

| DISPLAY_SIGNON_INFORMATION | DSPSGNINF          | VARCHAR(10)<br>Nullable | Indicates whether the sign-on information display is shown when the user signs on. Contains one of the following special values:<br><br><b>*NO</b> The sign-on information display is not shown when the user signs on.<br><br><b>*SYSVAL</b> The system value QDSPSGNINF determines if the sign-on information display is shown when the user signs on.<br><br><b>*YES</b> The sign-on information display is shown when the user signs on.                                                                    |
| LIMIT_DEVICE_SESSIONS      | LMTDEVSSN          | VARCHAR(10)<br>Nullable | Specifies if the number of device sessions allowed for a user is limited. Can contain one of the following special values:<br><br><b>*NO</b> The user is not limited to a specific number of device sessions.<br><br><b>*SYSVAL</b> The system value QLMTDEVSSN determines if the user is limited to a specific number of device sessions.<br><br><b>*YES</b> The user is limited to one device session.                                                                                                        |
| KEYBOARD_BUFFERING         | KBDBUF             | VARCHAR(10)<br>Nullable | The keyboard buffering value that is used when a job is initialized for this user. Contains one of the following special values:<br><br><b>*NO</b> The type-ahead and attention-key buffering options are not on.<br><br><b>*SYSVAL</b> The system value QKBDBUF determines the keyboard buffering value for this user.<br><br><b>*TYPEAHEAD</b> The type-ahead option is on, but the attention-key buffering option is not.<br><br><b>*YES</b> The type-ahead and attention-key buffering options are both on. |
| MAXIMUM_ALLOWED_STORAGE    | MAXSTGLRG          | BIGINT<br>Nullable      | The maximum amount of auxiliary storage (in kilobytes) that can be assigned to store permanent objects owned by the user. Contains null if the user has no maximum storage.                                                                                                                                                                                                                                                                                                                                     |
| STORAGE_USED               | STGUSED            | BIGINT<br>Nullable      | The amount of auxiliary storage (in kilobytes) occupied by this user's owned objects on *SYSBAS. The QSYS2.USER_STORAGE catalog should be used to determine the storage consumed on all ASPs.                                                                                                                                                                                                                                                                                                                   |

## Example

Determine which users have \*ALLOBJ special authority.

```
SELECT * FROM QSYS2.USER_INFO_BASIC
WHERE SPECIAL_AUTHORITIES LIKE '%*ALLOBJ%';
```

## Spool Services

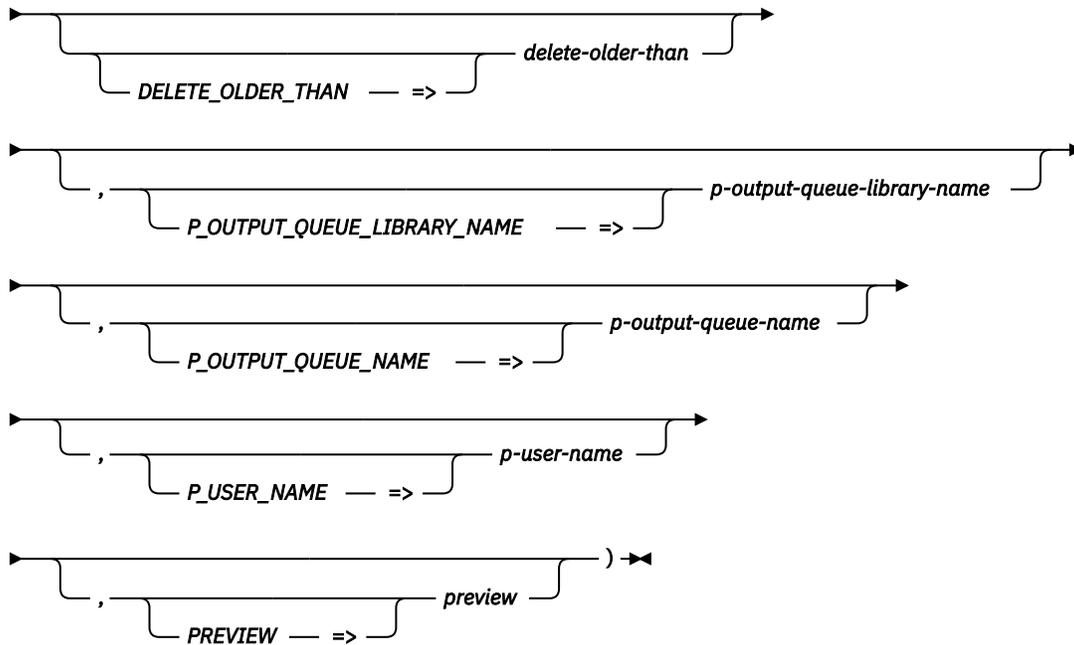

These views and functions provide information about spooled files.

### DELETE\_OLD\_SPOOLED\_FILES procedure

The DELETE\_OLD\_SPOOLED\_FILES procedure deletes spooled files according to filtering criteria. It can optionally return a preview of the files that meet the filtering criteria without performing the delete.

**Authorization:** See Note below.

➤ DELETE\_OLD\_SPOOLED\_FILES (→

The schema is SYSTOOLS.

- delete-older-than*** A timestamp value that defines the starting point for deleting spooled files. Any spooled file older than this timestamp is eligible for deletion. The default is CURRENT TIMESTAMP - 3 MONTHS.
- p-output-queue-library-name*** A character or graphic string that specifies the name of a library. Any spooled file in any output queue in this library is eligible for deletion. The default is \*ALL.
- p-output-queue-name*** A character or graphic string that specifies an output queue name. Any spooled file in this output queue is eligible for deletion. The default is \*ALL.
- p-user-name*** A character or graphic string that specifies the name of a user whose spooled files are to be deleted. Any spooled file with this user name is eligible for deletion. The default is \*ALL.
- preview*** A character or graphic string that indicates whether the identified spooled files should be deleted or returned as a result set.
  - NO** The spooled files will be deleted. This is the default.
  - YES** A result set list of spooled files will be returned. No files will be deleted.

## Note

This procedure is provided in the SYSTOOLS schema as an example of how to delete spooled files and how to return a result set using an SQL procedure. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar procedures, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

## Example

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

## Example

Convert the specified spooled file to PDF format and save it as /usr/listing1.

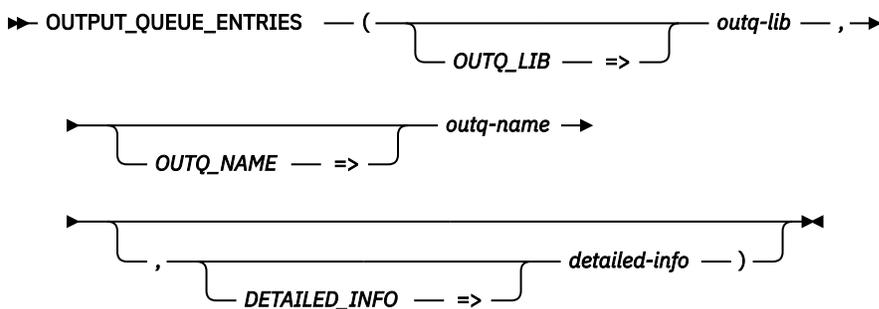

```
VALUES SYSTOOLS.GENERATE_PDF(
 JOB_NAME => '908049/QUSER/QZDASOINIT',
 SPOOLED_FILE_NAME => 'PGMA',
 SPOOLED_FILE_NUMBER => 2,
 PATH_NAME => '/usr/listing1');
```

## OUTPUT\_QUEUE\_ENTRIES table function

The OUTPUT\_QUEUE\_ENTRIES table function returns one row for each spooled file in an output queue.

**Authorization:** The caller must have:

- \*EXECUTE authority to the library containing the output queue, and
  - \*READ authority to the output queue object, or
  - \*SPLCTL special authority, or
  - \*JOBCTL special authority and the output queue is defined with OPRCTL(\*YES).

The schema is QSYS2.

**outq-lib** A character or graphic string expression that identifies the name of the library containing *outq-name*. If this parameter is blank, the default of \*LIBL is used.

**outq-name** A character or graphic string expression that identifies the name of an output queue.

**detailed-info** A character or graphic string expression that indicates the type of information to be returned.

**YES** All the information available for the output queue is returned.

**NO** Only the general information is returned for the output queue. This is the information in the columns prior to the `ACCOUNTING_CODE` column. This is the default.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 240. OUTPUT\_QUEUE\_ENTRIES table function

| Column Name       | Data Type   | Description                                                                                                                              |
|-------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------|
| CREATE_TIMESTAMP  | TIMESTAMP   | The timestamp when the file was created.                                                                                                 |
| SPOOLED_FILE_NAME | VARCHAR(10) | The file name that was specified by the user program when the file was created, or the name of the device file used to create this file. |

Table 240. OUTPUT\_QUEUE\_ENTRIES table function (continued)

| PAGE_LENGTH         | INTEGER      | The page length, in lines per page, used by the spooled file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| LINES_PER_INCH      | DECIMAL(5,1) | The number of lines per vertical inch defined in the printer file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| PAGE_WIDTH          | INTEGER      | The page width, in characters per printed line, used by the spooled file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| CHARACTERS_PER_INCH | DECIMAL(5,1) | The number of characters per horizontal inch, defined in the printer file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| PRINT_FIDELITY      | VARCHAR(8)   | The kind of error handling that is performed when printing.<br><br><b>*ABSOLUTE</b> The file is printed only if it can be printed exactly as specified in the data stream.<br><br><b>*CONTENT</b> The printing overrides errors in the data stream and continues printing with the printers best quality based on the content fidelity.                                                                                                                                                                                                                                           |
| PAGE_ROTATION       | VARCHAR(5)   | The degree of rotation of the text on the page, with respect to the way the form is loaded into the printer.<br><br><b>*AUTO</b> Computer output reduction is done automatically if the output is too large to fit on the form, regardless of the print quality.<br><br><b>*DEVD</b> The operating system sends a device default rotation value to the printer. Page rotation is dependent on the printer's specifications.<br><br><b>*COR</b> Output created for a form 13.2 inches wide by 11.0 inches long is adjusted to print on a form 11.0 inches wide by 8.5 inches long. |
| PRINT_BOTH_SIDES    | VARCHAR(7)   | How the information prints.<br><br><b>*FORMDF</b> The file uses a user-specified form definition. This value is used only for *LINE, *AFPDS, and *AFPDSLINE printer device type files.<br><br><b>*NO</b> The printing on the page is on one side only.<br><br><b>*YES</b> The printing is on both sides of the page with the top of each page the same for both sides.<br><br><b>*TUMBLE</b> The printing is on both sides with the top of one printed page at the opposite end from the top of the other printed page.                                                           |
| FILE_AVAILABLE      | VARCHAR(8)   | The time when this file becomes available to an output device for processing.<br><br><b>*IMMED</b> The file is available as soon as the file is opened.<br><br><b>*FILEEND</b> The file is available as soon as the file is closed.<br><br><b>*JOBEND</b> The file is available when the job that owns the file is completed.                                                                                                                                                                                                                                                     |
| STARTING_PAGE       | VARCHAR(10)  | The page at which printing is to start for the file. Can contain the following special value:<br><br><b>*ENDPAGE</b> Printing starts with the last page.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ENDING_PAGE         | VARCHAR(10)  | The page at which printing is to end for the file. Can contain the following special value:<br><br><b>*END</b> Printing ends with the last page.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| DEVICE_FILE_LIBRARY | VARCHAR(10)  | The name of the library that contains the device file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| DEVICE_FILE_NAME    | VARCHAR(10)  | The name of the device file used to create the spooled file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| USER_DEFINED_DATA   | BINARY(255)  | Data defined by the user to be used by user applications or user-specified programs that process spooled files.<br><br>Contains null when there is no user-defined data.                                                                                                                                                                                                                                                                                                                                                                                                          |

Table 240. OUTPUT\_QUEUE\_ENTRIES table function (continued)

| Column Name                      | Data Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

Can contain the following special value:<br><br><b>*FONT</b> The information specified on the font parameter is used instead of the character set and code page.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| CODE_PAGE_LIBRARY                | VARCHAR(10) | The name of the library containing the code page used to print this spooled file. Can contain one of these special values:<br><br><b>*CURLIB</b> The current library is searched for the code page name.<br><b>*LIBL</b> The library list is used to locate the code page name.<br><br>Contains null when no code page is specified for this spooled file.                                                                                                                                                                                                                                                                                                                          |
| CODE_PAGE_NAME                   | VARCHAR(10) | The name of the code page used to print this spooled file. Contains null when no code page is specified for this spooled file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Table 240. OUTPUT\_QUEUE\_ENTRIES table function (continued)

| Column Name               | Data Type    | Description                                                                                                                                                                                                                                                                                                                   |
|---------------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CHARACTER_SET_POINTSIZE   | DECIMAL(5,1) | The point size in which this file's characters should be printed. Contains null if the character set does not have a point size.                                                                                                                                                                                              |
| CODED_FONT_LIBRARY        | VARCHAR(10)  | The name of the library containing the coded font used to print this spooled file. Can contain one of these special values:<br><br><b>*CURLIB</b> The current library is searched for the coded font.<br><b>*LIBL</b> The library list is used to locate the coded font.<br>Contains null when CODED_FONT_NAME is *FNTCHRSET. |
| CODED_FONT_NAME           | VARCHAR(10)  | The name of the coded font used to print this spooled file. Can contain the following special value:<br><br><b>*FNTCHRSET</b> The values used are the values specified on the character set name and library name and code page name and library name fields.                                                                 |
| CODED_FONT_POINTSIZE      | DECIMAL(5,1) | The point size in which this file's characters should be printed. Contains null if the coded font does not have a point size.                                                                                                                                                                                                 |
| MULTIBYTE_DATA            | VARCHAR(10)  | Whether the file can contain double-byte character set (DBCS) data, Unicode data, or both. Values are *YES and *NO.                                                                                                                                                                                                           |
| DBCS_CODED_FONT_LIBRARY   | VARCHAR(10)  | The name of the library containing the DBCS-coded font. Can contain one of these special values:<br><br><b>*CURLIB</b> The current library is searched for the DBCS-coded font.<br><b>*LIBL</b> The library list is used to locate the DBCS-coded font.<br>Contains null when DBCS_CODED_FONT_NAME is *SYSVAL.                |
| DBCS_CODED_FONT_NAME      | VARCHAR(10)  | The name of the DBCS-coded font used to print DBCS-coded data on printers configured as AFP(*YES). Can contain the following special value:<br><br><b>*SYSVAL</b> The DBCS-coded font specified in the system value is used.                                                                                                  |
| DBCS_CODED_FONT_POINTSIZE | DECIMAL(5,1) | The point size in which this file's DCBS characters should be printed. Contains null if the DBCS-coded font does not have a point size.                                                                                                                                                                                       |

## Example

Find the 100 largest spool files in the QEZJOBLOG output queue. Since no detailed information is needed, specify NO to avoid the additional processing.

```
SELECT *
 FROM TABLE(QSYS2.OUTPUT_QUEUE_ENTRIES('*LIBL', 'QEZJOBLOG', 'NO')) A
 ORDER BY SIZE DESC
 FETCH FIRST 100 ROWS ONLY
```

## OUTPUT\_QUEUE\_ENTRIES view

The OUTPUT\_QUEUE\_ENTRIES view returns one row for each spooled file in every output queue. This view uses the QSYS2.OUTPUT\_QUEUE\_ENTRIES table function with DETAILED\_INFO => 'YES'.

**Authorization:** The caller must have:

- \*EXECUTE authority to the library containing the output queue, and
  - \*READ authority to the output queue object, or
  - \*SPLCTL special authority, or
  - \*JOBCTL special authority and the output queue is defined with OPRCTL(\*YES).

To achieve the best performance when querying the OUTPUT\_QUEUE\_ENTRIES view, the use of a WHERE clause is recommended if you are interested in examining specific output queue libraries or output queues. OUTPUT\_QUEUE\_ENTRIES\_BASIC typically performs much

better than OUTPUT\_QUEUE\_ENTRIES. OUTPUT\_QUEUE\_ENTRIES should only be used when OUTPUT\_QUEUE\_ENTRIES\_BASIC does not include the columns needed by the query.

The following table describes the columns in the view. The system name is OUTQ\_INFO. The schema is QSYS2.

Table 241. OUTPUT\_QUEUE\_ENTRIES view

| Column Name               | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| CODED_FONT_NAME           | FONTNAME           | VARCHAR(10)              | The name of the coded font used to print this spooled file. Can contain the following special value:<br><br><b>*FNTCHRSET</b> The values used are the values specified on the character set name and library name and code page name and library name fields.                                                          |
| CODED_FONT_POINTSIZE      | FONTSIZE           | DECIMAL(5,1)<br>Nullable | The point size in which this file's characters (defined by CODED_FONT) should be printed. Contains null if the coded font does not have a point size.                                                                                                                                                                  |
| MULTIBYTE_DATA            | MULTIBYTE          | VARCHAR(10)              | Whether the file can contain double-byte character set (DBCS) data, Unicode data, or both. Values are *YES and *NO.                                                                                                                                                                                                    |
| DBCS_CODED_FONT_LIBRARY   | DBCSLIB            | VARCHAR(10)<br>Nullable  | The name of the library containing the DBCS-coded font. Can contain one of these special values:<br><br><b>*CURLIB</b> The current library is searched for the DBCS-coded font.<br><br><b>*LIBL</b> The library list is used to locate the DBCS-coded font.<br><br>Contains null when DBCS_CODED_FONT_NAME is *SYSVAL. |
| DBCS_CODED_FONT_NAME      | DBCSNAME           | VARCHAR(10)              | The name of the DBCS-coded font used to print DBCS-coded data on printers configured as AFP(*YES). Can contain the following special value:<br><br><b>*SYSVAL</b> The DBCS-coded font specified in the system value is used.                                                                                           |
| DBCS_CODED_FONT_POINTSIZE | DBCSSIZE           | DECIMAL(5,1)<br>Nullable | The point size in which this file's DCBS characters (defined by DBCS_CODED_FONT) should be printed. Contains null if the DBCS-coded font does not have a point size.                                                                                                                                                   |

## Example

For the output queue with the largest number of files, determine how many kilobytes of data would be deleted by running the Delete Expired Spooled Files (DLTEXPSPLF) CL command.

```
WITH MOSTFILES(OUTQ_LIB, OUTQ_NAME) AS (
 SELECT OUTPUT_QUEUE_LIBRARY_NAME, OUTPUT_QUEUE_NAME
 FROM QSYS2.OUTPUT_QUEUE_INFO
 ORDER BY NUMBER_OF_FILES DESC
 LIMIT 1
)
SELECT SUM(SIZE) AS KB_TO_CLEAR
FROM MOSTFILES, QSYS2.OUTPUT_QUEUE_ENTRIES
WHERE OUTPUT_QUEUE_LIBRARY_NAME = OUTQ_LIB AND
 OUTPUT_QUEUE_NAME = OUTQ_NAME AND
 EXPIRATION_DATE IS NOT NULL AND
 EXPIRATION_DATE < CURRENT DATE;
```

## OUTPUT\_QUEUE\_ENTRIES\_BASIC view

The OUTPUT\_QUEUE\_ENTRIES\_BASIC view returns one row for each spooled file in every output queue. This view uses the QSYS2.OUTPUT\_QUEUE\_ENTRIES table function with DETAILED\_INFO => 'NO'.

**Authorization:** The caller must have:

- \*EXECUTE authority to the library containing the output queue, and
  - \*READ authority to the output queue object, or
  - \*SPLCTL special authority, or
  - \*JOBCTL special authority and the output queue is defined with OPRCTL(\*YES).

To achieve the best performance when querying the OUTPUT\_QUEUE\_ENTRIES\_BASIC view, the use of a WHERE clause is recommended if you are interested in examining specific

output queue libraries or output queues. OUTPUT\_QUEUE\_ENTRIES\_BASIC typically performs much better than OUTPUT\_QUEUE\_ENTRIES. OUTPUT\_QUEUE\_ENTRIES should only be used when OUTPUT\_QUEUE\_ENTRIES\_BASIC does not include the columns needed by the query.

The following table describes the columns in the view. The system name is OUTQ\_INFOB. The schema is QSYS2.

Table 242. OUTPUT\_QUEUE\_ENTRIES\_BASIC view

| Column Name               | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| FILE_NUMBER     | FILENUM            | INTEGER     | The spooled file number of the specified file.                                                                                                                                                                                                                                                                                                               |
| SYSTEM          | SYSTEM             | VARCHAR(8)  | The name of the system where the job that created the spooled file ran.                                                                                                                                                                                                                                                                                      |

## Examples

- Find the 100 largest spool files in the QEZJOBLOG output queue.

```
SELECT * FROM QSYS2.OUTPUT_QUEUE_ENTRIES_BASIC
WHERE OUTPUT_QUEUE_NAME = 'QEZJOBLOG'
ORDER BY SIZE DESC
FETCH FIRST 100 ROWS ONLY
```

- Find the top 10 consumers of SPOOL storage.

```
SELECT USER_NAME, SUM(SIZE) AS TOTAL_SPOOL_SPACE
FROM QSYS2.OUTPUT_QUEUE_ENTRIES_BASIC
WHERE USER_NAME NOT LIKE 'Q%'
GROUP BY USER_NAME
ORDER BY TOTAL_SPOOL_SPACE DESC LIMIT 10;
```

## OUTPUT\_QUEUE\_INFO view

The OUTPUT\_QUEUE\_INFO view returns one row for each output queue.

The values returned for the columns in the view are similar to the values returned by the [Retrieve Output Queue Information \(QSPROUTQ\) API](#). Refer to the API for more detailed information.

**Authorization:** The caller must have:

- \*EXECUTE authority to the library containing the output queue, and
  - \*READ authority to the output queue object, or
  - \*SPLCTL special authority, or
  - \*JOBCTL special authority and the output queue is defined with OPRCTL(\*YES).

The following table describes the columns in the view. The system name is OUTQ\_DTL. The schema is QSYS2.

Table 243. OUTPUT\_QUEUE\_INFO view

| Column Name               | System Column Name | Data Type   | Description                                                                           |
|---------------------------|--------------------|-------------|---------------------------------------------------------------------------------------|
| OUTPUT_QUEUE_NAME         | OUTQ               | VARCHAR(10) | Name of the output queue.                                                             |
| OUTPUT_QUEUE_LIBRARY_NAME | OUTQLIB            | VARCHAR(10) | The name of the library that contains the output queue.                               |
| NUMBER_OF_FILES           | FILES              | INTEGER     | The total number of spooled files currently on this output queue.                     |
| NUMBER_OF_WRITERS         | WRITERS            | INTEGER     | The number of printer writers that have been started to this output queue.            |
| WRITERS_TO_AUTOSTART      | AUTOSTART          | INTEGER     | The number of remote printer writers to autostart to this output queue at system IPL. |

| Column Name          | System Column Name | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------|--------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FORMS_CONTROL_BUFFER | FORMS_BUF          | VARCHAR(8)<br>Nullable | The forms control buffer (FCB) for files sent to a z/VM or z/OS host system. Contains either the name of the FCB or one of the following special values:<br><br><b>*PRTF</b> The first 8 characters of the printer file used to spool the file determines the name of the FCB.<br><br><b>*USRDTA</b> The first 8 characters of the user data (USRDATA) spooled file attribute determines the name of the FCB. If the user data is blank, no FCB is used.<br><br>Contains the null value if no FCB is used when sending spooled files or if NETWORK_CONNECTION_TYPE is not *SNA or DESTINATION_TYPE is not *S390. |
| VM_MVS_CLASS         | VM_CLASS           | CHAR(1)<br>Nullable    | The z/VM or z/OS SYSOUT class for distributions sent to a z/VM host system or to a z/OS host system. Values are A-Z, 0-9 to indicate the distribution class.<br><br>Contains the null value if not defined for this output queue.                                                                                                                                                                                                                                                                                                                                                                                |

## Example

```
SELECT * FROM QSYS2.OUTPUT_QUEUE_INFO
```

## PRINTER\_FILE\_INFO view

The PRINTER\_FILE\_INFO view returns many attributes of IBM i printer files.

The information is returned by using the Display File Description (DSPFD) CL command.

**Authorization:** See Note below.

The following table describes the columns in the view. The system name is PRTF\_INFO. The schema is SYSTOOLS.

Table 244. PRINTER\_FILE\_INFO view

| Column name                  | System column name | Data type               | Description                                                                                                                       |
|------------------------------|--------------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| PRINTER_FILE_LIBRARY         | PRTF_LIB           | VARCHAR(10)             | Name of the library that contains the printer file.                                                                               |
| PRINTER_FILE                 | PRTF               | VARCHAR(10)             | Name of the printer file.                                                                                                         |
| SPOOLED_OUTPUT_QUEUE_LIBRARY | OUTQ_LIB           | VARCHAR(10)<br>Nullable | Library containing output queue for spooled files.<br><br>Contains the null value if SPOOLED_OUTPUT_QUEUE is *JOB.                |
| SPOOLED_OUTPUT_QUEUE         | OUTQ               | VARCHAR(10)             | Output queue for spooled files. Can contain the following special value:<br><br><b>*JOB</b> The output queue for the job is used. |
| OWNER                        | OWNER              | VARCHAR(10)             | The owner of the printer file                                                                                                     |
| DEFINER                      | DEFINER            | VARCHAR(10)             | The user who created the printer file.                                                                                            |
| CREATE_TIMESTAMP             | CREATED            | TIMESTAMP               | The time the printer file was created.                                                                                            |
| LAST_USED_TIMESTAMP          | LAST_USED          | TIMESTAMP<br>Nullable   | The time the printer file was last used.<br><br>Contains the null value if the printer file has never been used.                  |
| SIZE                         | SIZE               | DECIMAL(15,0)           | The size of the printer file.                                                                                                     |
| TEXT_DESCRIPTION             | TEXT               | VARCHAR(50)<br>Nullable | Descriptive text for the printer file.<br><br>Contains the null value if there is no text description.                            |

Table 244. PRINTER\_FILE\_INFO view (continued)

| Column name         | System column name | Data type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| RECORD_FORMAT         | RCDFMT             | CLOB(1M) CCSID 1208<br>Nullable | A list of record formats for the printer file. The value is returned as a JSON array, with each array element containing a JSON object with information for one format. The array name is RCDFMT. The array elements consist of: <ul style="list-style-type: none"> <li>The format name, with a key of FORMAT_NAME</li> <li>The number of fields in the format, with a key of FORMAT_NUMBER_FIELDS</li> <li>The length of the format, with a key of FORMAT_RECORD_LENGTH</li> <li>The format level ID, with a key of FORMAT_LEVEL_ID</li> <li>Descriptive text for the format, with a key of FORMAT_TEXT</li> </ul> Contains the null value if record format information is not available for this printer file. |

## Note

This function is provided in the SYSTOOLS schema as an example of returning information from a CL command's OUTFILE. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

## Example

- Look at some printer file attributes for printer files in library APPLIB1.

```
SELECT PRINTER_FILE, TEXT_DESCRIPTION, MAXIMUM_RECORDS, OUTPUT_PRIORITY, FORM_TYPE
FROM SYSTOOLS.PRINTER_FILE_INFO
WHERE PRINTER_FILE_LIBRARY = 'APPLIB1';
```

- Expand the list of record formats for printer file APPLIB1/INVOICE.

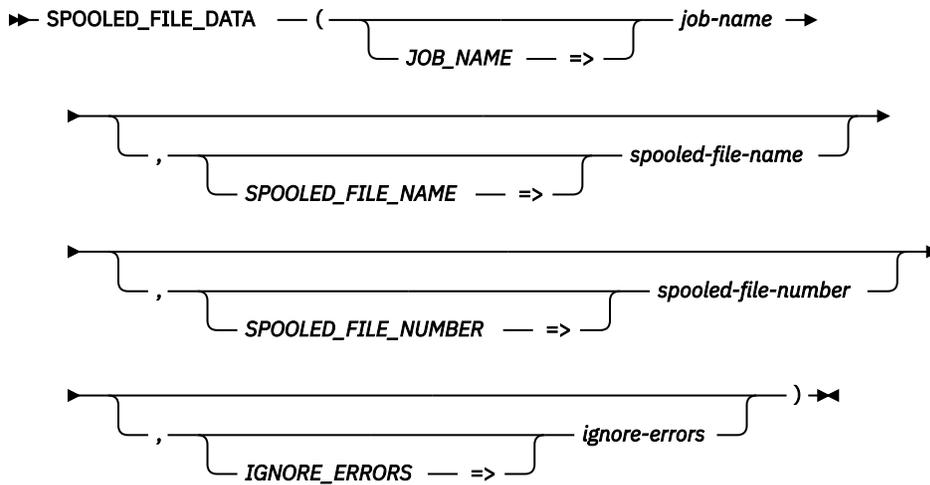

```
SELECT J.*
FROM SYSTOOLS.PRINTER_FILE_INFO,
 JSON_TABLE(RECORD_FORMAT, '1ax $.RCDFMT'
 COLUMNS (FORMAT_NAME VARCHAR(10),
 FORMAT_FIELDS INTEGER,
 FORMAT_LENGTH INTEGER,
 FORMAT_LEVEL_ID CHAR(13),
 FORMAT_TEXT VARCHAR(50))
) J
WHERE PRINTER_FILE_LIBRARY = 'APPLIB1' AND PRINTER_FILE = 'INVOICE';
```

## SPOOLED\_FILE\_DATA table function

The SPOOLED\_FILE\_DATA table function returns the content of a spooled file.

If the spooled file contains double byte data, the job CCSID must be a mixed CCSID.

**Authorization:** See Note below.

The schema is SYSTOOLS.

- job-name** A character string containing a qualified job name. Can contain the following special value:
- \* Use the name of the current job.
- spooled-file-name** A character string containing the name of the spooled file. If this parameter is omitted, QPJOBLOG is used.
- spooled-file-number** The number of the spooled file. If this parameter is omitted, the spooled file with the highest number matching *spooled-file-name* is used.
- ignore-errors** A character or graphic string expression that identifies what to do when an error is encountered.
- NO** An error is returned.
  - YES** A warning is returned.
- No row is returned when an error is encountered. This is the default.

The result of the function is a table containing a row for each record in the specified spooled file. The columns of the result table are described in the following table. The result columns are nullable.

Table 245. SPOOLED\_FILE\_DATA table function

| Column Name      | Data Type    | Description                                        |
|------------------|--------------|----------------------------------------------------|
| ORDINAL_POSITION | INTEGER      | Relative position of this row in the spooled file. |
| SPOOLED_DATA     | VARCHAR(378) | The data for this row in the spooled file.         |

## Note

This function is provided in the SYSTOOLS schema as an example of how spooled file data can be returned by embedding the CPYSPLF CL command in an SQL table function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

## Example

Return the most recent QSYSPRT file for a specific job:

```
SELECT * FROM TABLE(SYSTOOLS.SPOOLED_FILE_DATA (
 JOB_NAME =>'193846/SLROMANO/QPADEV0009',
 SPOOLED_FILE_NAME =>'QSYSPRT'))
ORDER BY ORDINAL_POSITION;
```

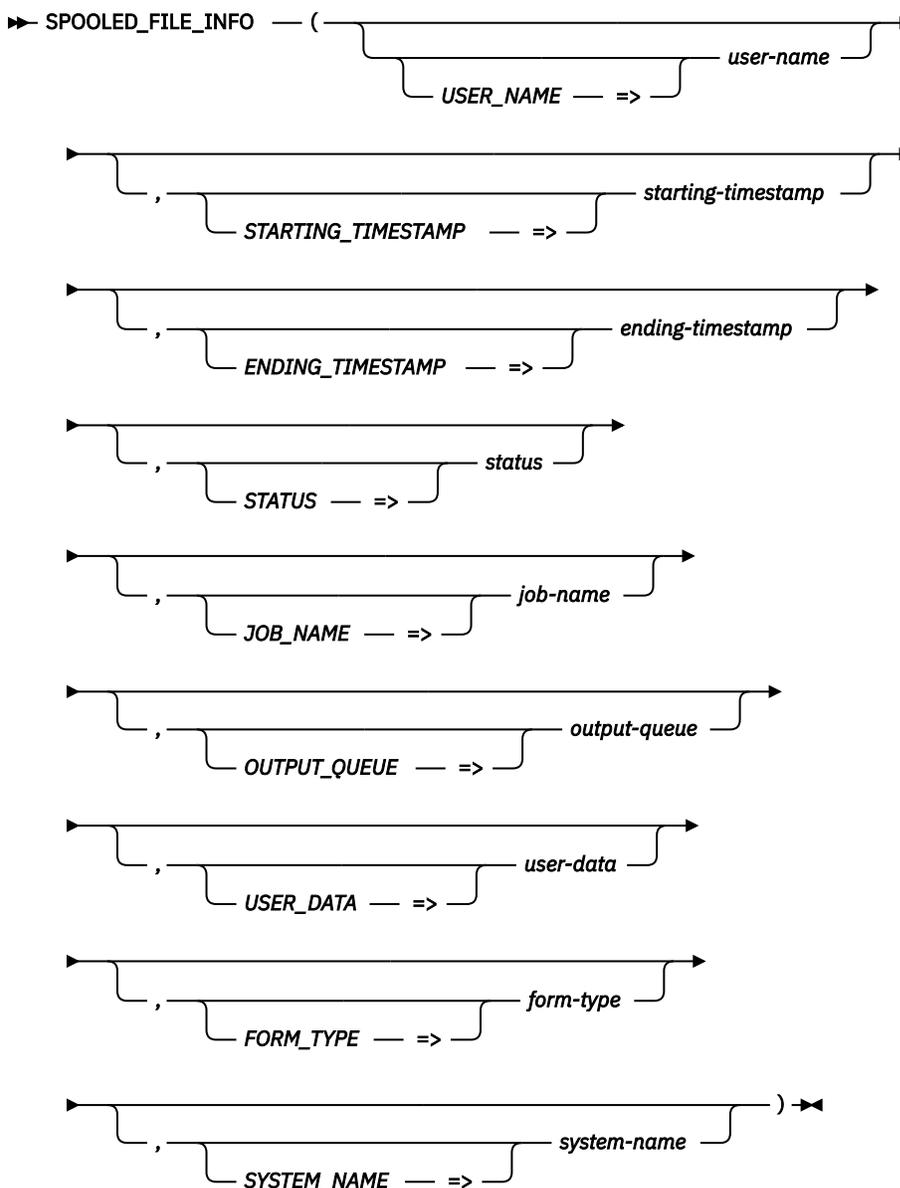

## SPOOLED\_FILE\_INFO table function

The SPOOLED\_FILE\_INFO table function returns a list of spooled files on the system.

This information is similar to what is returned by the Work with Spooled Files (WRKSPLF) CL command and the Open List of Spooled Files (QGYOLSPL) API.

**Authorization:** The caller must have:

- \*EXECUTE authority to the library containing the output queue, and
- \*USE authority to the output queue containing the spooled file.

The schema is QSYS2.

Filtering on multiple values of *user-name*, *output-queue*, or *user-data* is slower.

Additionally, filtering on *status* is slower.

- user-name*** A character string containing user profile names to filter on. The list can contain up to 20 values separated by blanks.  
Can be one of the following special values:
- \*ALL** The list is not filtered by user profile.
  - \*CURRENT** Spooled files owned by the current user profile are included in the list. This is the default.
- starting-timestamp*** A timestamp value for the earliest spooled file to return. If the parameter is omitted or the null value, all spooled files with a create timestamp less than or equal to *ending-timestamp* are returned.
- ending-timestamp*** A timestamp value for the latest spooled file to return. If the parameter is omitted or the null value, all spooled files with a create timestamp greater than or equal to *starting-timestamp* are returned.
- status*** A character string containing the spooled file status to filter on. The list can contain one or more status values separated by blanks.
- \*ALL** Spooled files are included in the list regardless of the current status. This is the default.
  - \*CLOSED** The file has been completely processed by a program, but SCHEDULE(\*JOBEND) was specified. The job that produced the spooled file has not finished.
  - \*DEFERRED** This spooled file has been deferred from printing.
  - \*FINISHED** This spooled file is no longer in the system. These spooled files are included in the list of spooled files only if the qualified job name is specified.
  - \*HELD** The file has been held.
  - \*MESSAGE** This file has a message that needs a reply or needs an action to be taken.
  - \*OPEN** The file has not been completely processed and is not ready to be selected by a writer.
  - \*PENDING** This file is pending (waiting) to be printed.
  - \*PRINTER** The file has been completely sent to the printer, but the print complete status has not been sent back.
  - \*READY** The file is available to be written to an output device by a writer.
  - \*SAVED** The file has been written and then saved. This file remains saved until it is released.
  - \*SENDING** This spooled file is being sent or has been sent to a remote system.
  - \*WRITING** This file is currently being produced by the writer on an output device.
- job-name*** A character string containing qualified job name.  
Can be one of the following special values:
- \*** The current job.
  - \*ALL** All jobs matching the other criteria are returned. This is the default.
- output-queue*** A character string containing the name of the output queue to filter on. An output queue name must be in the format *library-name/outq-name*. The list can contain up to 20 values separated by blanks.

\*LIBL or \*CURLIB can be specified for the library name.

Instead of a list of qualified output queue names, the following special value can be used:

**\*ALL** Spooled files are included in the list regardless of the output queue. This is the default.

***user-data***

A character string containing the value of the user-specified data or file name for spooled files to filter on.

Can be the following special value:

**\*ALL** Spooled files are included in the list regardless of the value for user-specified data. This is the default.

***form-type***

A character string containing the form type value to filter on.

Can be one of the following special values:

**\*ALL** Spooled files are included in the list regardless of the value for form type. This is the default.

**\*STD** Only files that specify the standard form type are included in the list.

***system-name***

A character string containing the name of the system where the job that created the spooled file ran.

Can be one of the following special values:

**\*ALL** The list is not filtered based on job system name. This is the default.

**\*CURRENT** Only spooled files created on the current system are to be returned.

The result of the function is a table containing rows with the format shown in the following table. All columns are nullable.

Table 246. SPOOLED\_FILE\_INFO table function

| Column Name         | Data Type   | Description                     |
|---------------------|-------------|---------------------------------|
| SPOOLED_FILE_NAME   | VARCHAR(10) | The name of the spooled file.   |
| SPOOLED_FILE_NUMBER | INTEGER     | The number of the spooled file. |

Table 246. SPOOLED\_FILE\_INFO table function (continued)

| Column Name                                                                             | Data Type    | Description                                                                                                                                                                                                                                                                      |
|-----------------------------------------------------------------------------------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STATUS                                                                                  | VARCHAR(15)  | The status of the file.                                                                                                                                                                                                                                                          |
|                                                                                         |              | <b>CLOSED</b> The file has been processed completely by a program, but SCHEDULE(*JOBEND) was specified. The job that produced the spooled file has not finished.                                                                                                                 |
|                                                                                         |              | <b>DEFERRED</b> Printing of the file has been deferred.                                                                                                                                                                                                                          |
|                                                                                         |              | <b>DELETED</b> This spooled file is no longer in the system. These spooled files are included in the list of spooled files only if the qualified job name is specified.                                                                                                          |
|                                                                                         |              | <b>HELD</b> The file has been held.                                                                                                                                                                                                                                              |
|                                                                                         |              | <b>MESSAGE WAITING</b> This file has a message which needs a reply or an action to be taken.                                                                                                                                                                                     |
|                                                                                         |              | <b>OPEN</b> The file has not been processed completely and is not ready to be selected by a writer.                                                                                                                                                                              |
|                                                                                         |              | <b>PENDING</b> This file is pending (waiting) to be printed.                                                                                                                                                                                                                     |
|                                                                                         |              | <b>PRINTING</b> The file has been completely sent to the printer, but the print complete status has not been sent back.                                                                                                                                                          |
|                                                                                         |              | <b>READY</b> The file is available to be written.                                                                                                                                                                                                                                |
|                                                                                         |              | <b>SAVED</b> The file has been written and then saved. This file remains saved until it is released.                                                                                                                                                                             |
| <b>SENDING</b> This spooled file is being sent or has been sent to a remote system.     |              |                                                                                                                                                                                                                                                                                  |
| <b>WRITING</b> This file currently is being produced by the writer on an output device. |              |                                                                                                                                                                                                                                                                                  |
| OUTPUT_PRIORITY                                                                         | INTEGER      | The priority of the spooled file. The priority ranges from 1 (highest) to 9 (lowest).<br>Contains the null value when STATUS is DELETED.                                                                                                                                         |
| CREATION_TIMESTAMP                                                                      | TIMESTAMP(0) | The timestamp, based on local job time, when the file was opened.                                                                                                                                                                                                                |
| USER_DATA                                                                               | VARCHAR(10)  | The user-specified data that describes the file.<br>Contains the null value if there is no user-specified data or STATUS is DELETED.                                                                                                                                             |
| SIZE                                                                                    | BIGINT       | The spooled file size in bytes. The size of the spooled file is the data stream size plus the spooled file's attributes, plus the "overhead" storage used to store the spooled file's data stream.<br>Contains the null value if the size is not available or STATUS is DELETED. |
| TOTAL_PAGES                                                                             | INTEGER      | The total number of pages or number of records for the spooled file.<br>Contains the null value if the total number of pages is not available or STATUS is DELETED.                                                                                                              |
| COPIES                                                                                  | INTEGER      | The number of copies remaining to print.<br>Contains the null value when STATUS is DELETED.                                                                                                                                                                                      |
| QUALIFIED_JOB_NAME                                                                      | VARCHAR(28)  | The qualified job name of the job that owns the spooled file.                                                                                                                                                                                                                    |
| JOB_NAME                                                                                | VARCHAR(10)  | The name of the job that owns the spooled file.                                                                                                                                                                                                                                  |
| JOB_USER                                                                                | VARCHAR(10)  | The name of the user that owns the spooled file.                                                                                                                                                                                                                                 |
| JOB_NUMBER                                                                              | VARCHAR(6)   | The number of the job that owns the spooled file.                                                                                                                                                                                                                                |

Table 246. SPOOLED\_FILE\_INFO table function (continued)

| Column Name                    | Data Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FILE_AVAILABLE                 | VARCHAR(8)  | The schedule of the spooled file.<br><br><b>*IMMED</b> The spooled file is schedule immediate. A spooling writer can process the spooled file immediately.<br><br><b>*FILEEND</b> The spooled file is schedule file end. A spooling writer cannot process the spooled file until it has been closed.<br><br><b>*JOBEND</b> The spooled file is schedule job end. A spooling writer cannot process the spooled file until the job of the spooled file has ended. |
| FORM_TYPE                      | VARCHAR(10) | Spooled file form type. The type of form to load in the printer to print this file.<br><br>Contains the null value when STATUS is DELETED.                                                                                                                                                                                                                                                                                                                      |
| OUTPUT_QUEUE_LIBRARY           | VARCHAR(10) | The library where the output queue is located.<br><br>Contains the null value when STATUS is DELETED.                                                                                                                                                                                                                                                                                                                                                           |
| OUTPUT_QUEUE                   | VARCHAR(10) | The name of the output queue in which the spooled file is located.<br><br>Contains the null value when STATUS is DELETED.                                                                                                                                                                                                                                                                                                                                       |
| ASP_NUMBER                     | INTEGER     | The auxiliary storage pool in which the spooled file resides. 1 indicates the system ASP.<br><br>Contains the null value when STATUS is DELETED.                                                                                                                                                                                                                                                                                                                |
| SYSTEM                         | VARCHAR(8)  | The name of the system where the job that created the spooled file ran.                                                                                                                                                                                                                                                                                                                                                                                         |
| INTERNET_PRINT_PROTOCOL_JOB_ID | INTEGER     | The IPP job identifier assigned by the system based on the output queue to which the file was added or moved. This value ranges from 1 to 2147483647 and is not guaranteed to be unique for a given output queue.<br><br>Contains the null value when STATUS is DELETED.                                                                                                                                                                                        |

## Example

- List all the spooled files for the current job.

```
SELECT * FROM TABLE(QSYS2.SPOOLED_FILE_INFO(JOB_NAME => '*'));
```

## Storage Services

These views provide information about storage and storage devices.

### ADD\_DEVICE\_LOCKING\_POLICY procedure

The ADD\_DEVICE\_LOCKING\_POLICY procedure adds a specific NVMe device, or all eligible NVMe devices, to the password policy.

**Authorization:** The caller must have \*IOSYSCFG and \*SERVICE special authorities.

```
➤➤ ADD_DEVICE_LOCKING_POLICY ((POLICY_PASSWORD => policy-password)
, (RESOURCE_NAME => resource-name)) ➤➤
```

The schema is QSYS2.

***policy-password*** A character string that contains the policy password. It must be at least 8 characters long and cannot exceed 32 characters.

**resource-name** A character string that contains the resource name of the NVMe device to be added to the locking policy.

The following special value can be specified:

**\*ALL** All NVMe devices that have a namespace configured are added to the locking policy.

## Example

- Add a new device to the locking policy.

```
CALL QSYS2.ADD_DEVICE_LOCKING_POLICY(POLICY_PASSWORD => 'My0dev9pw!',
 RESOURCE_NAME => 'UNIT2');
```

## ASP\_INFO view

The ASP\_INFO view returns information about auxiliary storage pools (ASPs).

The values returned for the columns in the view are similar to the values returned by the Work with Configuration Status (WRKCFGSTS) CL command and the Open List of ASPs (QYASPOL) API.

**Authorization:** None required.

The following table describes the columns in the view. The system name is ASP\_INFO. The schema is QSYS2.

Table 247. ASP\_INFO view

| Column Name             | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------|--------------------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DEVICE_DESCRIPTION_NAME | DEVD_NAME          | VARCHAR(10)<br>Nullable | The name of the device description that most recently brought the independent ASP (IASP) to varyon/active state.<br><br>Contains the null value if the ASP is not an IASP.                                                                                                                                                                                                                                               |
| ASP_NUMBER              | ASP_NUM            | INTEGER                 | A unique identifier for an ASP. Possible values are 1 through 255.<br><br><b>1</b> The system ASP<br><b>2-32</b> User ASPs<br><b>33-255</b> IASPs                                                                                                                                                                                                                                                                        |
| ASP_STATE               | ASP_STATE          | VARCHAR(10)             | The device configuration status of an ASP.<br><br><b>ACTIVE</b> The status of the ASP is active.<br><b>AVAILABLE</b> The status of the ASP is available.<br><b>FAILED</b> The status of the ASP is failed.<br><b>NONE</b> There is no status. This value is used for the system ASP and any basic user ASPs.<br><b>VARIED OFF</b> The status of the ASP is varyoff.<br><b>VARIED ON</b> The status of the ASP is varyon. |

Table 247. ASP\_INFO view (continued)

| Column Name                  | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                                                                                                            |

| COMPRESSION_RECOVERY_POLICY | COMP_RECOV         | VARCHAR(18)            | <p>The compression recovery policy for the ASP. If the ASP has compressed drives as part of its configuration, this value controls how overflow situations are handled for this ASP. The following policies allow the user to control what is done when the ASP appears full.</p> <p><b>OVERFLOW DELAY</b> When the ASP capacity is about to be exceeded, the operating system posts system reference code (SRC) A6xx 0277 in the system control panel and waits for a limited time for space to become available. If space becomes available before the limited time ends, the SRC is removed from the system control panel and normal operations resume. If space does not become available before the limited time ends, data overflows into the system ASP.</p> <p><b>OVERFLOW IMMEDIATE</b> When the ASP capacity is about to be exceeded, the data immediately overflows into the system ASP.</p> <p><b>WAIT</b> When the ASP capacity is about to be exceeded, the operating system posts SRC A6xx 0277 in the system control panel and waits indefinitely for space to become available. The user must take action before normal operation resumes. Possible actions include deleting objects from the ASP or changing the compression recovery policy to a value that allows the ASP to overflow.</p> |
| COMPRESSED_DISK_UNITS       | COMPRESSED         | VARCHAR(4)             | <p>Whether there are compressed disk units in the ASP.</p> <p><b>ALL</b> All disk units in this ASP are compressed.</p> <p><b>NONE</b> No compressed disk units in this ASP.</p> <p><b>SOME</b> Compressed and uncompressed disk units in this ASP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Column Name  | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|--------------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BALANCE_TYPE | BAL_TYPE           | VARCHAR(21)<br>Nullable | <p>The type of balance activity that is currently running or was done last.</p> <p><b>CAPACITY BALANCING</b> Capacity balancing. Capacity balancing redistributes data so that the percentage of disk space used is the same on all disk units within the ASP.</p> <p><b>CLEAR COLLECTION DATA</b> Clear collection data. Clear collection data removes the trace data created by running the Trace ASP Balance (TRCASPBAL) command.</p> <p><b>HSM BALANCING</b> Hierarchical Storage Management (HSM) balancing. HSM balancing can be run only on an ASP that contains a mixture of high-performance and low-performance disk units. An example of low-performance disk units is compressed disk units. The HSM balance function moves high-use data to high-performance units and moves low-use data to low-performance units. The high-use and low-use data is identified by running the Trace ASP Balance (TRCASPBAL) command.</p> <p><b>MOVE DATA</b> Move data. Move data is used to reduce the down time associated with removing a disk unit. The Check ASP Balance (CHKASPBAL) command can be used to determine which units are currently marked to no longer receive new allocations and to have their existing allocations moved to other disk units.</p> <p><b>MP BALANCING</b> Media Preference (MP) balancing. MP balancing can be run only on an ASP that contains a mixture of Solid State Disk (SSD) units and Hard Disk Drive (HDD) units. The goal of the MP balance function is to have high-use data on SSD units and low-use data on HDD units. The high-use and low-use data is identified by running the Trace ASP Balance (TRCASPBAL) command.</p> <p><b>NONE</b> No ASP balance activity was requested for the ASP.</p> <p><b>USAGE BALANCING</b> Usage balancing. Usage balancing redistributes data so that the percentage of disk activity is the same on all disk units within the ASP. High-use and low-use data is identified by running the Trace ASP Balance (TRCASPBAL) command. Usage balancing moves data among the disk units, guided by the trace results, in an attempt to equalize the utilizations.</p> <p>Contains the null value if ASP_STATE is not ACTIVE or AVAILABLE for IASP.</p> |

## Example

- Show ASP information for the partition.

```
SELECT * FROM QSYS2.ASP_INFO;
```

## ASP\_JOB\_INFO view

The ASP\_JOB\_INFO view returns information about active jobs that are using an independent auxiliary storage pool (IASP).

The information is similar to what is returned by the Work with ASP Jobs (WRKASPJOB) CL command.

**Authorization:** None required to see information for jobs where the caller's user profile is the same as the job user identity of the job for which the information is being returned. Otherwise, the caller must have \*JOBCTL special authority, or be authorized to the QIBM\_DB\_SQLADM or QIBM\_DB\_SYSMON function usage identifiers.

The following table describes the columns in the view. The system name is ASPJ\_INFO. The schema is QSYS2.

Table 248. ASP\_JOB\_INFO view

| Column Name | System Column Name | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Example

List all the jobs that are active for IASP33.

```
SELECT JOB_NAME, JOB_STATUS, JOB_TYPE, AUTHORIZATION_NAME
FROM QSYS2.ASP_JOB_INFO
WHERE IASP_NAME = 'IASP33';
```

## ASP\_VARY\_INFO view

The ASP\_VARY\_INFO view returns one row for each step associated with a vary on or vary off operation for all independent ASP devices.

The values returned for the columns in the view are similar to the values returned by the Display ASP Status (DSPASPSTS) CL command.

**Authorization:** The caller must have \*USE authority to the independent ASP device description.

The following table describes the columns in the view. The system name is VARY\_INFO. The schema is QSYS2.

Table 249. ASP\_VARY\_INFO view

| Column Name      | System Column Name | Data Type   | Description                                                                                                                                                    |
|------------------|--------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IASP_NAME        | IASP_NAME          | VARCHAR(10) | The name of the ASP device description.                                                                                                                        |
| OPERATION_NUMBER | OP_NUMBER          | INTEGER     | A value for an instance of a vary on or vary off operation, where the highest number is the most recent operation. The most recent 64 operations are returned. |

Table 249. ASP\_VARY\_INFO view (continued)

| Column Name     | System Column Name | Data Type                    | Description                                                                                                                                                                                                                                                                                |
|-----------------|--------------------|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OPERATION_TYPE  | OP_TYPE            | VARCHAR(8)                   | The type of vary operation.<br><br><b>VARY OFF</b><br><br><b>VARY ON</b>                                                                                                                                                                                                                   |
| OPERATION_STATE | OP_STATE           | VARCHAR(8)                   | The state of the entire operation.<br><br><b>ACTIVE</b> The operation is active. STEP_STATE shows the status of the steps that are part of the operation.<br><br><b>COMPLETE</b> The operation completed successfully.<br><br><b>FAILED</b> The operation failed to complete successfully. |
| STEP            | STEP               | VARGRAPHIC(50)<br>CCSID 1200 | The description of the operation step.                                                                                                                                                                                                                                                     |
| STEP_STATE      | STEP_STATE         | VARCHAR(8)                   | The state of the operation step.<br><br><b>ACTIVE</b> The step is active.<br><br><b>COMPLETE</b> The step completed successfully.<br><br><b>FAILED</b> The step failed to complete successfully.                                                                                           |
| START_TIMESTAMP | START              | TIMESTAMP                    | The timestamp for the start of this operation step.                                                                                                                                                                                                                                        |
| END_TIMESTAMP   | END                | TIMESTAMP<br>Nullable        | The timestamp for the end of this operation step.<br>Contains the null value if the operation step has not completed or may never complete.                                                                                                                                                |
| DURATION        | DURATION           | DECIMAL(12,6)<br>Nullable    | The time duration, in seconds, of this operation step.<br>Contains the null value if the operation step has not completed or may never complete.                                                                                                                                           |
| JOB_NAME        | JOB_NAME           | VARCHAR(28)<br>Nullable      | The qualified job name that initiated this vary operation.<br>Contains the null value if the job name is not available.                                                                                                                                                                    |
| IASP_NUMBER     | IASPNUM            | INTEGER                      | The number associated with the ASP device.                                                                                                                                                                                                                                                 |

## Example

- Return the steps from available vary on operations, listed from most expensive to least expensive.

```
SELECT * FROM QSYS2.ASP_VARY_INFO
WHERE OPERATION_TYPE = 'VARY ON'
ORDER BY IASP_NAME, DURATION DESC;
```

- Create a table to retain vary on historical data. Populate it with the current available values.

```
CREATE TABLE VARY_HISTORY AS
(SELECT * FROM QSYS2.ASP_VARY_INFO) WITH DATA;
```

- Update the table that contains vary on historical data with any new rows.

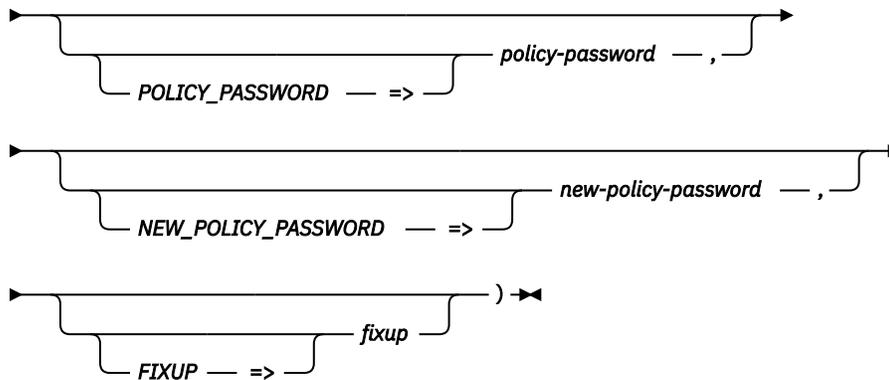

```
MERGE INTO VARY_HISTORY H
USING QSYS2.ASP_VARY_INFO N
ON H.OPERATION_NUMBER = N.OPERATION_NUMBER
WHEN NOT MATCHED THEN
INSERT VALUES (N.IASP_NAME, N.OPERATION_NUMBER, N.OPERATION_TYPE,
N.OPERATION_STATE, N.STEP, N.STEP_STATE,
N.START_TIMESTAMP, N.END_TIMESTAMP, N.DURATION,
N.JOB_NAME, N.IASP_NUMBER);
```

## CHANGE\_DEVICE\_LOCKING\_POLICY procedure

The CHANGE\_DEVICE\_LOCKING\_POLICY procedure changes the password policy for all NVMe devices.

**Authorization:** The caller must have \*IOSYSCFG and \*SERVICE special authorities.

► CHANGE\_DEVICE\_LOCKING\_POLICY — ( →

The schema is QSYS2.

- policy-password** A character string that contains the current device policy password used to unlock the device.  
If *policy-password* is specified, *new-policy-password* must also be provided.
- new-policy-password** A character string that contains the new policy password used to unlock the device and for changing the locking policy configuration.  
It must be at least 8 characters long and cannot exceed 32 characters.  
If *new-policy-password* is specified, *policy-password* must also be provided.
- fixup** A character string that indicates whether the NVMe device is to be resynchronized with the password stored in Platform KeyStore (PKS).  
The NVMe device must be under the locking policy.  
This option should only be used when the PASSWORD\_FIXUP\_REQUIRED column in the QSYS2.LOCKING\_POLICY\_INFO view has a value of YES.  
**YES** The NVMe device is to be resynchronized with the password stored in PKS.  
If *fixup* is YES, *new-policy-password* and *policy-password* must not be specified.

### Example

- Change a locking policy password for the current device.

```
CALL QSYS2.CHANGE_DEVICE_LOCKING_POLICY(POLICY_PASSWORD => 'My0dev9pw!',
NEW_POLICY_PASSWORD => 'changeit58');
```

## CHANGE\_DISK\_PATHS procedure

The CHANGE\_DISK\_PATHS procedure enables or disables all paths matching the parameters provided. The last path to a disk will not be disabled unless explicitly requested. This procedure is only supported for some external SCSI devices.

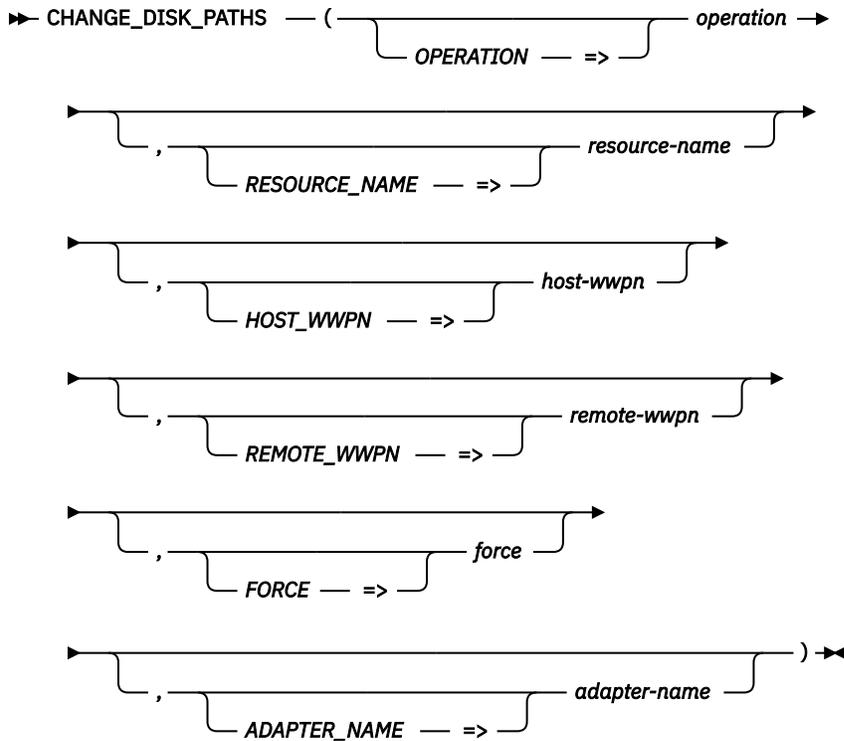

All paths are in an ENABLED state on IPL. Changes made through this procedure do not persist after IPL.

Any combination of *resource-name*, *host-wwpn*, *remote-wwpn*, and *adapter-name* can be specified. The specified operation will be applied to all the paths that match the provided parameters. A disable

operation must leave at least one remaining active path to all resources unless the *force* parameter with a value of YES is specified. If no paths match the provided parameters, no action is taken.

The world-wide port name (WWPN) values that can be changed by this procedure apply to an IO Adapter (IOA).

**Authorization:** The caller must have \*IOSYSCFG special authority.

The schema is QSYS2.

- operation** A character string that contains the operation to perform.
  - DISABLE** Disable all paths matching the parameters.
  - ENABLE** Enable all paths matching the parameters.
- resource-name** A character string that contains the resource name of the path to be changed. If *resource-name* is omitted or the null value, the operation will be applied to all the paths that match the world wide port name or adapter parameters that are provided.
- host-wwpn** A 16 character hexadecimal string representing the world wide port name for the host side of the paths to be enabled or disabled. If *resource-name*, *remote-wwpn*, or *adapter-name* is specified, this parameter can be omitted or have the null value.
 

If this parameter is not specified, the default is the null value, meaning that *host-wwpn* is not part of the request.
- remote-wwpn** A 16 character hexadecimal string representing the world wide port name for the remote side of the paths to be enabled or disabled. If *resource-name*, *host-wwpn*, or *adapter-name* is specified, this parameter can be omitted or have the null value.
 

If this parameter is not specified, the default is the null value, meaning that *remote-wwpn* is not part of the request.
- force** A character string that indicates whether the last path to a disk can be disabled by this procedure.

**NO** The last path to a disk will never be disabled. This is the default.

**YES** The last path to a disk can be disabled, overriding normal safety checks.

***adapter-name***

A character string that specifies an adapter on which all paths should be disabled. If *resource-name*, *host-wwpn*, or *remote-wwpn* is specified, this parameter can be omitted or have the null value.

If this parameter is not specified, the default is the null value, meaning that *adapter-name* is not part of the request.

v

- Enable a path.

```
CALL QSYS2.CHANGE_DISK_PATHS(OPERATION => 'ENABLE',
 RESOURCE_NAME => 'DMP001');
```

- Enable all paths on a host port.

```
CALL QSYS2.CHANGE_DISK_PATHS(OPERATION => 'ENABLE',
 HOST_WWPN => 'c050760a3038001e');
```

- Disable a path.

```
CALL QSYS2.CHANGE_DISK_PATHS(OPERATION => 'DISABLE',
 RESOURCE_NAME => 'DMP001');
```

- Disable a path, forcing the disk to be disabled if it is the last path to the disk.

```
CALL QSYS2.CHANGE_DISK_PATHS(OPERATION => 'DISABLE',
 RESOURCE_NAME => 'DMP001',
 FORCE => 'YES');
```

- Disable all paths on a host target pair.

```
CALL QSYS2.CHANGE_DISK_PATHS(OPERATION => 'DISABLE',
 HOST_WWPN => 'c050760a3038001e',
 REMOTE_WWPN => '5005076306181347');
```

- Disable all paths on a remote port.

```
CALL QSYS2.CHANGE_DISK_PATHS(OPERATION => 'DISABLE',
 REMOTE_WWPN => '5005076306181347');
```

- Enable all paths on an adapter.

```
CALL QSYS2.CHANGE_DISK_PATHS(OPERATION => 'ENABLE',
 ADAPTER_NAME => 'DC06');
```

- Enable all paths on an adapter to a specific remote port.

```
CALL QSYS2.CHANGE_DISK_PATHS(OPERATION => 'ENABLE',
 REMOTE_WWPN => '5005076306181347',
 ADAPTER_NAME => 'DC06');
```

- Disable all paths on an adapter.

```
CALL QSYS2.CHANGE_DISK_PATHS(OPERATION => 'DISABLE',
 ADAPTER_NAME => 'DC06');
```

- Disable all paths on an adapter to a specific remote port.

```
CALL QSYS2.CHANGE_DISK_PATHS(OPERATION => 'DISABLE',
 REMOTE_WWPN => '5005076306181347',
 ADAPTER_NAME => 'DC06');
```

## CREATE\_LOCKING\_POLICY procedure

The CREATE\_LOCKING\_POLICY procedure creates a password policy.

Prior to creating a password policy, the Platform KeyStore must be enabled through the **HMC's Partition Properties -> Advanced Settings -> Platform KeyStore Size** value must be set to a non-zero value.

Before creating the NVMe password protection policy on the partition, it is recommended that all of the system and user data be saved using *GO SAVE: Option 21 (saving the entire system)*.

All NVMe devices supported by IBM i are Self-Encrypting Drives (SED). This means the data is encrypted at rest. However, the key used to encrypt and decrypt the data is not protected. By creating a password policy and adding NVMe devices to it, the devices can protect the confidentiality of stored user data against unauthorized access once the device leaves the owner's control. This feature uses the Trusted Computer Group (TCG) Opal Security Subsystem Class (SSC) specification for storage. Each NVMe device that supports the Opal SSC is registered in a list of devices on which the administrator can establish a locking policy. Once the device is added to the locking policy the NVMe device will lock itself when Main Power loss or PCIe cold resets occur.

The NVMe device will be locked when:

- DLPAR Remove operation is performed on the device
- Concurrent Maintenance Power Off is performed on the device
- The partition is IPLed
- When the NVMe device is reset

Once the device is locked, reads and writes issued to the drive will fail. While the NVMe device remains in the partition, restoring power to the device will cause it to automatically unlock itself, using the policy password stored in the Platform KeyStore.

**Authorization:** The caller must have \*IOSYSCFG and \*SERVICE special authorities.

➤ CREATE\_LOCKING\_POLICY ( —  policy-password — ) ➤

The schema is QSYS2.

**policy-password** A character string that contains the initial policy password that will be used to unlock the device(s) and for changing the locking policy configuration.

It must be at least 8 characters long and cannot exceed 32 characters.

### Example

- Create a locking policy and add all configured NVMe devices to the policy.

```
CALL QSYS2.CREATE_LOCKING_POLICY(POLICY_PASSWORD => 'My0dev9pw!');
```

## DELETE\_LOCKING\_POLICY procedure

The DELETE\_LOCKING\_POLICY procedure deletes the password policy for all NVMe devices.

The password policy will be removed from all NVMe devices that are currently part of the policy. It will also remove the policy itself.

**Authorization:** The caller must have \*IOSYSCFG and \*SERVICE special authorities.

➤ DELETE\_LOCKING\_POLICY ( *POLICY\_PASSWORD* => *policy-password* ) ➤

The schema is QSYS2.

***policy-password*** A character string that contains the policy password.

### Example

- Delete the password policy for all NVMe devices.

```
CALL QSYS2.DELETE_LOCKING_POLICY(POLICY_PASSWORD => 'My0dev9pw!');
```

### FACTORY\_RESET\_DEVICE procedure

The FACTORY\_RESET\_DEVICE procedure resets an NVMe device to its factory settings. The device will lose all data when this procedure is called. The PSID value printed on the physical NVMe device label is needed to perform the reset.

**Authorization:** The caller must have \*IOSYSCFG and \*SERVICE special authorities.

➤ FACTORY\_RESET\_DEVICE ( *PSID\_PASSWORD* => *psid-password* , ➤  
*RESOURCE\_NAME* => *resource-name* ) ➤

The schema is QSYS2.

***psid-password*** A character string that contains the PSID value printed on the physical device label.

***resource-name*** A character string that contains the resource name of the device to be reset.

### Example

- Reset an NVMe device back to its initial settings.

```
CALL QSYS2.FACTORY_RESET_DEVICE(PSID_PASSWORD => 'My0dev9pw! ',
RESOURCE_NAME => 'UNIT2');
```

### LOCKING\_POLICY\_INFO view

The LOCKING\_POLICY\_INFO view returns a list of the NVMe devices under the partition with their locking capabilities and state.

One row is returned for each device.

**Authorization:** The caller must have \*IOSYSCFG and \*SERVICE special authorities.

The following table describes the columns in the view. The system name is LOCK\_POL. The schema is QSYS2.

Table 250. LOCKING\_POLICY\_INFO view

| Column Name   | System Column Name | Data Type   | Description                       |
|---------------|--------------------|-------------|-----------------------------------|
| RESOURCE_NAME | RESOURCE           | VARCHAR(10) | Resource name of the NVMe device. |
| SERIAL_NUMBER | SERIAL             | VARCHAR(12) | Serial number of the NVMe device. |

Table 250. LOCKING\_POLICY\_INFO view (continued)

| Column Name               | System Column Name | Data Type                  | Description                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------|--------------------|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TYPE                      | TYPE               | VARCHAR(4)                 | Device type number of the NVMe device.                                                                                                                                                                                                                                                                                                                                                                 |
| LOCKING_SUPPORTED         | LOCKING            | VARCHAR(3)                 | Whether this device supports locking.<br><br><b>NO</b> The device does not support locking.<br><b>YES</b> The NVMe device supports TCG Opal and has the correct firmware allowing it to be locked.                                                                                                                                                                                                     |
| ELIGIBLE_POLICY           | ELIGIBLE           | VARCHAR(3)                 | Whether the device is eligible to be added to the NVMe locking policy.<br><br><b>NO</b> The device is not eligible.<br><b>YES</b> The NVMe device is in the proper state that makes it eligible to be added to a policy.                                                                                                                                                                               |
| UNDER_POLICY              | IN_POLICY          | VARCHAR(3)                 | Whether the device is currently under the NVMe locking policy.<br><br><b>NO</b> The device is not under the policy.<br><b>YES</b> The device is under the policy.                                                                                                                                                                                                                                      |
| LOCK_STATE                | LOCK_STATE         | VARCHAR(3)                 | Whether device is locked. When a device is locked, it is read/write protected.<br><br><b>NO</b> The device is not locked.<br><b>YES</b> The device is not locked.                                                                                                                                                                                                                                      |
| UNLOCK_ATTEMPTS_EXHAUSTED | ATTEMPTS           | VARCHAR(3)                 | Whether the user has exhausted their attempts to unlock the NVMe device.<br><br><b>NO</b> Additional attempts are allowed.<br><b>YES</b> A power cycle of the NVMe device is required before additional attempts are allowed.                                                                                                                                                                          |
| PASSWORD_FIXUP_REQUIRED   | FIXUP              | VARCHAR(3)<br><br>Nullable | Whether password fixup is required.<br><br><b>NO</b> The NVMe device is synchronized with the password stored in Platform KeyStore (PKS).<br><b>YES</b> The NVMe device is not synchronized with the password stored in PKS. The QSYS2.CHANGE_DEVICE_LOCKING POLICY procedure with the 'FIXUP' parameter must be run to resynchronize the values.<br><br>Returns the null value if UNDER_POLICY is NO. |

## Example

- List information about all NVMe devices, including whether they are eligible to be included in a locking policy and whether a locking policy is in effect.

```
SELECT RESOURCE_NAME, LOCKING_SUPPORTED, ELIGIBLE_POLICY, UNDER_POLICY FROM
QSYS2.LOCKING_POLICY_INFO;
```

## NVME\_INFO view

The NVME\_INFO view contains information about Non-Volatile Memory Express (NVMe) devices.

**Authorization:** None required.

The following table describes the columns in the view. The system name is NVME\_INFO. The schema is QSYS2.

Table 251. NVME\_INFO view

| Column Name | System Column Name | Data Type  | Description                  |
|-------------|--------------------|------------|------------------------------|
| DEVICE_TYPE | DEV_TYPE           | VARCHAR(4) | The type of the NVMe device. |

Table 251. NVME\_INFO view (continued)

| Column Name              | System Column Name | Data Type              | Description                                                                                                                                                                |
|--------------------------|--------------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RESOURCE_NAME            | RESOURCE           | VARCHAR(10)            | The resource name of the NVMe device.                                                                                                                                      |
| DEVICE_MODEL             | DEV_MODEL          | VARCHAR(4)             | The model of the NVMe device assigned by IBM.                                                                                                                              |
| SERIAL_NUMBER            | SERIAL             | VARCHAR(15)            | The serial number of the NVMe device assigned by IBM.                                                                                                                      |
| HARDWARE_MODEL_NUMBER    | HDW_MODEL          | VARCHAR(40)            | The model number assigned by the device manufacturer.                                                                                                                      |
| HARDWARE_SERIAL_NUMBER   | HDW_SERIAL         | VARCHAR(20)            | The serial number assigned by the device manufacturer.                                                                                                                     |
| FIRMWARE_LEVEL           | FIRMWARE           | VARCHAR(8)<br>Nullable | The level of code running in the NVMe device.<br>Contains the null value if the information is not available.                                                              |
| IOP_NAME                 | IOP_NAME           | VARCHAR(10)            | The name of the I/O processor.                                                                                                                                             |
| BUS_NUMBER               | BUS_NUMBER         | INTEGER                | The bus number that the NVMe device is attached to.                                                                                                                        |
| LOCATION_CODE            | LOC_CODE           | VARCHAR(33)            | The location code.                                                                                                                                                         |
| PAGES_AVAILABLE          | PG_AVAIL           | BIGINT                 | The quantity of pages on the NVMe device which remain available to be allocated to namespaces.                                                                             |
| PAGES_USED               | PG_USED            | BIGINT                 | The quantity of pages on the NVMe device which have been allocated to namespaces.                                                                                          |
| PAGES_MAXIMUM            | PG_MAX             | BIGINT                 | The total quantity of pages which exist on the NVMe device.                                                                                                                |
| NAMESPACES_AVAILABLE     | NS_AVAIL           | INTEGER                | The quantity of namespaces available.                                                                                                                                      |
| NAMESPACES_USED          | NS_USED            | INTEGER                | The quantity of namespaces used.                                                                                                                                           |
| NAMESPACES_MAXIMUM       | NS_MAX             | INTEGER                | The maximum quantity of namespaces allowed on the NVMe device.                                                                                                             |
| NAMESPACES_CONFIGURED    | NS_CONFIG          | INTEGER                | The quantity of namespaces on the NVMe Device which represent disk units that are configured into an Auxiliary Storage Pool (ASP).                                         |
| FORMAT_CRYPT             | FMT_CRYPT          | VARCHAR(3)             | NVMe device supports Format Crypto.<br><br><b>NO</b> Does not support Format Crypto<br><b>YES</b> Supports Format Crypto                                                   |
| OVERWRITE                | OVERWRITE          | VARCHAR(3)             | NVMe device supports the Overwrite sanitize operation.<br><br><b>NO</b> Does not support overwrite<br><b>YES</b> Supports overwrite                                        |
| SECURE_ERASE             | SECURE_E           | VARCHAR(3)             | NVMe device supports the User Data Secure Erase sanitize operation.<br><br><b>NO</b> Does not support User Data Secure Erase<br><b>YES</b> Supports User Data Secure Erase |
| BLOCK_ERASE              | BLOCK_E            | VARCHAR(3)             | NVMe device supports the Block Erase sanitize operation.<br><br><b>NO</b> Does not support Block Erase<br><b>YES</b> Supports Block Erase                                  |
| CRYPTO_ERASE             | CRYPTO_E           | VARCHAR(3)             | NVMe device supports the Crypto Erase sanitize operation.<br><br><b>NO</b> Does not support Crypto Erase<br><b>YES</b> Supports Crypto Erase                               |
| SPARE_CAPACITY           | CAP_AVAIL          | INTEGER                | The percentage (0 to 100) of the remaining spare capacity available for this NVMe device.                                                                                  |
| SPARE_CAPACITY_THRESHOLD | CAP_THRESH         | INTEGER                | The threshold percentage (0 to 100) for the spare capacity for this NVMe device.                                                                                           |

Table 251. NVME\_INFO view (continued)

| Column Name                  | System Column Name | Data Type  | Description                                                                                                                                                                                                                                                    |
|------------------------------|--------------------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SPARE_CAPACITY_THRESHOLD_MET | CAP_MET            | VARCHAR(3) | Whether the available spare capacity (SPARE_CAPACITY) for the NVMe device has fallen below the threshold value (SPARE_THRESHOLD).<br><br><b>NO</b> Available spare space threshold has not been met<br><b>YES</b> Available spare space threshold has been met |
| LIFE_REMAINING               | LIFE               | INTEGER    | The manufacturer's estimate of the percentage of the NVMe device life remaining, based on actual usage and the manufacturer's prediction of NVMe life.                                                                                                         |
| MEMORY_BACKUP_DEVICE_FAILED  | BACKUPFAIL         | VARCHAR(3) | Whether the volatile memory backup device has failed.<br><br><b>NO</b> Volatile memory backup device has not failed<br><b>YES</b> Volatile memory backup device has failed                                                                                     |
| PMR_READ_ONLY                | PMR_RO             | VARCHAR(3) | Whether the persistent memory region has become read-only.<br><br><b>NO</b> Persistent memory region did not become read-only<br><b>YES</b> Persistent memory region became read-only                                                                          |
| READ_ONLY                    | DEV_RO             | VARCHAR(3) | Whether the NVMe device is in a mode that only allows read operations.<br><br><b>NO</b> Device is not in read-only mode<br><b>YES</b> Device is in read-only mode                                                                                              |
| DEGRADED                     | DEGRADED           | VARCHAR(3) | Whether the NVMe reliability has been degraded.<br><br><b>NO</b> Reliability has not been degraded<br><b>YES</b> Reliability has been degraded                                                                                                                 |
| TEMPERATURE_THRESHOLD        | HOT                | VARCHAR(3) | Whether the temperature of the NVMe device has exceeded the threshold.<br><br><b>NO</b> Temperature threshold has not been exceeded<br><b>YES</b> Temperature threshold has been exceeded                                                                      |
| DATA_READ                    | DATA_READ          | BIGINT     | The number of 512-byte data units that have been read from the NVMe device. This value is reported in thousands (a value of 1 corresponds to 1000 units of 512 bytes read). This value is never reset. It is for the life of the device.                       |
| DATA_WRITTEN                 | DATA_WRITE         | BIGINT     | The number of 512-byte data units that have been written to the NVMe device. This value is reported in thousands (a value of 1 corresponds to 1000 units of 512 bytes written). This value is never reset. It is for the life of the device.                   |
| HOST_READ_COMMANDS           | READ_CMDS          | BIGINT     | The number of read commands sent to the NVMe device by the host system.<br><br>This value is never reset. It is for the life of the device.                                                                                                                    |
| HOST_WRITE_COMMANDS          | WRITE_CMDS         | BIGINT     | The number of write commands sent to the NVMe device by the host system.<br><br>This value is never reset. It is for the life of the device.                                                                                                                   |
| CONTROLLER_BUSY_TIME         | BUSY_TIME          | BIGINT     | The time, in minutes, that the controller was busy servicing I/O commands.<br><br>This value is never reset. It is for the life of the device.                                                                                                                 |
| POWER_CYCLES                 | POWER_CYC          | BIGINT     | The number of times the NVMe device has been powered on and off.<br><br>This value is never reset. It is for the life of the device.                                                                                                                           |

Table 251. NVME\_INFO view (continued)

| Column Name               | System Column Name | Data Type | Description                                                                                                                                                                                                                                                                                     |
|---------------------------|--------------------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| POWER_ON_HOURS            | POWER_HOUR         | BIGINT    | The number of hours the NVMe device has been powered on.<br>This value is never reset. It is for the life of the device.                                                                                                                                                                        |
| UNSAFE_SHUTDOWNS          | POWER_LOSS         | BIGINT    | The number of times a power loss happened without a shutdown notification being sent.<br>This value is never reset. It is for the life of the device.                                                                                                                                           |
| MEDIA_ERRORS              | MEDIAERROR         | BIGINT    | The number of occurrences where the controller detected an unrecovered data integrity error.<br>This value is never reset. | SOFT_THERMAL_TRANSITIONS  | SOFT_TRANS         | INTEGER   | The number of times the controller transitioned to lower power active power states or performed manufacturer specific thermal management actions while minimizing the impact on performance in an attempt to reduce the composite temperature.                                                  |
| HARD_THERMAL_TRANSITIONS  | HARD_TRANS         | INTEGER   | The number of times the controller transitioned to lower power active power states or performed manufacturer specific thermal management actions regardless of the impact on performance in an attempt to reduce the composite temperature.                                                     |
| SOFT_THERMAL_TIME         | SOFT_TIME          | INTEGER   | The number of seconds that the controller has transitioned to lower power active power states or performed manufacturer specific thermal management actions while minimizing the impact on performance in order to attempt to reduce the composite temperature.                                 |
| HARD_THERMAL_TIME         | HARD_TIME          | INTEGER   | The number of seconds that the controller has transitioned to lower power active power states or performed manufacturer specific thermal management actions regardless of the impact on performance in order to attempt to reduce the composite temperature.                                    |
| COMPOSITE_TEMPERATURE     | TEMP_COMP          | INTEGER   | The composite temperature (in degrees Celsius) calculated for the device.                                                                                                                                                                                                                       |
| TEMPERATURE1              | TEMP1              | INTEGER   | The temperature (in degrees Celsius) reported by temperature sensor 1.                                                                                                                                                                                                                          |
| TEMPERATURE2              | TEMP2              | INTEGER   | The temperature (in degrees Celsius) reported by temperature sensor 2.                                                                                                                                                                                                                          |
| TEMPERATURE3              | TEMP3              | INTEGER   | The temperature (in degrees Celsius) reported by temperature sensor 3.                                                                                                                                                                                                                          |
| TEMPERATURE4              | TEMP4              | INTEGER   | The temperature (in degrees Celsius) reported by temperature sensor 4.                                                                                                                                                                                                                          |
| TEMPERATURE5              | TEMP5              | INTEGER   | The temperature (in degrees Celsius) reported by temperature sensor 5.                                                                                                                                                                                                                          |
| TEMPERATURE6              | TEMP6              | INTEGER   | The temperature (in degrees Celsius) reported by temperature sensor 6.                                                                                                                                                                                                                          |
| TEMPERATURE7              | TEMP7              | INTEGER   | The temperature (in degrees Celsius) reported by temperature sensor 7.                                                                                                                                                                                                                          |

Table 251. NVME\_INFO view (continued)

| Column Name  | System Column Name | Data Type | Description                                                            |
|--------------|--------------------|-----------|------------------------------------------------------------------------|
| TEMPERATURE8 | TEMP8              | INTEGER   | The temperature (in degrees Celsius) reported by temperature sensor 8. |

## Examples

- Return information for NVMe devices.

```
SELECT * FROM QSYS2.NVME_INFO;
```

## REMOVE\_DEVICE\_LOCKING\_POLICY procedure

The REMOVE\_DEVICE\_LOCKING\_POLICY procedure removes an NVMe device from the password policy.

If the specified device is under the locking policy, the password will be removed from the device and the device will no longer be under the locking policy. If the device isn't under the locking policy, the password will be used to remove the password from the device.

**Authorization:** The caller must have \*IOSYSCFG and \*SERVICE special authorities.

```
➤ REMOVE_DEVICE_LOCKING_POLICY (POLICY_PASSWORD =>)
 , resource-name) ➤
```

RESOURCENAME =>
RESOURCE\_NAME =>

The schema is QSYS2.

***policy-password*** A character string that contains the policy password.

***resource-name*** A character string that contains the resource name of the device to be removed from the locking policy.

## Example

- Remove a device from the locking policy.

```
CALL QSYS2.REMOVE_DEVICE_LOCKING_POLICY(POLICY_PASSWORD => 'My0dev9pw!',
 RESOURCE_NAME => 'UNIT2');
```

## SYSDISKSTAT table function

The SYSDISKSTAT table function contains information about disks. It provides an option to reset the baseline for collecting statistical information.

**Authorization:** None required.

```
➤ SYSDISKSTAT (reset-statistics) ➤
```

RESET\_STATISTICS =>

The schema is QSYS2.

***reset-statistics*** A character or graphic string expression that contains a value of YES or NO.

If this parameter has a value of YES, statistics are reset such that the time of this query execution is used as the new baseline. The columns that contain this statistical data have

names that are prefixed with ELAPSED\_. Future invocations of SYSDISKSTAT within this connection will return statistical detail relative to the new baseline. If this parameter has a value of NO, statistics are not reset for the invocation. If this parameter is not specified, the default is NO.

The result of the function is a table containing multiple rows with the format shown in the following table. All the columns are nullable.

Table 252. SYSDISKSTAT table function

| Column Name     | Data Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| SERIAL_NUMBER   | VARCHAR(15) | The serial number of the disk unit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| RESOURCE_NAME   | VARCHAR(10) | The unique system-assigned name of the disk unit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| RESOURCE_STATUS | VARCHAR(7)  | The status of the resource.<br><br><b>ACTIVE</b> RESOURCE_NAME is active.<br><b>PASSIVE</b> RESOURCE_NAME is not active.<br>Contains the null value if the path status is not known.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| HARDWARE_STATUS | VARCHAR(21) | The hardware status for the disk unit.<br><br><b>ACTIVE</b> The disk unit is operational and ready to accept input or output operations.<br><b>BUSY</b> The disk unit is being overwhelmed by a large number of read and write operations and the disk unit is busy.<br><b>DEGRADED</b> The disk unit is part of a disk unit subsystem that has RAID-5 device parity protection. A decrease in performance has occurred because a component that is not critical has failed.<br><b>FAILED</b> The disk unit is part of a disk unit subsystem that has device parity protection. This unit has failed. If another unit in the disk unit subsystem fails, data could be lost.<br><b>HARDWARE FAILURE</b> A hardware-related failure has occurred in a redundant component. The failure does not affect data or performance. However, the system may become unusable if another failure of a redundant component occurs.<br><b>NOT READY</b> The disk unit is not ready to perform read or write operations.<br><b>PARITY REBUILD</b> The disk unit is part of a disk unit subsystem that has device parity protection. The data on this unit is being rebuilt from other units in the disk unit subsystem. If two more disk units in the disk unit subsystem fail, data could be lost.<br><b>POWER LOSS</b> The disk unit cannot communicate with its I/O adapter.<br><b>READ WRITE PROTECTED</b> The disk unit is unable to perform read or write operations.<br><b>UNKNOWN</b> The hardware status is not known.<br><b>UNPROTECTED</b> The disk unit is part of a disk unit subsystem that has device parity protection. This unit is operational. However, another unit in the disk unit subsystem has failed. If another unit in the disk unit subsystem fails, data could be lost.<br><b>WRITE PROTECTED</b> The disk unit is unable to perform write operations. |
| IS_ZERO         | VARCHAR(3)  | Indicates whether all the pages on the disk unit are zero.<br><br><b>NO</b> All the pages on the disk unit are not zero.<br><b>YES</b> All the pages on the disk unit are zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|----------------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BLOCK_SIZE                 | INTEGER      | The size (in bytes) of each page on the disk unit.                                                                                                                                                                                                                                                                                                                                  |
| UNMAP_CAPABLE              | VARCHAR(3)   | Indicates whether the disk unit can perform the unmap function to return unused pages to the unallocated area.<br><br><b>NO</b> The disk unit cannot perform the unmap function.<br><b>YES</b> The disk unit can perform the unmap function.                                                                                                                                        |
| IOP_NAME                   | VARCHAR(10)  | The name of the I/O processor.                                                                                                                                                                                                                                                                                                                                                      |
| HOST_WWPN                  | CHAR(16)     | A hexadecimal string representing the resource's host world wide port name. Contains the null value if no host world wide port name is available for this device.                                                                                                                                                                                                                   |
| REMOTE_WWPN                | CHAR(16)     | A hexadecimal string representing the resource's remote world wide port name. Contains the null value if no remote world wide port name is available for this device.                                                                                                                                                                                                               |
| MULTIPLE_PATH_UNIT         | VARCHAR(3)   | A disk unit may have multiple resource names. Each resource name represents a unique connection to the disk unit. All active connections are used to communicate with the disk unit. This attribute indicates whether the disk unit has more than one connection.<br><br><b>NO</b> The disk unit has only one connection.<br><b>YES</b> The disk unit has more than one connection. |
| UNIT_TYPE                  | SMALLINT     | Indicates the type of disk unit:<br><br><b>0</b> Not solid state disk<br><b>1</b> Solid state disk (SSD)                                                                                                                                                                                                                                                                            |
| UNIT_NVME                  | SMALLINT     | Whether this is a Non-Volatile Memory Express (NVMe) unit.<br><br><b>0</b> Not NVMe<br><b>1</b> NVMe                                                                                                                                                                                                                                                                                |
| UNIT_STORAGE_CAPACITY      | BIGINT       | Unit storage capacity has the same value as the unit media capacity for configured disk units. This value is 0 for non-configured units.                                                                                                                                                                                                                                            |
| UNIT_SPACE_AVAILABLE       | BIGINT       | Space (in bytes) available on the unit for use.                                                                                                                                                                                                                                                                                                                                     |
| UNIT_SPACE_AVAILABLE_GB    | BIGINT       | Space, in billions of bytes, available on the unit for use.                                                                                                                                                                                                                                                                                                                         |
| PERCENT_USED               | DECIMAL(7,3) | The percentage that the disk unit has been consumed.                                                                                                                                                                                                                                                                                                                                |
| UNIT_MEDIA_CAPACITY        | BIGINT       | Storage capacity (in bytes) of the unit.                                                                                                                                                                                                                                                                                                                                            |
| UNIT_MEDIA_CAPACITY_GB     | BIGINT       | Storage capacity, in billions of bytes, of the unit.                                                                                                                                                                                                                                                                                                                                |
| STORAGE_FOR_SYSTEM         | BIGINT       | The amount of auxiliary storage on the disk unit, in millions of bytes, reserved for use by the system.                                                                                                                                                                                                                                                                             |
| STORAGE_ALLOCATION_ALLOWED | VARCHAR(3)   | An indicator of whether new storage allocations are allowed on the disk unit.<br><br><b>NO</b> The disk unit does not allow new storage allocations.<br><b>YES</b> The disk unit allows new storage allocations.                                                                                                                                                                    |
| PROTECTION_TYPE            | VARCHAR(8)   | The type of protection that has been assigned to this disk unit.<br><br><b>MIRRORED</b> The ASP is under system mirrored protection provided by the system software.<br><b>PARITY</b> This disk unit is part of a parity protection array.<br><br>Contains the null value if no storage protection has been set up for this disk unit.                                              |

Table 252. SYSDISKSTAT table function (continued)

| Column Name                  | Data Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| FIRMWARE_LEVEL               | VARCHAR(8)<br>Nullable    | The level of code running in the SSD device.<br>Contains the null value if this disk is not a mainstream SSD or if the information is not available. See <a href="#">Mainstream solid-state drives</a> for a description of mainstream solid-state drives.                                                                                                                     |
| SSD_PART_NUMBER              | VARCHAR(12)<br>Nullable   | The part number as reported by the SSD device.<br>Contains the null value if this disk is not a mainstream SSD or if the information is not available.                                                                                                                                                                                                                         |
| SSD_POWER_ON_DAYS            | BIGINT<br>Nullable        | The number of days that the SSD device has been active in a system.<br>Contains the null value if this disk is not a mainstream SSD or if the information is not available.                                                                                                                                                                                                    |
| SSD_LIFE_REMAINING           | INTEGER<br>Nullable       | The percentage of the lifetime remaining for the SSD device. This estimates the percentage of usable function remaining for the drive before it should be replaced. Calculations for this percentage include more than just the number of bytes written and supported.<br>Contains the null value if this disk is not a mainstream SSD or if the information is not available. |
| SSD_READ_WRITE_PROTECTED     | VARCHAR(3)<br>Nullable    | Whether the device is read/write protected.<br><br><b>NO</b> The SSD device is not read/write protected<br><b>YES</b> The SSD device is read/write protected<br><br>Contains the null value if this disk is not a mainstream SSD or if the information is not available.                                                                                                       |
| SSD_BYTES_WRITTEN            | DECIMAL(20,0)<br>Nullable | The lifetime number of bytes, in gigabytes, that have been physically written to the NAND memory in this particular SSD disk unit. This is strongly related to bytes written by the applications using the drive, but will not match.<br>Contains the null value if this disk is not a mainstream SSD or if the information is not available.                                  |
| SSD_SUPPORTED_BYTES_WRITTEN  | DECIMAL(20,0)<br>Nullable | The lifetime number of bytes, in gigabytes, that the SSD is expected to be able to physically write at a minimum. Additional writes beyond this number may start to fail due to the limited write endurance of a Read Intensive drive.<br>Contains the null value if this disk is not a mainstream SSD or if the information is not available.                                 |
| SSD_PFA_WARNING              | VARCHAR(3)<br>Nullable    | Whether the Predictive Failure Analysis warning has been logged.<br><br><b>NO</b> The Predictive Failure Analysis warning has not been logged.<br><b>YES</b> The Predictive Failure Analysis warning has been logged.<br><br>Contains the null value if this disk is not a mainstream SSD or if the information is not available.                                              |
| TOTAL_SAMPLE_COUNT           | BIGINT                    | The number of times the disk queue was checked to determine whether or not the queue is empty.                                                                                                                                                                                                                                                                                 |
| TOTAL_NOT_BUSY_COUNT         | BIGINT                    | The number of times the disk queue was empty during the same time period that the sample count was taken. The busy count can be calculated as TOTAL_SAMPLE_COUNT - TOTAL_NOT_BUSY_COUNT.                                                                                                                                                                                       |
| TOTAL_READ_REQUESTS          | BIGINT                    | The number of input data transfer requests processed for the disk unit since the last IPL. This value is not directly related to the number of blocks transferred for the disk unit because the number of blocks to be transferred for a given transfer request can vary greatly. This value will wrap back to 1 when 2,147,483,647 is reached.                                |

Table 252. SYSDISKSTAT table function (continued)

| Column Name                    | Data Type    | Description                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TOTAL_WRITE_REQUESTS           | BIGINT       | The number of output data transfer requests processed for the disk unit since the last IPL. This value is not directly related to the number of blocks transferred for the disk unit because the number of blocks to be transferred for a given transfer request can vary greatly. This value will wrap back to 1 when 2,147,483,647 is reached.                       |
| TOTAL_BLOCKS_READ              | BIGINT       | The number of 512-byte blocks transferred from the disk unit since the last IPL. This value will wrap back to 1 when 2,147,483,647 is reached.                                                                                                                                                                                                                         |
| TOTAL_BLOCKS_WRITTEN           | BIGINT       | The number of 512-byte blocks transferred to the disk unit since the last IPL. This value will wrap back to 1 when 2,147,483,647 is reached.                                                                                                                                                                                                                           |
| TOTAL_PERMANENT_BLOCKS_WRITTEN | BIGINT       | The number of 512-byte blocks of permanent storage transferred to the disk unit since the last IPL. This value will wrap back to 1 when 2,147,483,647 is reached.                                                                                                                                                                                                      |
| TOTAL_PERMANENT_WRITE_REQUESTS | BIGINT       | The number of output permanent data transfer requests processed for the disk unit since the last IPL. This value is not directly related to the permanent blocks transferred from main storage for the disk unit because the number of blocks transferred for a given transfer request can vary greatly. This value will wrap back to 1 when 2,147,483,647 is reached. |
| ELAPSED_TIME                   | INTEGER      | The time that has elapsed, in seconds, between the measurement start time and the current system time.                                                                                                                                                                                                                                                                 |
| ELAPSED_IO_REQUESTS            | DECIMAL(6,1) | The average number of I/O requests for read and write operations that occurred per second during the elapsed time.                                                                                                                                                                                                                                                     |
| ELAPSED_REQUEST_SIZE           | DECIMAL(6,1) | The average size of an I/O request in KB during the elapsed time.                                                                                                                                                                                                                                                                                                      |
| ELAPSED_READ_REQUESTS          | DECIMAL(6,1) | The average number of requests per second to transfer data from the disk unit during the elapsed time.                                                                                                                                                                                                                                                                 |
| ELAPSED_WRITE_REQUESTS         | DECIMAL(6,1) | The average number of requests per second to transfer data to the disk unit during the elapsed time.                                                                                                                                                                                                                                                                   |
| ELAPSED_DATA_READ              | DECIMAL(6,1) | The average amount of data, in KB, transferred from the disk unit, per request, during the elapsed time.                                                                                                                                                                                                                                                               |
| ELAPSED_DATA_WRITTEN           | DECIMAL(6,1) | The average amount of data, in KB, transferred to the disk unit, per request, during the elapsed time.                                                                                                                                                                                                                                                                 |
| ELAPSED_PERCENT_BUSY           | DECIMAL(4,1) | The estimated percentage of time the disk unit is being used during the elapsed time.                                                                                                                                                                                                                                                                                  |

## Example

- Return information about all disks, resetting the statistical information shown for the current job.

```
SELECT * FROM TABLE(QSYS2.SYSDISKSTAT(RESET_STATISTICS=>'YES'));
```

## SYSDISKSTAT view

The SYSDISKSTAT view contains information about spinning disk and solid-state drives (SSD).

The information returned is similar to the detail seen from the Work with Disk Status (WRKDSKSTS) command and from the Open List of ASPs (QYASPOL) API.

The view contains one or more rows for every disk unit on the system, including non-configured (unallocated) disk units. For non-configured units, the UNIT\_NUMBER is 0. For a disk which has multiple paths to the disk unit, there will be a row for each unique path to the disk unit. For such disks, the MULTIPLE\_PATH\_UNIT column will be YES and each RESOURCE\_NAME column will identify a different path to the disk unit.

**Authorization:** None required.

The following table describes the columns in the view. The system name is SYSDISKS. The schema is QSYS2.

Table 253. SYSDISKSTAT view

| Column Name | System Column Name | Data Type | Description                                                          |
|-------------|--------------------|-----------|----------------------------------------------------------------------|
| ASP_NUMBER  | ASP_NUMBER         | SMALLINT  | Specifies the storage pool (ASP) number. 1 indicates the system ASP. |

Table 253. SYSDISKSTAT view (continued)

| Column Name     | System Column Name | Data Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| HARDWARE_STATUS | HDW_STATUS         | VARCHAR(21) | The hardware status for the disk unit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                 |                    |             | <p><b>ACTIVE</b> The disk unit is operational and ready to accept input or output operations.</p> <p><b>BUSY</b> The disk unit is being overwhelmed by a large number of read and write operations and the disk unit is busy.</p> <p><b>DEGRADED</b> The disk unit is part of a disk unit subsystem that has RAID-5 device parity protection. A decrease in performance has occurred because a component that is not critical has failed.</p> <p><b>FAILED</b> The disk unit is part of a disk unit subsystem that has device parity protection. This unit has failed. If another unit in the disk unit subsystem fails, data could be lost.</p> <p><b>HARDWARE FAILURE</b> A hardware-related failure has occurred in a redundant component. The failure does not affect data or performance. However, the system may become unusable if another failure of a redundant component occurs.</p> <p><b>NOT READY</b> The disk unit is not ready to perform read or write operations.</p> <p><b>PARITY REBUILD</b> The disk unit is part of a disk unit subsystem that has device parity protection. The data on this unit is being rebuilt from other units in the disk unit subsystem. If two more disk units in the disk unit subsystem fail, data could be lost.</p> <p><b>POWER LOSS</b> The disk unit cannot communicate with its I/O adapter.</p> <p><b>READ WRITE PROTECTED</b> The disk unit is unable to perform read or write operations.</p> <p><b>UNKNOWN</b> The hardware status is not known.</p> <p><b>UNPROTECTED</b> The disk unit is part of a disk unit subsystem that has device parity protection. This unit is operational. However, another unit in the disk unit subsystem has failed. If another unit in the disk unit subsystem fails, data could be lost.</p> <p><b>WRITE PROTECTED</b> The disk unit is unable to perform write operations.</p> |

| Column Name                    | System Column Name | Data Type                 | Description                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------|--------------------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SSD_LIFE_REMAINING             | SSD_LIFE           | INTEGER<br>Nullable       | The percentage of the lifetime remaining for the SSD device. This estimates the percentage of usable function remaining for the drive before it should be replaced. Calculations for this percentage include more than just the number of bytes written and supported.<br><br>Contains the null value if this disk is not a mainstream SSD or if the information is not available. |
| SSD_READ_WRITE_PROTECTED       | SSD_PROT           | VARCHAR(3)<br>Nullable    | Whether the device is read/write protected.<br><br><b>NO</b> The SSD device is not read/write protected<br><b>YES</b> The SSD device is read/write protected<br><br>Contains the null value if this disk is not a mainstream SSD or if the information is not available.                                                                                                           |
| SSD_BYTES_WRITTEN              | SSD_WRITE          | DECIMAL(20,0)<br>Nullable | The lifetime number of bytes, in gigabytes, that have been physically written to the NAND memory in this particular SSD disk unit. This is strongly related to bytes written by the applications using the drive, but will not match.<br><br>Contains the null value if this disk is not a mainstream SSD or if the information is not available.                                  |
| SSD_SUPPORTED_BYTES_WRITTEN    | SSD_MAX_W          | DECIMAL(20,0)<br>Nullable | The lifetime number of bytes, in gigabytes, that the SSD is expected to be able to physically write at a minimum. Additional writes beyond this number may start to fail due to the limited write endurance of a Read Intensive drive.<br><br>Contains the null value if this disk is not a mainstream SSD or if the information is not available.                                 |
| SSD_PFA_WARNING                | SSD_PFA            | VARCHAR(3)<br>Nullable    | Whether the Predictive Failure Analysis warning has been logged.<br><br><b>NO</b> The Predictive Failure Analysis warning has not been logged.<br><b>YES</b> The Predictive Failure Analysis warning has been logged.<br><br>Contains the null value if this disk is not a mainstream SSD or if the information is not available.                                                  |
| TOTAL_SAMPLE_COUNT             | SAMPLED            | BIGINT                    | The number of times the disk queue was checked to determine whether or not the queue is empty.                                                                                                                                                                                                                                                                                     |
| TOTAL_NOT_BUSY_COUNT           | NOT_BUSY           | BIGINT                    | The number of times the disk queue was empty during the same time period that the sample count was taken. The busy count can be calculated as TOTAL_SAMPLE_COUNT - TOTAL_NOT_BUSY_COUNT.                                                                                                                                                                                           |
| TOTAL_READ_REQUESTS            | REQ_IN             | BIGINT                    | The number of input data transfer requests processed for the disk unit since the last IPL. This value is not directly related to the number of blocks transferred for the disk unit because the number of blocks to be transferred for a given transfer request can vary greatly. This value will wrap back to 1 when 2,147,483,647 is reached.                                    |
| TOTAL_WRITE_REQUESTS           | REQ_OUT            | BIGINT                    | The number of output data transfer requests processed for the disk unit since the last IPL. This value is not directly related to the number of blocks transferred for the disk unit because the number of blocks to be transferred for a given transfer request can vary greatly. This value will wrap back to 1 when 2,147,483,647 is reached.                                   |
| TOTAL_BLOCKS_READ              | BLOCK_IN           | BIGINT                    | The number of 512-byte blocks transferred from the disk unit since the last IPL. This value will wrap back to 1 when 2,147,483,647 is reached.                                                                                                                                                                                                                                     |
| TOTAL_BLOCKS_WRITTEN           | BLOCK_OUT          | BIGINT                    | The number of 512-byte blocks transferred to the disk unit since the last IPL. This value will wrap back to 1 when 2,147,483,647 is reached.                                                                                                                                                                                                                                       |
| TOTAL_PERMANENT_BLOCKS_WRITTEN | BLOCK_PERM         | BIGINT                    | The number of 512-byte blocks of permanent storage transferred to the disk unit since the last IPL. This value will wrap back to 1 when 2,147,483,647 is reached.                                                                                                                                                                                                                  |

| ELAPSED_DATA_READ              | ELAP_DTA_R         | DECIMAL(6,1)<br>Nullable | The average amount of data, in KB, transferred from the disk unit, per request, during the elapsed time.                                                                                                                                                                                                                                                               |
| ELAPSED_DATA_WRITTEN           | ELAP_DTA_W         | DECIMAL(6,1)<br>Nullable | The average amount of data, in KB, transferred to the disk unit, per request, during the elapsed time.                                                                                                                                                                                                                                                                 |
| ELAPSED_PERCENT_BUSY           | ELAP_BUSY          | DECIMAL(4,1)<br>Nullable | The estimated percentage of time the disk unit is being used during the elapsed time.                                                                                                                                                                                                                                                                                  |

## Notes

The values in the ELAPSED\_ columns are based on the TOTAL\_ columns. When an ELAPSED calculation notices that the ending value is less than the value at the start of the time interval, it adds 2,147,483,647 to the ending value for an accurate result. When this happens, a warning SQLSTATE '01687' is issued. It is recommended that the statistics get reset using the QSYS2.SYSDISKSTAT table function before the counters can wrap more than once. The frequency needed for this action depends on the size and activity of the disk units.

The ELAPSED\_ column information is derived from the values reported in the TOTAL\_ columns as shown in the following table. These formulas can be used to calculate identical statistics if you want to save historical disk statistics in a permanent table.

For clarity, the values prefixed by delta\_ indicate the difference between two rows in the corresponding TOTAL\_ columns. For example, delta\_READ\_REQUESTS means TOTAL\_READ\_REQUESTS(*time2*) - TOTAL\_READ\_REQUESTS(*time1*). The *delta\_time* value means the time in seconds between *time1* and *time2*.

Table 254. Calculating elapsed data

| Elapsed column name  | TOTAL_ columns used to calculate the elapsed value                                            | Notes                                                    |
|----------------------|-----------------------------------------------------------------------------------------------|----------------------------------------------------------|
| ELAPSED_IO_REQUESTS  | (delta_READ_REQUESTS + delta_WRITE_REQUESTS) / delta_time                                     |                                                          |
| ELAPSED_REQUEST_SIZE | ((delta_BLOCKS_READ + delta_BLOCKS_WRITTEN) / 2) (delta_READ_REQUESTS + delta_WRITE_REQUESTS) | Divide by 2 to convert value from 512 byte blocks to KB. |

Table 254. Calculating elapsed data (continued)

| Elapsed column name    | TOTAL_ columns used to calculate the elapsed value                                                     | Notes                                                    |
|------------------------|--------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| ELAPSED_READ_REQUESTS  | $\text{delta\_READ\_REQUESTS} / \text{delta\_time}$                                                    |                                                          |
| ELAPSED_WRITE_REQUESTS | $\text{delta\_WRITE\_REQUESTS} / \text{delta\_time}$                                                   |                                                          |
| ELAPSED_DATA_READ      | $(\text{delta\_BLOCKS\_READ} / 2) / \text{delta\_READ\_REQUESTS}$                                      | Divide by 2 to convert value from 512 byte blocks to KB. |
| ELAPSED_DATA_WRITTEN   | $(\text{delta\_BLOCKS\_WRITTEN} / 2) / \text{delta\_WRITE\_REQUESTS}$                                  | Divide by 2 to convert value from 512 byte blocks to KB. |
| ELAPSED_PERCENT_BUSY   | $((\text{delta\_SAMPLE\_COUNT} - \text{delta\_NOT\_BUSY\_COUNT}) / \text{delta\_SAMPLE\_COUNT}) * 100$ |                                                          |

## Examples

- Return information about all disks.

```
SELECT * FROM QSYS2.SYSDISKSTAT
```

- Return information for all SSD units.

```
SELECT * FROM QSYS2.SYSDISKSTAT WHERE UNIT_TYPE = 1
```

## SYSTMPSTG view

The SYSTMPSTG view contains one row for every temporary storage bucket that is tracking some amount of temporary storage across the system.

Temporary storage is application working storage that does not persist across a restart of the operating system. Accounting for all the temporary storage being used on the system is implemented using the concept of temporary storage buckets.

There are two types of temporary storage buckets:

- global buckets that are used to track temporary storage that is scoped to all jobs on the system.
- job buckets that are used to track temporary storage that is scoped to a single job.

Each bucket has a bucket number. Global buckets managed by the licensed internal code have bucket numbers from 1 to 4095. Global buckets managed by IBM i Work Management have bucket numbers from 4096 to 65535. Job buckets have numbers greater than 65535.

A job temporary storage bucket is assigned when the job starts and does not change for the life of the job. A job temporary storage bucket will normally be empty after the associated job ends and all working storage for the job is deleted or freed. If the job temporary storage bucket is empty after the job ends, the bucket becomes available to be associated with a new job. If the job associated with the job buckets ends and some temporary objects tracked to that job are not deleted, the job bucket will show a status of \*ENDED as well as the date and time that the job ended. These job buckets identify jobs that are not deleting all of their temporary storage when the job ends.

Statistics for each job bucket indicate the current amount of storage (in bytes) used for temporary storage tracked by the bucket, the storage limit (in bytes) for storage used for temporary storage tracked by the bucket, and the peak amount of storage (in bytes) used for temporary storage tracked by the bucket. A job bucket does not include any temporary storage used for SQL query execution. For job buckets, the storage limit will reflect the MAXTMPSTG value of the class (\*CLS) object specified when the job was submitted; a null value is returned if the job has a MAXTMPSTG value of \*NOMAX.

**Authorization:** None required.

The following table describes the columns in the view. The schema is QSYS2.

Table 255. SYSTMPSTG view

| Column Name         | System Column Name | Data Type                 | Description                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|--------------------|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BUCKET_NUMBER       | BKTNBR             | INTEGER                   | Number that uniquely identifies the temporary storage bucket.                                                                                                                                                                                                                                                                                                                 |
| GLOBAL_BUCKET_NAME  | GLBBKTNAME         | VARCHAR(30)<br>Nullable   | For global buckets, the name of the bucket.<br>For job buckets, contains the null value.                                                                                                                                                                                                                                                                                      |

| BUCKET_CURRENT_SIZE | BKTCURSZ           | DECIMAL(23,0)             | The current number of bytes of storage for this temporary storage bucket.                                                                                                                                                                                                                                                                                                     |
| BUCKET_LIMIT_SIZE   | BKTLMTSZ           | DECIMAL(23,0)<br>Nullable | The current limit, in bytes, for the amount of storage for this temporary storage bucket. If the temporary storage bucket has no limit, contains the null value.                                                                                                                                                                                                              |
| BUCKET_PEAK_SIZE    | BKTPEAKSZ          | DECIMAL(23,0)             | The largest number of bytes of storage for this temporary storage bucket. For global buckets, this is the peak amount of storage since the last restart of the operating system. For job buckets, this is the peak amount of storage since the job was started.                                                                                                               |
| JOB_STATUS          | JOBSTS             | VARCHAR(7)<br>Nullable    | For job buckets, indicates whether the bucket is associated with an active job or a job that ended without deleting all temporary objects associated with the job.<br><br><b>*ENDED</b> The job associated with this job bucket has ended.<br><br><b>*ACTIVE</b> The job associated with this job bucket is still active.<br><br>For global buckets, contains the null value. |
| JOB_ENDED_TIME      | JOBENDTIM          | TIMESTAMP<br>Nullable     | For job buckets associated with jobs that have ended, indicates the timestamp of when the associated job ended.<br><br>Contains the null value for global buckets and job buckets associated with active jobs.                                                                                                                                                                |

## UNLOCK\_DEVICE procedure

The UNLOCK\_DEVICE procedure attempts to unlock an NVMe device.

**Authorization:** The caller must have \*IOSYSCFG and \*SERVICE special authorities.

```

▶▶ UNLOCK_DEVICE ((POLICY_PASSWORD =>) policy-password , →
 RESOURCE_NAME => resource-name) ▶▶

```

The schema is QSYS2.

**policy-password** A character string that contains the policy password.

**resource-name** A character string that contains the resource name of the device to be unlocked.

### Example

- Unlock an NVMe device.

```
CALL QSYS2.UNLOCK_DEVICE(POLICY_PASSWORD => 'My0dev9pw! ',
 RESOURCE_NAME => 'UNIT2');
```

## USER\_STORAGE view

The USER\_STORAGE view contains details about storage by user profile.

The user storage consumption detail is determined by using [Retrieve User Information \(QSYRUSRI\) API](#).

You must have \*OBJOPR and \*READ authority to a \*USRPRF or it will not be returned. To see information for independent ASPs (iASPs), the iASP must be varied on.

User storage is broken down by SYSBAS and iASPs.

**Authorization:** The caller must have \*OBJOPR and \*READ authorities to the \*USRPRF.

The following table describes the columns in the view. The system name is USER\_STG. The schema is QSYS2.

Table 256. USER\_STORAGE view

| Column Name             | System Column Name | Data Type               | Description                                                                                                                                                                                            |
|-------------------------|--------------------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AUTHORIZATION_NAME      | USER_NAME          | VARCHAR(10)<br>Nullable | User profile name.                                                                                                                                                                                     |
| ASPGRP                  | ASPGRP             | VARCHAR(10)<br>Nullable | Name of the independent ASP or *SYSBAS.                                                                                                                                                                |
| MAXIMUM_STORAGE_ALLOWED | MAXSTG             | BIGINT<br>Nullable      | The maximum amount of auxiliary storage (in kilobytes) that can be assigned to store permanent objects owned by the user. Contains null if the user does not have a maximum amount of allowed storage. |
| STORAGE_USED            | STGUSED            | BIGINT<br>Nullable      | The amount of auxiliary storage (in kilobytes) occupied by the user's owned objects for this ASPGRP.                                                                                                   |

## Example

Determine how much storage user SCOTTFF has consumed.

```
SELECT * FROM QSYS2.USER_STORAGE
WHERE USER_NAME = 'SCOTTFF'
```

## System Health Services

For the most important system resources, the IBM i operating system automatically tracks the highest consumption and consumers.

The IBM i operating system is comprised of many products and components. As an integrated operating system, not only do the products and components frequently rely upon each other, but common building blocks and resources are used. Some of the resources are deemed to be critical because their proper use and consumption is directly related to achieving continued, normal operational behavior. The repository for this tracking lies within Db2 for i.

A table, a view, and global variables combine to provide information about limits on your system. Information about the important limits is logged in a Db2 for i supplied table named QSYS2.SYSLIMTBL. The QSYS2.SYSLIMITS view uses SYSLIMTBL and other Db2 resources to provide extended and formatted detail about these limits. You should generally work with the view rather than the underlying table. You can use Db2 for i provided global variables to control the number of rows kept for each type of limit in SYSLIMTBL.

The following tables list the limits that are tracked along with the corresponding limit ID, the system maximum value, the value that will cause the first row to be added to SYSLIMTBL (the floor), and the

amount of change after this first row is written that causes subsequent rows to be added to the table (the increment).

| <i>Table 257. Database limits</i>                         |                 |                   |               |                  |
|-----------------------------------------------------------|-----------------|-------------------|---------------|------------------|
| <b>Limit description</b>                                  | <b>Limit ID</b> | <b>Maximum</b>    | <b>Floor</b>  | <b>Increment</b> |
| Maximum number of all rows in a partition                 | 15000           | 4,294,967,288     | 100,000       | 500,000          |
| Maximum number of valid rows in a partition               | 15001           | 4,294,967,288     | 100,000       | 500,000          |
| Maximum number of deleted rows in a partition             | 15002           | 4,294,967,288     | 10,000        | 100,000          |
| Maximum size of a table                                   | 15003           | 1,869,169,767,219 | 536,865,792   | 1,073,731,584    |
| Maximum number of overflow rows in a partition            | 15004           | 4,294,967,288     | 10,000        | 100,000          |
| Maximum number of variable-length segments                | 15104           | 65,533            | 100           | 100              |
| Maximum number of indexes over a partition                | 15106           | 15,000            | 20            | 100              |
| Maximum size of a *MAX4GB index                           | 15400           | 4,294,967,296     | 838,860,800   | 167,772,160      |
| Maximum size of a *MAX1TB index                           | 15401           | 1,869,166,411,776 | 8,388,608,000 | 8,388,608,000    |
| Maximum size of an encoded vector index                   | 15403           | 2,199,023,255,552 | 1,677,721,600 | 8,388,608,000    |
| Maximum number of members in a source physical file       | 16100           | 32,767            | 100           | 50               |
| Maximum number of rows locked in a unit of work           | 16200           | 500,000,000       | 10,000        | 100,000          |
| Maximum number of row change operations in a unit of work | 16201           | storage           | 10,000        | 100,000          |
| Maximum size of an extended dynamic package               | 16806           | 1,056,964,608     | 335,544,320   | 8,388,608        |

| <i>Table 258. Journal limits</i>                                        |                 |                   |                |                  |
|-------------------------------------------------------------------------|-----------------|-------------------|----------------|------------------|

|--------------------------------------------------------------------------|----------|--------------------------------|------------|-------------|
| Maximum number of objects that can be associated with a *MAX250K journal | 18302    | 250,000                        | 10,000     | 50,000      |
| Maximum sequence number of a *MAXOPT3 journal                            | 18303    | 18,446,744,073<br>,709,551,600 | 10,000,000 | 100,000,000 |
| Maximum sequence number of a *MAXOPT1 or *MAXOPT2 journal                | 18304    | 9,999,999,999                  | 10,000,000 | 10,000,000  |

Table 259. File system limits

| Limit description                                           | Limit ID | Maximum           | Floor      | Increment |
|-------------------------------------------------------------|----------|-------------------|------------|-----------|
| Maximum number of object description entries in a library   | 18400    | 1,000,000         | 1,000      | 1,000     |
| Number of objects linked in a directory                     | 18402    | storage           | 100,000    | 10,000    |
| Maximum number of directories linked in a directory         | 18403    | 1,000,000         | 1,000      | 1,000     |
| Maximum number of file system objects in *SYSBAS ASPs       | 18404    | 2,147,483,647     | 100,000    | 10,000    |
| Maximum number of file system objects in an independent ASP | 18405    | 2,147,483,647     | 100,000    | 10,000    |
| Maximum number of document library objects in a folder      | 18406    | 65510             | 1,000      | 500       |
| Number of document library objects in the system ASP        | 18407    | storage           | 100,000    | 10,000    |
| Maximum number of document library objects in a user ASP    | 18408    | 1,000,000         | 100,000    | 10,000    |
| Maximum number of bytes in a stream file                    | 18409    | 1,099,511,627,776 | 16,777,216 | 1,048,576 |
| Maximum number of bytes in a document                       | 18410    | 2,147,483,647     | 16,777,216 | 1,048,576 |

Table 260. Work management limits

| Limit description                                       | Limit ID | Maximum    | Floor  | Increment |
|---------------------------------------------------------|----------|------------|--------|-----------|
| Maximum number of jobs                                  | 19000    | 970,000    | 1,000  | 400       |
| Maximum number of spool files                           | 19002    | 2,610,000  | 10,000 | 5,000     |
| Maximum number of spooled files in each independent ASP | 19003    | 10,000,000 | 10,000 | 5,000     |

## System limit alerts

Some system limits are instrumented by the IBM i operating system to send messages to the QSYSOPR message queue when a threshold value has been reached.

Once each day, the IBM i will look for any limits that have surpassed their alerting level. This happens when Collection Services is recycled, typically just past midnight. At this time, a call is made to the QSYS2.PROCESS\_SYSTEM\_LIMITS\_ALERTS procedure to identify and signal any alerts for the day.

The following limits are checked against their alerting level as part of this daily processing. If the level is exceeded, a severity 80 informational message SQL7062 is sent to the QSYSOPR message queue. Since these limits will prevent database or other system activity from continuing if they are reached, you should take action to get the object's percent used for the limit below the alerting level. Reducing data by archiving it is one example of an action that could be taken.

Table 261. System limits that send alerting messages

| Limit ID | Limit description                                   | Maximum           | Default Alerting Level | Alerting Cadence |
|----------|-----------------------------------------------------|-------------------|------------------------|------------------|
| 15000    | Maximum number of all rows in a partition           | 4,294,967,288     | Greater than 90%       | Once per day     |
| 15002    | Maximum number of deleted rows in a partition       | 4,294,967,288     | Greater than 50%       | Once per day     |
| 15003    | Maximum size of a table                             | 1,869,169,767,219 | Greater than 90%       | Once per day     |
| 15104    | Maximum number of variable-length segments          | 65,533            | Greater than 90%       | Once per day     |
| 15400    | Maximum *MAX4GB Index Size                          | 4,294,967,296     | Greater than 90%       | Once per day     |
| 15401    | Maximum *MAX1TB Index Size                          | 1,869,166,411,776 | Greater than 90%       | Once per day     |
| 15403    | Maximum Encoded Vector Index Size                   | 2,199,023,255,552 | Greater than 90%       | Once per day     |
| 16100    | Maximum number of members in a source physical file | 32,767            | Greater than 90%       | Once per day     |

Table 261. System limits that send alerting messages (continued)

| Limit ID | Limit description                                               | Maximum       | Default Alerting Level | Alerting Cadence |
|----------|-----------------------------------------------------------------|---------------|------------------------|------------------|
| 18304    | Maximum sequence number of a<br>*MAXOPT1 or<br>*MAXOPT2 journal | 9,999,999,999 | Greater than 90%       | Once per day     |
| 19002    | Maximum number of spooled files                                 | 2,610,000     | Greater than 90%       | Once per day     |

The SQL7062 QSYSOPR message is formatted like this:

```
MYLIB/MYTABLE *FILE HAS CONSUMED MORE THAN 90% OF THE LIMIT:
15000-MAXIMUM NUMBER OF ALL ROWS (4008420999 OF 4294967288=93.33%).
REFER TO ibm.biz/DB2foriAlerts FOR MORE DETAIL.
```

## System limit alerts global variables

For each limit that is instrumented to send a system limit alert, a corresponding global variable is defined that can be used to modify the consumption level that causes the alert to be issued.

The following are the names of the global variables. The schema is SYSIBMADM.

| Limit ID | Global variable                           | Shipped limit |
|----------|-------------------------------------------|---------------|
| 15000    | QIBM_SYSTEM_LIMITS_ALERT_15000_PERCENTAGE | 90            |
| 15002    | QIBM_SYSTEM_LIMITS_ALERT_15002_PERCENTAGE | 50            |
| 15003    | QIBM_SYSTEM_LIMITS_ALERT_15003_PERCENTAGE | 90            |
| 15104    | QIBM_SYSTEM_LIMITS_ALERT_15104_PERCENTAGE | 90            |
| 15400    | QIBM_SYSTEM_LIMITS_ALERT_15400_PERCENTAGE | 90            |
| 15401    | QIBM_SYSTEM_LIMITS_ALERT_15401_PERCENTAGE | 90            |
| 15403    | QIBM_SYSTEM_LIMITS_ALERT_15403_PERCENTAGE | 90            |
| 16100    | QIBM_SYSTEM_LIMITS_ALERT_16100_PERCENTAGE | 90            |
| 18304    | QIBM_SYSTEM_LIMITS_ALERT_18304_PERCENTAGE | 90            |
| 19002    | QIBM_SYSTEM_LIMITS_ALERT_19002_PERCENTAGE | 90            |

You can redefine any of the global variable values to change the alerting percent on your system. The change will take effect the next time the alerting levels are checked.

Use IBM i Access Client Solutions (ACS) to generate SQL for the global variable and use the OR REPLACE option to recreate it with a different default. For example, to send an alert when a file reaches 70% of its maximum size, use the following SQL statement:

```
CREATE OR REPLACE VARIABLE SYSIBMADM.QIBM_SYSTEM_LIMITS_ALERT_15000_PERCENTAGE
FOR SYSTEM NAME QIBM_15000
INTEGER
DEFAULT 70
```

## SYSLIMTBL table

The SYSLIMTBL table contains information about limits as they are being consumed. It is maintained by Db2 for i.

This table is not authorized or managed like a typical Db2 for i catalog. By default, all users have authority to view this table. If this table is removed or incompatibly altered, the IBM i operating system will automatically recreate it. The SYSLIMTBL table is designed to have as small a footprint as possible.

You can add AFTER INSERT or AFTER DELETE triggers to this table. This allows you to perform an action such as sending a notification when a limit is being logged to the table.

The following table describes the columns in the table. The schema is QSYS2.

Table 262. SYSLIMTBL table

| Column Name           | System Column Name | Data Type               | Description                                                                                                                                                                                                                                    |
|-----------------------|--------------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LAST_CHANGE_TIMESTAMP | LASTCHG            | TIMESTAMP               | The timestamp when this row was last changed.                                                                                                                                                                                                  |
| LIMIT_CATEGORY        | CATEGORY           | SMALLINT                | The category of this limit.<br><b>0</b> Database<br><b>1</b> Journal<br><b>2</b> Security<br><b>3</b> Miscellaneous<br><b>4</b> Work management<br><b>5</b> File system<br><b>6</b> Save/restore<br><b>7</b> Cluster<br><b>8</b> Communication |
| LIMIT_TYPE            | LIMTYPE            | SMALLINT                | The type of limit.<br><b>1</b> Object<br><b>2</b> Job<br><b>3</b> System<br><b>4</b> ASP                                                                                                                                                       |
| LIMIT_ID              | LIMIT_ID           | INTEGER                 | Unique identifier for this limit. Values are maintained in the SIZING_ID column in the QSYS2.SQL_SIZING table.                                                                                                                                 |
| JOB_NAME              | JOB_NAME           | VARCHAR(28)             | The name of the job that reported the current value.                                                                                                                                                                                           |
| USER_NAME             | CURUSER            | VARCHAR(10)             | The name of the user in effect when the current value was updated.                                                                                                                                                                             |
| CURRENT_VALUE         | CURVAL             | BIGINT                  | Reported value for this limit.                                                                                                                                                                                                                 |
| SYSTEM_SCHEMA_NAME    | SYS_NAME           | VARCHAR(10)<br>Nullable | The library name for the object. If no library name, contains the null value.                                                                                                                                                                  |
| SYSTEM_OBJECT_NAME    | SYS_ONAME          | VARCHAR(30)<br>Nullable | The object name for this row. If no object name, contains the null value.                                                                                                                                                                      |
| SYSTEM_TABLE_MEMBER   | SYS_MNAME          | VARCHAR(10)<br>Nullable | The member name for an object limit specific to database members. Contains the null value if this row is not for a member limit.                                                                                                               |
| OBJECT_TYPE           | OBJTYPE            | VARCHAR(7)<br>Nullable  | The IBM i object type when an object name has been logged in the SYSTEM_SCHEMA_NAME and SYSTEM_OBJECT_NAME columns. Contains the null value when no object name is specified.                                                                  |
| ASP_NUMBER            | ASPNUM             | SMALLINT<br>Nullable    | Contains the ASP number related to this row. Contains the null value if there is no ASP number.                                                                                                                                                |

Table 262. SYSLIMITBL table (continued)

| Column Name   | System Column Name | Data Type                                  | Description                                                                              |
|---------------|--------------------|--------------------------------------------|------------------------------------------------------------------------------------------|
| IFS_PATH_NAME | PATHNAME           | DBCLOB(5000)<br>CCSID 1200<br><br>Nullable | Integrated file system path for the object. Contains the null value if there is no path. |

## Example

Add a trigger to QSYS2.SYSLIMITBL to send a message when any table is approaching the maximum size. The trigger will be fired when any row is inserted into SYSLIMITBL. Within the trigger, it checks for the LIMIT\_ID indicating the maximum number of rows in a partition (15000) and the value when you want to be notified.

```

/* Force any pseudo closed cursors over SYSLIMITBL to be closed */
CL: ALCOBJ OBJ((QSYS2/SYSLIMITBL *FILE *EXCL)) CONFLICT(*RQSRLS) ;
CL: DLCOBJ OBJ((QSYS2/SYSLIMITBL *FILE *EXCL));

CREATE OR REPLACE TRIGGER MYLIB.SYSTEM_LIMITS_LARGE_FILE
AFTER INSERT ON QSYS2.SYSLIMITBL
REFERENCING NEW AS N FOR EACH ROW MODE DB2ROW
SET OPTION USRPRF=*OWNER, DYNUSRPRF=*OWNER
BEGIN ATOMIC
 DECLARE V_CMDSTMT VARCHAR(200) ;
 DECLARE "ERROR" INTEGER;
 DECLARE EXIT HANDLER FOR SQLEXCEPTION SET "ERROR" = 1;
 /* -----*/
 /* If a table is nearing the maximum size, alert the operator */
 /* -----*/
 IF (N.LIMIT_ID = 15000 AND
 N.CURRENT_VALUE > 3000000000) THEN
 SET V_CMDSTMT = 'SNMSG MSG('Table: '
 CONCAT N.SYSTEM_SCHEMA_NAME CONCAT '/' CONCAT N.SYSTEM_OBJECT_NAME
 CONCAT ' (' CONCAT N.SYSTEM_TABLE_MEMBER CONCAT
 ') IS GETTING VERY LARGE - ROW COUNT = '
 CONCAT CURRENT_VALUE CONCAT ' ') TOUSR(*SYSOPR) MSGTYPE(*INFO) ' ;
 CALL QSYS2.QCMDEXC(V_CMDSTMT);
 END IF;
END;

```

## SYSLIMITS view

The SYSLIMITS view contains information about limits. This view is built on the QSYS.SYSLIMITBL table along with other system information. If a job is still active, the view contains information about the job that logged the limit.

**Authorization:** For rows where the job is still active, the caller's user profile must be the same as the [job user identity](#) of the job for which the information is being returned, or must have \*JOBCTL user special authority, or QIBM\_DB\_SQLADM or QIBM\_DB\_SYSMON function usage authority. If the caller does not have sufficient authority, partial information is returned along with an SQL warning of '01548'.

For rows where LIMIT\_TYPE = 'OBJECT', additional authorization is required:

- If the user has \*EXECUTE authority to the library, and both \*OBJOPR and \*READ authority to an object, full details are returned.
- Otherwise, partial information is returned along with an SQL warning of '01548'.

The following table describes the columns in the view. The schema is QSYS2.

Table 263. SYSLIMITS view

| Column Name           | System Column Name | Data Type | Description                                   |
|-----------------------|--------------------|-----------|-----------------------------------------------|
| LAST_CHANGE_TIMESTAMP | LASTCHG            | TIMESTAMP | The timestamp when this row was last changed. |

Table 263. SYSLIMITS view (continued)

| Column Name          | System Column Name | Data Type                 | Description                                                                                                                                                                                                                                                                     |
|----------------------|--------------------|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LIMIT_CATEGORY       | CATEGORY           | VARCHAR(15)               | The category for this limit. <ul style="list-style-type: none"> <li>• DATABASE</li> <li>• JOURNAL</li> <li>• SECURITY</li> <li>• MISCELLANEOUS</li> <li>• WORK MANAGEMENT</li> <li>• FILE SYSTEM</li> <li>• SAVE RESTORE</li> <li>• CLUSTER</li> <li>• COMMUNICATION</li> </ul> |
| LIMIT_TYPE           | TYPE               | VARCHAR(7)                | The type of limit. <ul style="list-style-type: none"> <li>• OBJECT</li> <li>• JOB</li> <li>• SYSTEM</li> <li>• ASP</li> </ul>                                                                                                                                                   |

| Column Name     | System Column Name | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------|--------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SQL_OBJECT_TYPE | SQLOBJTYPE         | VARCHAR(9)<br>Nullable | The SQL type of the object when an object name has been logged in the SYSTEM_SCHEMA_NAME and SYSTEM_OBJECT_NAME columns. Values are: <ul style="list-style-type: none"> <li>• ALIAS</li> <li>• FUNCTION</li> <li>• INDEX</li> <li>• PACKAGE</li> <li>• PROCEDURE</li> <li>• ROUTINE</li> <li>• SEQUENCE</li> <li>• TABLE</li> <li>• TRIGGER</li> <li>• TYPE</li> <li>• VARIABLE</li> <li>• VIEW</li> <li>• XSR</li> </ul> Contains the null value if the object is not an SQL object or when no object name is specified. |
| ASP_NUMBER      | ASPNUM             | SMALLINT<br>Nullable   | Contains the ASP number related to this row.<br>Contains the null value if there is no ASP number.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| LIMIT_ID        | LIMIT_ID           | INTEGER                | Unique identifier for this limit. Values are maintained in the SIZING_ID column in the QSYS2.SQL_SIZING table.                                                                                                                                                                                                                                                                                                                                                                                                            |

## Examples

- Find the 50 largest integrated file system stream files. Remove any duplicates from the result. Note that only stream files that have reached the documented floor and increment values will appear in SYSLIMITS.

```
SELECT IFS_PATH_NAME, MAX(CURRENT_VALUE) AS MAX_BYTE_SIZE
FROM QSYS2.SYSLIMITS
WHERE LIMIT_ID = 18409
GROUP BY IFS_PATH_NAME
ORDER BY MAX_BYTE_SIZE DESC LIMIT 50;
```

- Review the consumption of the 'Total number of jobs', relative to the QMAXJOB system value.

```
WITH TT(JOB_MAXIMUM)
AS (SELECT CURRENT_NUMERIC_VALUE
FROM QSYS2.SYSTEM_VALUE_INFO
WHERE SYSTEM_VALUE_NAME = 'QMAXJOB')
SELECT LAST_CHANGE_TIMESTAMP AS INCREMENT_TIME, CURRENT_VALUE AS JOB_COUNT,
TT.JOB_MAXIMUM,
DEC(DEC(CURRENT_VALUE,19,2) / DEC(TT.JOB_MAXIMUM,19,2) * 100,19,2)
AS PERCENT_CONSUMED
FROM QSYS2.SYSLIMITS, TT
WHERE LIMIT_ID = 19000 ORDER BY CURRENT_VALUE DESC;
```

## SYSLIMITS\_BASIC view

The SYSLIMITS\_BASIC view contains information about limits. This view is built on the QSYS.SYSLIMITBL table along with other system information. It does not return information about the job that logged the limit. This view returns less information than the SYSLIMITS view, but it requires less authorization and typically performs significantly better.

**Authorization:** None required.

The following table describes the columns in the view. The system name is SYSLIMIT\_B. The schema is QSYS2.

Table 264. SYSLIMITS\_BASIC view

| Column Name           | System Column Name | Data Type                              | Description                                                                                                                                                                                                                                                                     |
|-----------------------|--------------------|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Examples

- Review the consumption of the 'Total number of jobs', relative to the QMAXJOB system value.

```

WITH TT(JOB_MAXIMUM)
 AS (SELECT CURRENT_NUMERIC_VALUE
 FROM QSYS2.SYSTEM_VALUE_INFO
 WHERE SYSTEM_VALUE_NAME = 'QMAXJOB')
SELECT LAST_CHANGE_TIMESTAMP AS INCREMENT_TIME, CURRENT_VALUE AS JOB_COUNT,
 TT.JOB_MAXIMUM,
 DEC(DEC(CURRENT_VALUE,19,2) / DEC(TT.JOB_MAXIMUM,19,2) * 100,19,2)
 AS PERCENT_CONSUMED
FROM QSYS2.SYSLIMITS_BASIC, TT
WHERE LIMIT_ID = 19000 ORDER BY CURRENT_VALUE DESC;

```

## PROCESS\_SYSTEM\_LIMITS\_ALERTS procedure

The QSYS2.PROCESS\_SYSTEM\_LIMITS\_ALERTS procedure can be called directly to look for any tracked limits that have exceeded their alerting level in the last 24 hours. If any are identified, an alert will be signaled. Calling it repeatedly can send duplicate alerts.

This procedure performs the same checks that are done by the system processing of the alerts. If a limit has reached its alerting level, message SQL7062 is sent to the QSYSOPR message queue. See [“System limit alerts”](#) on page 1011 for details.

This procedure can be submitted in a job to be run at a user-determined time to look for runaway situations.

**Authorization:** This procedure, implemented by the QSYS2/LIM\_ALERTS program, is shipped with \*PUBLIC \*EXCLUDE authority.

To call this procedure the user must have \*EXECUTE authority to the QSYS2/LIM\_ALERTS program.

►► PROCESS\_SYSTEM\_LIMITS\_ALERTS — ( — ) ◄◄

The schema is QSYS2.

### Example

To schedule a job that will run every weekday at noon to report system limits that have reached their reporting threshold values in the last 24 hours, the following CL command can be run.

```

ADDJOBSCDE JOB(chkalert)
CMD(RUNSQL SQL('CALL QSYS2.PROCESS_SYSTEM_LIMITS_ALERTS()') COMMIT(*NONE))
FRQ(*WEEKLY) SCDDATE(*NONE)
SCDDAY(*MON *TUE *WED *THU *FRI) SCDTIME('12:00:00')

```

## QIBM\_SYSTEM\_LIMITS global variables

To prevent excess storage consumption or retention of unnecessarily old system limits entries within the QSYS2/SYSLIMITBL table, Db2 for i will automatically delete (or prune) rows.

There are two ways the pruning is controlled. One method is by the number of days to keep a row. The other is by the maximum number of rows to keep for a specific limit. In each case, Db2 for i supplied global variables guide the pruning action.

Controls exist for deleting rows that have reached a certain age are handled with a set of Db2 for i provided global variables. These controls cause rows to be removed when they exceed the number of days.

The following are the names of the global variables that control pruning by number of days and the limit that is shipped for each one. The schema is SYSIBMADM.

| Global variable                   | Shipped limit |
|-----------------------------------|---------------|
| QIBM_SYSTEM_LIMITS_ASP_BY_DAYS    | 90            |
| QIBM_SYSTEM_LIMITS_JOB_BY_DAYS    | 90            |
| QIBM_SYSTEM_LIMITS_OBJECT_BY_DAYS | 90            |

| Global variable                   | Shipped limit |
|-----------------------------------|---------------|
| QIBM_SYSTEM_LIMITS_SYSTEM_BY_DAYS | 90            |

The second control for automatic deletion of rows is by the number of rows for a type of limit. For each type of limit, there are two global variables. The pruning variable is used to choose how many of the most recently logged entries should be retained. The high point variable is used to choose how many of the highest consumption value entries should be retained.

The following are the names of the global variables and the limit that is shipped for each one. The schema is SYSIBMADM.

| Global variable                               | Shipped limit |
|-----------------------------------------------|---------------|
| QIBM_SYSTEM_LIMITS_PRUNE_BY_ASP               | 20            |
| QIBM_SYSTEM_LIMITS_PRUNE_BY_JOB               | 20            |
| QIBM_SYSTEM_LIMITS_PRUNE_BY_OBJECT            | 20            |
| QIBM_SYSTEM_LIMITS_PRUNE_BY_SYSTEM            | 20            |
| QIBM_SYSTEM_LIMITS_SAVE_HIGH_POINTS_BY_ASP    | 25            |
| QIBM_SYSTEM_LIMITS_SAVE_HIGH_POINTS_BY_JOB    | 5             |
| QIBM_SYSTEM_LIMITS_SAVE_HIGH_POINTS_BY_OBJECT | 5             |
| QIBM_SYSTEM_LIMITS_SAVE_HIGH_POINTS_BY_SYSTEM | 25            |

You can adjust any of the global variable values to establish a custom behavior for the automatic deletion of system limits rows. The Db2 for i supplied global variables use the default value to guide an automatic row deletion process that runs nightly when Collection Services is recycled, which normally occurs just past midnight.

**Authorization:** To create or replace a global variable the caller must have:

- \*OBJMGT authority on the service program for the variable, and
- All authorities needed to DROP the variable, and
- \*READ authority on the SYSVARIABLES catalog table.

Use IBM i Access Client Solutions (ACS) to generate SQL for the global variable and use the OR REPLACE option to recreate it with a different default. For example, to remove all object limits older than 30 days, use the following SQL statement:

```
CREATE OR REPLACE VARIABLE SYSIBMADM.QIBM_SYSTEM_LIMITS_OBJECT_BY_DAYS
 INTEGER
 DEFAULT 30
```

## Work Management Services

These views and functions provide system value and job information.

### ACTIVE\_JOB\_INFO table function

The ACTIVE\_JOB\_INFO table function returns one row for every active job.

The information returned is similar to the detail seen from the Work with Active Jobs (WRKACTJOB) command and the List Job (QUSLJOB) API. The ACTIVE\_JOB\_INFO table function has two uses:

1. To see details for all, or a subset of, active jobs. A subset of active jobs can be requested by using the optional filter parameters.

2. To measure elapsed statistics for active jobs. You can use an optional parameter to reset statistics, similar to the WRKACTJOB command F10 Restart Statistics function. Measurements will be calculated based on this new starting point.

**Authorization:** None required to see general information or to see information for jobs where the caller's user profile is the same as the job user identity of the job for which the information is being returned.

For DETAILED\_INFO => NONE or DETAILED\_INFO => WORK:

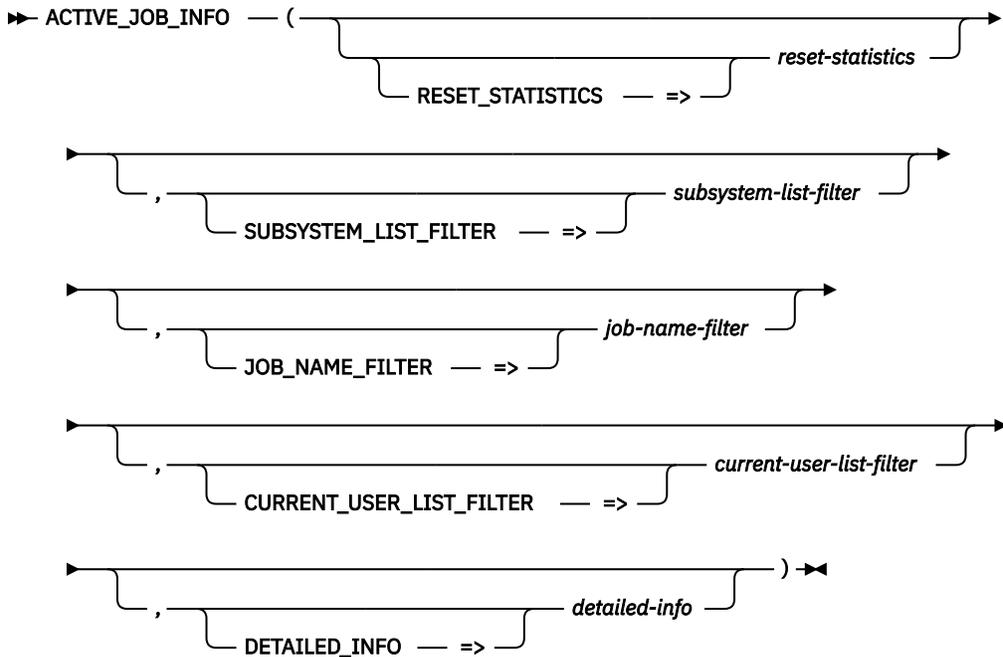

- None required.

For DETAILED\_INFO => QTEMP:

- The caller must have \*JOBCTL special authority.

For DETAILED\_INFO => ALL or FULL:

- None required to see detailed column information for the columns that are included with DETAILED\_INFO => WORK or the CLIENT\_IP\_ADDRESS, PAGE\_FAULTS, PRESTART\_JOB\_REUSE\_COUNT, PRESTART\_JOB\_MAX\_USE\_COUNT, and WORKLOAD\_GROUP columns.
- A caller who is authorized to the QIBM\_DB\_SQLADM or QIBM\_DB\_SYSMON function usage identifiers can see detailed column information related to SQL activity starting with the SQL\_STATEMENT\_TEXT column through the PSEUDO\_CLOSED\_CURSOR\_COUNT column.
- A caller with \*JOBCTL special authority can see all detailed column information.

The schema is QSYS2.

**reset-statistics**

A character or graphic string expression that contains a value of YES or NO.

If this parameter has a value of YES, statistics are reset such that the time of this query execution is used as the new baseline. Future invocations of `ACTIVE_JOB_INFO` within this connection will return statistical detail relative to the new baseline. If this parameter has a value of NO, statistics are not reset for the invocation unless the *subsystem-list-filter* or *job-name-filter* parameter values are different than the previous invocation. Changing the filter values will always cause statistics to be reset. If this parameter is not specified, the default is NO.

The first invocation of `ACTIVE_JOB_INFO` within a connection will always perform an implicit reset, regardless of whether a reset was explicitly requested.

**subsystem-list-filter** A character or graphic string expression that contains a list of up to 25 subsystem names separated by exactly one comma. The filter determines which subsystems to use to return job information.

If this parameter is not specified, is an empty string, or is the null value, information for all subsystems is returned.

**job-name-filter** A character or graphic string expression that contains an unqualified job name that determines the job information to be returned. The name can be a generic name.

The string can be one of the following special values:

- \* Only information for the current job is returned.
- \*ALL** Information for all jobs is returned.
- \*CURRENT** Information for all jobs with a job name that is the same as the current job is returned.
- \*SBS** Information for all active subsystem monitors is returned.
- \*SYS** Information for all active system jobs is returned. When using this value, the *subsystem-list-filter* must not be specified or must be the null value.

If this parameter is not specified, is an empty string, or is the null value, information for all jobs is returned.

**current-user-list-filter** A character or graphic string expression that contains a list of up to 10 user profile names separated by exactly one comma. The filter determines which current user values to use to return job information.

If this parameter is not specified, is an empty string, or is the null value, information for all users is returned.

**detailed-info** A character or graphic string expression that indicates the type of information to be returned.

- NONE** Only the general information is returned for active jobs. This is the information in the columns prior to the JOB\_DESCRIPTION\_LIBRARY column. This is the default.
- WORK** In addition to the general information for active jobs, additional work management information is returned.
- QTEMP** In addition to the general information for active jobs, the QTEMP\_SIZE column is returned.
- ALL** Information for all the columns is returned.

The result of the function is a table containing multiple rows with the format shown in the following table. All the columns are nullable.

The **DETAILED\_INFO option** column indicates which of the DETAILED\_INFO parameter values can return a non-null value for the corresponding result column.

Table 265. ACTIVE\_JOB\_INFO table function

| Column Name      | Data Type | DETAILED_INFO option         | Description                   |
|------------------|-----------|------------------------------|-------------------------------|
| ORDINAL_POSITION | INTEGER   | NONE<br>WORK<br>QTEMP<br>ALL | A unique number for each row. |

Table 265. ACTIVE\_JOB\_INFO table function (continued)

| Column Name            | Data Type   | DETAILED_INFO option         | Description                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|-------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JOB_NAME               | VARCHAR(28) | NONE<br>WORK<br>QTEMP<br>ALL | The qualified job name.                                                                                                                                                                                                                                                                                                                                                                                                           |

| DECIMAL_FORMAT            | VARCHAR(6)  | WORK<br>ALL          | <p>The decimal format used for this job.</p> <p><b>*BLANK</b> Uses a period for a decimal point, a comma for a 3-digit grouping character, and zero-suppress to the left of the decimal point.</p> <p><b>J</b> Uses a comma for a decimal point and a period for a 3-digit grouping character. The zero-suppression character is in the second position (rather than the first) to the left of the decimal notation. Balances with zero values to the left of the comma are written with one leading zero (0,04). The J entry also overrides any edit codes that might suppress the leading zero.</p> <p><b>I</b> Uses a comma for a decimal point, a period for a 3-digit grouping character, and zero-suppress to the left of the decimal point.</p> |
| TIMEZONE_DESCRIPTION      | VARCHAR(10) | ALL                  | The name of the time zone description that is used to calculate local job time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| MAXIMUM_ACTIVE_THREADS    | INTEGER     | ALL                  | <p>The maximum number of threads that a job can run with at any time. If multiple threads are initiated simultaneously, this value may be exceeded. If this maximum value is exceeded, the excess threads will be allowed to run to their normal completion. Initiation of additional threads will be inhibited until the maximum number of threads in the job drops below this maximum value.</p> <p>Contains the null value if there is no maximum.</p>                                                                                                                                                                                                                                                                          |

Table 265. ACTIVE\_JOB\_INFO table function (continued)

| Column Name                       | Data Type   | DETAILED_INFO option | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------|-------------|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SYSTEM_POOL_ID                    | INTEGER     | ALL                  | <p>The identifier of the system-related pool from which main storage is currently being allocated for the job's initial thread. These identifiers are not the same as those specified in the subsystem description, but are the same as the system pool identifiers shown on the system status display. If a thread reaches its time-slice end, the pool the thread is running in can be switched based on the job's time-slice end pool value. The current system pool identifier returned will be the actual pool in which the initial thread of the job is running.</p> <p>Contains the null value if the value is not available.</p>                                                                                     |
| POOL_NAME                         | VARCHAR(10) | ALL                  | <p>The name of the memory pool in which the job started running. The name may be a number, in which case it is a private pool associated with a subsystem. Can contain one of the following special values:</p> <p><b>*BASE</b> This job is running in the base system pool, which can be shared with other subsystems.</p> <p><b>*INTERACT</b> This job is running in the shared pool used for interactive work.</p> <p><b>*MACHINE</b> This job is running in the machine pool.</p> <p><b>*SHRPOOL1 - *SHRPOOL60</b> This job is running in the identified shared pool.</p> <p><b>*SPOOL</b> This job is running in the shared pool for spooled writers.</p> <p>Contains the null value if the value is not available.</p> |
| QTEMP_SIZE                        | INTEGER     | QTEMP<br>ALL         | <p>The amount of storage, in megabytes, used by objects in the job's temporary library (QTEMP). Objects that are locked, damaged, or not authorized are not included.</p> <p>Contains the null value if the size cannot be returned.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PEAK_TEMPORARY_STORAGE            | INTEGER     | ALL                  | <p>The maximum amount of auxiliary storage, in megabytes, that the job has used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| DEFAULT_WAIT                      | INTEGER     | ALL                  | <p>The default maximum time, in seconds, that a thread in the job waits for a system instruction, such as a LOCK machine interface (MI) instruction, to acquire a resource.</p> <p>Contains the null value if there is no maximum or if the value is not available.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| MAXIMUM_PROCESSING_TIME_ALLOWED   | INTEGER     | ALL                  | <p>The maximum processing unit time, in milliseconds, that the job can use. If the job consists of multiple routing steps, this is the maximum processing unit time that the current routing step can use. If the maximum time is exceeded, the job is held.</p> <p>Contains the null value if no maximum amount of processing unit time has been defined.</p>                                                                                                                                                                                                                                                                                                                                                               |
| MAXIMUM_TEMPORARY_STORAGE_ALLOWED | INTEGER     | ALL                  | <p>The maximum amount of auxiliary storage, in megabytes, that the job can use. If the job consists of multiple routing steps, this is the maximum temporary storage that the routing step can use. This temporary storage is used for storage required by the program itself and by implicitly created internal system objects used to support the routing step. (It does not include storage for objects in the QTEMP library.) If the maximum temporary storage is exceeded, the job is held. This does not apply to the use of permanent storage, which is controlled through the user profile.</p> <p>Contains the null value if no maximum amount of temporary storage has been defined.</p>                           |

Table 265. ACTIVE\_JOB\_INFO table function (continued)

| Column Name                     | Data Type      | DETAILED_INFO option | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------|----------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TIME_SLICE                      | INTEGER        | ALL                  | The maximum amount of processor time, in milliseconds, given to each thread in this job before other threads in this job and in other jobs are given the opportunity to run. The time slice establishes the amount of time needed by a thread in this job to accomplish a meaningful amount of processing. At the end of the time slice, the thread might be put in an inactive state so that other threads can become active in the storage pool. Values range from 8 through 9999999.<br><br>Contains the null value if the value is not available. |
| PAGE_FAULTS                     | BIGINT         | ALL                  | The number of times an active program referenced an address that was not in main storage during the current routing step of the specified job.                                                                                                                                                                                                                                                                                                                                                                                                        |
| TOTAL_RESPONSE_TIME             | BIGINT         | ALL                  | The total amount of response time for the initial thread, in milliseconds. This value does not include the time used by the machine, by the attached input/output (I/O) hardware, and by the transmission lines for sending and receiving data. Returns zero for jobs that have no interactions. A value of -1 is returned if the field is not large enough to hold the actual result.                                                                                                                                                                |
| INTERACTIVE_TRANSACTIONS        | INTEGER        | ALL                  | The count of operator interactions, such as pressing the Enter key or a function key. Returns zero for jobs that have no interactions.                                                                                                                                                                                                                                                                                                                                                                                                                |
| DATABASE_LOCK_WAITS             | INTEGER        | ALL                  | The number of times that the initial thread had to wait to obtain a database lock.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| NON_DATABASE_LOCK_WAITS         | INTEGER        | ALL                  | The number of times that the initial thread had to wait to obtain a nondatabase lock.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| SQE_CURSOR_COUNT           | INTEGER             | ALL                  | The number of cursors using SQE for this job. This includes SQL cursors (both fully opened and pseudo closed) and cursors used to implement native database queries.<br><br>Contains the null value if no cursors have used SQE for this job.                                                                                                                                                                                                                                                                                   |
| SQE_CURSOR_STORAGE         | INTEGER             | ALL                  | The amount of storage, in megabytes, used by cursors using SQE for this job.<br><br>Contains the null value if no cursors have used SQE for this job.                                                                                                                                                                                                                                                                                                                                                                           |
| LARGEST_QUERY_SIZE         | INTEGER             | ALL                  | The amount of storage, in megabytes, used by the SQE cursor that used the most storage for this job. This could be for a different query than the one listed in the SQL_STATEMENT_TEXT column.<br><br>Contains the null value if no cursors have used SQE for this job.                                                                                                                                                                                                                                                         |
| QRO_HASH                   | VARCHAR(8)          | ALL                  | An internally generated identifier for the SQE query referred to in the LARGEST_QUERY_SIZE column. This could be for a different query than the one listed in the SQL_STATEMENT_TEXT column. The QRO hash surfaces within Visual Explain and from Show Statements exploration of the SQL Plan Cache and SQL Plan Cache Snapshots.<br><br>Contains the null value if no cursors have used SQE for this job.                                                                                                                      |
| QRO_HASH_JSON              | CLOB(1M) CCSID 1208 | ALL                  | The list of QRO hashes associated with queries currently being optimized or running in this job. This list is returned as an array within a JSON object. The array is identified by QRO_HASH_LIST. Each entry in the JSON array identifies a QRO hash.<br><br>Note that the plan for a specific QRO hash may no longer be in the plan cache.                                                                                                                                                                                    |
| PLAN_IDENTIFIER_JSON       | CLOB(1M) CCSID 1208 | ALL                  | The list of plan identifiers associated with queries currently running in this job. This list is returned as an array within a JSON object. The array is identified by PLAN_IDENTIFIER. Each entry in the JSON array identifies a plan identifier.<br><br>Note that the plan for a specific plan identifier may no longer be in the plan cache.                                                                                                                                                                                 |
| OPEN_FILES                 | INTEGER             | ALL                  | The number of open files (*FILE objects) for this job. For details about the types of files and their usage, use the QSYS2.OPEN_FILES table function.                                                                                                                                                                                                                                                                                                                                                                           |

## Example

- **Example 1:** Looking at only QZDASOINIT jobs, find the top 10 consumers of Elapsed I/O.

```
SELECT JOB_NAME, AUTHORIZATION_NAME, ELAPSED_TOTAL_DISK_IO_COUNT, ELAPSED_CPU_PERCENTAGE
FROM TABLE(QSYS2.ACTIVE_JOB_INFO(
 JOB_NAME_FILTER => 'QZDASOINIT',
 SUBSYSTEM_LIST_FILTER => 'QUSRWRK')) X
ORDER BY ELAPSED_TOTAL_DISK_IO_COUNT DESC
FETCH FIRST 10 ROWS ONLY;
```

Note: The data in the ELAPSED\_xxx columns is updated upon each re-execution of the query. Elapsed data will not get returned the first time a query is run for ACTIVE\_JOB\_INFO for a connection. See the *reset-statistics* parameter for details.

- **Example 2:** Find the active jobs using the most temporary storage. Include the most recently executed SQL statement for each target job.

```
SELECT JOB_NAME, AUTHORIZATION_NAME, TEMPORARY_STORAGE, SQL_STATEMENT_TEXT
FROM TABLE (QSYS2.ACTIVE_JOB_INFO(DETAILED_INFO=>'ALL')) X
WHERE JOB_TYPE <> 'SYS'
ORDER BY TEMPORARY_STORAGE DESC;
```

## ADD\_TRACKED\_JOB\_QUEUE procedure

The ADD\_TRACKED\_JOB\_QUEUE procedure registers a job queue to be tracked by adding it to the tracked job queue list.

For a subsystem to track jobs, there must be at least one tracked job queue registered to the Submitted Job Tracker when that subsystem starts.

For more information about the Submitted Job Tracker, see [“Submitted Job Tracker” on page 1038](#).

**Authorization:** The caller must have \*JOBCTL special authority.

```
➔ ADD_TRACKED_JOB_QUEUE ((iasp-name , ➔
 IASP_NAME =>
 job-queue-library , ➔
 JOB_QUEUE_LIBRARY =>
 job-queue ➔
 JOB_QUEUE =>
 job-retention-period ➔
 JOB_RETENTION_PERIOD =>
) ➔
 tracking-file-iasp ➔
 TRACKING_FILE_IASP =>
```

The schema is QSYS2.

***iasp-name*** A character string that contains the name of the ASP where *job-queue-library* is located. The ASP does not need to exist. Can contain the following special value:

• **\*SYSBAS** The job queue library is located in the system ASP (ASP 1) or any basic user ASPs (ASPs 2-32).

***job-queue-library*** A character string that contains the name of the library containing *job-queue*. The library does not need to exist.

- job-queue** A character string that contains the name of the job queue to be tracked. A job queue can be registered even if it does not exist.  
Job queues in libraries QSYS and QGPL that start with Q are not eligible to be added.
- job-retention-period** An integer value that specifies the number of minutes job tracking information will be retained in the tracking file after the job has ended. The default is 0, which indicates that the job tracking information is immediately eligible for removal when the job ends.  
Once this time period has elapsed, the job tracking information becomes eligible to be removed from the job tracking file.
- tracking-file-iasp** A character string that contains the name of the IASP where the job tracking file for *job-queue* is to be created. If a value is provided for this parameter, *iasp-name* must have a value of \*SYSBAS.  
If this parameter is omitted, the job tracking file will be created on the ASP where *job-queue-library* is located.

## Example

- Add job queue APPLIB/APPJOBQ to the list of tracked job queues.

```
CALL QSYS2.ADD_TRACKED_JOB_QUEUE(IASP_NAME => '*SYSBAS',
 JOB_QUEUE_LIBRARY => 'APPLIB',
 JOB_QUEUE => 'APPJOBQ');
```

## Submitted Job Tracker

The Submitted Job Tracker is an IBM i work management feature that tracks the lifecycle of submitted jobs for a user specified set of jobs queues.

The ADD\_TRACKED\_JOB\_QUEUE procedure registers a job queue to be tracked by adding it to the Job Queue List (JQL). After a job queue has been registered, any jobs subsequently submitted to that job queue are tracked in a job tracking file. A user can use the information stored in the job tracking file to resubmit a job on the original node where the job was tracked or another node. The information in the job tracking file can help prepare for maintenance, recover from a node failure, or balance workload.

The job tracking file is a database file that keeps track of job submit parameters and job status for any jobs being tracked by Submitted Job Tracker. The job tracking files is named QSBMJOBTRK/QAMRDJTS<sup>3</sup> and can exist in SYSBAS or within an IASP.

## Tracking job lifecycle events

To track job lifecycle events, Submitted Job Tracker uses the following work management exit points:

- [Change Job](#) (QIBM\_QWT\_CHGJOB)
- [Job Notification](#) (QIBM\_QWT\_JOBNOTIFY)
- [Submit Job](#) (QIBM\_QWT\_SBMJOB)

See the details for how Submitted Job Tracker handles each lifecycle event below.

|                                                      |                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Submit Job (SBMJOB) command</b>                   | When a job is submitted to a tracked job queue with SBMJOB, parameters that would be necessary to resubmit the job are stored in the job tracking file.                                                                                                                                                                                                                                |
| <b>Change Job (CHGJOB) command or API (QWTCHGJB)</b> | When a tracked job is changed while it is on a job queue, the job tracking file is updated to reflect the changes.<br>When a tracked job is changed while it is active, the job tracking file is not updated.<br>If a tracked job is moved from an untracked job queue to one that is not tracked, then tracking ends for that job and no further updates are made to the job tracking |

<sup>3</sup> For an IASP, the QAMRDJTS job tracking file exists in library QSJTnnnnn.

file. However, the information for that job remains in the job tracking file until the job queue is no longer tracked or the job tracking file is cleared.

If a job is moved from an untracked job queue to one that is tracked, then the job remains not tracked.

**Note:** It is recommended to track all job queues involved in the lifecycle of a tracked job.

**Transfer Job (TFRJOB) or Transfer Batch Job (TFRBCHJOB) command**

Each time an active job is transferred to a tracked job queue, an additional entry is added to the job tracking file to represent the new routing step associated with that job. If the job queue for a routing step is not a tracked job queue, then no additional entry for that routing step is added to the job tracking file.

When the last routing step ends, all entries in the job tracking file for that job are updated to indicate the job end time. If the job queue for the last routing step is not a tracked job queue, then the job end time is not updated for any of the entries for that job in the job tracking file.

**Note:** It is recommended to track all job queues involved in the lifecycle of a tracked job.

**Job starts**

When a tracked job starts, the job tracking file is updated to indicate the job start time.

**Job ends**

When a tracked job ends, the job tracking file is updated to indicate the job end time and other completion details.

If a job is ended while it is on a tracked job queue that is not allocated to a subsystem, the job tracking file remains unchanged until the job queue is no longer tracked or the job tracking file is cleared.

**Job schedule entries**

Jobs that are scheduled to run at a future date or time using the Add Job Schedule Entry (ADDJOBSCDE) or Work with Job Schedule Entries (WRKJOBSCDE) commands are not tracked.

The job tracking file is updated asynchronously while tracked jobs encounter lifecycle events. Tracking information is gathered, processed, and stored in a job tracking file asynchronously by the Submitted Job Tracker job (QMRDBJNFY). Subsequently, tracking information in the job tracking file will always lag the real lifecycle event. The lag time should be small in most cases, but it is not zero. This means:

- A job that is queued at the time of a node failure may not appear in the job tracking file.
- A job that has started running at the time of node failure may not appear in the job tracking file or may be described in the job track file as still queued.
- A job that has ended at the time of node failure may be described in the job tracking file as still queued or running.

## Managing the Submitted Job Tracker

**Displaying tracked job queues**

The list of job queues that have been registered to be tracked is displayed using the [“TRACKED\\_JOB\\_QUEUES view”](#) on page 1150.

**Adding tracked job queues**

Job queues are registered to be tracked using the ADD\_TRACKED\_JOB\_QUEUE procedure.

**Note:** It is recommended to register all job queues allocated to a subsystem before starting the subsystem.

**Removing tracked job queues**

Job queues are removed from being tracked using the [“REMOVE\\_TRACKED\\_JOB\\_QUEUE procedure”](#) on page 1105.

## Displaying tracked jobs

Tracked jobs and their details are displayed using the [“TRACKED\\_JOB\\_INFO table function”](#) on page 1141.

## Clearing tracked jobs details

Tracked job information is eligible to be automatically removed from a job tracking file after the job has ended, the job tracking file has been updated with a job end time value, and the job retention period has elapsed. The job retention period is specified when a job queue is registered with the JQL. The Submitted Job Tracker job (QMRDBJNFY) periodically checks for tracked job information that is eligible to be removed and clears those entries.

All tracked job information for a particular job queue is removed from a job tracking file when that job queue is removed from the JQL.

There are several situations that may cause Submitted Job Tracker to not receive a notification that a job has ended and therefore the job end time in the job tracking file did not get updated. These entries must be manually cleared from the job tracking file. The following situations can cause a tracked job to get into this state:

- A node has an unplanned outage. When the node is active again, information in the job tracking file about active jobs when the outage occurred will not have a job end time value set.
- An IASP is varied off or is unavailable. While the IASP is unavailable, Submitted Job Tracker is unable to update the job tracking file. When it is varied on again, entries in the job tracking file may still exist for jobs that have ended but the job end time value is not set.
- A job is changed or transferred from a tracked job queue to an untracked job queue. This causes tracking to end for that job but information about it remains in the job tracking file and the job end time value is not set.
- A user registers a job queue to be tracked by adding it to the JQL after starting the subsystem where the jobs will run. This can prevent Submitted Job Tracker from receiving notifications when a job ends, which results in entries in the job tracking files not being properly updated with job end time values.
- A user submits a job to a tracked job queue and the job is ended before the job queue is allocated to a subsystem. Submitted Job Tracker does not receive a notification from work management that the job has ended in this case, therefore the job end time value is not set for the job in the job tracking file.
- The limit of eight data queues registered for the work management job notification exit point (QIBM\_QWT\_JOBNOTIFY) is exceeded. This may cause Submitted Job Tracker to not receive notifications when a job starts or ends, which results in entries in the job tracking file not being properly updated.

Tracked job information can be cleared manually using the [“CLEAR\\_TRACKED\\_JOB\\_INFO procedure”](#) on page 1041.

## Restoring Submitted Job Tracker data

The JQL, which is a database file named QSYS/QAMRDJQL, can be restored from save media. This will replace the existing list of tracked job queues with the list of tracked job queues from the save media. When the QAMRDJQL file is restored, each job queue on the restored list of tracked job queues is ensured to be properly registered with Submitted Job Tracker. If the restore causes a job queue to no longer be tracked, then the job tracking file will be cleared of entries for that job queue.

The job tracking file, which is a database file named QSBMJOBTRK/QAMRDJTS<sup>4</sup>, cannot be restored from save media. If an attempt is made to restore this system object, it will not be restored and the existing object is left unchanged. If other objects are included in the restore request, they will be processed normally.

<sup>4</sup> For an IASP, the QAMRDJTS job tracking file exists in library QSJTnnnnn.

## AUTOSTART\_JOB\_INFO view

The AUTOSTART\_JOB\_INFO view returns information about autostart jobs.

The values returned for the columns in the view are closely related to the values returned by the Display Autostart Job Entries panel accessed through the DSPSBSD (Display Subsystem Description) CL command and by the List Subsystem Entries (QWDLSE) API.

**Authorization:** The caller must have:

- \*EXECUTE authority to the library containing the subsystem description, and
- \*USE authority to the subsystem description.

The following table describes the columns in the view. The system name is AUTOJ\_INFO. The schema is QSYS2.

Table 266. AUTOSTART\_JOB\_INFO view

| Column Name                   | System Column Name | Data Type   | Description                                                                                        |
|-------------------------------|--------------------|-------------|----------------------------------------------------------------------------------------------------|
| SUBSYSTEM_DESCRIPTION_LIBRARY | SBSD_LIB           | VARCHAR(10) | The name of the library in which the subsystem description resides.                                |
| SUBSYSTEM_DESCRIPTION         | SBSD               | VARCHAR(10) | The name of the subsystem about which information is being returned.                               |
| AUTOSTART_JOB_NAME            | AJ_NAME            | VARCHAR(10) | The simple name of the job that is automatically started when the associated subsystem is started. |
| JOB_DESCRIPTION_LIBRARY       | JOBDLIB            | VARCHAR(10) | The name of the library in which the job description for the autostart job entry resides.          |
| JOB_DESCRIPTION               | JOBID              | VARCHAR(10) | The name of the job description for the autostart job entry.                                       |

### Example

- List all the autostart job entries in the QUSRWRK subsystem.

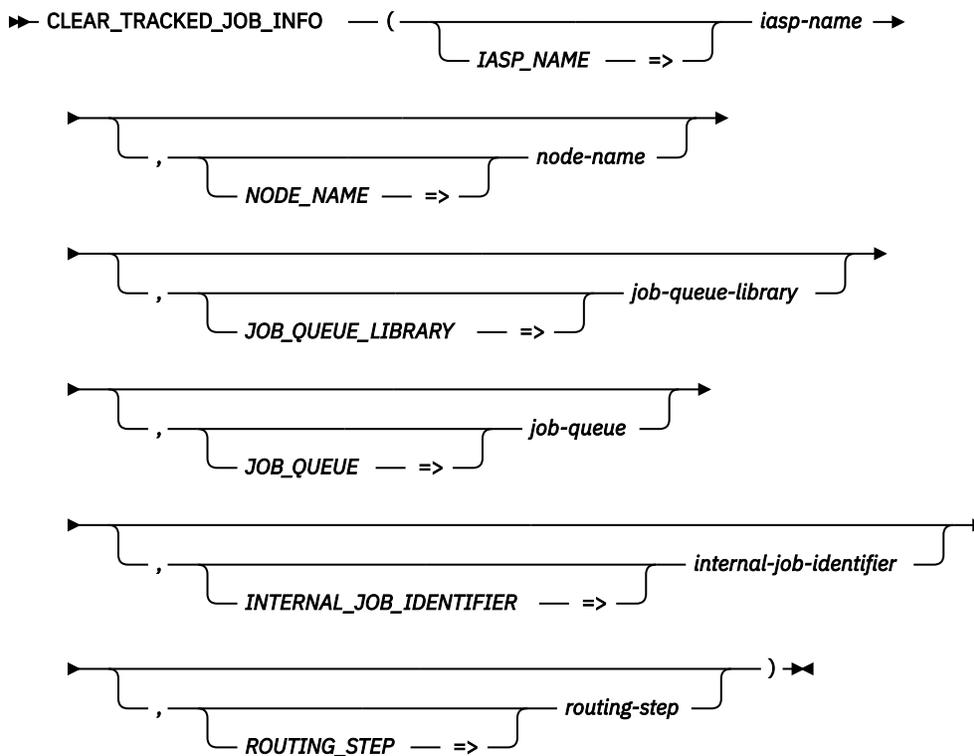

```
SELECT AUTOSTART_JOB_NAME, JOB_DESCRIPTION_LIBRARY, JOB_DESCRIPTION
FROM QSYS2.AUTOSTART_JOB_INFO
WHERE SUBSYSTEM_DESCRIPTION_LIBRARY = 'QSYS' AND
 SUBSYSTEM_DESCRIPTION = 'QSYSWRK'
ORDER BY 1, 2, 3;
```

## CLEAR\_TRACKED\_JOB\_INFO procedure

The CLEAR\_TRACKED\_JOB\_INFO procedure removes entries from the job tracking file that exists on the specified ASP group.

Many filters are provided to restrict the entries that are removed from job tracking files by this procedure. The filters are additive, with each one further limiting the entries to be removed. If none of the filter parameters are specified, all entries are removed from the job tracking file.

**Authorization:** The caller must have \*JOBCTL special authority.

The schema is QSYS2.

- iasp-name** A character string that contains the name of the IASP where the job tracking file to be cleared is located. Can contain the following special value:
- \*SYSBAS** The job tracking file is located in the system ASP (ASP 1) or any basic user ASPs (ASPs 2-32).
- node-name** A character string that contains a node name. Entries in a job tracking file for this node are removed. Can contain the following special value:
- \*LOCAL** The node where the procedure is being run is used.
- If this parameter is omitted, the node name is not used to limit entries to be removed.
- job-queue-library** A character string that contains a job queue library name. Entries in a job tracking file for a job queue in this library are removed.
- If this parameter is omitted, the job queue library name is not used to limit entries to be removed.
- job-queue** A character string that contains a job queue name. Entries in a job tracking file for a job queue with this name are removed.
- If this parameter is omitted, the job queue name is not used to limit entries to be removed.
- internal-job-identifier** A binary string that contains an internal job identifier. Entries in a job tracking file with this internal job identifier on *node-name* are removed.
- When *internal-job-identifier* is specified, *node-name* must be specified. *job-queue-library* and *job-queue* must not be specified.
- If this parameter is omitted, the internal job identifier is not used to limit entries to be removed.
- routing-step** An integer that contains a routing step number. Entries in a job tracking file with this routing step and *internal-job-identifier* on *node-name* are removed.

When *routing-step* is specified, *internal-job-identifier* and *node-name* must be specified. *job-queue-library* and *job-queue* must not be specified.

If this parameter is omitted, the routing step number is not used to limit entries to be removed.

## Examples

- Clear all tracked job information from the job tracking file in \*SYSBAS.

```
CALL QSYS2.CLEAR_TRACKED_JOB_INFO(IASP_NAME => '*SYSBAS');
```

- Clear tracked job information for all jobs submitted to any job queue in library MYLIB on any node.

```
CALL QSYS2.CLEAR_TRACKED_JOB_INFO(IASP_NAME => '*SYSBAS',
 JOB_QUEUE_LIBRARY => 'MYLIB');
```

- Clear tracked job information for all jobs submitted to any job queue named MYJOBQ in any library on any node.

```
CALL QSYS2.CLEAR_TRACKED_JOB_INFO(IASP_NAME => '*SYSBAS',
 JOB_QUEUE => 'MYJOBQ');
```

- Clear tracked job information for all jobs submitted to job queue MYJOBQ in library MYLIB on the local node.

```
CALL QSYS2.CLEAR_TRACKED_JOB_INFO(IASP_NAME => '*SYSBAS',
 NODE_NAME => '*LOCAL',
 JOB_QUEUE_LIBRARY => 'MYLIB',
 JOB_QUEUE => 'MYJOBQ');
```

- Clear tracked job information for a specific job on the local node.

```
CALL QSYS2.CLEAR_TRACKED_JOB_INFO(IASP_NAME => '*SYSBAS',
 NODE_NAME => '*LOCAL',
 INTERNAL_JOB_IDENTIFIER => BX'0000000100142F00AAE4AE8F89E30001');
```

- Clear tracked job information for routing step 2 of a specific job on the local node.

```
CALL QSYS2.CLEAR_TRACKED_JOB_INFO(IASP_NAME => '*SYSBAS',
 NODE_NAME => '*LOCAL',
 INTERNAL_JOB_IDENTIFIER => BX'0000000100142F00AAE4AE8F89E30001',
 ROUTING_STEP => 2);
```

## COMMUNICATIONS\_ENTRY\_INFO view

The COMMUNICATIONS\_ENTRY\_INFO view returns information about subsystem communications entries.

The values returned for the columns in the view are closely related to the values returned by the Display Communications Entries and Display Remote Location Name Entries panels accessed through the DSPSBSD (Display Subsystem Description) CL command and by the List Subsystem Entries (QWDLBSBE) API.

**Authorization:** The caller must have:

- \*EXECUTE authority to the library containing the subsystem description, and
- \*USE authority to the subsystem description.

The following table describes the columns in the view. The system name is COMM\_INFO. The schema is QSYS2.

Table 267. COMMUNICATIONS\_ENTRY\_INFO view

| Column Name                   | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| JOB_DESCRIPTION     | JOBID              | VARCHAR(10)             | <p>The name of the job description used when a job is started as a result of receiving a program start request and processed through this communications entry. Can contain the following special value:</p> <p><b>*USRPRF</b> The job description name that is specified in the user profile of the user that made the program start request is used for jobs that are processed through this communications entry.</p>                                                                                                                                                                   |
| DEFAULT_USER        | DFT_USER           | VARCHAR(10)<br>Nullable | <p>The name of the default user profile used for evoke requests that enter the subsystem through this entry and contain no security information. Can contain the following special value:</p> <p><b>*SYS</b> All user program start requests are treated the same as if no user profile is specified as the default. For program start requests that are sent by system functions, the request runs under a predetermined user profile if a user profile is not specified on the program start request.</p> <p>Contains the null value if no user profile is specified as the default.</p> |
| MAXIMUM_ACTIVE_JOBS | MAX_ACTIVE         | INTEGER<br>Nullable     | <p>The maximum number of jobs that can be active at the same time through this entry.</p> <p>Contains the null value if the entry specifies *NOMAX, indicating that there is no maximum.</p>                                                                                                                                                                                                                                                                                                                                                                                               |

## Example

- List all the communications entries defined for the QCMN subsystem.

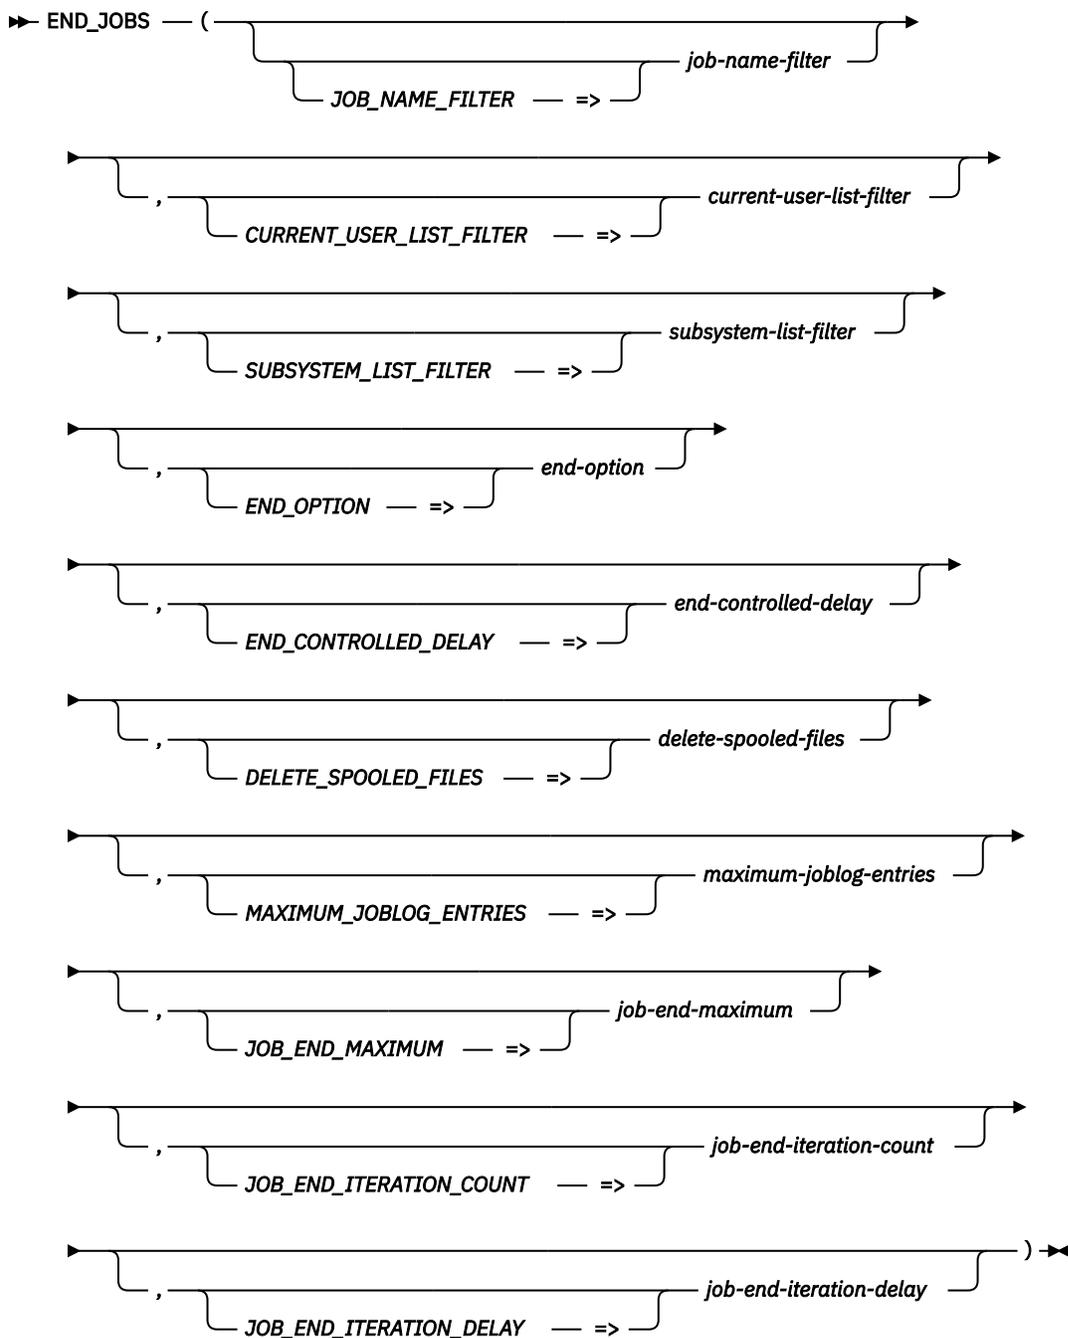

```
SELECT *
FROM QSYS2.COMMUNICATIONS_ENTRY_INFO
WHERE SUBSYSTEM_DESCRIPTION_LIBRARY = 'QSYS' AND
SUBSYSTEM_DESCRIPTION = 'QCMN';
```

## END\_JOBS procedure

The END\_JOBS procedure ends a set of active jobs specified by a set of filters.

This procedure uses the End job (ENDJOB) CL command to end the selected jobs in controlled groups. This can prevent the system from being overwhelmed by a huge number of requests at the same time.

**Authorization:** See Note below.

The schema is SYSTOOLS.

**job-name-filter** A character string expression that contains an unqualified job name to use to determine the jobs to be ended.  
 The special value of \*ALL indicates that all jobs are eligible to be ended. This is the default.  
 When this parameter is not specified or has a value of \*ALL, a value must be provided for *current-user-list-filter* or *subsystem-list-filter*.

**current-user-list-filter** A character string expression that contains a list of up to 10 user profile names separated by exactly one comma. The filter determines which current user values to use to find jobs to be ended.  
 If this parameter is not specified, jobs for all users are eligible to be ended.

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b><i>subsystem-list-filter</i></b>   | A character string expression that contains a list of up to 25 subsystem names separated by exactly one comma. The filter determines which subsystems to use to find jobs to be ended.<br>If this parameter is not specified, jobs in all subsystems are eligible to be ended.                                                                                                                                                                                                                                                                                            |
| <b><i>end-option</i></b>              | How to end each job.<br><br><b>CONTROLLED</b> The job ends in a controlled manner. This allows the program running to perform end-of-job processing. This is the default.<br><br><b>IMMEDIATE</b> The job ends immediately and the system performs end-of-job cleanup.                                                                                                                                                                                                                                                                                                    |
| <b><i>end-controlled-delay</i></b>    | When <i>end-option</i> is CONTROLLED, the number of seconds to wait before ending a job with the IMMEDIATE option.<br>The value can be from 1 to 999999. The default is 30.                                                                                                                                                                                                                                                                                                                                                                                               |
| <b><i>delete-spooled-files</i></b>    | Whether the spooled files generated by the job being ended are kept or deleted.<br><br><b>NO</b> The spooled files created by the job being ended are kept for normal processing by a writer. When the job ends, the spooled file action (SPLFACN) job attribute determines whether spooled files are detached from the job or kept with the job. This is the default.<br><br><b>YES</b> The spooled files created by the job being ended and which are on output queues in the library name space of the thread ending the jobs are deleted. The job log is not deleted. |
| <b><i>maximum-joblog-entries</i></b>  | The maximum number of entries in the message queue of the job being ended that are written to the job log.<br><br><b>integer</b> The maximum number of messages that can be written to the job log. A value of 0 indicates that no job log should be generated.<br><br><b>*NOMAX</b> All messages on the job message queue are written to the job log.<br><br><b>*SAME</b> The job's message logging limit does not change. This is the default.                                                                                                                          |
| <b><i>job-end-maximum</i></b>         | The maximum number of jobs to end. The default is no maximum.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b><i>job-end-iteration-count</i></b> | The maximum number of jobs to end in a single iteration. The default is 100 jobs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b><i>job-end-iteration-delay</i></b> | The number of seconds to delay between end job iterations. The default is 60 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Note

This procedure is provided in the SYSTOOLS schema as an example of how to end a group of jobs. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar procedures, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

## Example

- Find and end all the active jobs with a job name of BATCHTEST. For every job, end using the controlled option, save any spooled files, and do not generate a job log. With the knowledge that there are a limited

number of jobs with this name, all of them will be ended in a single iteration using the default iteration size of 100.

```
CALL SYSTOOLS.END_JOBS(JOB_NAME_FILTER => 'BATCTEST',
 END_OPTION => 'CONTROLLED',
 DELETE_SPOOLED_FILES => 'NO',
 MAXIMUM_JOBLOG_ENTRIES => 0);
```

- Find and end all the active jobs in the QBATCH subsystem that ANGELA is running with a job name of RUNAWAY. End 20 jobs at a time, with a 15 second delay in between requests to end groups of 20 jobs. For every job, end using the immediate option, do not save any spooled files, and do not generate a job log.

```
CALL SYSTOOLS.END_JOBS(JOB_NAME_FILTER => 'RUNAWAY',
 CURRENT_USER_LIST_FILTER => 'ANGELA',
 SUBSYSTEM_LIST_FILTER => 'QBATCH',
 END_OPTION => 'IMMEDIATE',
 DELETE_SPOOLED_FILES => 'YES',
 MAXIMUM_JOBLOG_ENTRIES => 0,
 JOB_END_ITERATION_COUNT => 20,
 JOB_END_ITERATION_DELAY => 15);
```

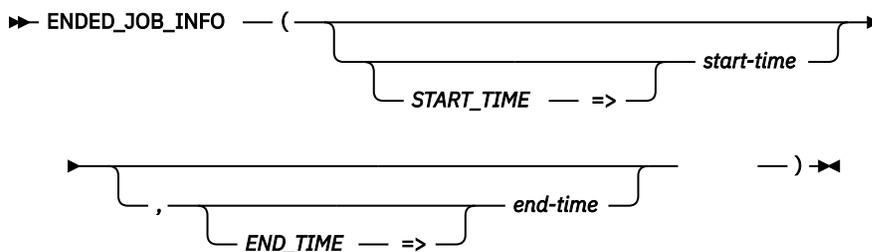

- Find and end up to 2000 active jobs in the QBATCH subsystem that ANGELA is running with a job name of RUNAWAY. End 50 jobs at a time, with a 30 second delay in between requests to end groups of 50 jobs. For every job, end using the immediate option, do not save any spooled files, and do not generate a job log.

```
CALL SYSTOOLS.END_JOBS(JOB_NAME_FILTER => 'RUNAWAY',
 CURRENT_USER_LIST_FILTER => 'ANGELA',
 SUBSYSTEM_LIST_FILTER => 'QBATCH',
 END_OPTION => 'IMMEDIATE',
 DELETE_SPOOLED_FILES => 'YES',
 MAXIMUM_JOBLOG_ENTRIES => 0,
 JOB_END_MAXIMUM => 2000,
 JOB_END_ITERATION_COUNT => 50,
 JOB_END_ITERATION_DELAY => 30);
```

## ENDED\_JOB\_INFO table function

The ENDED\_JOB\_INFO table function returns information about jobs that have ended. This information is gathered from CPF1164 messages recorded in the history log.

**Authorization:** See Note below.

The schema is SYSTOOLS.

**start-time** A timestamp expression that indicates the starting timestamp to use for returning ended job information.

If this parameter is omitted, the default of CURRENT DATE - 1 DAY is used.

**end-time** A timestamp expression that indicates the ending timestamp to use for returning ended job information.

If this parameter is omitted, the default of '9999-12-30-00.00.00.000000' is used.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 268. ENDED\_JOB\_INFO table function

| Column Name       | Data Type     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MESSAGE_TIMESTAMP | TIMESTAMP     | The timestamp when the CPF1164 message was sent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| FROM_USER         | VARCHAR(10)   | The user name of the job from which the CPF1164 message was sent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Table 268. ENDED\_JOB\_INFO table function (continued)

| Column Name                  | Data Type    | Description                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SECONDARY_ENDING_CODE        | SMALLINT     | The job's secondary ending code.<br><br><b>0</b> No secondary ending code<br><b>100</b> Disconnect time interval exceeded<br><b>101</b> Session device deleted<br><b>102</b> Error calling Disconnect Job (DSCJOB)<br><b>300</b> Device error and DEVRCYACN set to *ENDJOB<br><b>301</b> Job ended due to looping on device errors                                                                                    |
| SECONDARY_ENDING_CODE_DETAIL | VARCHAR(100) | Descriptive text corresponding to SECONDARY_ENDING_CODE.                                                                                                                                                                                                                                                                                                                                                              |
| JOB_ENTERED_SYSTEM_TIME      | TIMESTAMP(0) | The time the job entered the system.<br>Returns the null value if the value is not available.                                                                                                                                                                                                                                                                                                                         |
| JOB_ACTIVE_TIME              | TIMESTAMP(0) | The time the job started to run.<br>Returns the null value if the value is not available.                                                                                                                                                                                                                                                                                                                             |
| TOTAL_RESPONSE_TIME          | INTEGER      | The total response time for an interactive job.                                                                                                                                                                                                                                                                                                                                                                       |
| SUBSYSTEM                    | VARCHAR(10)  | Subsystem where the job was run.                                                                                                                                                                                                                                                                                                                                                                                      |
| INTERACTIVE_TRANSACTIONS     | INTEGER      | The total number of operator interactions, such as pressing the Enter key, for the job.                                                                                                                                                                                                                                                                                                                               |
| SYNC_AUX_IO_COUNT            | INTEGER      | The number of synchronous (physical) disk I/O operations performed by the job. This value is the sum of the synchronous database and non-database reads and writes.                                                                                                                                                                                                                                                   |
| JOB_TYPE                     | VARCHAR(11)  | The type of job.<br><br><b>AUTOSTART</b> The job is an autostart job.<br><b>BATCH</b> The job is a batch job.<br><b>INTERACTIVE</b> The job is an interactive job.<br><b>MONITOR</b> The job is a subsystem monitor job.<br><b>READER</b> The job is a spooled reader job.<br><b>SCPF</b> The job is the SCPF system job.<br><b>SYSTEM</b> The job is a system job.<br><b>WRITER</b> The job is a spooled writer job. |
| PEAK_TEMPORARY_STORAGE       | INTEGER      | The maximum temporary storage, in megabytes, used by the job.                                                                                                                                                                                                                                                                                                                                                         |

## Note

This function is provided in the SYSTOOLS schema as an example of how to extract information from message substitution variables. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

## Example

List the 10 jobs from yesterday and today that were the top consumers of temporary storage.

```
SELECT FROM_USER, FROM_JOB, PEAK_TEMPORARY_STORAGE, JOB_ACTIVE_TIME
FROM TABLE (SYSTOOLS.ENDED_JOB_INFO())
ORDER BY PEAK_TEMPORARY_STORAGE DESC
LIMIT 10;
```

## GET\_JOB\_INFO table function

The GET\_JOB\_INFO table function returns one row containing the information about a specific job.

**Authorization:** None required for a job where the caller's user profile is the same as the job user identity of the job for which the information is being returned.

Otherwise, the caller must have either \*JOBCTL special authority, or be authorized to the QIBM\_DB\_SQLADM or QIBM\_DB\_SYSMON function usage identifiers.

```

▶▶ GET_JOB_INFO ((job-name)
 (ignore-errors))

```

V\_JOB\_NAME    =>    job-name  
 V\_IGNORE\_ERRORS    =>    ignore-errors

The schema is QSYS2.

**job-name** A character or graphic string expression that identifies the name of a job. Two forms of a job name are supported.

1. A fully qualified job name in the form *job-number/job-user/job-name*.
2. The first 10 characters are the job name, the second 10 characters are the user name, and the last 6 characters are the job number.

The special value of '\*' indicates the current job.

**ignore-errors** A character or graphic string expression that identifies what to do when an error is encountered.

**NO** An error is returned. This is the default.

**YES** A warning is returned. No row is returned when an error is encountered.

The result of the function is a table containing a single row with the format shown in the following table. All the columns are nullable.

Table 269. GET\_JOB\_INFO table function

| Column Name         | Data Type | Description                                                                                                                                                                                                                                                                                   |
|---------------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V_JOB_STATUS        | CHAR(10)  | Status of the job.<br><br><b>*ACTIVE</b> Job is active. It could be a group job, system request job, or disconnected job.<br><b>*JOBQ</b> Job is currently on job queue.<br><b>*OUTQ</b> Job has completed running but has output on an output queue or the job log has not yet been written. |
| V_ACTIVE_JOB_STATUS | CHAR(4)   | The active status of the initial thread of the job.<br><br>For the list of values see <a href="#">Work Management API Attribute Descriptions in Application Programming Interfaces</a> and search on "Active job status".<br><br>Returns null if the job is in transition or is not active.   |

Table 269. GET\_JOB\_INFO table function (continued)

| Column Name            | Data Type      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V_ACTIVE_JOB_TYPE      | VARCHAR(3)     | Type of active job.<br><br><b>ASJ</b> Autostart<br><b>BCH</b> Batch<br><b>BCI</b> Batch Immediate<br><b>EVK</b> Started by a procedure start request<br><b>INT</b> Interactive<br><b>M36</b> Advanced 36 server job<br><b>MRT</b> Multiple requester terminal<br><b>PDJ</b> Print driver job<br><b>PJ</b> Prestart job<br><b>RDR</b> Spool reader<br><b>SBS</b> Subsystem monitor<br><b>SYS</b> System<br><b>WTR</b> Spool writer<br><br>Returns null if the job type is not available for jobs that are no longer active. |
| V_RUN_PRIORITY         | INTEGER        | The priority at which the job competes for the processing unit relative to other jobs that are active at the same time. The run priority ranges from 1 (highest priority) to 99 (lowest priority).                                                                                                                                                                                                                                                                                                                         |
| V_AUTHORIZATION_NAME   | VARCHAR(10)    | The user profile under which the initial thread is running at this time. For jobs that swap user profiles, this user profile name and the user profile that initiated the job can be different.                                                                                                                                                                                                                                                                                                                            |
| V_SBS_NAME             | CHAR(10)       | Name of subsystem where job is running.<br>Returns null if the job is not active.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| V_CPU_USED             | BIGINT         | The amount of CPU time (in milliseconds) that has been currently used by this job.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| V_TEMP_STORAGE_USED_MB | INTEGER        | The amount of auxiliary storage (in megabytes) that is currently allocated to this job.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| V_AUX_IO_REQUESTED     | BIGINT         | The number of auxiliary I/O requests performed by the job across all routing steps. This includes both database and nondatabase paging.                                                                                                                                                                                                                                                                                                                                                                                    |
| V_PAGE_FAULTS          | BIGINT         | The number of times an active program referenced an address that was not in main storage during the current routing step of the specified job.                                                                                                                                                                                                                                                                                                                                                                             |
| V_CLIENT_WRKSTNNAME    | CHAR(255)      | Value of the SQL CLIENT_WRKSTNNAME special register.<br>Returns null if the job is not active.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| V_CLIENT_APPLNAME      | CHAR(255)      | Value of the SQL CLIENT_APPLNAME special register.<br>Returns null if the job is not active.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| V_CLIENT_ACCTNG        | CHAR(255)      | Value of the SQL CLIENT_ACCTNG special register.<br>Returns null if the job is not active.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| V_CLIENT_PROGRAMID     | CHAR(255)      | Value of the SQL CLIENT_PROGRAMID special register.<br>Returns null if the job is not active.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| V_CLIENT_USERID        | CHAR(255)      | Value of the SQL CLIENT_USERID special register.<br>Returns null if the job is not active.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| V_SQL_STATEMENT_TEXT   | VARCHAR(10000) | Statement text of the last SQL statement to run or the SQL statement that is currently running.<br>Returns null if the job is not active.                                                                                                                                                                                                                                                                                                                                                                                  |

Table 269. GET\_JOB\_INFO table function (continued)

| Column Name                | Data Type   | Description                                                                                                                                                                                                                                                                                                                           |
|----------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V_SQL_STMT_STATUS          | CHAR(8)     | The status of SQL within this job.<br><br><b>ACTIVE</b> An SQL statement is currently running<br><b>COMPLETE</b> At least one SQL statement has run and has completed<br><b>UNKNOWN</b> The SQL status is not known<br>Returns null if no SQL statement has been run.                                                                 |
| V_SQL_STMT_START_TIMESTAMP | TIMESTAMP   | The timestamp of the execution start for an active SQL statement. If there is no active SQL statement, the null value is returned.                                                                                                                                                                                                    |
| V_QUERY_OPTIONS_LIB_NAME   | CHAR(10)    | The name of the QAQQINI options library in use for this job.                                                                                                                                                                                                                                                                          |
| V_CLIENT_IP_ADDRESS        | VARCHAR(45) | Client IP address being used by the job.<br>Returns null when no client IP address exists or the job is using IPv6.                                                                                                                                                                                                                   |
| V_PJ_REUSE_COUNT           | INTEGER     | The number of times the prestart job has been used. The prestart job reuse count is incremented when a disconnect is processed for a prestart job. When the prestart job reuse count exceeds the prestart job maximum number of uses, the job is ended.<br>Returns null if the job is not active or if the job is not a prestart job. |
| V_PJ_MAXUSE_COUNT          | INTEGER     | The maximum number of times the prestart job can be used before it is ended. A value of -1 is returned for *NOMAX.<br>Returns null if the job is not active or if the job is not a prestart job.                                                                                                                                      |

## Example

Return information about job 347117/QUSER/QZDASOINIT.

```
SELECT * FROM TABLE(QSYS2.GET_JOB_INFO('347117/QUSER/QZDASOINIT'));
```

## JOB\_DESCRIPTION\_INFO view

The JOB\_DESCRIPTION\_INFO view returns information about job descriptions.

The values returned for the columns in the view are closely related to the values returned by the Display Job Description (DSPJOBDD) CL command and the [Retrieve Job Description Information \(QWDRJOBDD\) API](#).

**Authorization:** The caller must have:

- \*EXECUTE authority to the library containing the job description, and
- \*OBJOPR and \*READ authorities to the job description.

The following table describes the columns in the view. The system name is JOBDD\_INFO. The schema is QSYS2.

Table 270. JOB\_DESCRIPTION\_INFO view

| Column Name             | System Column Name | Data Type        | Description                                                                                                                                                                        |
|-------------------------|--------------------|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JOB_DESCRIPTION_LIBRARY | JOBDLIB            | VARCHAR(10)      | The name of the library in which the job description resides.                                                                                                                      |
| JOB_DESCRIPTION         | JOBDD              | VARCHAR(10)      | The name of the job description about which information is being returned.                                                                                                         |
| AUTHORIZATION_NAME      | USER_NAME          | VARCHAR(10)      | The name of the user profile associated with this job description. Can contain the following special value:<br><br><b>*RQD</b> A user name is required to use the job description. |
| JOB_DATE                | JOB_DATE           | DATE<br>Nullable | The date that will be assigned to jobs using this job description when they are started.<br><br>Contains the null value if this job will use the QDATE system value.               |

Table 270. JOB\_DESCRIPTION\_INFO view (continued)

| Column Name          | System Column Name | Data Type                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|--------------------|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACCOUNTING_CODE      | ACGCDE             | VARCHAR(15)               | An identifier assigned to jobs that use this job description. This code is used to collect system resource use information. Can contain the following special value:<br><br><b>*USRPRF</b> The accounting code used for jobs using this job description is obtained from the job's user profile.                                                                                                                                                                                                              |
| ROUTING_DATA         | RTGDTA             | VARCHAR(80)               | The routing data that is used with this job description to start jobs. Can contain one of the following special values:<br><br><b>QCMDI</b> The default routing data QCMDI is used by the IBM-supplied interactive subsystem to route the job to the IBM-supplied control language processor QCMD in the QSYS library.<br><br><b>*RQSDTA</b> Up to the first 80 characters of the request data specified in the request data field are used as the routing data for the job.                                  |
| REQUEST_DATA         | RQSDTA             | VARCHAR(256)<br>Nullable  | The request data that is placed as the last entry in the job's message queue for jobs that use this job description. Can contain the following special value:<br><br><b>*RTGDTA</b> The data specified in the routing data parameter is placed as the last entry in the job's message queue.<br><br>Contains the null value if no request data is placed in the job's message queue.                                                                                                                          |
| LIBRARY_LIST_COUNT   | LIBL_COUNT         | INTEGER                   | The number of libraries in the user portion of the initial library list.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| LIBRARY_LIST         | LIBL               | VARCHAR(2750)<br>Nullable | The initial library list that is used for jobs that use this job description. Only the libraries in the user portion of the library list are included. The list is an array of 11 character entries. Each entry contains a ten character name followed by one blank. Can contain the following special value:<br><br><b>*SYSVAL</b> The jobs using this job description will use the library list specified by the QUSRLIBL system value.<br><br>Contains the null value if there is no initial library list. |
| JOB_SWITCHES         | SWITCHES           | CHAR(8)                   | The initial settings for a group of eight job switches used by jobs that use this job description. These switches can be set or tested in a program and used to control a program's flow. The possible values are '0' (off) and '1' (on).                                                                                                                                                                                                                                                                     |
| TEXT_DESCRIPTION     | TEXT               | VARCHAR(50)<br>Nullable   | The user text, if any, used to briefly describe the job description.<br>Contains the null value if there is no descriptive text.                                                                                                                                                                                                                                                                                                                                                                              |
| JOB_QUEUE_LIBRARY    | JOBQLIB            | VARCHAR(10)               | The library of the job queue into which batch jobs using this job description are placed.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| JOB_QUEUE            | JOBQ               | VARCHAR(10)               | The name of the job queue into which batch jobs using this job description are placed.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| JOB_QUEUE_PRIORITY   | JOBQ_PRI           | SMALLINT                  | The scheduling priority of each job that uses this job description. The highest priority is 1 and the lowest priority is 9.                                                                                                                                                                                                                                                                                                                                                                                   |
| HOLD_ON_JOB_QUEUE    | JOBQ_HOLD          | VARCHAR(4)                | Whether jobs using this job description are put on the job queue with a status of held.<br><br><b>*NO</b> Jobs using this job description are not put on the job queue as held.<br><br><b>*YES</b> Jobs using this job description are put on the job queue as held.                                                                                                                                                                                                                                          |
| OUTPUT_QUEUE_LIBRARY | OUTQLIB            | VARCHAR(10)<br>Nullable   | The name of the library in which the output queue resides.<br>Contains the null value if OUTPUT_QUEUE is a special value.                                                                                                                                                                                                                                                                                                                                                                                     |

| SYNTAX_CHECK_SEVERITY         | SYNTAX             | SMALLINT<br>Nullable | <p>Whether requests placed on the job's message queue are checked for syntax as CL commands, and the message severity that causes a syntax error to end processing of a job. The possible values are:</p> <p><b>0-99</b> Specifies the lowest message severity that causes a running job to end. The request data is checked for syntax as CL commands, and, if a syntax error occurs that is greater than or equal to the error message severity specified here, the running of the job that contains the erroneous command is suppressed.</p> <p>Contains the null value if the request data is not checked for syntax as CL commands. This is equivalent to *NOCHK.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| JOB_END_SEVERITY              | JOB_ENDSEV         | SMALLINT             | <p>The message severity level of escape messages that can cause a batch job to end. The batch job ends when a request in the batch input stream sends an escape message whose severity is equal to or greater than this value to the request processing program. The possible values are from 0 through 99.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| JOBLOG_OUTPUT                 | JOBLOG_OUT         | VARCHAR(10)          | <p>How the job log will be produced when the job completes. This does not affect job logs produced when the message queue is full and the job message queue full action specifies *PRTWRAP. Messages in the job message queue are written to a spooled file, from which the job log can be printed, unless the Control Job Log Output (QMHCTLJL) API was used in the job to specify that the messages in the job log are to be written to a database file.</p> <p>The job log output value can be changed at any time until the job log has been produced or removed. To change the job log output value for a job, use the Change Job (QWCHGJJB) API or the Change Job (CHGJOB) command.</p> <p>The job log can be displayed at any time until the job log has been produced or removed. To display the job log, use the Display Job Log (DSPJOBLOG) command.</p> <p>The job log can be removed when the job has completed and the job log has not yet been produced or removed. To remove the job log, use the Remove Pending Job Log (QWTRMVJL) API or the End Job (ENDJOB) command.</p> <p>The possible values are:</p> <p><b>*JOBEND</b> The job log will be produced by the job itself. If the job cannot produce its own job log, the job log will be produced by a job log server. For example, a job does not produce its own job log when the system is processing a Power Down System (PWRDWNSYS) command.</p> <p><b>*JOBLOGSVR</b> The job log will be produced by a job log server. For more information about job log servers, refer to the Start Job Log Server (STRLOGSVR) command.</p> <p><b>*PND</b> The job log will not be produced. The job log remains pending until removed.</p> <p><b>*SYSVAL</b> The value is specified by the QLOGOUTPUT system value.</p> |

| Column Name              | System Column Name | Data Type  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------|--------------------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INQUIRY_MESSAGE_REPLY    | INQ_REPLY          | VARCHAR(8) | <p>How inquiry messages are answered for jobs that use this job description.</p> <p><b>*DFT</b> The system uses the default message reply to answer any inquiry messages issued while the job is running. The default reply is either defined in the message description or is the default system reply.</p> <p><b>*RQD</b> The job requires an answer for any inquiry messages that occur while the job is running.</p> <p><b>*SYSRPYL</b> The system reply list is checked to see if there is an entry for an inquiry message issued while the job is running. If a match occurs, the system uses the reply value for that entry. If no entry exists for that message, the system uses an inquiry message.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| MESSAGE_LOGGING_LEVEL    | LOG_LEVEL          | SMALLINT   | <p>The type of information logged.</p> <p><b>0</b> No messages are logged.</p> <p><b>1</b> All messages sent to the job's external message queue with a severity greater than or equal to the message logging severity are logged. This includes the indication of job start, job end, and job completion status.</p> <p><b>2</b> The following information is logged:</p> <ul style="list-style-type: none"> <li>• Level 1 information.</li> <li>• Request messages that result in a high-level message with a severity code greater than or equal to the logging severity cause the request message and all associated messages to be logged.</li> </ul> <p><b>Note:</b> A high-level message is one that is sent to the program message queue of the program that receives the request message. For example, QCMD is an IBM-supplied request processing program that receives request messages.</p> <p><b>3</b> The following information is logged:</p> <ul style="list-style-type: none"> <li>• Level 1 and 2 information.</li> <li>• All request messages.</li> <li>• Commands run by a CL program are logged if it is allowed by the logging of CL programs job attribute and the log attribute of the CL program.</li> </ul> <p><b>4</b> The following information is logged:</p> <ul style="list-style-type: none"> <li>• All request messages and all messages with a severity greater than or equal to the message logging severity, including trace messages.</li> <li>• Commands run by a CL program are logged if it is allowed by the logging of CL programs job attribute and the log attribute of the CL program.</li> </ul> |
| MESSAGE_LOGGING_SEVERITY | LOG_SEV            | SMALLINT   | <p>The severity level that is used in conjunction with the logging level to determine which error messages are logged in the job log. The possible values are from 0 through 99.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| MESSAGE_LOGGING_TEXT     | LOG_TEXT           | VARCHAR(7) | <p>The level of message text that is written in the job log when a message is logged according to the logging level and logging severity.</p> <p><b>*MSG</b> Only the message text is written to the job log.</p> <p><b>*NOLIST</b> If the job ends normally, no job log is produced. If the job ends abnormally (if the job end code is 20 or higher), a job log is produced. The messages that appear in the job log contain both the message text and the message help.</p> <p><b>*SECLVL</b> Both the message text and the message help (cause and recovery) of the error message are written to the job log.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| LOG_CL_PROGRAM_COMMANDS | LOG_CL             | VARCHAR(4)  | <p>Whether or not commands are logged for CL programs that are run.</p> <p><b>*NO</b> CL programs are not logged.</p> <p><b>*YES</b> CL programs are logged.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| DEVICE_RECOVERY_ACTION  | DEVRECOVER         | VARCHAR(13) | <p>The action to take when an I/O error occurs for the interactive job's requesting program device.</p> <p><b>*DSCENDRQS</b> Disconnects the job when an I/O error occurs. When the job reconnects, the system sends the End Request (ENDRQS) command to return control to the previous request level.</p> <p><b>*DSCMSG</b> Disconnects the job when an I/O error occurs. When the job reconnects, the system sends a message to the application program indicating the job has reconnected and that the workstation device has recovered.</p> <p><b>*ENDJOB</b> Ends the job when an I/O error occurs. A message is sent to the job's log and to the history log (QHST). This message indicates that the job ended because of a device error.</p> <p><b>*ENDJOBNO LIST</b> Ends the job when an I/O error occurs. There is no job log produced for the job. The system sends a message to the history log (QHST). This message indicates that the job ended because of a device error.</p> <p><b>*MSG</b> Signals the I/O error message to the application and lets the application program perform error recovery.</p> <p><b>*SYSVAL</b> The value in the system value QDEVRCYACN at the time the job is started is used as the device recovery action for this job description.</p> |
| TIME_SLICE_END_POOL     | TIME_SLICE         | VARCHAR(7)  | <p>Whether interactive jobs using this job description should be moved to another main storage pool when they reach time-slice end.</p> <p><b>*BASE</b> The job is moved to the base pool when it reaches time-slice end.</p> <p><b>*NONE</b> The job is not moved when it reaches time-slice end.</p> <p><b>*SYSVAL</b> The system value is used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| ALLOW_MULTIPLE_THREADS  | ALWMLTTHD          | VARCHAR(4)  | <p>Whether or not the job is allowed to run with multiple user threads. This attribute does not prevent the operating system from creating system threads in the job. This attribute is not allowed to be changed once a job starts. This attribute applies to autostart jobs, prestart jobs, batch jobs submitted from job schedule entries, and jobs started by using the Submit Job (SBMJOB) and Batch Job (BCHJOB) commands. This attribute is ignored when starting all other types of jobs. This attribute should be set to *YES only in job descriptions that are used exclusively with functions that create multiple user threads.</p> <p><b>*NO</b> The job is not allowed to run with multiple user threads.</p> <p><b>*YES</b> The job is allowed to run with multiple user threads.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

Table 270. JOB\_DESCRIPTION\_INFO view (continued)

| Column Name      | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                                                  |
|------------------|--------------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORKLOAD_GROUP   | WRK_GROUP          | VARCHAR(10)<br>Nullable | The name of the workload group that is used for jobs that use this job description. Can contain the following special value:<br><br><b>*SBSD</b> The workload group named in the subsystem description is used.<br><br>Contains the null value if jobs using this job description do not have a defined workload group.      |
| ASPGRP           | ASPGRP             | VARCHAR(10)<br>Nullable | The name of the ASP group. This is the name of the primary ASP device in an ASP group or the name of an ASP device description. This specifies the initial ASP group setting for jobs using this job description.<br><br>Contains the null value if jobs using this job description do not have an initial ASP group.        |
| DDM_CONVERSATION | DDM_CONV           | VARCHAR(5)              | Whether the Distributed Data Management conversations are kept or dropped when they are not being used. The possible values are:<br><br><b>*DROP</b> The system ends a DDM-allocated conversation when there are no users.<br><br><b>*KEEP</b> The system keeps DDM conversation connections active when there are no users. |

## Examples

- Review information about the job queues associated with each job description.

```
SELECT JOB_DESCRIPTION_LIBRARY, JOB_DESCRIPTION,
 JOB_QUEUE_LIBRARY, JOB_QUEUE, JOB_QUEUE_PRIORITY
FROM QSYS2.JOB_DESCRIPTION_INFO;
```

- Find the job descriptions that have APPLIB1 in their library list

```
SELECT JOB_DESCRIPTION_LIBRARY, JOB_DESCRIPTION, LIBRARY_LIST
FROM QSYS2.JOB_DESCRIPTION_INFO
WHERE LIBRARY_LIST LIKE '%APPLIB1%';
```

- Examine the library lists for every job description.

Since the library list column returns a character string containing a list of libraries, to see the individual library names it needs to be broken apart. To do this, you can create a table function that takes the library list string and returns a list of library names.

```
CREATE OR REPLACE FUNCTION QGPL.GET_LIB_NAMES(JOBD_LIBL VARCHAR(2750),
 JOBD_LIBL_CNT INT)
RETURNS TABLE(LIBL_POSITION INT, LIBRARY_NAME VARCHAR(10))
BEGIN
 DECLARE IN_POS INT;
 DECLARE LIB_CNT INT;
 SET IN_POS = 1;
 SET LIB_CNT = 1;
 WHILE LIB_CNT <= JOBD_LIBL_CNT
 DO
 PIPE (LIB_CNT, RTRIM((SUBSTR(JOBD_LIBL, IN_POS, 10))));
 SET IN_POS = IN_POS + 11;
 SET LIB_CNT = LIB_CNT + 1;
 END WHILE;
 RETURN;
END;
```

Now this function can be used to return the list of library names.

```
SELECT JOB_DESCRIPTION, JOB_DESCRIPTION_LIBRARY, LIBL_POSITION, LIBRARY_NAME
FROM QSYS2.JOB_DESCRIPTION_INFO,
 TABLE (QGPL.GET_LIB_NAMES(LIBRARY_LIST, LIBRARY_LIST_COUNT)) X;
```

## JOB\_INFO table function

The JOB\_INFO table function returns one row for each job meeting the selection criteria.

It returns information similar to what is returned by the Work with User Jobs (WRKUSRJOB), Work with Subsystem Jobs (WRKSBSJOB), and Work with Submitted Jobs (WRKSBMJOB) CL commands and the List Job (QUSLJOB) API.

**Authorization:** None required.

The schema is QSYS2.

### **job-status-filter**

A character or graphic string expression that specifies the value to use as the job status filtering criteria. The string must be one of the following special values:

- \*ALL** Jobs of any status including jobs on job queues, active jobs, and jobs on an output queue.
- \*ACTIVE** Jobs that are active. You can use the QSYS2.ACTIVE\_JOB\_INFO table function to get additional details for these jobs.
- \*JOBQ** Jobs that are not active because they are waiting on a job queue.
- \*OUTQ** Jobs that have completed execution and have output on an output queue.

If this parameter is not provided, a value of **\*ALL** is used.

### **job-type-filter**

A character or graphic string expression that specifies the value to use as the job type filtering criteria. The string must be one of the following special values:

- \*ALL** All types of user jobs, including interactive jobs and batch jobs.
- \*BATCH** Only batch user jobs, including prestart jobs, batch immediate jobs, and autostart jobs.
- \*INTERACT** Only interactive user jobs.

If this parameter is not provided, a value of **\*ALL** is used.

**job-subsystem-filter**

A character or graphic string expression that specifies the subsystem value to use as the job subsystem filtering criteria. The string can be a subsystem name or the following value:

**\*ALL** All jobs in all subsystems, including jobs that are on job queues and on output queues.

If a subsystem name is provided, only active jobs are found.

If this parameter is not provided, a value of **\*ALL** is used.

**job-user-filter**

The USER special register or a character or graphic string expression that specifies the user profile name to use as the job user filtering criteria.

The string can be a user name or one of the following special values:

**\*ALL** All jobs being processed under all user names.

**\*USER** The user part of the qualified job name.

The USER special register is specified as a non-string value. It represents the current user of the job invoking the function.

If this parameter is not provided, the value of the USER special register is used.

**job-submitter-filter**

A character or graphic string expression that specifies the type of submitted jobs to return. The string must be one of the following values:

**\*ALL** All submitted jobs.

**\*JOB** Jobs that were submitted from the same job that is invoking this function.

**\*USER** Jobs that were submitted from a job having the same user profile as the job invoking this function.

**\*WRKSTN** Jobs that were submitted from the same work station as the job invoking this function.

If this parameter is not provided, a value of **\*ALL** is used.

**job-name-filter**

A character string expression that contains an unqualified job name that determines the job information to be returned.

The string can be a job name or the following special value:

**\*ALL** All jobs being processed under all job names.

If this parameter is not provided, a value of **\*ALL** is used.

**Restrictions:**

- If a value other than **\*ALL** is specified for *job-submitter-filter*, you must specify **\*ALL** for *job-subsystem-filter*, *job-user-filter*, and *job-name-filter*.

**Notes:**

- Jobs submitted with **\*NO** specified for the Allow display by WRKSBMJOB (DPSB MJOB) parameter of the SB MJOB command are not returned by this table function.

For each of the WRKSB MJOB, WRKSBSJOB, and WRKUSRJOB CL commands shown below, the corresponding invocation of JOB\_INFO will return the same list of jobs. Note that to get exact equivalence, predicates must be added to some queries to achieve equivalent results:

- For equivalence with WRKUSRJOB, a query must always include the predicate WHERE JOB\_TYPE NOT IN ('SBS','SYS','RDR','WTR')

- For equivalence with WRKSBSJOB SBS(\*OUTQ) or WRKSBSJOB SBS(\*ALL), a query must always include the predicate WHERE JOB\_TYPE NOT IN ('SBS','SYS')

|-------------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JOB_STATUS  | VARCHAR(6) | <p>The status of the job.</p> <p><b>ACTIVE</b> The job has started, and it can use system resources (processing unit, main storage, and so on). This does not guarantee that the job is currently running, however. For example, an active job may be in one of the following states where it is not in a position to use system resources:</p> <ul style="list-style-type: none"> <li>• The Hold Job (HLDJOB) command holds the job; the Release Job (RLSJOB) command allows the job to run again.</li> <li>• The Transfer Group Job (TFRGRPJOB) or Transfer Secondary Job (TFRSECJOB) command suspends the job. When control returns to the job, the job can run again.</li> <li>• The job is disconnected using the Disconnect Job (DSCJOB) command. When the interactive user signs back on, thereby connecting back into the job, the job can run again.</li> <li>• The job is waiting for any reason. For example, when the job receives the reply for an inquiry message, the job can start running again.</li> </ul> <p><b>JOBQ</b> The job is currently on a job queue. The job possibly was previously active and was placed back on the job queue because of the Transfer Job (TFRJOB) or Transfer Batch Job (TFRBCHJOB) command, or the job was never active because it was just submitted.</p> <p><b>OUTQ</b> The job has completed running and has spooled output that has not yet printed or the job's job log has not yet been written.</p> |
| JOB_TYPE    | VARCHAR(3) | <p>The type of job.</p> <p><b>ASJ</b> Autostart</p> <p><b>BCH</b> Batch</p> <p><b>BCI</b> Batch Immediate</p> <p><b>EVK</b> Started by a procedure start request</p> <p><b>INT</b> Interactive</p> <p><b>M36</b> Advanced 36 server job</p> <p><b>MRT</b> Multiple requester terminal</p> <p><b>PDJ</b> Print driver job</p> <p><b>PJ</b> Prestart job</p> <p><b>RDR</b> Spool reader</p> <p><b>SBS</b> Subsystem monitor</p> <p><b>SYS</b> System</p> <p><b>WTR</b> Spool writer</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Column Name                  | Data Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TIME_SLICE                   | INTEGER     | <p>The maximum amount of processor time, in milliseconds, given to each thread in this job before other threads in this job and in other jobs are given the opportunity to run. The time slice establishes the amount of time needed by a thread in this job to accomplish a meaningful amount of processing. At the end of the time slice, the thread might be put in an inactive state so that other threads can become active in the storage pool. Values range from 8 through 9999999.</p> <p>Contains the null value if JOB_STATUS is OUTQ or for a job on a job queue if a value has not been set for the job.</p>                                                                                                     |
| JOB_SWITCHES                 | CHAR(8)     | <p>The current setting of the job switches used by this job.</p> <p>Contains the null value no job switches are set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ROUTING_DATA                 | VARCHAR(80) | <p>The routing data that is used to determine the routing entry that identifies the program to start for the routing step.</p> <p>Contains the null value if there is no routing data for this job.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| CCSID                        | INTEGER     | <p>The coded character set identifier (CCSID) used for this job.</p> <p>Contains the null value if no CCSID is defined for this job.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| CHARACTER_IDENTIFIER_CONTROL | VARCHAR(9)  | <p>The character identifier control for the job. This attribute controls the type of CCSID conversion that occurs for display files, printer files, and panel groups. The *CHRIDCTL special value must be specified on the CHRID command parameter on the create, change, or override command for display files, printer files, and panel groups before this attribute will be used.</p> <p><b>*DEV D</b> The *DEV D special value performs the same function as on the CHRID command parameter for display files, printer files, and panel groups.</p> <p><b>*JOBCCSID</b> The *JOBCCSID special value performs the same function as on the CHRID command parameter for display files, printer files, and panel groups.</p> |
| SORT_SEQUENCE_LIBRARY        | VARCHAR(10) | <p>The name or the library that contains the sort sequence table.</p> <p>Contains the null value if no sort sequence table is defined for this job or if SORT_SEQUENCE_NAME is a special value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| SORT_SEQUENCE_NAME           | VARCHAR(10) | <p>The name of the sort sequence table associated with this job.</p> <p>Contains the null value if no sort sequence table is defined for this job.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| LANGUAGE_ID                  | CHAR(3)     | The language identifier associated with this job.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| COUNTRY_ID                   | CHAR(2)     | The country or region identifier associated with this job.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| DATE_FORMAT                  | CHAR(4)     | <p>The date format used for this job.</p> <p><b>*DMY</b> Day, month, year format.</p> <p><b>*JUL</b> Julian format (year and day).</p> <p><b>*MDY</b> Month, day, year format.</p> <p><b>*YMD</b> Year, month, day format.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| DATE_SEPARATOR               | CHAR(1)     | The date separator used for this job.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| TIME_SEPARATOR               | CHAR(1)     | The time separator used for this job.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Column Name                | Data Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DECIMAL_FORMAT             | VARCHAR(6)  | <p>The decimal format used for this job.</p> <p><b>*BLANK</b> Uses a period for a decimal point, a comma for a 3-digit grouping character, and zero-suppress to the left of the decimal point.</p> <p><b>J</b> Uses a comma for a decimal point and a period for a 3-digit grouping character. The zero-suppression character is in the second position (rather than the first) to the left of the decimal notation. Balances with zero values to the left of the comma are written with one leading zero (0,04). The J entry also overrides any edit codes that might suppress the leading zero.</p> <p><b>I</b> Uses a comma for a decimal point, a period for a 3-digit grouping character, and zero-suppress to the left of the decimal point.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| TIME_ZONE_DESCRIPTION_NAME | VARCHAR(10) | The name of the time zone description that is used to calculate local job time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| MESSAGE_LOGGING_LEVEL      | SMALLINT    | <p>The type of information that is logged.</p> <p><b>0</b> No messages are logged.</p> <p><b>1</b> All messages sent to the job's external message queue with a severity greater than or equal to the message logging severity are logged. This includes the indication of job start, job end and job completion status.</p> <p><b>2</b> The following information is logged:</p> <ul style="list-style-type: none"> <li>• Level 1 information</li> <li>• Request messages that result in a high-level message with a severity code greater than or equal to the logging severity cause the request message and all associated messages to be logged.</li> </ul> <p>Note: A high-level message is one that is sent to the program message queue of the program that receives the request message. For example, QCMD is an IBM-supplied request processing program that receives request messages.</p> <p><b>3</b> The following information is logged:</p> <ul style="list-style-type: none"> <li>• Level 1 and 2 information</li> <li>• All request messages</li> <li>• Commands run by a CL program are logged if it is allowed by the logging of CL programs job attribute and the log attribute of the CL program.</li> </ul> <p><b>4</b> The following information is logged:</p> <ul style="list-style-type: none"> <li>• All request messages and all messages with a severity greater than or equal to the message logging severity, including trace messages.</li> <li>• Commands run by a CL program are logged if it is allowed by the logging of CL programs job attribute and the log attribute of the CL program.</li> </ul> |
| MESSAGE_LOGGING_SEVERITY   | SMALLINT    | The severity level that is used in conjunction with the logging level to determine which error messages are logged in the job log. The values range from 0 through 99.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| MESSAGE_LOGGING_TEXT       | VARCHAR(7)  | <p>The level of message text that is written in the job log when a message is logged according to the logging level and logging severity.</p> <p><b>*MSG</b> Only the message text is written to the job log.</p> <p><b>*NOLIST</b> If the job ends normally, no job log is produced. If the job ends abnormally (the job end code is 20 or higher), a job log is produced. The messages that appear in the job log contain both the message text and the message help.</p> <p><b>*SECLVL</b> Both the message text and the message help (cause and recovery) of the error message are written to the job log.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

Table 272. JOB\_INFO table function (continued)

| Column Name             | Data Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOG_CL_PROGRAM_COMMANDS | VARCHAR(4)  | Specifies whether or not commands are logged for CL programs that are run.<br><br><b>*NO</b> Commands are not logged.<br><b>*YES</b> Commands are logged.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| STATUS_MESSAGE          | VARCHAR(7)  | Specifies whether status messages are displayed for this job.<br><br><b>*NONE</b> This job does not display status messages.<br><b>*NORMAL</b> This job displays status messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| INQUIRY_MESSAGE_REPLY   | VARCHAR(8)  | Specifies how the job answers inquiry messages.<br><br><b>*RQD</b> The job requires an answer for any inquiry messages that occur while this job is running.<br><b>*DFT</b> The system uses the default message reply to answer any inquiry messages issued while this job is running. The default reply is either defined in the message description or is the default system reply.<br><b>*SYSRPLY</b> The system reply list is checked to see if there is an entry for an inquiry message issued while this job is running. If a match occurs, the system uses the reply value for that entry. If no entry exists for that message, the system uses an inquiry message. |
| BREAK_MESSAGE           | VARCHAR(7)  | Specifies how this job handles break messages.<br><br><b>*HOLD</b> The message queue holds break messages until a user or program requests them. The work station user uses the Display Message (DSPMSG) command to display the messages; a program must issue a Receive Message (RCVMSG) command to receive a message and handle it.<br><b>*NORMAL</b> The message queue status determines break message handling.<br><b>*NOTIFY</b> The system notifies the job's message queue when a message arrives. For interactive jobs, the audible alarm sounds if there is one, and the message-waiting light comes on.                                                          |
| JOB_LOG_OUTPUT          | VARCHAR(10) | Specifies how the job log will be produced when the job completes.<br><br><b>*JOBEND</b> The job log will be produced by the job itself. If the job cannot produce its own job log, the job log will be produced by a job log server. For example, a job does not produce its own job log when the system is processing a Power Down System (PWRDWN SYS) command.<br><b>*JOBLOGSVR</b> The job log will be produced by a job log server. For more information about job log servers, refer to the Start Job Log Server (STRLOGSVR) command.<br><b>*PND</b> The job log will not be produced. The job log remains pending until removed.                                    |
| JOB_LOG_PENDING         | VARCHAR(3)  | Specifies whether there is a job log that has not yet been written. The writing of the job log may become pending based on the value of the job log output job attribute when the job completes its activity.<br><br><b>NO</b> Job log is not pending.<br><b>YES</b> Job log is pending.                                                                                                                                                                                                                                                                                                                                                                                   |
| OUTPUT_QUEUE_PRIORITY   | SMALLINT    | The output priority for spooled output files that this job produces. The highest priority is 0, and the lowest is 9.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| OUTPUT_QUEUE_LIBRARY    | VARCHAR(10) | The name of the library that contains the default output queue.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| OUTPUT_QUEUE_NAME       | VARCHAR(10) | The name of the default output queue that is used for spooled output produced by this job and the name of the library that contains the output queue. The default output queue is only for spooled printer files that specify *JOB for the output queue.                                                                                                                                                                                                                                                                                                                                                                                                                   |

Table 272. JOB\_INFO table function (continued)

| Column Name            | Data Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| PRINT_TEXT             | VARCHAR(30) | <p>The line of text that is printed at the bottom of each page of printed output for the job.</p> <p>Contains the null value if there is no text defined to print at the bottom of each page.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| DEVICE_NAME            | VARCHAR(10) | <p>The name of the device as identified to the system. For an interactive job it is the device where the job started.</p> <p>Contains the null value if this is not an interactive job.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| DEVICE_RECOVERY_ACTION | VARCHAR(13) | <p>The action taken for interactive jobs when an I/O error occurs for the job's requesting program device.</p> <p><b>*DSCENDRQS</b> Disconnects the job when an I/O error occurs. When the job reconnects, the system sends the End Request (ENDRQS) command to return control to the previous request level.</p> <p><b>*DSCMSG</b> Disconnects the job when an I/O error occurs. When the job reconnects, the system sends an error message to the application program, indicating the job has reconnected and that the work station device has recovered.</p> <p><b>*ENDJOB</b> Ends the job when an I/O error occurs. A message is sent to the job's log and to the history log (QHST) indicating the job ended because of a device error.</p> <p><b>*ENDJOBNO LIST</b> Ends the job when an I/O error occurs. There is no job log produced for the job. The system sends a message to the QHST log indicating the job ended because of a device error.</p> <p><b>*MSG</b> Signals the I/O error message to the application and lets the application program perform error recovery.</p> <p>Contains the null value if this is not an interactive job.</p> |

| DDM_CONVERSATION | VARCHAR(5) | <p>Specifies whether connections using distributed data management (DDM) protocols remain active when they are not being used. The connections include APPC conversations, active TCP/IP connections or Opti-Connect connections.</p> <p><b>*DROP</b> The system ends a DDM connection when there are no users. Examples include when an application closes a DDM file, or when a DRDA application runs a SQL DISCONNECT statement.</p> <p><b>*KEEP</b> The system keeps DDM connections active when there are no users, except for the following:</p> <ul style="list-style-type: none"> <li>• The routing step ends on the source system. The routing step ends when the job ends or when the job is rerouted to another routing step.</li> <li>• The Reclaim Distributed Data Management Conversation (RCLDDMCNV) command or the Reclaim Resources (RCLRSC) command runs.</li> <li>• A communications failure or an internal failure occurs.</li> <li>• A DRDA connection to an application server not running on the system ends.</li> </ul> |
| MODE_NAME        | VARCHAR(8) | <p>The mode name of the advanced program-to-program communications device that started the job. The following special value may be returned:</p> <p><b>*BLANK</b> The mode name is a blank name.</p> <p>Contains the null value if the job is not using advanced program-to-program communications (APPC).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| UNIT_OF_WORK_ID  | CHAR(24)   | <p>The unit of work ID is used to track jobs across multiple systems.</p> <p>Contains the null value if the job is not associated with a source or target system using advanced program-to-program communications (APPC).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| INTERNAL_JOB_ID  | BINARY(16) | The internal job identifier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Examples

- Find all interactive jobs.

```
SELECT * FROM TABLE(QSYS2.JOB_INFO(JOB_TYPE_FILTER => '*INTERACT')) X;
```

- Find jobs submitted by SCOTTF that have not been started.

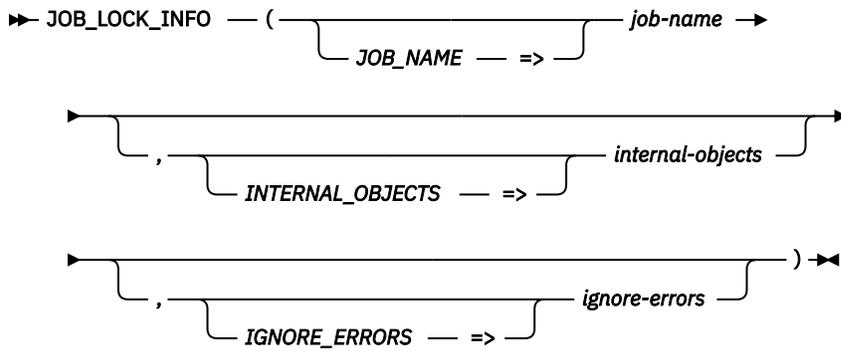

```
SELECT * FROM TABLE(QSYS2.JOB_INFO(JOB_USER_FILTER => 'SCOTTF',
JOB_STATUS_FILTER => '*JOBQ')) X;
```

## JOB\_LOCK\_INFO table function

The JOB\_LOCK\_INFO table function returns a list of objects that have been locked or have lower level locks acquired by the specified job. If the job is not active, no rows are returned.

This information is similar to what is returned by the Retrieve Job Locks (QWCRJBLK) API.

**Authorization:** None required to see information for jobs where the caller's user profile is the same as the job user identity of the job for which the information is being returned. Otherwise, the caller must have \*JOBCTL special authority.

The schema is QSYS2.

**job-name** A character or graphic string expression that identifies the qualified name of a job. The special value of '\*' indicates the current job.

**internal-objects** A character or graphic string expression that indicates whether rows are returned for internal objects.

**NO** Only external objects are returned. This is the default.

**YES** Rows for internal objects and internal space objects are returned in addition to external objects.

**ignore-errors** A character or graphic string expression that identifies what to do when an error is encountered.

**NO** An error is returned.

**YES** A warning is returned.

No row is returned when an error is encountered. This is the default.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 273. JOB\_LOCK\_INFO table function

| Column Name                                            | Data Type   | Description                                                                                                                                                                           |
|--------------------------------------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOCK_CATEGORY                                          | VARCHAR(23) | The type of entity to which this row of lock information applies.                                                                                                                     |
|                                                        |             | <b>EXTERNAL</b> IBM i external object                                                                                                                                                 |
|                                                        |             | <b>EXTERNAL SPACE LOCATION</b> IBM i external object space location                                                                                                                   |
|                                                        |             | <b>INTERNAL</b> Internal system object<br>This type of row is only returned if the <i>internal-objects</i> parameter value is YES.                                                    |
|                                                        |             | <b>INTERNAL SPACE LOCATION</b> Internal system object space location<br>This type of row is only returned if the <i>internal-objects</i> parameter value is YES.                      |
|                                                        |             | <b>LOCK SPACE</b> Lock space object                                                                                                                                                   |
|                                                        |             | <b>MEMBER</b> Member object                                                                                                                                                           |
| Contains the null value if LOCK_CATEGORY is not known. |             |                                                                                                                                                                                       |
| OBJECT_LIBRARY                                         | VARCHAR(10) | The name of the library containing the locked object.<br>Contains the null value if LOCK_CATEGORY is INTERNAL or INTERNAL SPACE LOCATION or if the library name cannot be determined. |

| THREAD_ID                                               | BIGINT      | A value which uniquely identifies a thread within a job holding a thread scope lock or the thread waiting for a lock.<br>Contain the null value if this lock is not thread scoped.                                                                                                        |                                  |
| THREAD_HANDLE                                           | INTEGER     | A value which addresses a particular thread within a job holding a thread scope lock or the thread waiting for a lock.<br>Contain the null value if this lock is not thread scoped.                                                                                                       |                                  |
| ASP_NAME                                                | VARCHAR(10) | The name of the Auxiliary Storage Pool (ASP) that contains the object that is locked.<br>Contains the null value if the name of the ASP device cannot be determined.                                                                                                                      |                                  |
| ASP_NUMBER                                              | INTEGER     | The numeric identifier of the ASP containing the locked object. 1 indicates the system ASP.<br>Contains the null value if the name of the ASP device cannot be determined.                                                                                                                |                                  |
| OBJECT_LOCK_HANDLE                                      | BINARY(64)  | An identifier that can be input to Retrieve Lock Information (QWCRLCKI) API to find additional information about other holders of locks on this object.<br>Contains the null value if additional information cannot be retrieved.                                                         |                                  |
| LOCK_REQUEST_HANDLE                                     | BINARY(64)  | A handle to lock request information. Using the Retrieve Lock Request Information (QWCRLRQI) API and passing in this handle you can retrieve additional information about the program that requested this lock.<br>Contains the null value if additional information cannot be retrieved. |                                  |

### Example

- Retrieve information about locks for the current job.

```
SELECT * FROM TABLE(QSYS2.JOB_LOCK_INFO('*'));
```

## JOB\_QUEUE\_ENTRIES view

The JOB\_QUEUE\_ENTRIES view returns one row for each entry in a job queue.

**Authorization:** See Note below.

The following table describes the columns in the view. The system name is JOBQ\_ENT. The schema is SYSTOOLS.

Table 274. JOB\_QUEUE\_ENTRIES view

| Column Name       | System Column Name | Data type   | Description                                             |
|-------------------|--------------------|-------------|---------------------------------------------------------|
| JOB_QUEUE_LIBRARY | JOBQ_LIB           | VARCHAR(10) | The name of the library containing the job queue.       |
| JOB_QUEUE_NAME    | JOBQ               | VARCHAR(10) | The name of the job queue that the job is currently on. |

Table 274. JOB\_QUEUE\_ENTRIES view (continued)

| Column Name      | System Column Name | Data type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Column Name                       | System Column Name | Data type               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------|--------------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAXIMUM_PROCESSING_TIME_ALLOWED   | MAX_TIME           | INTEGER<br>Nullable     | The maximum processing unit time, in milliseconds, that the job can use. If the job consists of multiple routing steps, this is the maximum processing unit time that the current routing step can use. If the maximum time is exceeded, the job is held.<br><br>Contains the null value if no maximum amount of processing unit time has been defined.                                                                                                                                                                                                                                                                                                                                                             |
| MAXIMUM_TEMPORARY_STORAGE_ALLOWED | MAX_STG            | INTEGER<br>Nullable     | The maximum amount of auxiliary storage, in megabytes, that the job can use. If the job consists of multiple routing steps, this is the maximum temporary storage that the routing step can use. This temporary storage is used for storage required by the program itself and by implicitly created internal system objects used to support the routing step. (It does not include storage for objects in the QTEMP library.) If the maximum temporary storage is exceeded, the job is held. This does not apply to the use of permanent storage, which is controlled through the user profile.<br><br>Contains the null value if no maximum amount of temporary storage has been defined.                         |
| TIME_SLICE                        | TIME_SLICE         | INTEGER<br>Nullable     | The maximum amount of processor time, in milliseconds, given to each thread in this job before other threads in this job and in other jobs are given the opportunity to run. The time slice establishes the amount of time needed by a thread in this job to accomplish a meaningful amount of processing. At the end of the time slice, the thread might be put in an inactive state so that other threads can become active in the storage pool. Values range from 8 through 9999999.<br><br>Contains the null value if a value has not been set for the job.                                                                                                                                                     |
| JOB_SWITCHES                      | SWITCHES           | CHAR(8)<br>Nullable     | The current setting of the job switches used by this job.<br><br>Contains the null value no job switches are set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ROUTING_DATA                      | RTGDTA             | VARCHAR(80)<br>Nullable | The routing data that is used to determine the routing entry that identifies the program to start for the routing step.<br><br>Contains the null value if there is no routing data for this job.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| CCSID                             | CCSID              | INTEGER<br>Nullable     | The coded character set identifier (CCSID) used for this job.<br><br>Contains the null value if no CCSID is defined for this job.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| CHARACTER_IDENTIFIER_CONTROL      | CHRIDCTL           | VARCHAR(9)              | The character identifier control for the job. This attribute controls the type of CCSID conversion that occurs for display files, printer files, and panel groups. The *CHRIDCTL special value must be specified on the CHRID command parameter on the create, change, or override command for display files, printer files, and panel groups before this attribute will be used.<br><br><b>*DEVD</b> The *DEVD special value performs the same function as on the CHRID command parameter for display files, printer files, and panel groups.<br><br><b>*JOBCCSID</b> The *JOBCCSID special value performs the same function as on the CHRID command parameter for display files, printer files, and panel groups. |

| DECIMAL_FORMAT             | DECFMT             | VARCHAR(6)              | The decimal format used for this job.<br><br><b>*BLANK</b> Uses a period for a decimal point, a comma for a 3-digit grouping character, and zero-suppress to the left of the decimal point.<br><br><b>J</b> Uses a comma for a decimal point and a period for a 3-digit grouping character. The zero-suppression character is in the second position (rather than the first) to the left of the decimal notation. Balances with zero values to the left of the comma are written with one leading zero (0,04). The J entry also overrides any edit codes that might suppress the leading zero.<br><br><b>I</b> Uses a comma for a decimal point, a period for a 3-digit grouping character, and zero-suppress to the left of the decimal point. |
| TIME_ZONE_DESCRIPTION_NAME | TIME_ZONE          | VARCHAR(10)             | The name of the time zone description that is used to calculate local job time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Column Name           | System Column Name | Data type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------|--------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STATUS_MESSAGE        | STATUS_MSG         | VARCHAR(7)  | Specifies whether status messages are displayed for this job.<br><br><b>*NONE</b> This job does not display status messages.<br><br><b>*NORMAL</b> This job displays status messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| INQUIRY_MESSAGE_REPLY | INQ_REPLY          | VARCHAR(8)  | Specifies how the job answers inquiry messages.<br><br><b>*RQD</b> The job requires an answer for any inquiry messages that occur while this job is running.<br><br><b>*DFT</b> The system uses the default message reply to answer any inquiry messages issued while this job is running. The default reply is either defined in the message description or is the default system reply.<br><br><b>*SYSRPLY</b> The system reply list is checked to see if there is an entry for an inquiry message issued while this job is running. If a match occurs, the system uses the reply value for that entry. If no entry exists for that message, the system uses an inquiry message. |
| BREAK_MESSAGE         | BREAK_MSG          | VARCHAR(7)  | Specifies how this job handles break messages.<br><br><b>*HOLD</b> The message queue holds break messages until a user or program requests them. The work station user uses the Display Message (DSPMSG) command to display the messages; a program must issue a Receive Message (RCVMSG) command to receive a message and handle it.<br><br><b>*NORMAL</b> The message queue status determines break message handling.<br><br><b>*NOTIFY</b> The system notifies the job's message queue when a message arrives. For interactive jobs, the audible alarm sounds if there is one, and the message-waiting light comes on.                                                          |
| JOB_LOG_OUTPUT        | JOBLOG_OUT         | VARCHAR(10) | Specifies how the job log will be produced when the job completes.<br><br><b>*JOBEND</b> The job log will be produced by the job itself. If the job cannot produce its own job log, the job log will be produced by a job log server. For example, a job does not produce its own job log when the system is processing a Power Down System (PWRDWN SYS) command.<br><br><b>*JOBLOGSVR</b> The job log will be produced by a job log server. For more information about job log servers, refer to the Start Job Log Server (STRLOGSVR) command.<br><br><b>*PND</b> The job log will not be produced. The job log remains pending until removed.                                    |
| OUTPUT_QUEUE_PRIORITY | OUTQ_PRI           | INTEGER     | The output priority for spooled output files that this job produces. The highest priority is 0, and the lowest is 9.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| OUTPUT_QUEUE_LIBRARY  | OUTQLIB            | VARCHAR(10) | The name of the library that contains the default output queue.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| DDM_CONVERSATION | DDM_CONV           | VARCHAR(5)             | <p>Specifies whether connections using distributed data management (DDM) protocols remain active when they are not being used. The connections include APPC conversations, active TCP/IP connections or Opti-Connect connections.</p> <p><b>*DROP</b> The system ends a DDM connection when there are no users. Examples include when an application closes a DDM file, or when a DRDA application runs a SQL DISCONNECT statement.</p> <p><b>*KEEP</b> The system keeps DDM connections active when there are no users, except for the following:</p> <ul style="list-style-type: none"> <li>• The routing step ends on the source system. The routing step ends when the job ends or when the job is rerouted to another routing step.</li> <li>• The Reclaim Distributed Data Management Conversation (RCLDDMCNV) command or the Reclaim Resources (RCLRSC) command runs.</li> <li>• A communications failure or an internal failure occurs.</li> <li>• A DRDA connection to an application server not running on the system ends.</li> </ul> |
| MODE_NAME        | MODE_NAME          | VARCHAR(8)<br>Nullable | <p>The mode name of the advanced program-to-program communications device that started the job. The following special value may be returned:</p> <p><b>*BLANK</b> The mode name is a blank name.</p> <p>Contains the null value if the job is not using advanced program-to-program communications (APPC).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| UNIT_OF_WORK_ID  | UWID               | CHAR(24)<br>Nullable   | <p>The unit of work ID is used to track jobs across multiple systems.</p> <p>Contains the null value if the job is not associated with a source or target system using advanced program-to-program communications (APPC).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| INTERNAL_JOB_ID  | JOB_ID             | BINARY(16)             | The internal job identifier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Note

This function is provided in the SYSTOOLS schema as an example of how to create a view based on information from a table function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

## Example

List all the jobs on the APP1/BATCHJQ job queue.

```
SELECT * FROM SYSTOOLS.JOB_QUEUE_ENTRIES
WHERE JOB_QUEUE_LIBRARY = 'APP1' AND JOB_QUEUE_NAME = 'BATCHJQ';
```

## JOB\_QUEUE\_INFO view

The JOB\_QUEUE\_INFO view returns one row for each job queue.

The values returned for the columns in the view are similar to the values returned by the Work with Job Queue (WRKJOBQ) CL command and the [Retrieve Job Queue Information \(QSPRJOBQ\) API](#).

**Authorization:** The caller must have:

- \*EXECUTE authority to the job queue library, and
  - \*READ authority to the job queue, or
  - \*SPLCTL special authority, or
  - \*JOBCTL special authority and the job queue is defined with OPRCTL(\*YES).

The following table describes the columns in the view. The system name is JOBQ\_INFO. The schema is QSYS2.

Table 275. JOB\_QUEUE\_INFO view

| Column Name            | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                         |

Table 275. JOB\_QUEUE\_INFO view (continued)

| Column Name               | System Column Name | Data Type | Description                                                                            |
|---------------------------|--------------------|-----------|----------------------------------------------------------------------------------------|
| RELEASED_JOBS_PRIORITY_7  | RELEASED7          | INTEGER   | The number of priority 7 jobs currently sitting on the job queue in *RELEASED status.  |
| RELEASED_JOBS_PRIORITY_8  | RELEASED8          | INTEGER   | The number of priority 8 jobs currently sitting on the job queue in *RELEASED status.  |
| RELEASED_JOBS_PRIORITY_9  | RELEASED9          | INTEGER   | The number of priority 9 jobs currently sitting on the job queue in *RELEASED status.  |
| SCHEDULED_JOBS_PRIORITY_0 | SCHEDULED0         | INTEGER   | The number of priority 0 jobs currently sitting on the job queue in *SCHEDULED status. |
| SCHEDULED_JOBS_PRIORITY_1 | SCHEDULED1         | INTEGER   | The number of priority 1 jobs currently sitting on the job queue in *SCHEDULED status. |
| SCHEDULED_JOBS_PRIORITY_2 | SCHEDULED2         | INTEGER   | The number of priority 2 jobs currently sitting on the job queue in *SCHEDULED status. |
| SCHEDULED_JOBS_PRIORITY_3 | SCHEDULED3         | INTEGER   | The number of priority 3 jobs currently sitting on the job queue in *SCHEDULED status. |
| SCHEDULED_JOBS_PRIORITY_4 | SCHEDULED4         | INTEGER   | The number of priority 4 jobs currently sitting on the job queue in *SCHEDULED status. |
| SCHEDULED_JOBS_PRIORITY_5 | SCHEDULED5         | INTEGER   | The number of priority 5 jobs currently sitting on the job queue in *SCHEDULED status. |
| SCHEDULED_JOBS_PRIORITY_6 | SCHEDULED6         | INTEGER   | The number of priority 6 jobs currently sitting on the job queue in *SCHEDULED status. |
| SCHEDULED_JOBS_PRIORITY_7 | SCHEDULED7         | INTEGER   | The number of priority 7 jobs currently sitting on the job queue in *SCHEDULED status. |
| SCHEDULED_JOBS_PRIORITY_8 | SCHEDULED8         | INTEGER   | The number of priority 8 jobs currently sitting on the job queue in *SCHEDULED status. |
| SCHEDULED_JOBS_PRIORITY_9 | SCHEDULED9         | INTEGER   | The number of priority 9 jobs currently sitting on the job queue in *SCHEDULED status. |
| HELD_JOBS_PRIORITY_0      | HELD0              | INTEGER   | The number of priority 0 jobs currently sitting on the job queue in *HELD status.      |
| HELD_JOBS_PRIORITY_1      | HELD1              | INTEGER   | The number of priority 1 jobs currently sitting on the job queue in *HELD status.      |
| HELD_JOBS_PRIORITY_2      | HELD2              | INTEGER   | The number of priority 2 jobs currently sitting on the job queue in *HELD status.      |
| HELD_JOBS_PRIORITY_3      | HELD3              | INTEGER   | The number of priority 3 jobs currently sitting on the job queue in *HELD status.      |
| HELD_JOBS_PRIORITY_4      | HELD4              | INTEGER   | The number of priority 4 jobs currently sitting on the job queue in *HELD status.      |
| HELD_JOBS_PRIORITY_5      | HELD5              | INTEGER   | The number of priority 5 jobs currently sitting on the job queue in *HELD status.      |
| HELD_JOBS_PRIORITY_6      | HELD6              | INTEGER   | The number of priority 6 jobs currently sitting on the job queue in *HELD status.      |
| HELD_JOBS_PRIORITY_7      | HELD7              | INTEGER   | The number of priority 7 jobs currently sitting on the job queue in *HELD status.      |
| HELD_JOBS_PRIORITY_8      | HELD8              | INTEGER   | The number of priority 8 jobs currently sitting on the job queue in *HELD status.      |
| HELD_JOBS_PRIORITY_9      | HELD9              | INTEGER   | The number of priority 9 jobs currently sitting on the job queue in *HELD status.      |

## Example

- Examine the job queues with the largest number of active jobs

```
SELECT * FROM QSYS2.JOB_QUEUE_INFO
WHERE ACTIVE_JOBS IS NOT NULL
ORDER BY NUMBER_OF_JOBS DESC;
```

Table 276. MEMORY\_POOL table function (continued)

| Column Name                  | Data Type     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SUBSYSTEM_NAME               | VARCHAR(10)   | The subsystem with which this storage pool is associated. Contains the null value for shared pools.                                                                                                                                                                                                                                                                                                                                                                    |
| DESCRIPTION                  | VARCHAR(50)   | The description of the shared pool. Contains the null value for private pools or if a description does not exist for a shared pool.                                                                                                                                                                                                                                                                                                                                    |
| PAGING_OPTION                | VARCHAR(10)   | Whether the system will dynamically adjust the paging characteristics of the storage pool for optimum performance.<br><br><b>*FIXED</b> The system does not dynamically adjust the paging characteristics.<br><br><b>*CALC</b> The system dynamically adjusts the paging characteristics.<br><br><b>USRDFN</b> The system does not dynamically adjust the paging characteristics for the storage pool but uses values that have been defined through the QWCCHGTN API. |
| ELAPSED_TIME                 | INTEGER       | The time, in seconds, since the measurement start time.                                                                                                                                                                                                                                                                                                                                                                                                                |
| ELAPSED_DATABASE_FAULTS      | DECIMAL(10,1) | The rate, in page faults per second, of database page faults against pages containing either database access paths or data.                                                                                                                                                                                                                                                                                                                                            |
| ELAPSED_NON_DATABASE_FAULTS  | DECIMAL(10,1) | The rate, in page faults per second, of nondatabase page faults against pages other than those designated as database pages.                                                                                                                                                                                                                                                                                                                                           |
| ELAPSED_TOTAL_FAULTS         | DECIMAL(10,1) | The rate, in page faults per second, of database faults and non-database faults.                                                                                                                                                                                                                                                                                                                                                                                       |
| ELAPSED_DATABASE_PAGES       | DECIMAL(10,1) | The rate, in pages per second, at which database pages are brought into the storage pool.                                                                                                                                                                                                                                                                                                                                                                              |
| ELAPSED_NON_DATABASE_PAGES   | DECIMAL(10,1) | The rate in pages per second at which nondatabase pages are brought into the storage pool.                                                                                                                                                                                                                                                                                                                                                                             |
| ELAPSED_ACTIVE_TO_WAIT       | DECIMAL(10,1) | The rate, in transitions per minute, of transitions of threads from an active condition to a waiting condition.                                                                                                                                                                                                                                                                                                                                                        |
| ELAPSED_WAIT_TO_INELIGIBLE   | DECIMAL(10,1) | The rate, in transitions per minute, of transitions of threads from a waiting condition to an ineligible condition.                                                                                                                                                                                                                                                                                                                                                    |
| ELAPSED_ACTIVE_TO_INELIGIBLE | DECIMAL(10,1) | The rate, in transitions per minute, of transitions of threads from an active condition to an ineligible condition.                                                                                                                                                                                                                                                                                                                                                    |
| TUNING_PRIORITY              | INTEGER       | The priority of the shared storage pool used by the system when making automatic performance adjustments. Contains the null value for private pools defined in subsystem descriptions.                                                                                                                                                                                                                                                                                 |
| TUNING_MINIMUM_SIZE          | DECIMAL(10,2) | The minimum amount of storage to allocate to the shared storage pool (as a percentage of total main storage). Contains the null value for private pools defined in subsystem descriptions.                                                                                                                                                                                                                                                                             |
| TUNING_MAXIMUM_SIZE          | DECIMAL(10,2) | The maximum amount of storage to allocate to the shared storage pool (as a percentage of total main storage). Contains the null value for private pools defined in subsystem descriptions.                                                                                                                                                                                                                                                                             |
| TUNING_MINIMUM_FAULTS        | DECIMAL(10,2) | The maximum page faults per second to use as a guideline for the shared storage pool. Contains the null value for private pools defined in subsystem descriptions.                                                                                                                                                                                                                                                                                                     |
| TUNING_MAXIMUM_FAULTS        | DECIMAL(10,2) | The minimum page faults per second to use as a guideline for the shared storage pool. Contains the null value for private pools defined in subsystem descriptions.                                                                                                                                                                                                                                                                                                     |
| TUNING_THREAD_FAULTS         | DECIMAL(10,2) | The page faults per second for each active thread to use as a guideline for the shared storage pool. Contains the null value for private pools defined in subsystem descriptions.                                                                                                                                                                                                                                                                                      |
| TUNING_MINIMUM_ACTIVITY      | DECIMAL(10,2) | The minimum value that the shared pool's activity level can be set to by the performance adjuster when the QPFRADJ system value is set to 2 or 3. Contains the null value for private pools defined in subsystem descriptions.                                                                                                                                                                                                                                         |
| TUNING_MAXIMUM_ACTIVITY      | DECIMAL(10,2) | The maximum value that the shared pool's activity level can be set to by the performance adjuster when the QPFRADJ system value is set to 2 or 3. Contains the null value for private pools defined in subsystem descriptions.                                                                                                                                                                                                                                         |

## Example

Return all available pool information, both private and shared, active and inactive. Specify to reset all the elapsed values to 0.

```
SELECT * FROM TABLE(QSYS2.MEMORY_POOL(RESET_STATISTICS=>'YES')) X;
```

## MEMORY\_POOL\_INFO view

The MEMORY\_POOL\_INFO view returns one row for every active pool.

The information returned is similar to the detail seen from the Work System Status (WRKSYSSTS) command. It does not reset the statistical columns; to do this, use the associated table function, [MEMORY\\_POOL](#).

**Authorization:** None required.

The following table describes the columns in the view. The system name is POOL\_INFO. The schema is QSYS2.

Table 277. MEMORY\_POOL\_INFO view

| Column Name                | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------|--------------------|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SYSTEM_POOL_ID             | POOL_ID            | INTEGER                 | The system-related pool identifier for each of the system storage pools that currently has main storage allocated to it.                                                                                                                                                                                                                                                                                                                                    |
| POOL_NAME                  | POOL_NAME          | VARCHAR(10)             | The name of this storage pool. The name may be a number, in which case it is a private pool associated with a subsystem, or one of the following special values.<br><br><b>*MACHINE</b> The machine pool.<br><b>*BASE</b> The base system pool, which can be shared with other subsystems.<br><b>*INTERACT</b> The shared pool used for the QINTER subsystem.<br><b>*SPOOL</b> The shared pool used for spooled writers.<br><b>*SHRPOOLx</b> A shared pool. |
| CURRENT_SIZE               | CURR_SIZE          | DECIMAL(20,2)           | The amount of main storage, in megabytes, in the pool.                                                                                                                                                                                                                                                                                                                                                                                                      |
| RESERVED_SIZE              | RSVD_SIZE          | DECIMAL(10,2)           | The amount of storage, in megabytes, in the pool reserved for system use (for example, for save/restore operations).                                                                                                                                                                                                                                                                                                                                        |
| DEFINED_SIZE               | DFND_SIZE          | DECIMAL(20,2)           | The size of the pool, in megabytes, as defined in the shared pool, subsystem description, or system value QMCHPOOL. Contains the null value for a pool without a defined size.                                                                                                                                                                                                                                                                              |
| MAXIMUM_ACTIVE_THREADS     | MAX_THREAD         | INTEGER                 | The maximum number of threads that can be active in the pool at any one time.                                                                                                                                                                                                                                                                                                                                                                               |
| CURRENT_THREADS            | CURR_THRD          | INTEGER                 | The number of threads currently using the pool.                                                                                                                                                                                                                                                                                                                                                                                                             |
| CURRENT_INELIGIBLE_THREADS | INEL_THRD          | INTEGER                 | The number of ineligible threads in the pool.                                                                                                                                                                                                                                                                                                                                                                                                               |
| SUBSYSTEM_LIBRARY_NAME     | SUBLIB_NAM         | VARCHAR(10)<br>Nullable | The library containing the subsystem name. Contains the null value for shared pools.                                                                                                                                                                                                                                                                                                                                                                        |
| SUBSYSTEM_NAME             | SUB_NAME           | VARCHAR(10)<br>Nullable | The subsystem with which this storage pool is associated. Contains the null value for shared pools.                                                                                                                                                                                                                                                                                                                                                         |
| DESCRIPTION                | DESC               | VARCHAR(50)<br>Nullable | The description of the shared pool. Contains the null value for private pools or if a description does not exist for a shared pool.                                                                                                                                                                                                                                                                                                                         |

Contains the null value for private pools defined in subsystem descriptions.                                                                                                                                                                                                                                                                                                     |
| TUNING_THREAD_FAULTS         | TUN_THR_FT         | DECIMAL(10,2)<br>Nullable | The page faults per second for each active thread to use as a guideline for the shared storage pool. Contains the null value for private pools defined in subsystem descriptions.                                                                                                                                                                                                                                                                                      |
| TUNING_MINIMUM_ACTIVITY      | TUN_MIN_AC         | DECIMAL(10,2)<br>Nullable | The minimum value that the shared pool's activity level can be set to by the performance adjuster when the QPFRADJ system value is set to 2 or 3. Contains the null value for private pools defined in subsystem descriptions.                                                                                                                                                                                                                                         |
| TUNING_MAXIMUM_ACTIVITY      | TUN_MAX_AC         | DECIMAL(10,2)<br>Nullable | The maximum value that the shared pool's activity level can be set to by the performance adjuster when the QPFRADJ system value is set to 2 or 3. Contains the null value for private pools defined in subsystem descriptions.                                                                                                                                                                                                                                         |

## Example

Return all active pool information.

```
SELECT * FROM QSYS2.MEMORY_POOL_INFO;
```

## OBJECT\_LOCK\_INFO view

The OBJECT\_LOCK\_INFO view returns one row for every lock held for every object on the partition in \*SYSBAS and in the current thread's ASP group.

The values returned for the columns in the view are closely related to the values returned by [Retrieve Lock Information API](#) and [Retrieve Lock Request Information API](#). Refer to the APIs for more detailed information.

**Authorization:** The caller must have:

- \*EXECUTE authority to the library containing the object, and
- \*OBJOPR and \*READ authority to the database file

The following table describes the columns in the view. The system name is OBJ\_LOCK. The schema is QSYS2.

Table 278. OBJECT\_LOCK\_INFO view

| Column Name          | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|--------------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OBJECT_SCHEMA        | OSHEMA             | VARCHAR(128)            | The name of the schema containing the object.                                                                                                                                                                                                                                                                                                                                            |

## Example

Find all the jobs holding object locks over the SALES table:

```
SELECT * FROM QSYS2.OBJECT_LOCK_INFO
WHERE SYSTEM_OBJECT_SCHEMA = 'TOYSTORE' AND
SYSTEM_OBJECT_NAME = 'SALES'
```

## OPEN\_FILES table function

The OPEN\_FILES table function returns a list of files (\*FILE objects) that are open in all threads for a job.

This information is similar to what can be accessed through the Display Job (DSPJOB) CL command and by the List Open Files (QDMLOPNF) API.

**Authorization:** None required to see information for jobs where the caller's user profile is the same as the job user identity of the job for which the information is being returned. To see information for other jobs, the caller must have \*JOBCTL special authority.

►► OPEN\_FILES — ( JOB\_NAME — => — ) —►►

The schema is QSYS2.

**job-name** A character or graphic string expression that identifies the qualified name of a job. The special value of '\*' indicates the current job.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 279. OPEN\_FILES table function

| Column Name  | Data Type   | Description                                                                                                         |
|--------------|-------------|---------------------------------------------------------------------------------------------------------------------|
| LIBRARY_NAME | VARCHAR(10) | The name of the library that contains the open file.<br>Contains the null value if the file is an inline data file. |
| FILE_NAME    | VARCHAR(10) | The name of the file that is open. For an unnamed inline data file, contains the value QINLINE.                     |

Table 279. OPEN\_FILES table function (continued)

| Column Name             | Data Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FILE_TYPE               | VARCHAR(7)  | The type of file that is open.<br><br><b>BSCF</b> Binary Synchronous Communications (BSC) file<br><b>CMNF</b> Communications file<br><b>DDMF</b> Distributed Data Management file<br><b>DKTF</b> Diskette file (spooled and non-spooled)<br><b>DSPF</b> Display file<br><b>ICFF</b> Intersystem Communications Function file<br><b>LF</b> Logical file<br><b>MXDF</b> Mixed file<br><b>PF</b> Physical file<br><b>PRTF</b> Printer file (spooled and non-spooled)<br><b>SAVF</b> Save file<br><b>TAPF</b> Tape file<br><b>*INLINE</b> Inline data file |
| MEMBER_NAME             | VARCHAR(10) | If FILE_TYPE is physical (PF) or logical (LF), the name of the database member. If multiple member processing is being performed, the value is *ALL.<br><br>Contains the null value for a DDM file, an inline data file, and a device file.                                                                                                                                                                                                                                                                                                            |
| DEVICE_NAME             | VARCHAR(10) | The name of the last program device used for an I/O operation if FILE_TYPE is a device file (BSCF, CMNF, DKTF, DSPF, ICFF, MXDF, PRTF, SAVF, or TAPF). If the file is a spooled file, the value is *SPOOL.<br><br>Contains the null value for a device file when no I/O operation has been performed, a database physical or logical file, a DDM file, and an inline data file.                                                                                                                                                                        |
| RECORD_FORMAT           | VARCHAR(10) | The name of the last record format that was used for an I/O operation to the file.<br><br>Contains the null value if no record format name was used or no I/O operations have been performed.                                                                                                                                                                                                                                                                                                                                                          |

If record blocking is in effect for the file, this is the number of record blocks.                                                                                                                                                                                                                                                                                                                                         |
| READ_COUNT              | BIGINT      | Number of successful read operations. If record blocking is not in effect for the file, this is the number of records. If record blocking is in effect for the file, this is the number of record blocks.                                                                                                                                                                                                                                                                                                                                              |

Table 279. OPEN\_FILES table function (continued)

| Column Name            | Data Type   | Description                                                                                                                                                                                                                                                                                                    |
|------------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WRITE_READ_COUNT       | BIGINT      | The number of successful write/read operations.                                                                                                                                                                                                                                                                |
| OTHER_IO_COUNT         | BIGINT      | Number of successful I/O operations of the following types: <ul style="list-style-type: none"> <li>• update</li> <li>• delete</li> <li>• change end-of-data</li> <li>• force end-of-data</li> <li>• force end-of-volume</li> <li>• release record lock</li> <li>• acquire or release program device</li> </ul> |
| RELATIVE_RECORD_NUMBER | BIGINT      | Relative record number of the last record referred to by an I/O or open operation for database files.<br><br>Contains the null value for nondatabase files and database files on which no I/O operations have been performed.                                                                                  |
| IASP_NAME              | VARCHAR(10) | The auxiliary storage pool (ASP) device name where the library is stored. If the library is in the system ASP or one of the basic user ASPs, contains *SYSBAS.<br><br>Contains the null value if the file is an inline data file or if the name of the ASP device cannot be determined.                        |
| IASP_NUMBER            | INTEGER     | The number of the auxiliary storage pool (ASP) from which the system allocates storage for the library. 1 indicates the system ASP.<br><br>Contains the null value if the file is an inline data file or if the number of the ASP device cannot be determined.                                                 |

### Example

- List all the database files that are open for job 429467/QUSER/QZDASOINIT.

```
SELECT * FROM TABLE(QSYS2.OPEN_FILES('429467/QUSER/QZDASOINIT'))
WHERE FILE_TYPE IN ('PF', 'LF');
```

## POWER\_SCHEDULE\_INFO view

The POWER\_SCHEDULE\_INFO view returns one row for each date in the next year that has a power on or power off scheduled.

The information returned is similar to the detail shown by the Display Power On/Off Schedule (DSPPWRSCD) CL command and returned by the Retrieve Power Schedule Entry (RTVPWRSCDE) CL command.

**Authorization:** See Note below.

The following table describes the columns in the view. The system name is POWER\_INFO. The schema is SYSTOOLS.

Table 280. POWER\_SCHEDULE\_INFO view

| Column Name   | System Column Name | Data type        | Description                                                                                                                                         |
|---------------|--------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| POWER_DATE    | POWER_DATE         | DATE             | The date when a power off or power on is scheduled. Only dates that have a POWER_ON_TIME or a POWER_OFF_TIME are returned.                          |
| DAY_OF_WEEK   | POWER_DAY          | VARCHAR(18)      | The day of the week that corresponds to POWER_DATE. The name of the day is retrieved from message CPX9034 in message file QCPFMSG in library *LIBL. |
| POWER_ON_TIME | POWER_ON           | TIME<br>Nullable | The time of the power on for this date.<br><br>Contains the null value if a power on is not scheduled for this date.                                |

Table 280. POWER\_SCHEDULE\_INFO view (continued)

| Column Name      | System Column Name | Data type               | Description                                                                                                        |
|------------------|--------------------|-------------------------|--------------------------------------------------------------------------------------------------------------------|
| POWER_OFF_TIME   | POWER_OFF          | TIME<br>Nullable        | The time of the power off for this date.<br>Contains the null value if a power off is not scheduled for this date. |
| TEXT_DESCRIPTION | TEXT               | VARCHAR(38)<br>Nullable | The text description for this activity.<br>Contains the null value if a description is not available.              |
| MESSAGE_INTERVAL | INTERVAL           | INTEGER                 | The number of minutes prior to a scheduled power off that a message is sent to display station users.              |

## Note

This function is provided in the SYSTOOLS schema as an example of how SQL can return information from a CL program. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

## Example

List all the scheduled power events.

```
SELECT * FROM SYSTOOLS.POWER_SCHEDULE_INFO;
```

## PRESTART\_JOB\_INFO view

The PRESTART\_JOB\_INFO view returns information about prestart jobs.

The values returned for the columns in the view are closely related to the values returned by the Display Prestart Job Entries panel accessed through the DSPSBSD (Display Subsystem Description) CL command and by the List Subsystem Entries (QWDLSE) API.

**Authorization:** The caller must have:

- \*EXECUTE authority to the library containing the subsystem description, and
- \*USE authority to the subsystem description.

The following table describes the columns in the view. The system name is PREJ\_INFO. The schema is QSYS2.

Table 281. PRESTART\_JOB\_INFO view

| Column Name                   | System Column Name | Data Type   | Description                                                                                                                                                                 |
|-------------------------------|--------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SUBSYSTEM_DESCRIPTION_LIBRARY | SBSD_LIB           | VARCHAR(10) | The name of the library in which the subsystem description resides.                                                                                                         |
| SUBSYSTEM_DESCRIPTION         | SBSD               | VARCHAR(10) | The name of the subsystem about which information is being returned.                                                                                                        |
| PRESTART_JOB_PROGRAM_LIBRARY  | PJ_PGM_LIB         | VARCHAR(10) | The name of the library in which the prestart job program resides.                                                                                                          |
| PRESTART_JOB_PROGRAM          | PJ_PGM             | VARCHAR(10) | The program name that is used to match an incoming request with an available prestart job.                                                                                  |
| SUBSYSTEM_ACTIVE              | SBS_ACTIVE         | VARCHAR(3)  | Whether the subsystem for this prestart job is active.<br><br><b>NO</b> The status of the subsystem is not ACTIVE.<br><br><b>YES</b> The status of the subsystem is ACTIVE. |

Table 281. PRESTART\_JOB\_INFO view (continued)

| Column Name             | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|--------------------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| USER_PROFILE            | USRPRF             | VARCHAR(10)             | The name of the user profile under which the prestart job runs.                                                                                                                                                                                                                                                                                                                                                    |
| PRESTART_JOB_NAME       | PJ_NAME            | VARCHAR(10)             | The name of the prestart job.                                                                                                                                                                                                                                                                                                                                                                                      |
| JOB_DESCRIPTION_LIBRARY | JOBDLIB            | VARCHAR(10)<br>Nullable | The name of the library in which the job description for the prestart job entry resides.<br>Contains the null value if JOB_DESCRIPTION is *USRPRF.                                                                                                                                                                                                                                                                 |
| JOB_DESCRIPTION         | JOBID              | VARCHAR(10)             | The name of the job description that is used for the prestart job entry. Can contain the following special value:<br><br><b>*USRPRF</b> The job description that has the same name as the user profile that is used.                                                                                                                                                                                               |
| START_JOBS              | START_JOBS         | VARCHAR(3)              | Whether the prestart jobs are started at the time the subsystem is started.<br><br><b>NO</b> The prestart jobs are not started at the time the subsystem is started. The Start Prestart Jobs (STRPJ) command is used to start these prestart jobs.<br><br><b>YES</b> The prestart jobs are started at the time the subsystem is started.                                                                           |
| INITIAL_JOBS            | INIT_JOBS          | INTEGER                 | The initial number of prestart jobs that are started when the subsystem is started.                                                                                                                                                                                                                                                                                                                                |
| THRESHOLD               | THRESHOLD          | INTEGER                 | The number at which additional prestart jobs are started. When the pool of available jobs (jobs available to service a program start request) is reduced below this number, more jobs (specified by ADDITIONAL_JOBS) are started and added to the available pool. This number is checked after a prestart job is attached to a procedure start request.                                                            |
| ADDITIONAL_JOBS         | ADD_JOBS           | INTEGER                 | The additional number of prestart jobs that are started when the number of prestart jobs drops below the value of THRESHOLD.                                                                                                                                                                                                                                                                                       |
| MAXIMUM_JOBS            | MAX_JOBS           | INTEGER                 | The maximum number of prestart jobs that can be active at the same time for this prestart job entry. A value of -1 indicates *NOMAX.                                                                                                                                                                                                                                                                               |
| MAXIMUM_USES            | MAX_USES           | INTEGER                 | The maximum number of requests that can be handled by each prestart job in the pool before the job is ended. A value of -1 indicates *NOMAX.                                                                                                                                                                                                                                                                       |
| WAIT_FOR_JOB            | WAIT               | VARCHAR(3)              | Whether requests wait for a prestart job to become available or are rejected if a prestart job is not immediately available when the request is received.<br><br><b>NO</b> Requests are rejected if a prestart job is not immediately available when the request is received.<br><br><b>YES</b> Requests wait until there is an available prestart job, or until a prestart job is started, to handle the request. |
| POOL_ID                 | POOL_ID            | INTEGER                 | The subsystem pool in which the prestart jobs will run.                                                                                                                                                                                                                                                                                                                                                            |
| CLASS_LIBRARY           | CLASS1_LIB         | VARCHAR(10)             | The name of the library in which the first class resides.                                                                                                                                                                                                                                                                                                                                                          |
| CLASS                   | CLASS1             | VARCHAR(10)             | The name of the first class that the prestart jobs run under. Jobs start by using the first class that is specified until the number of jobs specified for the first class is reached. After the number of jobs that are specified for the first class is reached, then jobs are started by using the second class.                                                                                                |

## Example

- List all the prestart job entries in the QUSRWRK subsystem.

```
SELECT *
FROM QSYS2.PRESTART_JOB_INFO
WHERE SUBSYSTEM_DESCRIPTION_LIBRARY = 'QSYS' AND
SUBSYSTEM_DESCRIPTION = 'QUSRWRK';
```

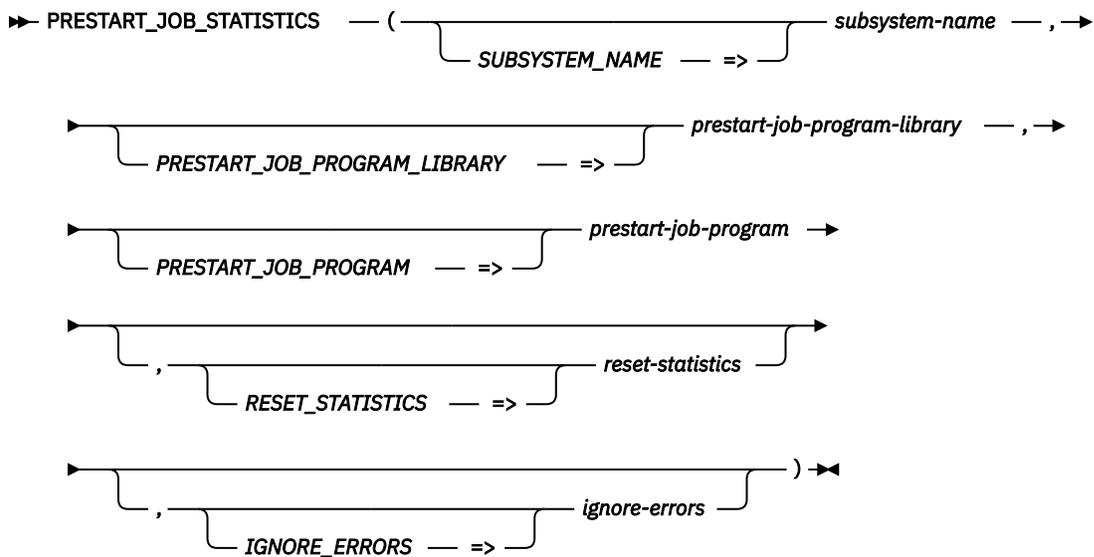

## PRESTART\_JOB\_STATISTICS table function

The PRESTART\_JOB\_STATISTICS table function returns statistics and performance information for an active prestart job entry in an active subsystem. The information is collected from the time the reset key is pressed on the Display Active Prestart Jobs (DSPACTPJ) command, from the time the prestart job entry is started, or from the time RESET\_STATISTICS => 'YES' is run for this table function. The prestart job entry is started when the subsystem starts or when the Start Prestart Jobs (STRPJ) command is used.

This information is similar to what is returned by the Display Active Prestart Jobs (DSPACTPJ) command and the Retrieve Active Prestart Jobs Status (QWTRAPJS) API.

**Authorization:** The caller must have:

- \*EXECUTE authority to the prestart job's program library.
- \*USE authority to the ASP device description, if the subsystem description specifies an ASP group name.

The schema is QSYS2.

- subsystem-name** A character or graphic string expression that contains the name of the active subsystem that contains the prestart job entry.
- prestart-job-program-library** A character or graphic string expression that contains the name of the library where *prestart-job-program* is located. Can contain the following special values:
- \*CURLIB** The thread's current library is used to locate *prestart-job-program*.
  - \*LIBL** The library list is used to locate *prestart-job-program*.
- prestart-job-program** A character or graphic string expression that contains the name of the program that identifies the active prestart job entry.
- reset-statistics** A character or graphic string expression that contains a value of YES or NO to indicate whether the statistical information should be reset. If this parameter is not specified, the default is NO.
- If the value is YES, the statistics are reset after the information is gathered. The reset applies to the statistics shown by the Display Active Prestart Jobs (DSPACTPJ) command as well.
- ignore-errors** A character or graphic string expression that identifies what to do when an error is encountered.
- NO** An error is returned.
  - YES** A warning is returned.  
No row is returned when an error is encountered. This is the default.

The result of the function is a table containing multiple rows with the format shown in the following table. All the columns are nullable.

Table 282. PRESTART\_JOB\_STATISTICS view

| Column Name                  | Data Type   | Description                                                                   |
|------------------------------|-------------|-------------------------------------------------------------------------------|
| SUBSYSTEM_NAME               | VARCHAR(10) | The name of the active subsystem that contains the prestart job entry.        |
| PRESTART_JOB_PROGRAM_LIBRARY | VARCHAR(10) | The library where the prestart job program is located.                        |
| PRESTART_JOB_PROGRAM         | VARCHAR(10) | The program that identifies the active prestart job entry.                    |
| STATUS_TIMESTAMP             | TIMESTAMP   | The date and time this active prestart jobs status information was collected. |

Table 282. PRESTART\_JOB\_STATISTICS view (continued)

| Column Name           | Data Type     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ELAPSED_TIME          | INTEGER       | The time that has elapsed, in seconds, since the last reset date/time.<br>The value will not reflect elapsed time beyond 10,000 hours. A value of 0 might mean that the elapsed time could not be calculated.                                                                                                                                                                                                                                                         |
| CURRENT_JOBS          | INTEGER       | The current number of active jobs associated with the prestart job entry.                                                                                                                                                                                                                                                                                                                                                                                             |
| AVERAGE_JOBS          | DECIMAL(10,1) | The average number of jobs that have been active since the reset date/time. This value is based on calculations involving time intervals and is inaccurate if the system clock was changed while information is being collected.<br>This value will be recalculated after statistics are reset.                                                                                                                                                                       |
| PEAK_JOBS             | INTEGER       | The maximum number of jobs that have been active since the reset date/time.<br>This value will be recalculated after statistics are reset.                                                                                                                                                                                                                                                                                                                            |
| CURRENT_INUSE_JOBS    | INTEGER       | The current number of jobs in use.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| AVERAGE_INUSE_JOBS    | DECIMAL(10,1) | The average number of jobs in use since the reset date/time. This value is based on calculations involving time intervals and is inaccurate if the system clock was changed while information is being collected.<br>This value will be recalculated after statistics are reset.                                                                                                                                                                                      |
| PEAK_INUSE_JOBS       | INTEGER       | The maximum number of jobs in use since the reset date/time.<br>This value will be recalculated after statistics are reset.                                                                                                                                                                                                                                                                                                                                           |
| CURRENT_WAIT_REQUESTS | INTEGER       | The number of requests that are waiting for a prestart job.                                                                                                                                                                                                                                                                                                                                                                                                           |
| AVERAGE_WAIT_REQUESTS | DECIMAL(10,1) | The average number of requests that have waited for a prestart job since the reset date/time. This value is based on calculations involving time intervals and is inaccurate if the system clock was changed while information is being collected.<br>This value will be recalculated after statistics are reset.                                                                                                                                                     |
| PEAK_WAIT_REQUESTS    | INTEGER       | The maximum number of requests that have waited at one time for an available prestart job since the reset date/time.<br>This value will be recalculated after statistics are reset.                                                                                                                                                                                                                                                                                   |
| AVERAGE_WAIT_TIME     | DECIMAL(10,1) | The average time, in seconds, that requests have waited to be attached to a prestart job since the reset date/time. This includes requests that wait and requests that do not wait. This value is based on calculations involving time intervals and is inaccurate if the system clock was changed while information is being collected.<br>This value will be recalculated after statistics are reset.                                                               |
| ACCEPTED_REQUESTS     | INTEGER       | The total number of accepted requests since the reset date/time. An accepted request is one that is either attached immediately to a prestart job, or is queued because a prestart job is not available.<br>This value will be recalculated after statistics are reset.                                                                                                                                                                                               |
| REJECTED_REQUESTS     | INTEGER       | The total number of rejected requests since the reset date/time. A request is rejected if <ul style="list-style-type: none"> <li>*NO is specified for the WAIT parameter on the prestart job entry and there are no jobs currently available to handle the request.</li> <li>*YES is specified for the WAIT parameter and there are more program start requests than the maximum jobs allowed.</li> </ul> This value will be recalculated after statistics are reset. |

## Example

List the current statistics for all prestart jobs in the QUSRWRK subsystem. A warning will be issued for each prestart job returned from PRESTART\_JOB\_INFO that is not active.

```
SELECT PJ.PRESTART_JOB_NAME, STAT.*
FROM QSYS2.PRESTART_JOB_INFO PJ,
 LATERAL (
 SELECT * FROM TABLE
 (QSYS2.PRESTART_JOB_STATISTICS (PJ.SUBSYSTEM_DESCRIPTION,
 PJ.PRESTART_JOB_PROGRAM_LIBRARY,
 PJ.PRESTART_JOB_PROGRAM))) AS STAT
```

```
WHERE PJ.SUBSYSTEM_ACTIVE = 'YES' AND
PJ.SUBSYSTEM_DESCRIPTION = 'QUSRWRK';
```

## RECORD\_LOCK\_INFO view

The RECORD\_LOCK\_INFO view returns one row for every record lock for the partition.

The values returned for the columns in the view are closely related to the values returned by [Retrieve Record Locks API](#). Refer to the APIs for more detailed information.

**Authorization:** The caller must have:

- \*EXECUTE authority to the library containing the database file, and
- \*OBJOPR and \*READ authority to the database file

The following table describes the columns in the view. The system name is RCD\_LOCK. The schema is QSYS2.

Table 283. RECORD\_LOCK\_INFO view

| Column Name            | System Column Name | Data Type    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| RELATIVE_RECORD_NUMBER | RRN                | BIGINT       | The relative record number (RRN) of the record that is locked.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| LOCK_STATE             | LOCK_STATE         | VARCHAR(8)   | The lock condition for the record.<br><br><b>READ</b> The record is locked for read. Another job may read the same record but cannot lock the record for update intent. The record cannot be changed by another job as long as one job holds a read lock on the record.<br><br><b>UPDATE</b> The record is locked for update intent. Another job may read the record but may not obtain a read or update lock on it until the lock is released.<br><br><b>INTERNAL</b> The row is locked internally for read. For a short time the operating system holds an internal lock to access the row. Another job may read the same row and may even have the row locked for update intent. However, if another job does have the row locked for update intent, the actual change of the row will not proceed until the internal lock is released. |
| LOCK_STATUS            | STATUS             | VARCHAR(9)   | The status of the lock.<br><br><b>HELD</b> The lock is currently held by the job.<br><br><b>WAITING</b> The job is waiting for the lock.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| LOCK_SCOPE             | LOCK_SCOPE         | VARCHAR(10)  | The scope of the lock. Values are: <ul style="list-style-type: none"> <li>• JOB</li> <li>• THREAD</li> <li>• LOCK SPACE</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| THREAD_ID     | THREAD_ID          | BIGINT<br>Nullable     | The thread that is associated with the lock.<br><br><ul style="list-style-type: none"> <li>If a held lock is job scoped, returns the null value. If a held lock is thread scoped, contains the identifier for the thread holding the lock.</li> <li>If the scope of the lock is to the lock space and the lock is not held, contains the identifier of the thread requesting the lock.</li> <li>If the lock is requested but not yet available, contains the identifier of the thread requesting the lock.</li> </ul> |
| LOCK_SPACE_ID | LOCKID             | BINARY(20)<br>Nullable | When the LOCK_SCOPE column value is LOCK SPACE and the lock is being waited on by a thread, contains the lock space ID value for which the lock is being waited on.<br><br>Otherwise, contains the null value.                                                                                                                                                                                                                                                                                                        |

## Example

Review the jobs that are updating the SALES table:

```
SELECT JOB_NAME, COUNT(*) AS ROWS_UPDATING
FROM QSYS2.RECORD_LOCK_INFO
WHERE SYSTEM_TABLE_NAME = 'SALES' AND
 SYSTEM_TABLE_SCHEMA = 'TOYSTORE' AND
 LOCK_STATE = 'UPDATE'
GROUP BY JOB_NAME
ORDER BY ROWS_UPDATING DESC
```

## REMOVE\_TRACKED\_JOB\_QUEUE procedure

The REMOVE\_TRACKED\_JOB\_QUEUE procedure removes a job queue from the tracked job queue list.

All information associated with the specified job queue is removed from the job tracking file.

Unless *ignore-errors* is YES, the tracking file's IASP must be in the caller's namespace or it must be the name of an IASP that does not exist. The IASP for the tracking file was specified on the QSYS2.ADD\_TRACKED\_JOB\_QUEUE procedure with the *tracking-file-iasp* parameter. It is returned in the TRACKING\_FILE\_IASP column of the QSYS2.TRACKED\_JOB\_QUEUES view.

**Authorization:** The caller must have \*JOBCTL special authority.

```
➤➤ REMOVE_TRACKED_JOB_QUEUE ((IASP_NAME =>) iasp-name , ➤➤
 (JOB_QUEUE_LIBRARY =>) job-queue-library , ➤➤
 (JOB_QUEUE =>) job-queue ➤➤
 , (IGNORE_ERRORS =>) ignore-errors) ➤➤
```

The schema is QSYS2.

**iasp-name** A character string that contains the name of the ASP where *job-queue-library* is located. Can contain the following special value:

**\*SYSBAS** The job queue library is located in the system ASP (ASP 1) or any basic user ASPs (ASPs 2-32).

- job-queue-library** A character string that contains the name of the library containing *job-queue*.
- job-queue** A character string that contains the name of the job queue to be removed from being tracked.
- ignore-errors** A character string expression that identifies what to do when an error is encountered while removing information from the job tracking file.
  - NO** An error is returned, and the job queue is not removed from tracking. This is the default.
  - YES** A warning is returned.
    - The job queue will be removed from tracking without removing associated information from the job tracking file.

## Example

- Remove job queue APPLIB/APPJOBQ from the list of tracked job queues.

```
CALL QSYS2.REMOVE_TRACKED_JOB_QUEUE(IASP_NAME => '*SYSBAS',
 JOB_QUEUE_LIBRARY => 'APPLIB',
 JOB_QUEUE => 'APPJOBQ');
```

## ROUTING\_ENTRY\_INFO view

The ROUTING\_ENTRY\_INFO view returns information about routing entries.

The values returned for the columns in the view are closely related to the values returned by the Display Routing Entries panel accessed through the DSPSBSD (Display Subsystem Description) CL command and by the List Subsystem Entries (QWDLSE) API.

**Authorization:** The caller must have:

- \*EXECUTE authority to the library containing the subsystem description, and
- \*USE authority to the subsystem description.

The following table describes the columns in the view. The system name is RTG\_INFO. The schema is QSYS2.

Table 284. ROUTING\_ENTRY\_INFO view

| Column Name                   | System Column Name | Data Type               | Description                                                                                                                |
|-------------------------------|--------------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------|
| SUBSYSTEM_DESCRIPTION_LIBRARY | SBSD_LIB           | VARCHAR(10)             | The name of the library in which the subsystem description resides.                                                        |
| SUBSYSTEM_DESCRIPTION         | SBSD               | VARCHAR(10)             | The name of the subsystem about which information is being returned.                                                       |
| SEQUENCE_NUMBER               | SEQNO              | INTEGER                 | The sequence number of the routing entry.                                                                                  |
| PROGRAM_LIBRARY               | PGM_LIB            | VARCHAR(10)<br>Nullable | The name of the library in which the routing entry program resides.<br>Contains the null value if PROGRAM_NAME is *RTGDTA. |

Table 284. ROUTING\_ENTRY\_INFO view (continued)

| Column Name              | System Column Name | Data Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------|--------------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PROGRAM_NAME             | PGM_NAME           | VARCHAR(10)         | <p>The name of the program that is started when a routing step is started through this routing entry. Can contain the following special value:</p> <p><b>*RTGDTA</b> The program name is taken from the routing data that was supplied and matched against this entry. The qualified program name will be taken from the routing data in this case, where the program name is specified in positions 37 through 46 and the library name is taken from positions 47 through 56.</p> |
| CLASS_LIBRARY            | CLASS_LIB          | VARCHAR(10)         | The name of the library in which the routing entry class resides.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| CLASS                    | CLASS              | VARCHAR(10)         | The name of the class that is used when a routing step is started through this routing entry.                                                                                                                                                                                                                                                                                                                                                                                      |
| MAXIMUM_STEPS            | MAX_STEPS          | INTEGER<br>Nullable | <p>The maximum number of routing steps (jobs) that can be active at the same time through this routing entry.</p> <p>Contains the null value if the routing entry specifies *NOMAX, indicating that there is no maximum.</p>                                                                                                                                                                                                                                                       |
| POOL_ID                  | POOL_ID            | INTEGER             | The pool identifier of the storage pool in which the routing entry program is run.                                                                                                                                                                                                                                                                                                                                                                                                 |
| COMPARISON_DATA          | COMPDATA           | VARCHAR(80)         | <p>A value that is compared with the routing data to determine whether this is the routing entry that is used for starting a routing step. Can contain the following special value:</p> <p><b>*ANY</b> Any routing data is considered a match.</p>                                                                                                                                                                                                                                 |
| COMPARISON_START         | COMP_START         | INTEGER<br>Nullable | <p>The starting position for the routing data comparison. The comparison between the compare value and the routing data begins with this position in the routing data character string, and the last character position compared must be less than or equal to the length of the routing data used in the comparison.</p> <p>Contains the null value when COMPARISON_DATA is *ANY.</p>                                                                                             |
| RESOURCES_AFFINITY_GROUP | RAG                | VARCHAR(3)          | <p>Specifies whether jobs using this routing entry are grouped together having affinity to the same set of processors and memory.</p> <p><b>NO</b> The jobs will not be grouped together. They will be spread across all the available system resources.</p> <p><b>YES</b> The jobs will be grouped together such that they will have affinity to the same system resources.</p>                                                                                                   |

Table 284. ROUTING\_ENTRY\_INFO view (continued)

| Column Name                     | System Column Name | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| THREAD_RESOURCES_AFFINITY_GROUP | T_RAG              | VARCHAR(7)             | <p>Specifies whether secondary threads running in jobs that started through this routing entry are grouped together with the initial thread, or spread across the system resources.</p> <p><b>GROUP</b> Secondary threads will all have affinity to the same set of processors and memory as the initial thread.</p> <p><b>NOGROUP</b> Secondary threads will not necessarily have affinity to the same set of processors and memory as the initial thread. They will be spread across all the available system resources.</p> <p><b>SYSVAL</b> The thread resources affinity group and level in the QTHDRSCAFN system value will be used when the job starts.</p> |
| THREAD_RESOURCES_AFFINITY_LEVEL | T_RAL              | VARCHAR(6)<br>Nullable | <p>The degree to which the system tries to maintain the affinity between threads and system resources.</p> <p><b>HIGH</b> A thread will only use the resources it has affinity to, and will wait until they become available if necessary.</p> <p><b>NORMAL</b> A thread will use any processor or memory in the system if the resources it has affinity to are not readily available.</p> <p>Contains the null value when THREAD_RESOURCES_AFFINITY_GROUP is SYSVAL.</p>                                                                                                                                                                                          |

## Example

- List all the routing entries defined for the QBATC subsystem.

```
SELECT *
FROM QSYS2.ROUTING_ENTRY_INFO
WHERE SUBSYSTEM_DESCRIPTION_LIBRARY = 'QSYS' AND
SUBSYSTEM_DESCRIPTION = 'QBATCH';
```

## SCHEDULED\_JOB\_INFO view

The SCHEDULED\_JOB\_INFO view returns information that can also be seen through the Work with Job Schedule Entries (WRKJOBSCDE) command interface. Each job schedule entry contains the information to automatically submit a batch job once or at regularly scheduled intervals.

**Authorization:** No authority is required to access scheduled job rows. Some columns return the null value if the caller does not have the required authority. The caller must have \*JOBCTL special authority or be the user profile listed in the SCHEDULED\_BY column to see the data in all columns.

The following table describes the columns in the view. The system name is SCHED\_JOB. The schema is QSYS2.

Table 285. SCHEDULED\_JOB\_INFO view

| Column Name                | System Column Name | Data Type | Description                                                                                |
|----------------------------|--------------------|-----------|--------------------------------------------------------------------------------------------|
| SCHEDULED_JOB_ENTRY_NUMBER | ENTRYNO            | INTEGER   | The number assigned to the job schedule entry when the entry is added to the job schedule. |

Table 285. SCHEDULED\_JOB\_INFO view (continued)

| Column Name            | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| LAST_ATTEMPTED_SUBMISSION_STATUS     | SBMJOBSTS          | VARCHAR(68)<br>Nullable  | The status from when this scheduled job was last submitted. Values are: <ul style="list-style-type: none"> <li>• JOB SUCCESSFULLY SUBMITTED</li> <li>• LAST JOB SUBMISSION FAILED, CHECK THE JOB MESSAGE QUEUE FOR DETAILS</li> <li>• JOB NOT SUBMITTED DUE TO HELD STATUS</li> <li>• JOB SUBMITTED AFTER SCHEDULED TIME AS SPECIFIED BY RECOVERY ACTION</li> <li>• JOB NOT SUBMITTED AS SPECIFIED BY RECOVERY ACTION</li> </ul> Contains the null value if the scheduled job has never been submitted or if the information is not available. |
| KEEP_ENTRY                           | KEEP               | VARCHAR(3)<br>Nullable   | Whether the job schedule entry is kept or removed after the job has been submitted. <p><b>YES</b>     The job schedule entry is kept.</p> <p><b>NO</b>        The job schedule entry is removed.</p> Contains the null value when the FREQUENCY column does not contain *ONCE or if the information is not available.                                                                                                                                                                                                                          |

## Example

Review the job scheduled entries which are no longer in effect, either because they were explicitly held or because they were scheduled to run a single time and the scheduled date and time has passed.

```
SELECT * FROM QSYS2.SCHEDULED_JOB_INFO WHERE STATUS IN ('HELD', 'SAVED')
ORDER BY SCHEDULED_BY;
```

## SUBSYSTEM\_INFO view

The SUBSYSTEM\_INFO view returns information about all subsystems.

The values returned for the columns in the view are closely related to the values returned by the WRKSBS (Work with Subsystems) CL command and by the Retrieve Subsystem Information (QWDRSBSD) API.

**Authorization:** The caller must have:

- \*EXECUTE authority to the library containing the subsystem description, and
- \*USE authority to the subsystem description.

The following table describes the columns in the view. The system name is SBS\_INFO. The schema is QSYS2.

Table 286. SUBSYSTEM\_INFO view

| Column Name                   | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------|--------------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SUBSYSTEM_DESCRIPTION_LIBRARY | SBSD_LIB           | VARCHAR(10)             | The name of the library in which the subsystem description resides.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| SUBSYSTEM_DESCRIPTION         | SBSD               | VARCHAR(10)             | The name of the subsystem about which information is being returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| STATUS                        | STATUS             | VARCHAR(10)             | The status of the subsystem.<br><br><b>ACTIVE</b> The subsystem is running.<br><b>ENDING</b> An ENDSBS command has been issued for the subsystem or an ENDSYS command has been issued, but the subsystem is still running.<br><b>INACTIVE</b> The subsystem is not running.<br><b>RESTRICTED</b> An ENDSBS command for the controlling subsystem, an ENDSYS *ALL command, or an ENDSYS command has placed the controlling subsystem in a restricted condition.<br><b>STARTING</b> A STRSBS command has been issued for the subsystem, but it is still in the process of being started. |
| MAXIMUM_ACTIVE_JOBS           | MAX_ACT            | INTEGER<br>Nullable     | The maximum number of jobs that can run or use resources in the subsystem at one time.<br><br>Contains the null value if the subsystem description specifies *NOMAX, indicating that there is no maximum.                                                                                                                                                                                                                                                                                                                                                                              |
| CURRENT_ACTIVE_JOBS           | CUR_ACT            | INTEGER                 | The number of jobs currently active in the subsystem. This number includes held jobs but excludes jobs that are disconnected or suspended because of a transfer secondary job or a transfer group job. If STATUS is INACTIVE, returns 0.                                                                                                                                                                                                                                                                                                                                               |
| SUBSYSTEM_MONITOR_JOB         | SBSMONJOB          | VARCHAR(28)<br>Nullable | The qualified job name for the subsystem monitor job as identified to the system.<br><br>Contains the null value if STATUS is INACTIVE.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| TEXT_DESCRIPTION              | TEXT               | VARCHAR(50)<br>Nullable | The text description of the subsystem description.<br><br>Contains the null value if there is no text description.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| CONTROLLING_SUBSYSTEM         | CTL_SBS            | VARCHAR(3)              | Whether this subsystem is the controlling subsystem.<br><br><b>NO</b> This subsystem is not the controlling subsystem.<br><b>YES</b> This subsystem is the controlling subsystem.                                                                                                                                                                                                                                                                                                                                                                                                      |
| WORKLOAD_GROUP                | WRK_GROUP          | VARCHAR(10)<br>Nullable | The name of the workload group used for jobs started in this subsystem.<br><br>Contains the null value if there is no workload group defined for the subsystem.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| SIGNON_DEVICE_FILE_LIBRARY    | DEVFILELIB         | VARCHAR(10)             | The name of the library in which the sign-on device file resides.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| SIGNON_DEVICE_FILE            | DEVFILE            | VARCHAR(10)             | The name of the sign-on device file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Table 286. SUBSYSTEM\_INFO view (continued)

| Column Name                | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------|--------------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SECONDARY_LANGUAGE_LIBRARY | LANG_LIB           | VARCHAR(10)<br>Nullable | The name of the subsystem's secondary language library.<br><br>Contains the null value if there is no secondary language library defined for the subsystem.                                                                                                                                                                                                                                                                                              |
| IASP_NAME                  | IASP_NAME          | VARCHAR(10)<br>Nullable | The name of the auxiliary storage pool (ASP) group associated with the subsystem monitor job. This is the name of the primary ASP device in an ASP group or the name of an ASP device description.<br><br>Contains the null value if the subsystem does not have an auxiliary storage pool (ASP) group associated with it. Only the libraries in the system ASP and any basic user ASPs will be in the library name space for the subsystem monitor job. |

## Example

- Show information for all active subsystems.

```
SELECT *
FROM QSYS2.SUBSYSTEM_INFO
WHERE STATUS = 'ACTIVE' ;
```

## SUBSYSTEM\_POOL\_INFO view

The SUBSYSTEM\_POOL\_INFO view returns information about storage pools defined for subsystems.

The values returned for the columns in the view are closely related to the values returned by the WRKSBS (Work with Subsystems) CL command and by the Retrieve Subsystem Information (QWDRSBSD) API.

**Authorization:** The caller must have:

- \*EXECUTE authority to the library containing the subsystem description, and
- \*USE authority to the subsystem description.

The following table describes the columns in the view. The system name is SBS\_POOL. The schema is QSYS2.

Table 287. SUBSYSTEM\_POOL\_INFO view

| Column Name                   | System Column Name | Data Type   | Description                                                               |
|-------------------------------|--------------------|-------------|---------------------------------------------------------------------------|
| SUBSYSTEM_DESCRIPTION_LIBRARY | SBSD_LIB           | VARCHAR(10) | The name of the library in which the subsystem description resides.       |
| SUBSYSTEM_DESCRIPTION         | SBSD               | VARCHAR(10) | The name of the subsystem about which pool information is being returned. |
| POOL_ID                       | POOL_ID            | INTEGER     | The pool ID for the subsystem pool.                                       |

## Example

- List all the system storage pools in the QBATCH subsystem.

```
SELECT *
FROM QSYS2.SUBSYSTEM_POOL_INFO
WHERE SUBSYSTEM_DESCRIPTION_LIBRARY = 'QSYS' AND
SUBSYSTEM_DESCRIPTION = 'QBATCH' AND
POOL_NAME <> '*USERPOOL';
```

## SYSTEM\_ACTIVITY\_INFO table function

The SYSTEM\_ACTIVITY\_INFO table function returns a single row containing statistical information about CPU usage.

The information returned is similar to the detail provided by the Work with System Activity (WRKSYSACT) CL command.

**Authorization:** The caller must have \*JOBCTL special authority.

►► SYSTEM\_ACTIVITY\_INFO ( — ( ————— ) ) ◄◄  
└──────────────────┘ delay-seconds  
└──────────┘ DELAY\_SECONDS — =>

The schema is QSYS2.

**delay-seconds** An integer value that specifies an interval of time to wait between statistical readings. Detail gathered from two points in time is used to calculate the table function results.

**integer** A delay of *integer* seconds separates the collection of details. *integer* must be a value of 1 or greater. One second is the default.

No response from the table function is returned until at least *integer* seconds have elapsed.

The result of the function is a table containing a single row with the format shown in the following table. All the columns are nullable.

Table 288. SYSTEM\_ACTIVITY\_INFO table function

| Column Name             | Data Type     | Description                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AVERAGE_CPU_RATE        | DECIMAL(20,2) | The average CPU rate expressed as a percentage where 100% indicates the processor is running at its nominal frequency. A value above or below 100% indicates how much the processor has been slowed down (throttled) or speeded up (turbo) relative to the nominal frequency for the processor model. For instance, a value of 120% indicates the processor is running 20% faster against its nominal speed. |
| AVERAGE_CPU_UTILIZATION | DECIMAL(20,2) | The average CPU utilization for all the active processors.                                                                                                                                                                                                                                                                                                                                                   |
| MINIMUM_CPU_UTILIZATION | DECIMAL(20,2) | The CPU utilization of the processor that reported the minimum amount of CPU utilization.                                                                                                                                                                                                                                                                                                                    |
| MAXIMUM_CPU_UTILIZATION | DECIMAL(20,2) | The CPU utilization of the processor that reported the maximum amount of CPU utilization.                                                                                                                                                                                                                                                                                                                    |

### Example

Return statistical CPU information. Use the default one second interval.

```
SELECT * FROM TABLE(QSYS2.SYSTEM_ACTIVITY_INFO());
```

### SYSTEM\_STATUS table function

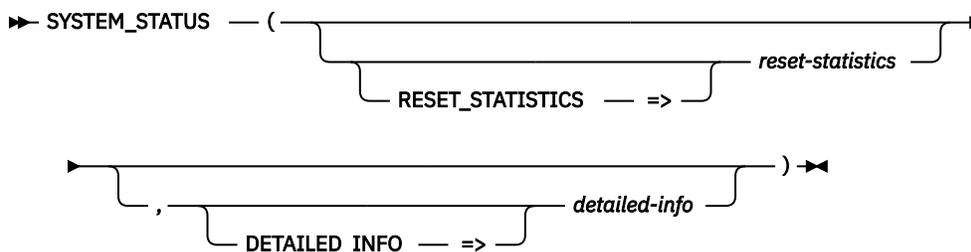

The SYSTEM\_STATUS table function returns a single row containing details about the current partition.

The information returned is similar to the detail seen from the Work with System Status (WRKSYSSTS), Work with System Activity (WRKSYSACT), and Display Job Tables (DSPJOBTL) commands, and information available in the HMC and with the Retrieve Partition Information (dlpar\_get\_info) API.

**Authorization:** To see non-null values for the columns from PARTITION\_NAME through UNUSED\_CPU\_TIME\_SHARED\_POOL, the caller must have \*USE authority to the QSYS/QPMLPMGT service program.

To return values for TEMPORARY\_JOB\_STRUCTURES\_AVAILABLE and PERMANENT\_JOB\_STRUCTURES\_AVAILABLE, the caller must have:

- \*JOBCTL special authority, and
- \*USE authority to the QSYS/QWTCTJBS program.

The schema is QSYS2.

**reset-  
statistics**

A character or graphic string expression that contains a value of YES or NO.

If this parameter has a value of YES, statistics are reset such that the time of this query execution is used as the new baseline. The columns that contain this statistical data have names that are prefixed with ELAPSED\_. Future invocations of SYSTEM\_STATUS within this connection will return statistical detail relative to the new baseline. If this parameter has a value of NO, statistics are not reset for the invocation. If this parameter is not specified, the default is NO.

**detailed-  
info**

A character or graphic string expression that indicates the type of information to be returned.

**ALL** All available system information is returned.

**BASIC** Only the basic system information is returned. Values for the columns from TOTAL\_JOB\_TABLE\_ENTRIES through the JOBLLOG\_PENDING\_JOB\_TABLE\_ENTRIES, and JOBS\_SIGNED\_ON through BATCH\_PRINT\_WAITING are not returned and will always contain the null value. This is the default.

The result of the function is a table containing multiple rows with the format shown in the following table. All the columns are nullable.

Table 289. SYSTEM\_STATUS table function

| Column Name                | Data Type     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TOTAL_JOBS_IN_SYSTEM       | INTEGER       | The total number of user and system jobs that are currently in the system. The total includes: <ul style="list-style-type: none"> <li>All jobs on job queues waiting to be processed.</li> <li>All jobs currently active (being processed).</li> <li>All jobs that have completed running but still have output on output queues to be produced.</li> </ul>                                                                                          |
| MAXIMUM_JOBS_IN_SYSTEM     | INTEGER       | The maximum number of jobs that are allowed on the system. When the number of jobs reaches this maximum, you can no longer submit or start more jobs on the system. The total includes: <ul style="list-style-type: none"> <li>All jobs on job queues waiting to be processed.</li> <li>All jobs currently active (being processed).</li> <li>All jobs that have completed running but still have output on output queues to be produced.</li> </ul> |
| ACTIVE_JOBS_IN_SYSTEM      | INTEGER       | The number of jobs active in the system (jobs that have been started, but have not yet ended), including both user and system jobs.                                                                                                                                                                                                                                                                                                                  |
| INTERACTIVE_JOBS_IN_SYSTEM | DECIMAL(10,2) | The percentage of interactive performance assigned to this logical partition. This value is a percentage of the total interactive performance available to the entire physical system.                                                                                                                                                                                                                                                               |
| JOBS_SIGNED_ON             | INTEGER       | The number of jobs currently signed on the system. System request jobs and group jobs are not included in this number.<br><br>Contains the null value when the DETAILED_INFO parameter is BASIC.                                                                                                                                                                                                                                                     |
| JOBS_DISCONNECTED          | INTEGER       | The number of jobs that have been disconnected due to either the selection of option 80 (Temporary sign-off) or the entry of the Disconnect Job (DSCJOB) command.<br><br>Contains the null value when the DETAILED_INFO parameter is BASIC.                                                                                                                                                                                                          |
| JOBS_SUSPENDED_BY_SYSREQ   | INTEGER       | The number of user jobs that have been temporarily suspended by system request jobs so that another job may be run.<br><br>Contains the null value when the DETAILED_INFO parameter is BASIC.                                                                                                                                                                                                                                                        |

Table 289. SYSTEM\_STATUS table function (continued)

| Column Name                 | Data Type     | Description                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JOBS_SUSPENDED_BY_GROUP_JOB | INTEGER       | The number of user jobs that have been temporarily suspended by group jobs so that another job may be run.<br><br>Contains the null value when the DETAILED_INFO parameter is BASIC.                                                                                                                                                                              |
| JOBS_PRINT_WAITING          | INTEGER       | The number of sessions that have ended with printer output files waiting to print.<br><br>Contains the null value when the DETAILED_INFO parameter is BASIC.                                                                                                                                                                                                      |
| BATCH_RUNNING               | INTEGER       | The number of batch jobs currently running on the system.<br><br>Contains the null value when the DETAILED_INFO parameter is BASIC.                                                                                                                                                                                                                               |
| BATCH_WAITING_TO_RUN        | INTEGER       | The number of batch jobs on the system that are currently waiting to run, including those that were submitted to run at a future date and time. Jobs on the job schedule that have not been submitted are not included.<br><br>Contains the null value when the DETAILED_INFO parameter is BASIC.                                                                 |
| BATCH_ENDING                | INTEGER       | The number of batch jobs that are in the process of ending due to one of the following conditions: <ul style="list-style-type: none"> <li>• The job finished processing normally.</li> <li>• The job ended before its normal completion point and is being removed from the system.</li> </ul> Contains the null value when the DETAILED_INFO parameter is BASIC. |
| BATCH_MESSAGE_WAIT          | INTEGER       | The number of batch jobs waiting for a reply to a message before they can continue to run.<br><br>Contains the null value when the DETAILED_INFO parameter is BASIC.                                                                                                                                                                                              |
| BATCH_HELD_WHILE_RUNNING    | INTEGER       | The number of batch jobs that had started running, but are now held.<br><br>Contains the null value when the DETAILED_INFO parameter is BASIC.                                                                                                                                                                                                                    |
| BATCH_HELD_ON_JOBQ          | INTEGER       | The number of batch jobs that were submitted, but were held before they could begin running.<br><br>Contains the null value when the DETAILED_INFO parameter is BASIC.                                                                                                                                                                                            |

| BATCH_ON_UNASSIGNED_JOBQ    | INTEGER       | The number of batch jobs on job queues that have not been assigned to a subsystem.<br><br>Contains the null value when the DETAILED_INFO parameter is BASIC.                                                                                                                                                                                                      |
| BATCH_PRINT_WAITING         | INTEGER       | The number of completed batch jobs that produced printer output that is waiting to print.<br><br>Contains the null value when the DETAILED_INFO parameter is BASIC.                                                                                                                                                                                               |
| ELAPSED_TIME                | INTEGER       | The time that has elapsed, in seconds, between the measurement start time and the current system time.                                                                                                                                                                                                                                                            |
| ELAPSED_CPU_USED            | DECIMAL(10,2) | The average of the elapsed time during which the processing units were in use.                                                                                                                                                                                                                                                                                    |

Table 289. SYSTEM\_STATUS table function (continued)

| Column Name                   | Data Type     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ELAPSED_CPU_SHARED            | DECIMAL(10,2) | The percentage of the total shared processor pool capacity used by all partitions using the pool during the elapsed time.<br><br>Returns null if this is a dedicated partition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| ELAPSED_CPU_UNCAPPED_CAPACITY | DECIMAL(10,2) | The percentage of the uncapped shared processing capacity for the partition used since the last time statistics were reset.<br><br>Returns null if this partition cannot use more than its configured processing capacity.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| CONFIGURED_CPUS               | INTEGER       | Total number of configured CPUs for the partition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| CPU_SHARING_ATTRIBUTE         | VARCHAR(8)    | This attribute indicates whether this partition is sharing processors. If the value indicates the partition does not share physical processors, then this partition uses only dedicated processors. If the value indicates the partition shares physical processors, then this partition uses physical processors from a shared pool of physical processors.<br><br><b>CAPPED</b> Partition shares processors. The partition is limited to using its configured capacity.<br><br><b>UNCAPPED</b> Partition shares processors. The partition can use more than its configured capacity.<br><br>Contains the null value if this is a dedicated partition. |
| CURRENT_CPU_CAPACITY          | DECIMAL(10,2) | The current processing capacity specifies the processor units that are being used in the partition. For a partition sharing physical processors, the current processing capacity represents the share of the physical processors in the pool it is running. For a partition using dedicated processors, the current processing capacity represents the number of virtual processors that are currently active in the partition.                                                                                                                                                                                                                         |

| SQL_CPU_UTILIZATION           | DECIMAL(10,2) | Always contains the null value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| MAIN_STORAGE_SIZE             | BIGINT        | The amount of main storage, in kilobytes, in the system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| SYSTEM_ASP_STORAGE            | BIGINT        | The storage capacity of the system auxiliary storage pool (ASP number 1) in millions of bytes. This value represents the amount of space available for storage of both permanent and temporary objects.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| TOTAL_AUXILIARY_STORAGE       | BIGINT        | The total auxiliary storage, in millions of bytes, on the system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Table 289. SYSTEM\_STATUS table function (continued)

| Column Name                        | Data Type     | Description                                                                                                                                                                                                                                                     |
|------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SYSTEM_ASP_USED                    | DECIMAL(10,2) | The percentage of the system storage pool (ASP number 1) currently in use.                                                                                                                                                                                      |
| CURRENT_TEMPORARY_STORAGE          | INTEGER       | The current amount of storage, in millions of bytes, in use for temporary objects.                                                                                                                                                                              |
| MAXIMUM_TEMPORARY_STORAGE_USED     | INTEGER       | The largest amount of storage, in millions of bytes, used for temporary objects at any one time since the last IPL.                                                                                                                                             |
| PERMANENT_ADDRESS_RATE             | DECIMAL(6,3)  | The percentage of the maximum possible addresses for permanent objects that have been used.                                                                                                                                                                     |
| TEMPORARY_ADDRESS_RATE             | DECIMAL(6,3)  | The percentage of the maximum possible addresses for temporary objects that have been used.                                                                                                                                                                     |
| TEMPORARY_256MB_SEGMENTS           | DECIMAL(10,2) | The percentage of the maximum possible temporary 256MB segments that have been used.                                                                                                                                                                            |
| TEMPORARY_4GB_SEGMENTS             | DECIMAL(10,2) | The percentage of the maximum possible temporary 4GB segments that have been used.                                                                                                                                                                              |
| PERMANENT_256MB_SEGMENTS           | DECIMAL(10,2) | The percentage of the maximum possible permanent 256MB segments that have been used.                                                                                                                                                                            |
| PERMANENT_4GB_SEGMENTS             | DECIMAL(10,2) | The percentage of the maximum possible permanent 4GB segments that have been used.                                                                                                                                                                              |
| TEMPORARY_JOB_STRUCTURES_AVAILABLE | INTEGER       | The number of temporary job structures that currently exist on the system that are not in use.<br><br>Returns the null value if the user does not have *USE authority on the QSYS/QWTCTJBS program.                                                             |
| PERMANENT_JOB_STRUCTURES_AVAILABLE | INTEGER       | The number of permanent job structures that currently exist on the system that are not in use.<br><br>Returns the null value if the user does not have *USE authority on the QSYS/QWTCTJBS program.                                                             |
| TOTAL_JOB_TABLE_ENTRIES            | INTEGER       | The total number of job table entries. This includes AVAILABLE_JOB_TABLE_ENTRIES and IN_USE_JOB_TABLE_ENTRIES.<br><br>Contains the null value when the DETAILED_INFO parameter is BASIC.                                                                        |
| AVAILABLE_JOB_TABLE_ENTRIES        | INTEGER       | The total number of job table entries that are available.<br><br>Contains the null value when the DETAILED_INFO parameter is BASIC.                                                                                                                             |
| IN_USE_JOB_TABLE_ENTRIES           | INTEGER       | The total number of job table entries that are in use. This includes ACTIVE_JOB_TABLE_ENTRIES, JOBQ_JOB_TABLE_ENTRIES, OUTQ_JOB_TABLE_ENTRIES, and JOBLLOG_PENDING_JOB_TABLE_ENTRIES.<br><br>Contains the null value when the DETAILED_INFO parameter is BASIC. |
| ACTIVE_JOB_TABLE_ENTRIES           | INTEGER       | The total number of entries that are in use by active jobs.<br><br>Contains the null value when the DETAILED_INFO parameter is BASIC.                                                                                                                           |

This does not include processors on demand that have not been turned on.                                                                                                                                            |
| PHYSICAL_PROCESSORS_SHARED_POOL                                                                                                                                                                       | INTEGER                    | The number of physical processors that are allocated to the shared processor pool used by this partition.<br><br>Contains the null value if DEDICATED_PROCESSORS is YES.                                                                                                                                   |
| MAXIMUM_PHYSICAL_PROCESSORS                                                                                                                                                                           | INTEGER                    | The maximum number of physical processors that can be active in this physical machine without installing additional processors. This value includes currently active processors and any standby (on demand) processors that are present in this physical machine.                                          |

Table 289. SYSTEM\_STATUS table function (continued)

| Column Name                          | Data Type    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DEFINED_VIRTUAL_PROCESSORS           | INTEGER      | The number of virtual processors configured for this partition through the HMC.                                                                                                                                                                                                                                                                                                                                                                                                    |
| VIRTUAL_PROCESSORS                   | INTEGER      | The number of virtual processors currently used by this partition.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| MINIMUM_VIRTUAL_PROCESSORS           | INTEGER      | The minimum number of virtual processors that can be configured for this partition.                                                                                                                                                                                                                                                                                                                                                                                                |
| MAXIMUM_VIRTUAL_PROCESSORS           | INTEGER      | The maximum number of virtual processors that can be configured for this partition.                                                                                                                                                                                                                                                                                                                                                                                                |
| DEFINED_PROCESSING_CAPACITY          | DECIMAL(5,2) | The amount of processing capacity that was configured for this partition through the HMC.                                                                                                                                                                                                                                                                                                                                                                                          |
| PROCESSING_CAPACITY                  | DECIMAL(5,2) | The current (usable) amount of processing capacity available to the partition (also known as partition's entitled capacity).                                                                                                                                                                                                                                                                                                                                                       |
| UNALLOCATED_PROCESSING_CAPACITY      | DECIMAL(5,2) | The amount of processing capacity in the partition group this partition belongs to, which is not allocated to any partition and is available for allocation.                                                                                                                                                                                                                                                                                                                       |
| MINIMUM_REQUIRED_PROCESSING_CAPACITY | DECIMAL(5,2) | The minimum amount of processing capacity that the operating system in this partition requires for its operation.                                                                                                                                                                                                                                                                                                                                                                  |
| MAXIMUM_LICENSED_PROCESSING_CAPACITY | DECIMAL(5,2) | The current limit on processing capacity of this partition imposed by the operating system software license for this partition.                                                                                                                                                                                                                                                                                                                                                    |
| MINIMUM_PROCESSING_CAPACITY          | DECIMAL(5,2) | The minimum amount of processing capacity that can be assigned to this partition.                                                                                                                                                                                                                                                                                                                                                                                                  |
| MAXIMUM_PROCESSING_CAPACITY          | DECIMAL(5,2) | The maximum amount of processing capacity that can be assigned to this partition.                                                                                                                                                                                                                                                                                                                                                                                                  |
| PROCESSING_CAPACITY_INCREMENT        | DECIMAL(5,2) | The smallest capacity that can be added to or removed from this partition's processing capacity.                                                                                                                                                                                                                                                                                                                                                                                   |
| DEFINED_INTERACTIVE_CAPACITY         | DECIMAL(5,2) | The amount of interactive capacity that was configured for this partition through the HMC. A partition's interactive capacity is defined as this partition's portion of total interactive capacity of the physical machine.                                                                                                                                                                                                                                                        |
| INTERACTIVE_CAPACITY                 | DECIMAL(5,2) | This partition's current (usable) portion of the physical machine interactive capacity.                                                                                                                                                                                                                                                                                                                                                                                            |
| INTERACTIVE_THRESHOLD                | DECIMAL(5,2) | The maximum interactive CPU utilization which can be sustained in this partition, without causing a disproportionate increase in system overhead.                                                                                                                                                                                                                                                                                                                                  |
| UNALLOCATED_INTERACTIVE_CAPACITY     | DECIMAL(5,2) | The amount of interactive capacity in the partition group this partition belongs to, which is not allocated to any partition and is available for allocation. Interactive capacity is defined as the portion of total interactive capacity of the physical machine.                                                                                                                                                                                                                |
| MINIMUM_INTERACTIVE_CAPACITY         | DECIMAL(5,2) | The minimum portion of the physical machine's interactive capacity that can be assigned to this partition.                                                                                                                                                                                                                                                                                                                                                                         |
| MAXIMUM_INTERACTIVE_CAPACITY         | DECIMAL(5,2) | The maximum portion of the physical machine's interactive capacity that can be assigned to this partition.                                                                                                                                                                                                                                                                                                                                                                         |
| DEFINED_VARIABLE_CAPACITY_WEIGHT     | INTEGER      | The weighting factor that was configured for this partition through the HMC. Variable capacity weight is used for uncapped partitions when they compete for unused CPU cycles in the shared pool. Variable capacity weight can be in the range of 0 - 255. The larger the weight, the more the chance this partition will get additional CPU cycles from the shared pool.<br><br>Contains the null value if the DEDICATED_PROCESSORS is YES or if CPU_SHARING_ATTRIBUTE is CAPPED. |

Table 289. SYSTEM\_STATUS table function (continued)

| Column Name                          | Data Type     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VARIABLE_CAPACITY_WEIGHT             | INTEGER       | The weighting factor that is used to assign additional unused CPU cycles (from the shared processor pool) to the partition. Variable capacity weight is used for uncapped partitions when they compete for unused CPU cycles in the shared pool. This factor is in the range of 0 - 255. The larger the weight, the greater the chance this partition will get additional CPU cycles from the pool. A value of 0 effectively caps this partition at its current (usable) processing capacity.<br><br>Contains the null value if the DEDICATED_PROCESSORS is YES or if CPU_SHARING_ATTRIBUTE is CAPPED. |
| UNALLOCATED_VARIABLE_CAPACITY_WEIGHT | INTEGER       | The amount of capacity weight that is available for allocation to the partition's variable capacity weight.<br><br>Contains the null value if the DEDICATED_PROCESSORS is YES or if CPU_SHARING_ATTRIBUTE is CAPPED.                                                                                                                                                                                                                                                                                                                                                                                   |
| HARDWARE_MULTITHREADING              | VARCHAR(3)    | Indicates whether hardware multi-threading is enabled.<br><br><b>NO</b> Hardware multi-threading is not enabled.<br><b>YES</b> Hardware multi-threading is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| BOUND_HARDWARE_THREADS               | VARCHAR(3)    | Whether hardware threads are bound.<br><br><b>NO</b> Hardware threads are not bound.<br><b>YES</b> Hardware threads are bound.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| THREADS_PER_PROCESSOR                | INTEGER       | The number of hardware threads per processor when hardware multi-threading is enabled.<br><br>Contains the null value if HARDWARE_MULTITHREADING is NO.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| DISPATCH_LATENCY                     | DECIMAL(20,0) | The maximum time in nanoseconds between dispatches of this partition on a physical processor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| DISPATCH_WHEEL_ROTATION_TIME         | DECIMAL(20,0) | The number of nanoseconds in the hypervisor's scheduling window. Each virtual processor will be given the opportunity to execute on a physical processor some time during this period. The amount of time each virtual processor is able to use a physical processor is determined by partition processing capacity.                                                                                                                                                                                                                                                                                   |
| TOTAL_CPU_TIME                       | DECIMAL(20,0) | The number of nanoseconds of CPU time used by this partition since IPL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| INTERACTIVE_CPU_TIME                 | DECIMAL(20,0) | The amount of CPU time, in nanoseconds, used by interactive processes in this partition since partition IPL. An interactive process is any process doing 5250 display device I/O.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| INTERACTIVE_CPU_TIME_ABOVE_THRESHOLD | DECIMAL(20,0) | The amount of CPU time, in nanoseconds, used by interactive processes while exceeding the interactive threshold. This is a total since IPL.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| UNUSED_CPU_TIME_SHARED_POOL          | DECIMAL(20,0) | The number of nanoseconds of CPU time that the physical processors in a shared processor pool have been idle since system IPL.<br><br>Contains the null value if DEDICATED_PROCESSORS is YES or if the partition is not authorized to retrieve shared pool data.                                                                                                                                                                                                                                                                                                                                       |
| MACHINE_TYPE                         | CHAR(4)       | The machine type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| MACHINE_MODEL                        | CHAR(4)       | The machine model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| JOURNAL_RECOVERY_COUNT  | INTEGER    | <p>Specifies the system wide default journal recovery count. The journal recovery count allows you to choose between faster runtime processing of changes to journaled objects and faster IPL or vary on recovery after an abnormal shutdown. The value specified influences the frequency with which journaled objects are forced to auxiliary storage as those objects are changed. The specified journal recovery count indicates the approximate number of journaled changes that would need to be recovered during journal synchronization for this journal in the event of an IPL or vary on after an abnormal shutdown. A smaller value decreases the number of changes that would need to be recovered from this journal by increasing the frequency with which changed objects are forced to disk. A larger value increases the runtime processing of changes to journaled objects by decreasing the frequency with which changed objects are forced to disk. Changing this value may affect overall system performance as it affects the utilization of auxiliary storage devices.</p> <p>This value can be changed with the Change Journal Attributes (CHGJRNA) CL command.</p> <p>The system default for this value is 250,000.</p> |
| JOURNAL_CACHE_WAIT_TIME | INTEGER    | <p>The cache wait time, in seconds, for journal environments with caching enabled. The cache wait time is the maximum number of seconds that the system will wait before writing any lingering journal entries from main memory to disk.</p> <p>This value can be changed with the Change Journal Attributes (CHGJRNA) CL command.</p> <p>The system default for this value is 30 seconds.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Column Name                         | Data Type  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACCESS_PATH_TARGET_RECOVERY_TIME    | VARCHAR(7) | <p>The time, in minutes, targeted for access path protection for the system.</p> <p><b>1-1440</b> The number of minutes set for the system access path recovery time.</p> <p><b>*MIN</b> The system access path recovery time is set to the minimum access path recovery time for the system, which provides for the fastest access path recovery. The eligible access paths for the entire system are protected.</p> <p><b>*NONE</b> No system access path recovery time is set. No access path protection is provided by the system unless needed to meet an ASP specific target access path recovery time. However, current access path exposure is monitored and estimated access path recovery times are available.</p> <p><b>*OFF</b> No access path protection is provided by the system. The system does not monitor current exposure and no estimated access path recovery times are available.</p> <p><b>*SYSDFT</b> The system access path recovery time is set to the system default value of 50 minutes.</p> <p>Contains the null value if the user does not have *JOBCTL special authority.</p> |
| SMAPP_INCLUDE_ACCESS_PATHS          | VARCHAR(9) | <p>Indicates whether the access path recovery time includes only those access paths which are considered eligible for protection or includes all access paths.</p> <p><b>*ALL</b> The access path recovery time includes all access paths, both those that are and those that are not eligible.</p> <p><b>*ELIGIBLE</b> The access path recovery time includes only those access paths which are considered eligible for protection.</p> <p>Contains the null value when ACCESS_PATH_RECOVERY_TIME is *OFF or if the user does not have *JOBCTL special authority.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| ACCESS_PATH_ESTIMATED_RECOVERY_TIME | INTEGER    | <p>The amount of time, in minutes, that the system will take to recover the access paths on the system during initial program load (IPL) and during the vary on of all currently available independent storage pools (IASPs). This value assumes that all access paths that are protected are recovered at IPL or during vary on of IASPs.</p> <p>The estimated system access path recovery time is influenced by SMAPP_INCLUDE_ACCESS_PATHS.</p> <ul style="list-style-type: none"> <li>If SMAPP_INCLUDE_ACCESS_PATHS is *ELIGIBLE, this value is the estimated system access path recovery time of all the eligible access paths that are not chosen for protection.</li> <li>If SMAPP_INCLUDE_ACCESS_PATHS is *ALL, this value is the estimated system access path recovery time of all the eligible access paths that are not chosen for protection plus all the access paths that are not eligible for protection.</li> </ul> <p>Contains the null value when ACCESS_PATH_RECOVERY_TIME is *OFF or if the user does not have *JOBCTL special authority.</p>                                              |

Table 289. SYSTEM\_STATUS table function (continued)

| Column Name                                    | Data Type           | Description                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACCESS_PATH_ESTIMATED_INELIGIBLE_RECOVERY_TIME | INTEGER             | The total time, in minutes, that it will take to recover all access paths which are not eligible for system-managed access path protection.<br><br>Contains the null value when ACCESS_PATH_RECOVERY_TIME is *OFF or if the user does not have *JOBCTL special authority.                                                                                                                                           |
| SMAPP_DISK_STORAGE_USED                        | BIGINT              | The total amount of auxiliary disk storage, in megabytes, used by internal objects that are used exclusively for system-managed access path protection (SMAPP). This value is the sum of the auxiliary storage used for access path protection for each auxiliary storage pool (ASP).<br><br>Contains the null value when ACCESS_PATH_RECOVERY_TIME is *OFF or if the user does not have *JOBCTL special authority. |
| POWER_ENTERPRISE_POOL_PROCESSORS               | INTEGER<br>Nullable | The number of cores assigned to this system as a member of a Power Enterprise Pool. Contains the value -1 if the system is at a level higher than Power Enterprise Pool level 1.0.<br><br>Contains the null value if this system is not a member of a Power Enterprise Pool.                                                                                                                                        |

## Example

Return storage and CPU status for the partition. Specify to reset all the elapsed values to 0.

```
SELECT * FROM TABLE(QSYS2.SYSTEM_STATUS(RESET_STATISTICS=>'YES')) X;
```

## SYSTEM\_STATUS\_INFO view

The SYSTEM\_STATUS\_INFO view returns a single row containing details about the current partition. This view uses the QSYS2.SYSTEM\_STATUS table function with DETAILED\_INFO => 'ALL'.

For better performance, use SYSTEM\_STATUS\_INFO\_BASIC except when the additional job table columns returned by SYSTEM\_STATUS\_INFO are needed by the query.

The information returned is similar to the detail seen from the Work with System Status (WRKSYSSTS), Work with System Activity (WRKSYSACT), and Display Job Tables (DSPJOBTBL) commands, information available in the HMC and with the Retrieve Partition Information (dlpar\_get\_info) API, and journal attribute values. It does not reset the statistical columns; to do this, use the associated table function, “SYSTEM\_STATUS table function” on page 1115.

**Authorization:** To see non-null values for the columns from PARTITION\_NAME through UNUSED\_CPU\_TIME\_SHARED\_POOL, the caller must have \*USE authority to the QSYS/QPMLPMGT service program.

To return values for TEMPORARY\_JOB\_STRUCTURES\_AVAILABLE and PERMANENT\_JOB\_STRUCTURES\_AVAILABLE, the caller must have:

- \*JOBCTL special authority, and
- \*USE authority to the QSYS/QWTCTJBS program.

The following table describes the columns in the view. The system name is SYS\_STATUS. The schema is QSYS2.

Table 290. SYSTEM\_STATUS\_INFO view

| Column Name                 | System Column Name | Data Type    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|--------------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TOTAL_JOBS_IN_SYSTEM        | TOTAL_JOBS         | INTEGER      | The total number of user and system jobs that are currently in the system. The total includes: <ul style="list-style-type: none"> <li>All jobs on job queues waiting to be processed.</li> <li>All jobs currently active (being processed).</li> <li>All jobs that have completed running but still have output on output queues to be produced.</li> </ul>                                                                                          |
| MAXIMUM_JOBS_IN_SYSTEM      | MAX_JOBS           | INTEGER      | The maximum number of jobs that are allowed on the system. When the number of jobs reaches this maximum, you can no longer submit or start more jobs on the system. The total includes: <ul style="list-style-type: none"> <li>All jobs on job queues waiting to be processed.</li> <li>All jobs currently active (being processed).</li> <li>All jobs that have completed running but still have output on output queues to be produced.</li> </ul> |
| ACTIVE_JOBS_IN_SYSTEM       | ACT_JOBS           | INTEGER      | The number of jobs active in the system (jobs that have been started, but have not yet ended), including both user and system jobs.                                                                                                                                                                                                                                                                                                                  |
| INTERACTIVE_JOBS_IN_SYSTEM  | INTER_JOBS         | DECIMAL(5,2) | The percentage of interactive performance assigned to this logical partition. This value is a percentage of the total interactive performance available to the entire physical system.                                                                                                                                                                                                                                                               |
| JOBS_SIGNED_ON              | JOBS_ON            | INTEGER      | The number of jobs currently signed on the system. System request jobs and group jobs are not included in this number.                                                                                                                                                                                                                                                                                                                               |
| JOBS_DISCONNECTED           | JOBS_DSC           | INTEGER      | The number of jobs that have been disconnected due to either the selection of option 80 (Temporary sign-off) or the entry of the Disconnect Job (DSCJOB) command.                                                                                                                                                                                                                                                                                    |
| JOBS_SUSPENDED_BY_SYSREQ    | JOBS_SYSRQ         | INTEGER      | The number of user jobs that have been temporarily suspended by system request jobs so that another job may be run.                                                                                                                                                                                                                                                                                                                                  |
| JOBS_SUSPENDED_BY_GROUP_JOB | JOBS_GRP           | INTEGER      | The number of user jobs that have been temporarily suspended by group jobs so that another job may be run.                                                                                                                                                                                                                                                                                                                                           |
| JOBS_PRINT_WAITING          | JOBS_PRT           | INTEGER      | The number of sessions that have ended with printer output files waiting to print.                                                                                                                                                                                                                                                                                                                                                                   |
| BATCH_RUNNING               | BATCH_RUN          | INTEGER      | The number of batch jobs currently running on the system.                                                                                                                                                                                                                                                                                                                                                                                            |
| BATCH_WAITING_TO_RUN        | BATCH_WAIT         | INTEGER      | The number of batch jobs on the system that are currently waiting to run, including those that were submitted to run at a future date and time. Jobs on the job schedule that have not been submitted are not included.                                                                                                                                                                                                                              |
| BATCH_ENDING                | BATCH_END          | INTEGER      | The number of batch jobs that are in the process of ending due to one of the following conditions: <ul style="list-style-type: none"> <li>The job finished processing normally.</li> <li>The job ended before its normal completion point and is being removed from the system.</li> </ul>                                                                                                                                                           |
| BATCH_MESSAGE_WAIT          | BATCH_MSGW         | INTEGER      | The number of batch jobs waiting for a reply to a message before they can continue to run.                                                                                                                                                                                                                                                                                                                                                           |
| BATCH_HELD_WHILE_RUNNING    | BATCH_RHLD         | INTEGER      | The number of batch jobs that had started running, but are now held.                                                                                                                                                                                                                                                                                                                                                                                 |
| BATCH_HELD_ON_JOBQ          | BATCH_SHLD         | INTEGER      | The number of batch jobs that were submitted, but were held before they could begin running.                                                                                                                                                                                                                                                                                                                                                         |
| BATCH_ON_HELD_JOBQ          | BATCH_JHLD         | INTEGER      | The number of batch jobs on job queues that have been assigned to a subsystem, but are being held.                                                                                                                                                                                                                                                                                                                                                   |
| BATCH_ON_UNASSIGNED_JOBQ    | BATCH_NOS          | INTEGER      | The number of batch jobs on job queues that have not been assigned to a subsystem.                                                                                                                                                                                                                                                                                                                                                                   |
| BATCH_PRINT_WAITING         | BATCH_PRT          | INTEGER      | The number of completed batch jobs that produced printer output that is waiting to print.                                                                                                                                                                                                                                                                                                                                                            |
| ELAPSED_TIME                | ELAP_TIME          | INTEGER      | The time that has elapsed, in seconds, between the measurement start time and the current system time.                                                                                                                                                                                                                                                                                                                                               |
| ELAPSED_CPU_USED            | ELAP_USED          | DECIMAL(5,2) | The average of the elapsed time during which the processing units were in use.                                                                                                                                                                                                                                                                                                                                                                       |

Table 290. SYSTEM\_STATUS\_INFO view (continued)

| Column Name                    | System Column Name | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------|--------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ELAPSED_CPU_SHARED             | ELAP_SHARE         | DECIMAL(5,2)<br>Nullable | The percentage of the total shared processor pool capacity used by all partitions using the pool during the elapsed time.<br><br>Returns null if this is a dedicated partition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| ELAPSED_CPU_UNCAPPED_CAPACITY  | ELAP_UNCAP         | DECIMAL(5,2)<br>Nullable | The percentage of the uncapped shared processing capacity for the partition used since the last time statistics were reset. Returns null if this partition cannot use more than its configured processing capacity.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| CONFIGURED_CPUS                | CONFIGCPUS         | INTEGER                  | Total number of configured CPUs for the partition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| CPU_SHARING_ATTRIBUTE          | CPU_SHARE          | VARCHAR(8)<br>Nullable   | This attribute indicates whether this partition is sharing processors. If the value indicates the partition does not share physical processors, then this partition uses only dedicated processors. If the value indicates the partition shares physical processors, then this partition uses physical processors from a shared pool of physical processors.<br><br><b>CAPPED</b> Partition shares processors. The partition is limited to using its configured capacity.<br><br><b>UNCAPPED</b> Partition shares processors. The partition can use more than its configured capacity.<br><br>Contains the null value if this is a dedicated partition. |
| CURRENT_CPU_CAPACITY           | CPU_CAP            | DECIMAL(5,2)             | The current processing capacity specifies the processor units that are being used in the partition. For a partition sharing physical processors, the current processing capacity represents the share of the physical processors in the pool it is running. For a partition using dedicated processors, the current processing capacity represents the number of virtual processors that are currently active in the partition.                                                                                                                                                                                                                         |

| Column Name                          | System Column Name | Data Type                | Description                                                                                                                                                                                                                                                                                                |
|--------------------------------------|--------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PARTITION_GROUP_ID                   | PART_GROUP         | INTEGER<br>Nullable      | The LPAR group for this partition.                                                                                                                                                                                                                                                                         |
| SHARED_PROCESSOR_POOL_ID             | POOL_ID            | INTEGER<br>Nullable      | The shared processor pool this partition is a member of. A shared processor pool is a set of physical processors on the physical machine that is used to run a set of shared processor partitions. A value of 0 indicates the default pool.<br><br>Contains the null value if DEDICATED_PROCESSORS is YES. |
| DEFINED_MEMORY                       | DEF_MEM            | BIGINT<br>Nullable       | The amount of memory (in megabytes) that was configured for this partition through the HMC.                                                                                                                                                                                                                |
| MINIMUM_MEMORY                       | MIN_MEM            | BIGINT<br>Nullable       | The minimum amount of main storage (in megabytes) that can be assigned to this partition.                                                                                                                                                                                                                  |
| MAXIMUM_MEMORY                       | MAX_MEM            | BIGINT<br>Nullable       | The maximum amount of main storage (in megabytes) that can be assigned to this partition.                                                                                                                                                                                                                  |
| MEMORY_INCREMENT                     | MEM_INCR           | BIGINT<br>Nullable       | The smallest amount of main storage (in megabytes) that can be added to or removed from this partition's memory.                                                                                                                                                                                           |
| DEDICATED_PROCESSORS                 | DED_PROC           | VARCHAR(3)<br>Nullable   | Whether the partition uses dedicated processors.<br><br><b>NO</b> The partition does not use dedicated processors.<br><b>YES</b> The partition uses dedicated processors.                                                                                                                                  |
| PHYSICAL_PROCESSORS                  | PHY_PROC           | INTEGER<br>Nullable      | The number of physical processors in this physical machine that are available for use. This does not include processors on demand that have not been turned on.                                                                                                                                            |
| PHYSICAL_PROCESSORS_SHARED_POOL      | PHY_SHARE          | INTEGER<br>Nullable      | The number of physical processors that are allocated to the shared processor pool used by this partition.<br><br>Contains the null value if DEDICATED_PROCESSORS is YES.                                                                                                                                   |
| MAXIMUM_PHYSICAL_PROCESSORS          | MAX_PHY            | INTEGER<br>Nullable      | The maximum number of physical processors that can be active in this physical machine without installing additional processors. This value includes currently active processors and any standby (on demand) processors that are present in this physical machine.                                          |
| DEFINED_VIRTUAL_PROCESSORS           | DEF_VIRT           | INTEGER<br>Nullable      | The number of virtual processors configured for this partition through the HMC.                                                                                                                                                                                                                            |
| VIRTUAL_PROCESSORS                   | VIRT_PROC          | INTEGER<br>Nullable      | The number of virtual processors currently used by this partition.                                                                                                                                                                                                                                         |
| MINIMUM_VIRTUAL_PROCESSORS           | MIN_VIRT           | INTEGER<br>Nullable      | The minimum number of virtual processors that can be configured for this partition.                                                                                                                                                                                                                        |
| MAXIMUM_VIRTUAL_PROCESSORS           | MAX_VIRT           | INTEGER<br>Nullable      | The maximum number of virtual processors that can be configured for this partition.                                                                                                                                                                                                                        |
| DEFINED_PROCESSING_CAPACITY          | DEF_CAP            | DECIMAL(5,2)<br>Nullable | The amount of processing capacity that was configured for this partition through the HMC.                                                                                                                                                                                                                  |
| PROCESSING_CAPACITY                  | CAPACITY           | DECIMAL(5,2)<br>Nullable | The current (usable) amount of processing capacity available to the partition (also known as partition's entitled capacity).                                                                                                                                                                               |
| UNALLOCATED_PROCESSING_CAPACITY      | AVAIL_CAP          | DECIMAL(5,2)<br>Nullable | The amount of processing capacity in the partition group this partition belongs to, which is not allocated to any partition and is available for allocation.                                                                                                                                               |
| MINIMUM_REQUIRED_PROCESSING_CAPACITY | MIN_REQCAP         | DECIMAL(5,2)<br>Nullable | The minimum amount of processing capacity that the operating system in this partition requires for its operation.                                                                                                                                                                                          |

| Column Name                          | System Column Name | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------|--------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAXIMUM_LICENSED_PROCESSING_CAPACITY | MAX_LICCAP         | DECIMAL(5,2)<br>Nullable | The current limit on processing capacity of this partition imposed by the operating system software license for this partition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| MINIMUM_PROCESSING_CAPACITY          | MIN_CAP            | DECIMAL(5,2)<br>Nullable | The minimum amount of processing capacity that can be assigned to this partition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| MAXIMUM_PROCESSING_CAPACITY          | MAX_CAP            | DECIMAL(5,2)<br>Nullable | The maximum amount of processing capacity that can be assigned to this partition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PROCESSING_CAPACITY_INCREMENT        | CAP_INCR           | DECIMAL(5,2)<br>Nullable | The smallest capacity that can be added to or removed from this partition's processing capacity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| DEFINED_INTERACTIVE_CAPACITY         | DEF_INTCAP         | DECIMAL(5,2)<br>Nullable | The amount of interactive capacity that was configured for this partition through the HMC. A partition's interactive capacity is defined as this partition's portion of total interactive capacity of the physical machine.                                                                                                                                                                                                                                                                                                                                                                        |
| INTERACTIVE_CAPACITY                 | INT_CAP            | DECIMAL(5,2)<br>Nullable | This partition's current (usable) portion of the physical machine interactive capacity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| INTERACTIVE_THRESHOLD                | INT_THRESH         | DECIMAL(5,2)<br>Nullable | The maximum interactive CPU utilization which can be sustained in this partition, without causing a disproportionate increase in system overhead.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| UNALLOCATED_INTERACTIVE_CAPACITY     | AVL_INTCAP         | DECIMAL(5,2)<br>Nullable | The amount of interactive capacity in the partition group this partition belongs to, which is not allocated to any partition and is available for allocation. Interactive capacity is defined as the portion of total interactive capacity of the physical machine.                                                                                                                                                                                                                                                                                                                                |
| MINIMUM_INTERACTIVE_CAPACITY         | MIN_INTCAP         | DECIMAL(5,2)<br>Nullable | The minimum portion of the physical machine's interactive capacity that can be assigned to this partition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| MAXIMUM_INTERACTIVE_CAPACITY         | MAX_INTCAP         | DECIMAL(5,2)<br>Nullable | The maximum portion of the physical machine's interactive capacity that can be assigned to this partition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| DEFINED_VARIABLE_CAPACITY_WEIGHT     | DEF_CAPW           | INTEGER<br>Nullable      | The weighting factor that was configured for this partition through the HMC. Variable capacity weight is used for uncapped partitions when they compete for unused CPU cycles in the shared pool. Variable capacity weight can be in the range of 0 - 255. The larger the weight, the more the chance this partition will get additional CPU cycles from the shared pool.<br><br>Contains the null value if DEDICATED_PROCESSORS is YES or if CPU_SHARING_ATTRIBUTE is CAPPED.                                                                                                                     |
| VARIABLE_CAPACITY_WEIGHT             | VAR_CAPW           | INTEGER<br>Nullable      | The weighting factor that is used to assign additional unused CPU cycles (from the shared processor pool) to the partition. Variable capacity weight is used for uncapped partitions when they compete for unused CPU cycles in the shared pool. This factor is in the range of 0 - 255. The larger the weight, the greater the chance this partition will get additional CPU cycles from the pool. A value of 0 effectively caps this partition at its current (usable) processing capacity.<br><br>Contains the null value if DEDICATED_PROCESSORS is YES or if CPU_SHARING_ATTRIBUTE is CAPPED. |
| UNALLOCATED_VARIABLE_CAPACITY_WEIGHT | AVAIL_CAPW         | INTEGER<br>Nullable      | The amount of capacity weight that is available for allocation to the partition's variable capacity weight.<br><br>Contains the null value if DEDICATED_PROCESSORS is YES or if CPU_SHARING_ATTRIBUTE is CAPPED.                                                                                                                                                                                                                                                                                                                                                                                   |
| HARDWARE_MULTITHREADING              | HW_MLT_THR         | VARCHAR(3)<br>Nullable   | Indicates whether hardware multi-threading is enabled.<br><br><b>NO</b> Hardware multi-threading is not enabled.<br><b>YES</b> Hardware multi-threading is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| BOUND_HARDWARE_THREADS               | HW_BND_THR         | VARCHAR(3)<br>Nullable   | Whether hardware threads are bound.<br><br><b>NO</b> Hardware threads are not bound.<br><b>YES</b> Hardware threads are bound.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Table 290. SYSTEM\_STATUS\_INFO view (continued)

| Column Name                          | System Column Name | Data Type                 | Description                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------|--------------------|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| THREADS_PER_PROCESSOR                | THREADS_PP         | INTEGER<br>Nullable       | The number of hardware threads per processor when hardware multi-threading is enabled.<br><br>Contains the null value if HARDWARE_MULTITHREADING is NO.                                                                                                                                                                                                                                            |
| DISPATCH_LATENCY                     | LATENCY            | DECIMAL(20,0)<br>Nullable | The maximum time in nanoseconds between dispatches of this partition on a physical processor.                                                                                                                                                                                                                                                                                                      |
| DISPATCH_WHEEL_ROTATION_TIME         | DISPATCH_T         | DECIMAL(20,0)<br>Nullable | The number of nanoseconds in the hypervisor's scheduling window. Each virtual processor will be given the opportunity to execute on a physical processor some time during this period. The amount of time each virtual processor is able to use a physical processor is determined by partition processing capacity.                                                                               |
| TOTAL_CPU_TIME                       | CPU_TOTAL          | DECIMAL(20,0)<br>Nullable | The number of nanoseconds of CPU time used by this partition since IPL.                                                                                                                                                                                                                                                                                                                            |
| INTERACTIVE_CPU_TIME                 | CPU_INTER          | DECIMAL(20,0)<br>Nullable | The amount of CPU time, in nanoseconds, used by interactive processes in this partition since partition IPL. An interactive process is any process doing 5250 display device I/O.                                                                                                                                                                                                                  |
| INTERACTIVE_CPU_TIME_ABOVE_THRESHOLD | CPU_THRESH         | DECIMAL(20,0)<br>Nullable | The amount of CPU time, in nanoseconds, used by interactive processes while exceeding the interactive threshold. This is a total since IPL.                                                                                                                                                                                                                                                        |
| UNUSED_CPU_TIME_SHARED_POOL          | CPU_UNUSED         | DECIMAL(20,0)<br>Nullable | The number of nanoseconds of CPU time that the physical processors in a shared processor pool have been idle since system IPL.<br><br>Contains the null value if DEDICATED_PROCESSORS is YES or if the partition is not authorized to retrieve shared pool data.                                                                                                                                   |
| MACHINE_TYPE                         | MACH_TYPE          | CHAR(4)                   | The machine type.                                                                                                                                                                                                                                                                                                                                                                                  |

|----------------------------------|--------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JOURNAL_RECOVERY_COUNT           | JRNRCYCNT          | INTEGER                | <p>Specifies the system wide default journal recovery count. The journal recovery count allows you to choose between faster runtime processing of changes to journaled objects and faster IPL or vary on recovery after an abnormal shutdown. The value specified influences the frequency with which journaled objects are forced to auxiliary storage as those objects are changed. The specified journal recovery count indicates the approximate number of journaled changes that would need to be recovered during journal synchronization for this journal in the event of an IPL or vary on after an abnormal shutdown. A smaller value decreases the number of changes that would need to be recovered from this journal by increasing the frequency with which changed objects are forced to disk. A larger value increases the runtime processing of changes to journaled objects by decreasing the frequency with which changed objects are forced to disk. Changing this value may affect overall system performance as it affects the utilization of auxiliary storage devices.</p> <p>This value can be changed with the Change Journal Attributes (CHGJRNA) CL command.</p> <p>The system default for this value is 250,000.</p> |
| JOURNAL_CACHE_WAIT_TIME          | CACHEWAIT          | INTEGER                | <p>The cache wait time, in seconds, for journal environments with caching enabled. The cache wait time is the maximum number of seconds that the system will wait before writing any lingering journal entries from main memory to disk.</p> <p>This value can be changed with the Change Journal Attributes (CHGJRNA) CL command.</p> <p>The system default for this value is 30 seconds.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| ACCESS_PATH_ESTIMATED_RECOVERY_TIME            | AP_RECOV           | INTEGER<br>Nullable | <p>The amount of time, in minutes, that the system will take to recover the access paths on the system during initial program load (IPL) and during the vary on of all currently available independent storage pools (IASPs). This value assumes that all access paths that are protected are recovered at IPL or during vary on of IASPs.</p> <p>The estimated system access path recovery time is influenced by SMAPP_INCLUDE_ACCESS_PATHS.</p> <ul style="list-style-type: none"> <li>If SMAPP_INCLUDE_ACCESS_PATHS is *ELIGIBLE, this value is the estimated system access path recovery time of all the eligible access paths that are not chosen for protection.</li> <li>If SMAPP_INCLUDE_ACCESS_PATHS is *ALL, this value is the estimated system access path recovery time of all the eligible access paths that are not chosen for protection plus all the access paths that are not eligible for protection.</li> </ul> <p>Contains the null value when ACCESS_PATH_RECOVERY_TIME is *OFF or if the user does not have *JOBCTL special authority.</p> |
| ACCESS_PATH_ESTIMATED_INELIGIBLE_RECOVERY_TIME | AP_INELIG          | INTEGER<br>Nullable | <p>The total time, in minutes, that it will take to recover all access paths which are not eligible for system-managed access path protection.</p> <p>Contains the null value when ACCESS_PATH_RECOVERY_TIME is *OFF or if the user does not have *JOBCTL special authority.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| SMAPP_DISK_STORAGE_USED                        | SMAPP_STG          | BIGINT<br>Nullable  | <p>The total amount of auxiliary disk storage, in megabytes, used by internal objects that are used exclusively for system-managed access path protection (SMAPP). This value is the sum of the auxiliary storage used for access path protection for each auxiliary storage pool (ASP).</p> <p>Contains the null value when ACCESS_PATH_RECOVERY_TIME is *OFF or if the user does not have *JOBCTL special authority.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| POWER_ENTERPRISE_POOL_PROCESSORS               | PEP_PROC           | INTEGER<br>Nullable | <p>The number of cores assigned to this system as a member of a Power Enterprise Pool. Contains the value -1 if the system is at a level higher than Power Enterprise Pool level 1.0.</p> <p>Contains the null value if this system is not a member of a Power Enterprise Pool.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Examples

- Review the state of the job table entries for the partition.

```
SELECT TOTAL_JOB_TABLE_ENTRIES, AVAILABLE_JOB_TABLE_ENTRIES,
 IN_USE_JOB_TABLE_ENTRIES, ACTIVE_JOB_TABLE_ENTRIES,
 JOBQ_JOB_TABLE_ENTRIES, OUTQ_JOB_TABLE_ENTRIES,
 JOBLLOG_PENDING_JOB_TABLE_ENTRIES
FROM QSYS2.SYSTEM_STATUS_INFO;
```

## SYSTEM\_STATUS\_INFO\_BASIC view

The SYSTEM\_STATUS\_INFO\_BASIC view returns a single row containing details about the current partition. This view uses the QSYS2.SYSTEM\_STATUS table function with DETAILED\_INFO => 'BASIC'.

This view contains the same information as SYSTEM\_STATUS\_INFO except it excludes the job table columns.

The information returned is similar to the detail seen from the Work with System Status (WRKSYSSTS) and the Work with System Activity (WRKSYSACT) commands, information available in the HMC and with the Retrieve Partition Information (dlpar\_get\_info) API, and journal attribute values. It does not reset the statistical columns; to do this, use the associated table function, “SYSTEM\_STATUS table function” on [page 1115](#).

**Authorization:** To see non-null values for the columns from PARTITION\_NAME through UNUSED\_CPU\_TIME\_SHARED\_POOL, the caller must have \*USE authority to the QSYS/QPMLPMGT service program.

To return values for TEMPORARY\_JOB\_STRUCTURES\_AVAILABLE and PERMANENT\_JOB\_STRUCTURES\_AVAILABLE, the caller must have:

- \*JOBCTL special authority, and
- \*USE authority to the QSYS/QWTCTJBS program.

The following table describes the columns in the view. The system name is SYS\_STAT\_B. The schema is QSYS2.

Table 291. SYSTEM\_STATUS\_INFO\_BASIC view

| Column Name                   | System Column Name | Data Type                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------|--------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TOTAL_JOBS_IN_SYSTEM          | TOTAL_JOBS         | INTEGER                  | The total number of user and system jobs that are currently in the system. The total includes: <ul style="list-style-type: none"> <li>• All jobs on job queues waiting to be processed.</li> <li>• All jobs currently active (being processed).</li> <li>• All jobs that have completed running but still have output on output queues to be produced.</li> </ul>                                                                                                                                                                                                                                                                                       |
| MAXIMUM_JOBS_IN_SYSTEM        | MAX_JOBS           | INTEGER                  | The maximum number of jobs that are allowed on the system. When the number of jobs reaches this maximum, you can no longer submit or start more jobs on the system. The total includes: <ul style="list-style-type: none"> <li>• All jobs on job queues waiting to be processed.</li> <li>• All jobs currently active (being processed).</li> <li>• All jobs that have completed running but still have output on output queues to be produced.</li> </ul>                                                                                                                                                                                              |
| ACTIVE_JOBS_IN_SYSTEM         | ACT_JOBS           | INTEGER                  | The number of jobs active in the system (jobs that have been started, but have not yet ended), including both user and system jobs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| INTERACTIVE_JOBS_IN_SYSTEM    | INTER_JOBS         | DECIMAL(5,2)             | The percentage of interactive performance assigned to this logical partition. This value is a percentage of the total interactive performance available to the entire physical system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| ELAPSED_TIME                  | ELAP_TIME          | INTEGER                  | The time that has elapsed, in seconds, between the measurement start time and the current system time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| ELAPSED_CPU_USED              | ELAP_USED          | DECIMAL(5,2)             | The average of the elapsed time during which the processing units were in use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ELAPSED_CPU_SHARED            | ELAP_SHARE         | DECIMAL(5,2)<br>Nullable | The percentage of the total shared processor pool capacity used by all partitions using the pool during the elapsed time.<br>Returns null if this is a dedicated partition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| ELAPSED_CPU_UNCAPPED_CAPACITY | ELAP_UNCAP         | DECIMAL(5,2)<br>Nullable | The percentage of the uncapped shared processing capacity for the partition used since the last time statistics were reset. Returns null if this partition cannot use more than its configured processing capacity.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| CONFIGURED_CPUS               | CONFIGCPUS         | INTEGER                  | Total number of configured CPUs for the partition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| CPU_SHARING_ATTRIBUTE         | CPU_SHARE          | VARCHAR(8)<br>Nullable   | This attribute indicates whether this partition is sharing processors. If the value indicates the partition does not share physical processors, then this partition uses only dedicated processors. If the value indicates the partition shares physical processors, then this partition uses physical processors from a shared pool of physical processors.<br><br><b>CAPPED</b> Partition shares processors. The partition is limited to using its configured capacity.<br><br><b>UNCAPPED</b> Partition shares processors. The partition can use more than its configured capacity.<br><br>Contains the null value if this is a dedicated partition. |
| CURRENT_CPU_CAPACITY          | CPU_CAP            | DECIMAL(5,2)             | The current processing capacity specifies the processor units that are being used in the partition. For a partition sharing physical processors, the current processing capacity represents the share of the physical processors in the pool it is running. For a partition using dedicated processors, the current processing capacity represents the number of virtual processors that are currently active in the partition.                                                                                                                                                                                                                         |

| SQL_CPU_UTILIZATION                | CPU_SQL            | DECIMAL(5,2)<br>Nullable | Always contains the null value.                                                                                                                                                                         |
| MAIN_STORAGE_SIZE                  | MAIN_STG           | BIGINT                   | The amount of main storage, in kilobytes, in the system.                                                                                                                                                |
| SYSTEM_ASP_STORAGE                 | SYS_STG            | BIGINT                   | The storage capacity of the system auxiliary storage pool (ASP number 1) in millions of bytes. This value represents the amount of space available for storage of both permanent and temporary objects. |
| TOTAL_AUXILIARY_STORAGE            | AUX_STG            | BIGINT                   | The total auxiliary storage, in millions of bytes, on the system.                                                                                                                                       |
| SYSTEM_ASP_USED                    | SYS_RATE           | DECIMAL(5,2)             | The percentage of the system storage pool (ASP number 1) currently in use.                                                                                                                              |
| CURRENT_TEMPORARY_STORAGE          | TEMP_CUR           | INTEGER                  | The current amount of storage, in millions of bytes, in use for temporary objects.                                                                                                                      |
| MAXIMUM_TEMPORARY_STORAGE_USED     | TEMP_MAX           | INTEGER                  | The largest amount of storage, in millions of bytes, used for temporary objects at any one time since the last IPL.                                                                                     |
| PERMANENT_ADDRESS_RATE             | PERM_RATE          | DECIMAL(6,3)             | The percentage of the maximum possible addresses for permanent objects that have been used.                                                                                                             |
| TEMPORARY_ADDRESS_RATE             | TEMP_RATE          | DECIMAL(6,3)             | The percentage of the maximum possible addresses for temporary objects that have been used.                                                                                                             |
| TEMPORARY_256MB_SEGMENTS           | TEMP_256MB         | DECIMAL(5,2)             | The percentage of the maximum possible temporary 256MB segments that have been used.                                                                                                                    |
| TEMPORARY_4GB_SEGMENTS             | TEMP_4GB           | DECIMAL(5,2)             | The percentage of the maximum possible temporary 4GB segments that have been used.                                                                                                                      |
| PERMANENT_256MB_SEGMENTS           | PERM_256MB         | DECIMAL(5,2)             | The percentage of the maximum possible permanent 256MB segments that have been used.                                                                                                                    |
| PERMANENT_4GB_SEGMENTS             | PERM_4GB           | DECIMAL(5,2)             | The percentage of the maximum possible permanent 4GB segments that have been used.                                                                                                                      |
| TEMPORARY_JOB_STRUCTURES_AVAILABLE | TEMP_JS            | INTEGER<br>Nullable      | The number of temporary job structures that currently exist on the system that are not in use.<br>Returns the null value if the user does not have *USE authority on the QSYS/QWTCTJBS program.         |
| PERMANENT_JOB_STRUCTURES_AVAILABLE | PERM_JS            | INTEGER<br>Nullable      | The number of permanent job structures that currently exist on the system that are not in use.<br>Returns the null value if the user does not have *USE authority on the QSYS/QWTCTJBS program.         |
| HOST_NAME                          | HOST_NAME          | VARCHAR(255)             | Name of the system where this information was generated. This is the name set by CHGNETA.                                                                                                               |
| PARTITION_ID                       | PART_ID            | INTEGER                  | The identifier for the partition in which this view is being run.                                                                                                                                       |

| DEFINED_PROCESSING_CAPACITY          | DEF_CAP            | DECIMAL(5,2)<br>Nullable | The amount of processing capacity that was configured for this partition through the HMC.                                                                                                                                                                                                                                                                                                                                                                                      |
| PROCESSING_CAPACITY                  | CAPACITY           | DECIMAL(5,2)<br>Nullable | The current (usable) amount of processing capacity available to the partition (also known as partition's entitled capacity).                                                                                                                                                                                                                                                                                                                                                   |
| UNALLOCATED_PROCESSING_CAPACITY      | AVAIL_CAP          | DECIMAL(5,2)<br>Nullable | The amount of processing capacity in the partition group this partition belongs to, which is not allocated to any partition and is available for allocation.                                                                                                                                                                                                                                                                                                                   |
| MINIMUM_REQUIRED_PROCESSING_CAPACITY | MIN_REQCAP         | DECIMAL(5,2)<br>Nullable | The minimum amount of processing capacity that the operating system in this partition requires for its operation.                                                                                                                                                                                                                                                                                                                                                              |
| MAXIMUM_LICENSED_PROCESSING_CAPACITY | MAX_LICCAP         | DECIMAL(5,2)<br>Nullable | The current limit on processing capacity of this partition imposed by the operating system software license for this partition.                                                                                                                                                                                                                                                                                                                                                |
| MINIMUM_PROCESSING_CAPACITY          | MIN_CAP            | DECIMAL(5,2)<br>Nullable | The minimum amount of processing capacity that can be assigned to this partition.                                                                                                                                                                                                                                                                                                                                                                                              |
| MAXIMUM_PROCESSING_CAPACITY          | MAX_CAP            | DECIMAL(5,2)<br>Nullable | The maximum amount of processing capacity that can be assigned to this partition.                                                                                                                                                                                                                                                                                                                                                                                              |
| PROCESSING_CAPACITY_INCREMENT        | CAP_INCR           | DECIMAL(5,2)<br>Nullable | The smallest capacity that can be added to or removed from this partition's processing capacity.                                                                                                                                                                                                                                                                                                                                                                               |
| DEFINED_INTERACTIVE_CAPACITY         | DEF_INTCAP         | DECIMAL(5,2)<br>Nullable | The amount of interactive capacity that was configured for this partition through the HMC. A partition's interactive capacity is defined as this partition's portion of total interactive capacity of the physical machine.                                                                                                                                                                                                                                                    |
| INTERACTIVE_CAPACITY                 | INT_CAP            | DECIMAL(5,2)<br>Nullable | This partition's current (usable) portion of the physical machine interactive capacity.                                                                                                                                                                                                                                                                                                                                                                                        |
| INTERACTIVE_THRESHOLD                | INT_THRESH         | DECIMAL(5,2)<br>Nullable | The maximum interactive CPU utilization which can be sustained in this partition, without causing a disproportionate increase in system overhead.                                                                                                                                                                                                                                                                                                                              |
| UNALLOCATED_INTERACTIVE_CAPACITY     | AVL_INTCAP         | DECIMAL(5,2)<br>Nullable | The amount of interactive capacity in the partition group this partition belongs to, which is not allocated to any partition and is available for allocation. Interactive capacity is defined as the portion of total interactive capacity of the physical machine.                                                                                                                                                                                                            |
| MINIMUM_INTERACTIVE_CAPACITY         | MIN_INTCAP         | DECIMAL(5,2)<br>Nullable | The minimum portion of the physical machine's interactive capacity that can be assigned to this partition.                                                                                                                                                                                                                                                                                                                                                                     |
| MAXIMUM_INTERACTIVE_CAPACITY         | MAX_INTCAP         | DECIMAL(5,2)<br>Nullable | The maximum portion of the physical machine's interactive capacity that can be assigned to this partition.                                                                                                                                                                                                                                                                                                                                                                     |
| DEFINED_VARIABLE_CAPACITY_WEIGHT     | DEF_CAPW           | INTEGER<br>Nullable      | The weighting factor that was configured for this partition through the HMC. Variable capacity weight is used for uncapped partitions when they compete for unused CPU cycles in the shared pool. Variable capacity weight can be in the range of 0 - 255. The larger the weight, the more the chance this partition will get additional CPU cycles from the shared pool.<br><br>Contains the null value if DEDICATED_PROCESSORS is YES or if CPU_SHARING_ATTRIBUTE is CAPPED. |

| JOURNAL_RECOVERY_COUNT           | JRNRCYCNT          | INTEGER             | <p>Specifies the system wide default journal recovery count. The journal recovery count allows you to choose between faster runtime processing of changes to journaled objects and faster IPL or vary on recovery after an abnormal shutdown. The value specified influences the frequency with which journaled objects are forced to auxiliary storage as those objects are changed. The specified journal recovery count indicates the approximate number of journaled changes that would need to be recovered during journal synchronization for this journal in the event of an IPL or vary on after an abnormal shutdown. A smaller value decreases the number of changes that would need to be recovered from this journal by increasing the frequency with which changed objects are forced to disk. A larger value increases the runtime processing of changes to journaled objects by decreasing the frequency with which changed objects are forced to disk. Changing this value may affect overall system performance as it affects the utilization of auxiliary storage devices.</p> <p>This value can be changed with the Change Journal Attributes (CHGJRNA) CL command.</p> <p>The system default for this value is 250,000.</p> |
| JOURNAL_CACHE_WAIT_TIME          | CACHEWAIT          | INTEGER             | <p>The cache wait time, in seconds, for journal environments with caching enabled. The cache wait time is the maximum number of seconds that the system will wait before writing any lingering journal entries from main memory to disk.</p> <p>This value can be changed with the Change Journal Attributes (CHGJRNA) CL command.</p> <p>The system default for this value is 30 seconds.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| POWER_ENTERPRISE_POOL_PROCESSORS | PEP_PROC           | INTEGER<br>Nullable | <p>The number of cores assigned to this system as a member of a Power Enterprise Pool. Contains the value -1 if the system is at a level higher than Power Enterprise Pool level 1.0.</p> <p>Contains the null value if this system is not a member of a Power Enterprise Pool.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Examples

- Review the storage and CPU status for the partition.

```
SELECT * FROM QSYS2.SYSTEM_STATUS_INFO_BASIC;
```

- Return job structure information.

```

SELECT
 (SELECT CURRENT_NUMERIC_VALUE FROM QSYS2.SYSTEM_VALUE_INFO
 WHERE SYSTEM_VALUE_NAME = 'QTOTJOB') AS INITIAL_PERM_JOB_STRUCTURES,
 (SELECT CURRENT_NUMERIC_VALUE FROM QSYS2.SYSTEM_VALUE_INFO
 WHERE SYSTEM_VALUE_NAME = 'QADLTOTJ') AS ADDITIONAL_PERM_JOB_STRUCTURES,
 PERMANENT_JOB_STRUCTURES_AVAILABLE AS AVAILABLE_PERM_JOB_STRUCTURES,
 PERMANENT_JOB_STRUCTURES_AVAILABLE + TOTAL_JOBS_IN_SYSTEM AS TOTAL_PERM_JOB_STRUCTURES,
 (SELECT CURRENT_NUMERIC_VALUE FROM QSYS2.SYSTEM_VALUE_INFO
 WHERE SYSTEM_VALUE_NAME = 'QACTJOB') AS INITIAL_TEMP_JOB_STRUCTURES,
 (SELECT CURRENT_NUMERIC_VALUE FROM QSYS2.SYSTEM_VALUE_INFO
 WHERE SYSTEM_VALUE_NAME = 'QADLACTJ') AS ADDITIONAL_TEMP_JOB_STRUCTURES,
 TEMPORARY_JOB_STRUCTURES_AVAILABLE AS AVAILABLE_TEMP_JOB_STRUCTURES,
 (SELECT BUCKET_CURRENT_SIZE FROM QSYS2.SYSTMPSTG
 WHERE GLOBAL_BUCKET_NAME = '*ACTJOB') AS TOTAL_TEMP_STORAGE_USED
FROM QSYS2.SYSTEM_STATUS_INFO_BASIC;

```

## SYSTEM\_VALUE\_INFO view

The SYSTEM\_VALUE\_INFO view contains information about system values.

The values returned for the columns in the view are closely related to the values returned by the Display System Value (DSPSYSVAL) CL command. The complete list of system values can be found in [Retrieve System Values \(QWCRSVAL\) API](#).

**Authorization:** The caller must have \*ALLOBJ or \*AUDIT special authority to retrieve the values for QAUDCTL, QAUDENDACN, QAUDFRCLVL, QAUDLVL, QAUDLVL2, and QCRTOBJAUD. The value of \*NOTAVL or -1 is returned when accessed by an unauthorized user.

The following table describes the columns in the view. The system name is SYSVALINFO. The schema is QSYS2.

Table 292. SYSTEM\_VALUE\_INFO view

| SHIPPED_DEFAULT_VALUE   | DEFAULT            | VARGRAPHIC(3840)<br>CCSID(1200)             | The default value that is shipped for the system value.                                                                                                                                                                                                        |

## Example

Look at the system values related to maximums and their system shipped defaults..

```
SELECT SYSTEM_VALUE_NAME, SYSTEM_VALUE, SHIPPED_DEFAULT_VALUE FROM
QSYS2.SYSTEM_VALUE_INFO
WHERE SYSTEM_VALUE_NAME LIKE '%MAX%';
```

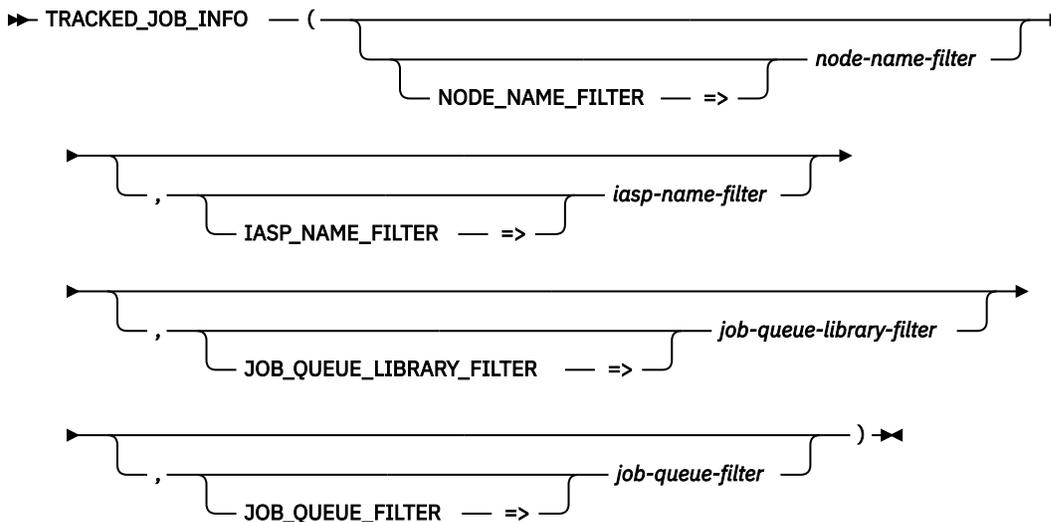

returns

| SYSTEM_VALUE_NAME | SYSTEM_VALUE | SHIPPED_DEFAULT_VALUE |
|-------------------|--------------|-----------------------|
| QMAXACTLVL        | *NOMAX       | *NOMAX                |
| QMAXSIGN          | 10           | 3                     |

| QMAXSGNACN        | 3            | 3                     |
| QMAXJOB           | 163520       | 163520                |
| QMAXSPLF          | 9999         | 9999                  |

## TRACKED\_JOB\_INFO table function

The TRACKED\_JOB\_INFO table function returns information about the requested jobs. The information can be used to resubmit the job. Some information can be provided on the SBMJOB CL command. Other information can be provided on the CHGJOB CL command.

**Authorization:** The caller must have \*JOBCTL special authority.

The schema is QSYS2.

- node-name-filter** A string containing a node name in the job tracking files to be included in the result. If this parameter is omitted, information for all nodes is eligible to be returned.
- iasp-name-filter** A string containing a job queue independent ASP name in the job tracking files to be included in the result. Can contain the special value \*SYSBAS. If this parameter is omitted, information for all ASPs is eligible to be returned.
- job-queue-library-filter** A string containing a job queue library name in the job tracking files to be included in the result. If this parameter is omitted, information for all tracked job queue libraries is eligible to be returned.
- job-queue-filter** A string containing a job queue name in the job tracking files to be included in the result. If this parameter is omitted, information for all tracked job queue queues is eligible to be returned.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 293. TRACKED\_JOB\_INFO table function

| Column Name             | Data Type      | Description                                                                                                                                                                                                                                                                                           |
|-------------------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NODE_NAME               | VARCHAR(8)     | The name of the IBM i partition where the tracked job queue is located.                                                                                                                                                                                                                               |
| QUALIFIED_JOB_NAME      | VARCHAR(28)    | The qualified job name.                                                                                                                                                                                                                                                                               |
| JOB_NAME                | VARCHAR(10)    | The name of the job.                                                                                                                                                                                                                                                                                  |
| JOB_USER                | VARCHAR(10)    | The user profile for the job.                                                                                                                                                                                                                                                                         |
| JOB_NUMBER              | VARCHAR(6)     | The number of the job.                                                                                                                                                                                                                                                                                |
| COMMAND_OR_REQUEST_DATA | VARCHAR(20000) | The command the job will run or the request data that is placed as an entry in the job's message queue.<br>Contains the null value if no command or request data for the job has been set.                                                                                                            |
| JOB_ENTERED_SYSTEM_TIME | TIMESTAMP(0)   | The timestamp for when the job was placed on the system.                                                                                                                                                                                                                                              |
| JOB_ACTIVE_TIME         | TIMESTAMP(0)   | The timestamp for when the job started.<br>Contains the null value if the job has not started.                                                                                                                                                                                                        |
| JOB_END_TIME            | TIMESTAMP(0)   | The timestamp for when the job ended.<br>Contains the null value if the job has not ended.                                                                                                                                                                                                            |
| JOB_QUEUE_ASP_NAME      | VARCHAR(10)    | The ASP device name where the job queue is located.                                                                                                                                                                                                                                                   |
| JOB_QUEUE_LIBRARY       | VARCHAR(10)    | The name of the library containing the job queue.                                                                                                                                                                                                                                                     |
| JOB_QUEUE               | VARCHAR(10)    | The name of the job queue for the submitted job.                                                                                                                                                                                                                                                      |
| JOB_DESCRIPTION_LIBRARY | VARCHAR(10)    | The name of the library containing the job description.                                                                                                                                                                                                                                               |
| JOB_DESCRIPTION         | VARCHAR(10)    | The name of the job description used for this job.                                                                                                                                                                                                                                                    |
| JOB_END_SEVERITY        | INTEGER        | The return code of the job when it ended.<br>Contains the null value if the job has not ended.                                                                                                                                                                                                        |
| PROCESSING_UNIT_TIME    | BIGINT         | The amount of processing unit time used by the job, in milliseconds.<br>Contains the null value if the job has not ended.                                                                                                                                                                             |
| JOB_QUEUE_PRIORITY      | INTEGER        | The scheduling priority of the job compared to other jobs on the same job queue. The highest priority is 0 and the lowest is 9.                                                                                                                                                                       |
| PRINTER_DEVICE_NAME     | VARCHAR(10)    | The printer device used for printing output from this job.                                                                                                                                                                                                                                            |
| OUTPUT_QUEUE_LIBRARY    | VARCHAR(10)    | The name of the library that contains the default output queue.<br>Contains the null value if OUTPUT_QUEUE contains a special value.                                                                                                                                                                  |
| OUTPUT_QUEUE            | VARCHAR(10)    | The name of the default output queue that is used for spooled output produced by this job. The default output queue is only for spooled printer files that specify *JOB for the output queue. Can contain the special value *DEV.                                                                     |
| OUTPUT_QUEUE_PRIORITY   | INTEGER        | The output priority for spooled output files that this job produces. The highest priority is 0, and the lowest is 9.                                                                                                                                                                                  |
| JOB_ACCOUNTING_CODE     | VARCHAR(15)    | An identifier assigned to the job by the system to collect resource use information for the job when job accounting is active.                                                                                                                                                                        |
| RUN_PRIORITY            | INTEGER        | The priority at which the job or thread competes for the processing unit relative to other jobs and threads that are active at the same time. The run priority ranges from 1 (highest priority) to 99 (lowest priority).<br>Contains the null value if the run priority for the job has not been set. |
| PRINT_TEXT              | VARCHAR(30)    | The line of text that is printed at the bottom of each page of printed output for the job.                                                                                                                                                                                                            |

| Column Name               | Data Type     | Description                                                                                                                                                                                                                                                                                          |
|---------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ROUTING_DATA              | VARCHAR(80)   | <p>The routing data that is used to determine the routing entry that identifies the program to start for the routing step. Can contain the following special value:</p> <p><b>*RQSDTA</b> The first 80 characters of COMMAND_OR_REQUEST_DATA are used as the routing data for the job.</p>           |
| CURRENT_LIBRARY           | VARCHAR(10)   | <p>The current library. Can contain the following special value:</p> <p><b>*CRTDFT</b> There is no current library for the submitted job. If objects are created in the current library, QGPL is used as the default current library.</p>                                                            |
| SYSTEM_LIBRARY_LIST_COUNT | INTEGER       | The number of libraries in the system portion of the library list.                                                                                                                                                                                                                                   |
| SYSTEM_LIBRARY_LIST       | VARCHAR(165)  | <p>The system portion of the library list. The list is an array of 11 character entries. Each entry contains a ten character name followed by one blank.</p> <p>Contains the null value if the system library list specified when the job was submitted was empty.</p>                               |
| USER_LIBRARY_LIST_COUNT   | INTEGER       | The number of libraries in the user portion of the library list.                                                                                                                                                                                                                                     |
| USER_LIBRARY_LIST         | VARCHAR(2750) | <p>The user portion of the library list. The list is an array of 11 character entries. Each entry contains a ten character name followed by one blank.</p> <p>Contains the null value if no user library list was specified when the job was submitted, or the specified library list was empty.</p> |
| INITIAL_JOB_ASP_GROUP     | VARCHAR(10)   | <p>The initial setting for the auxiliary storage pool (ASP) group name for the initial thread of the submitted job. Can contain the following special value:</p> <p><b>*NONE</b> The initial thread of the submitted job will be started with no ASP group.</p>                                      |

| Column Name                    | Data Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JOB_LOG_OUTPUT                 | VARCHAR(10) | <p>Specifies how the job log will be produced when the job completes.</p> <p><b>*JOBEND</b> The job log will be produced by the job itself. If the job cannot produce its own job log, the job log will be produced by a job log server. For example, a job does not produce its own job log when the system is processing a Power Down System (PWRDWNSYS) command.</p> <p><b>*JOBLOGSVR</b> The job log will be produced by a job log server. For more information about job log servers, refer to the Start Job Log Server (STRLOGSVR) command.</p> <p><b>*PND</b> The job log will not be produced. The job log remains pending until removed.</p>                                     |
| MAXIMUM_JOB_MESSAGE_QUEUE_SIZE | INTEGER     | The maximum size, in megabytes, that the job message queue can become. The range is 2 to 64.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| JOB_MESSAGE_QUEUE_FULL_ACTION  | VARCHAR(8)  | <p>The action to take when the message queue is full.</p> <p><b>*NOWRAP</b> When the job message queue is full, do not wrap. This action causes the job to end.</p> <p><b>*PRTWRAP</b> When the job message queue is full, wrap the message queue and print the messages that are being overlaid because of the wrapping.</p> <p><b>*WRAP</b> When the job message queue is full, wrap to the beginning and start filling again.</p>                                                                                                                                                                                                                                                      |
| INQUIRY_MESSAGE_REPLY          | VARCHAR(8)  | <p>Specifies how the job answers inquiry messages.</p> <p><b>*RQD</b> The job requires an answer for any inquiry messages that occur while this job is running.</p> <p><b>*DFT</b> The system uses the default message reply to answer any inquiry messages issued while this job is running. The default reply is either defined in the message description or is the default system reply.</p> <p><b>*SYSRPLY</b> The system reply list is checked to see if there is an entry for an inquiry message issued while this job is running. If a match occurs, the system uses the reply value for that entry. If no entry exists for that message, the system uses an inquiry message.</p> |
| HOLD_ON_JOB_QUEUE              | VARCHAR(4)  | <p>Whether this job is on the job queue with a status of held.</p> <p><b>*NO</b> It was not added to the job queue with a status of held.</p> <p><b>*YES</b> It was added to the job queue with a status of held.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Table 293. TRACKED\_JOB\_INFO table function (continued)

| Column Name        | Data Type    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BREAK_MESSAGE      | VARCHAR(10)  | <p>Specifies how this job handles break messages.</p> <p><b>*HOLD</b> The message queue holds break messages until a user or program requests them. The work station user uses the Display Message (DSPMSG) command to display the messages; a program must issue a Receive Message (RCVMSG) command to receive a message and handle it.</p> <p><b>*NORMAL</b> The message queue status determines break message handling.</p> <p><b>*NOTIFY</b> The system notifies the job's message queue when a message arrives. For interactive jobs, the audible alarm sounds if there is one, and the message-waiting light comes on.</p> <p>Contains the null value if the break message for the job has not been set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                    |
| STATUS_MESSAGE     | VARCHAR(10)  | <p>Specifies whether status messages are displayed for this job.</p> <p><b>*NONE</b> This job does not display status messages.</p> <p><b>*NORMAL</b> This job displays status messages.</p> <p>Contains the null value if the status message for the job has not been set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DDM_CONVERSATION   | VARCHAR(5)   | <p>Specifies whether connections using distributed data management (DDM) protocols remain active when they are not being used. The connections include APPC conversations, active TCP/IP connections or Opti-Connect connections.</p> <p><b>*DROP</b> The system ends a DDM connection when there are no users. Examples include when an application closes a DDM file, or when a DRDA application runs a SQL DISCONNECT statement.</p> <p><b>*KEEP</b> The system keeps DDM connections active when there are no users, except for the following:</p> <ul style="list-style-type: none"> <li>• The routing step ends on the source system. The routing step ends when the job ends or when the job is rerouted to another routing step.</li> <li>• The Reclaim Distributed Data Management Conversation (RCLDDMCNV) command or the Reclaim Resources (RCLRSC) command runs.</li> <li>• A communications failure or an internal failure occurs.</li> <li>• A DRDA connection to an application server not running on the system ends.</li> </ul> <p>Contains the null value if the DDM conversation for the job has not been set.</p> |
| JOB_SCHEDULED_TIME | TIMESTAMP(0) | <p>The timestamp for when the job is scheduled to become active.</p> <p>Contains the null value if this is not a scheduled job.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Column Name                | Data Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PURGE_ALLOWED              | VARCHAR(4)  | <p>Specifies whether the job is eligible to be moved out of main storage and put into auxiliary storage at the end of a time slice or when entering a long wait (such as waiting for a work station user's response).</p> <p><b>*NO</b> The job is not eligible to be moved out of main storage and put into auxiliary storage.</p> <p><b>*YES</b> The job is eligible to be moved out of main storage and put into auxiliary storage.</p> <p>Contains the null value if the purge setting for the job has not been set.</p>                                                       |
| DEFAULT_WAIT               | INTEGER     | <p>The default maximum time, in seconds, that a thread in the job waits for a system instruction, such as a LOCK machine interface (MI) instruction, to acquire a resource.</p> <p>Contains the null value if a default wait time for the job has not been set.</p>                                                                                                                                                                                                                                                                                                                |
| PRINT_KEY_FORMAT           | VARCHAR(10) | <p>Specifies whether border and header information is provided when the Print key is pressed.</p> <p><b>*NONE</b> The border and header information is not included with output from the Print key.</p> <p><b>*PRTBDR</b> The border information is included with output from the Print key.</p> <p><b>*PRTHDR</b> The header information is included with output from the Print key.</p> <p><b>*PRTALL</b> The border and header information is included with output from the Print key.</p> <p>Contains the null value if the print key format for the job has not been set.</p> |
| SORT_SEQUENCE_LIBRARY      | VARCHAR(10) | <p>The name or the library that contains the sort sequence table.</p> <p>Contains the null value when SORT_SEQUENCE is a special value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| SORT_SEQUENCE              | VARCHAR(10) | <p>The name of the sort sequence table associated with this job. Can contain the following special values:</p> <p><b>*HEX</b> No sort sequence is used.</p> <p><b>*LANGIDSHR</b> The shared sort sequence for the language identifier is used.</p> <p><b>*LANGIDUNQ</b> The unique sort sequence for the language identifier is used.</p>                                                                                                                                                                                                                                          |
| LANGUAGE_ID                | CHAR(3)     | The language identifier associated with this job.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| COUNTRY_ID                 | CHAR(2)     | The country or region identifier associated with this job.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| CCSID                      | INTEGER     | The coded character set identifier (CCSID) used for this job.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| COPY_ENVIRONMENT_VARIABLES | VARCHAR(4)  | <p>Specifies whether the environment variables from the submitting job are copied to the new job.</p> <p><b>*NO</b> The environment variables are not copied.</p> <p><b>*YES</b> The environment variables are copied.</p>                                                                                                                                                                                                                                                                                                                                                         |
| ALLOW_MULTIPLE_THREADS     | VARCHAR(4)  | <p>Indicates whether this job allows multiple user threads. This attribute does not prevent the operating system from creating system threads in the job.</p> <p><b>*NO</b> This job does not allow multiple user threads.</p> <p><b>*YES</b> This job allows multiple user threads.</p>                                                                                                                                                                                                                                                                                           |

Table 293. TRACKED\_JOB\_INFO table function (continued)

| Column Name                     | Data Type  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DECIMAL_FORMAT                  | VARCHAR(6) | <p>The decimal format used for this job.</p> <p><b>*BLANK</b> Uses a period for a decimal point, a comma for a 3-digit grouping character, and zero-suppress to the left of the decimal point.</p> <p><b>J</b> Uses a comma for a decimal point and a period for a 3-digit grouping character. The zero-suppression character is in the second position (rather than the first) to the left of the decimal notation. Balances with zero values to the left of the comma are written with one leading zero (0,04). The J entry also overrides any edit codes that might suppress the leading zero.</p> <p><b>I</b> Uses a comma for a decimal point, a period for a 3-digit grouping character, and zero-suppress to the left of the decimal point.</p> <p>Contains the null value if the decimal format for the job has not been set.</p> |
| CHARACTER_IDENTIFIER_CONTROL    | VARCHAR(9) | <p>The character identifier control for the job. This attribute controls the type of CCSID conversion that occurs for display files, printer files, and panel groups. The *CHRIDCTL special value must be specified on the CHRID command parameter on the create, change, or override command for display files, printer files, and panel groups before this attribute will be used.</p> <p><b>*DEV D</b> The *DEV D special value performs the same function as on the CHRID command parameter for display files, printer files, and panel groups.</p> <p><b>*JOBCCSID</b> The *JOBCCSID special value performs the same function as on the CHRID command parameter for display files, printer files, and panel groups.</p> <p>Contains the null value if the character identifier control for the job has not been set.</p>             |
| SPOOLED_FILE_ACTION             | VARCHAR(7) | <p>Specifies whether spooled files are accessed through job interfaces after the job has completed is normal activity.</p> <p><b>*DETACH</b> The spooled files are detached from the job when the job completes its activity.</p> <p><b>*KEEP</b> When the job completes its activity, as long as at least one spooled file for the job exists in the system auxiliary storage pool (ASP 1) or in a basic user ASP (ASPs 2-32), the spooled files are kept with the job and the status of the job is updated to indicate that the job has completed. If all remaining spooled files for the job are in independent ASPs (ASPs 33-255), the spooled files will be detached from the job and the job will be removed from the system.</p>                                                                                                   |
| MAXIMUM_PROCESSING_TIME_ALLOWED | INTEGER    | <p>The maximum processing unit time, in milliseconds, that the job can use. If the job consists of multiple routing steps, this is the maximum processing unit time that the current routing step can use. If the maximum time is exceeded, the job is held.</p> <p>Contains the null value if the maximum processing unit time for the job has not been set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

Table 293. TRACKED\_JOB\_INFO table function (continued)

| Column Name                       | Data Type   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAXIMUM_TEMPORARY_STORAGE_ALLOWED | INTEGER     | The maximum amount of auxiliary storage, in megabytes, that the job can use. If the job consists of multiple routing steps, this is the maximum temporary storage that the routing step can use. This temporary storage is used for storage required by the program itself and by implicitly created internal system objects used to support the routing step. (It does not include storage for objects in the QTEMP library.) If the maximum temporary storage is exceeded, the job is held. This does not apply to the use of permanent storage, which is controlled through the user profile.<br><br>Contains the null value if the maximum auxiliary storage for the job has not been set.                                                                                                         |
| PROCESSOR_RESOURCES_PRIORITY      | VARCHAR(10) | If simultaneous multithreading (SMT) is enabled for the system, the relative importance of the job when it is dispatched compared to other jobs that are dispatched.<br><br><b>*HIGH</b> The operating system will isolate this job and its threads, when possible, to processors with fewer threads running concurrently.<br><br><b>*LOW</b> The job and its threads will be dispatched to processors with other low priority jobs executing, when possible.<br><br><b>*NORMAL</b> The job and its threads will be dispatched uniformly across the maximum number of available processors.<br><br><b>*SYSCTL</b> The system determines the processor resources priority for the job and its threads.<br><br>Contains the null value if the processor resources priority for the job has not been set. |
| ROUTING_STEP                      | INTEGER     | A unique number. When TFRJOB is performed for a tracked job, a higher number is generated for a new job record.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| INTERNAL_JOB_IDENTIFIER           | BINARY(16)  | The internal job identifier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Example

- Show all entries in the job queues tracking table for jobs that have not completed for job queue MYJOBQ in library JQLIB.

```
SELECT * FROM TABLE(QSYS2.TRACKED_JOB_INFO(JOB_QUEUE_LIBRARY_FILTER => 'JQLIB',
 JOB_QUEUE_FILTER => 'MYJOBQ'))
WHERE JOB_END_TIME IS NULL;
```

## TRACKED\_JOB\_QUEUES view

The TRACKED\_JOB\_QUEUES view returns a list of job queues that have been registered to be tracked.

Job queues can be added or removed from tracking using the [ADD\\_TRACKED\\_JOB\\_QUEUE](#) and [REMOVE\\_TRACKED\\_JOB\\_QUEUE](#) procedures.

**Authorization:** The caller must have \*JOBCTL special authority.

The following table describes the columns in the view. The system name is TRACKED\_JQ. The schema is QSYS2.

Table 294. TRACKED\_JOB\_QUEUES view

| Column Name          | System Column Name | Data Type   | Description                                                                                                                                                                                                                                        |
|----------------------|--------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IASP_NAME            | JOBQ_IASP          | VARCHAR(10) | The name of the auxiliary storage pool (ASP) device where the job queue resides. Can contain the following special value:<br><br><b>*SYSBAS</b> The job queue resides in the system ASP (ASP 1) or one of the defined basic user ASPs (ASPs 2-32). |
| JOB_QUEUE_LIBRARY    | JOBQ_LIB           | VARCHAR(10) | The library that contains JOB_QUEUE_NAME.                                                                                                                                                                                                          |
| JOB_QUEUE            | JOBQ               | VARCHAR(10) | The name of the job queue that is being tracked.                                                                                                                                                                                                   |
| JOB_RETENTION_PERIOD | RET_PERIOD         | INTEGER     | The number of minutes job tracking information will be retained in the tracking file after the job has ended.                                                                                                                                      |
| TRACKING_FILE_IASP   | TRACK_IASP         | VARCHAR(10) | The name of the IASP device where the job tracking file is created.                                                                                                                                                                                |

### Example

- Review all job queues being tracked:

```
SELECT *
FROM QSYS2.TRACKED_JOB_QUEUES
ORDER BY IASP_NAME, JOB_QUEUE_LIBRARY, JOB_QUEUE;
```

## WORKLOAD\_GROUP\_INFO view

The WORKLOAD\_GROUP\_INFO view returns information about workload groups including their product entries.

The values returned for the columns in the view are closely related to the detail generated by the DSPWLCGRP CL command and the Retrieve Workload Groups Information (QLZRTVWC) API.

**Authorization:** The caller must have \*USE authority to the QSYS/QLZRTVWC program.

The following table describes the columns in the view. The system name is WLG\_INFO. The schema is QSYS2.

Table 295. WORKLOAD\_GROUP\_INFO view

| Column Name        | System Column Name | Data Type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORKLOAD_GROUP     | WL_GRP             | VARCHAR(10)            | The workload group name.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PROCESSOR_LIMIT    | PROC_LIMIT         | INTEGER                | The processor limit for jobs and threads associated with this workload group. Values are 1-256.                                                                                                                                                                                                                                                                                                                                              |
| NUMBER_OF_PRODUCTS | PROD_COUNT         | INTEGER                | Number of products defined for this workload group. The view returns one row for each of the products defined for a specific WORKLOAD_GROUP value.                                                                                                                                                                                                                                                                                           |
| PRODUCT_ID         | LICPGM             | VARCHAR(7)<br>Nullable | The identifier of the product.<br>Contains the null value if NUMBER_OF_PRODUCTS is 0.                                                                                                                                                                                                                                                                                                                                                        |
| LICENSE_TERM       | LIC_TERM           | VARCHAR(6)<br>Nullable | The license term associated with this workload group, in one of the following formats:<br><br><b>Vx, VxRy, or VxRyMz</b> where x and y are a number from 0 through 9, and z is a number 0 through 9 or a letter A through Z<br><br><b>vv, vvr, or vvrmm</b> where vv and rr are a number from 00 through 35, and mm is a number 00 through 09 or a letter sequence 0A through 0Z.<br><br>Contains the null value if NUMBER_OF_PRODUCTS is 0. |

Table 295. WORKLOAD\_GROUP\_INFO view (continued)

| Column Name | System Column Name | Data Type              | Description                                                                                                                                                |
|-------------|--------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FEATURE_ID  | FEATURE            | VARCHAR(4)<br>Nullable | The feature number of the product associated with this workload group. Values are 5001 to 9999.<br><br>Contains the null value if NUMBER_OF_PRODUCTS is 0. |

## Example

- Return information about all workload groups.

```
SELECT * FROM QSYS2.WORKLOAD_GROUP_INFO;
```

## WORKSTATION\_INFO view

The WORKSTATION\_INFO view returns information about workstation entries.

The values returned for the columns in the view are closely related to the values returned by the Display Work Station Name Entries and the Display Work Station Type Entries panels accessed through the DSPSBSD (Display Subsystem Description) CL command and by the List Subsystem Entries (QWDLSE) API.

**Authorization:** The caller must have:

- \*EXECUTE authority to the library containing the subsystem description, and
- \*USE authority to the subsystem description.

The following table describes the columns in the view. The system name is WRKST\_INFO. The schema is QSYS2.

Table 296. WORKSTATION\_INFO view

| Column Name                   | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------|--------------------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SUBSYSTEM_DESCRIPTION_LIBRARY | SBSD_LIB           | VARCHAR(10)             | The name of the library in which the subsystem description resides.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| SUBSYSTEM_DESCRIPTION         | SBSD               | VARCHAR(10)             | The name of the subsystem about which information is being returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| WORKSTATION_NAME              | WS_NAME            | VARCHAR(10)<br>Nullable | The name of the workstation that is used by the subsystem. It can be a generic workstation entry like DSP*.<br><br>Contains the null value if WORKSTATION_TYPE is not null.                                                                                                                                                                                                                                                                                                                                                                                                          |
| WORKSTATION_TYPE              | WS_TYPE            | VARCHAR(10)<br>Nullable | The display device type. Can contain the following special values:<br><br><p><b>*ALL</b> All workstation devices. This includes devices with 5250, ASCII, and 327x device types.</p> <p><b>*ASCII</b> ASCII display station.</p> <p><b>*CONS</b> System console display. This entry overrides a device type entry that specifies the same device type as the device being used as the console.</p> <p><b>*NONASCII</b> All workstation devices that use a 5250 data stream. This includes the 327x device types.</p> <p>Contains the null value if WORKSTATION_NAME is not null.</p> |

Table 296. WORKSTATION\_INFO view (continued)

| Column Name             | System Column Name | Data Type               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|--------------------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JOB_DESCRIPTION_LIBRARY | JOBDLIB            | VARCHAR(10)<br>Nullable | The name of the library in which the job description resides.<br><br>Contains the null value if JOB_DESCRIPTION is *USRPRF.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| JOB_DESCRIPTION         | JOB                | VARCHAR(10)             | The name of the job description that is used for jobs started through this workstation entry. Can contain the following special value:<br><br><b>*USRPRF</b> The job description named in the user profile of the user that signs on at this type of workstation is used for jobs started through this entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| ALLOCATION              | ALLOCATION         | VARCHAR(7)              | How the workstations that are associated with this entry are allocated.<br><br><b>*ENTER</b> The workstations are not allocated when the subsystem is started. However, the interactive jobs that are associated with the workstations are allowed to enter this subsystem through the Transfer Job (TFRJOB) command.<br><br><b>*SIGNON</b> The workstations are allocated when the subsystem is started if the workstation is not already in use (signed on) in another subsystem. A sign-on prompt is displayed at each workstation that is associated with this work entry. If a workstation becomes allocated to a different subsystem, interactive jobs that are associated with the workstation are allowed to enter this subsystem through the Transfer Job (TFRJOB) command. |
| MAXIMUM_ACTIVE_JOBS     | MAX_ACTIVE         | INTEGER<br>Nullable     | The maximum number of jobs that can be active at the same time through this entry.<br><br>Contains the null value if the entry specifies *NOMAX, indicating that there is no maximum.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Example

- List all the workstation entries in the QINTER subsystem.

```
SELECT *
FROM QSYS2.WORKSTATION_INFO
WHERE SUBSYSTEM_DESCRIPTION_LIBRARY = 'QSYS' AND
SUBSYSTEM_DESCRIPTION = 'QINTER';
```

## SYSTOOLS

SYSTOOLS is a set of Db2 for IBM i supplied examples and tools.

SYSTOOLS is the name of a Database supplied schema (library). SYSTOOLS differs from other Db2 for i supplied schemas (QSYS, QSYS2, SYSIBM, and SYSIBMADM) in that it is not part of the default system path. As general purpose useful tools or examples are built by IBM, they are considered for inclusion within SYSTOOLS. SYSTOOLS provides a wider audience with the opportunity to extract value from the tools.

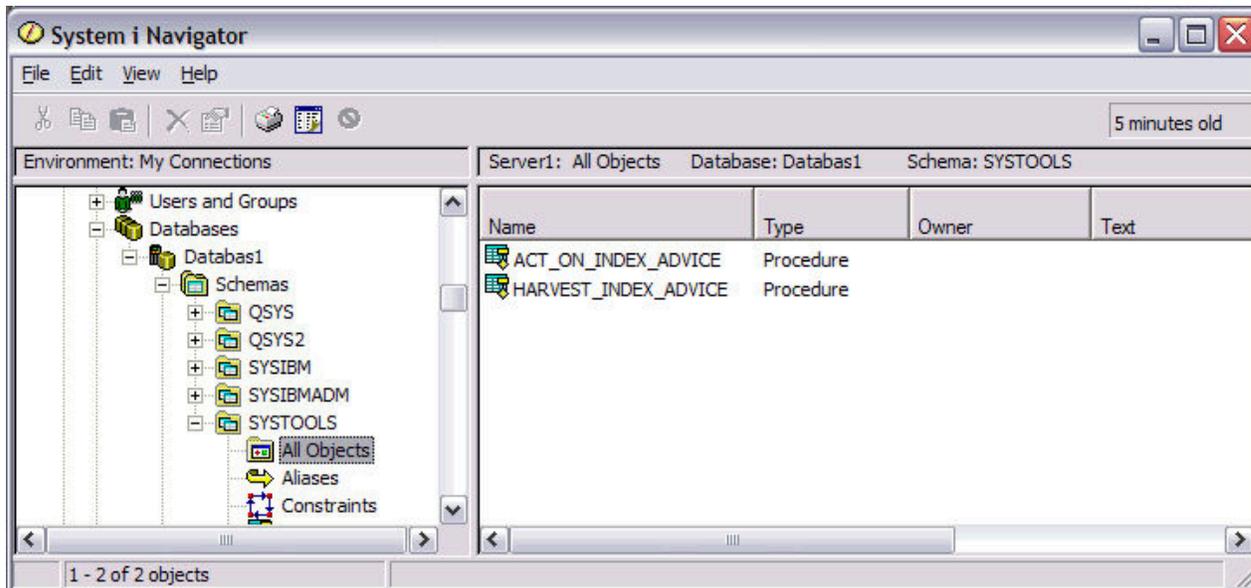

It is the intention of IBM to add content dynamically to SYSTOOLS, either on base releases or through PTFs for field releases. A best practice for customers who are interested in such tools would be to periodically review the contents of SYSTOOLS.

## Using SYSTOOLS

You can generate the sample SQL procedures, learn how to call the procedures, and understand the outcome that is expected. You can also modify the procedure source to customize an example into your business operations.

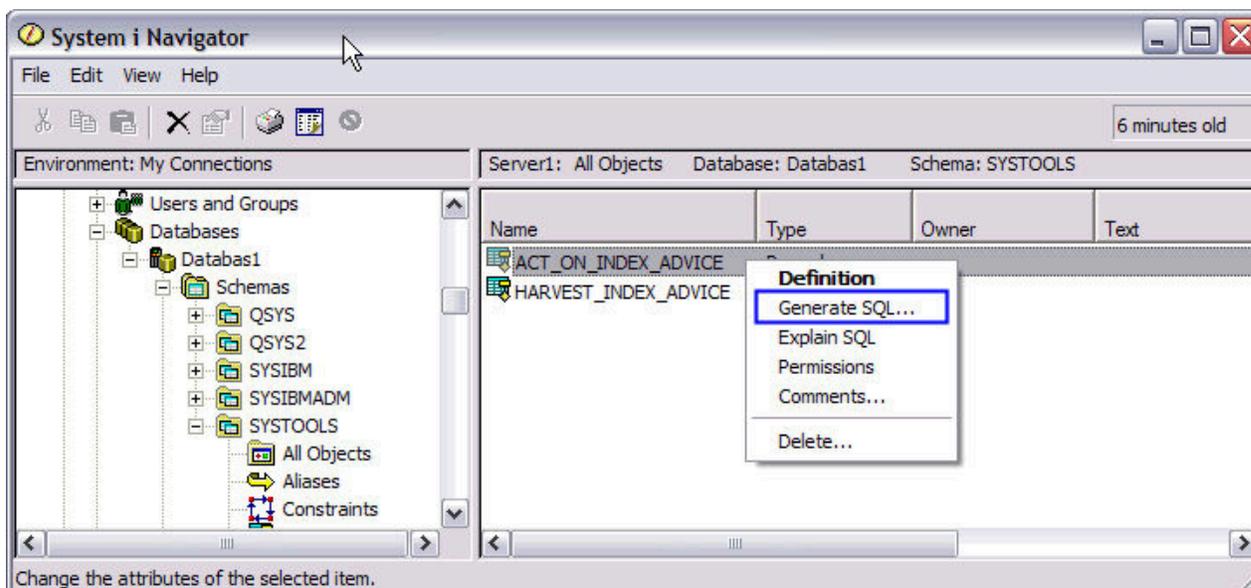

Use System i Navigator, as shown in Figure 1.

Figure 1. System i Navigator schema view of SYSTOOLS:

Start with the Generate SQL action, as shown in Figure 2, to discover and learn within SYSTOOLS. This action utilizes the Generate Data Definition Language (QSQGNDL) API to produce the CREATE PROCEDURE (SQL) statement. This statement is needed to create a replica of the IBM supplied procedure.

Figure 2. Launching Generate SQL from System i Navigator:

After the Generate SQL action completes, as shown in figure 3, you will have a Run SQL Scripts window active, allowing you to do the following:

1. Scroll down and read the procedure prolog.
2. Understand how to call the procedure and the outcome that is expected.

3. Modify the procedure source, including the procedure name and schema. This capability could be the most useful aspect of SYSTOOLS, allowing you to quickly claim and customize an IBM supplied example into your business operations.

Figure 3. Run SQL Scripts view of the generated SQL:

```
-- Example: PROCEDURE SYSTOOLS.ACT_ON_INDEX_ADVICE
--
-- Created on July 16, 2009 by Bob Smith (IBMer@us.ibm.com)
--
-- Disclaimer:
-- This example is being provided by IBM to allow IBM i users to understand how index advice
-- could be consumed to improve an index strategy. The creation of indexes can be time consuming
-- and having seldom used indexes may result in a performance degradation. As with any index
-- strategy, it is recommended that you carefully consider the performance characteristics of
-- your application prior to creating new indexes and that you evaluate the index usage
-- statistics.
--
-- While efforts were made to verify the completeness and accuracy of this sample procedure,
-- this sample is provided 'as is' without any warranty whatsoever and to the maximum extent permitted,
-- IBM disclaims all implied warranties.
--
-- Parameters:
-- 1) P_LIBRARY - The system name of the library which contains the file (table)
-- 2) P_FILE - The system name of the file (table) which may have advised indexes
-- 3) P_TIMES_ADVISED - The number of times an index should be advised before creation of a permanent index.
-- Pass in 1 if you don't want to limit the index creation by times advised.
-- 4) P_MTI_USED - The number of times an Maintained Temporary Index has been used since a matching
-- permanent index did not exist.
-- Pass in 0 if you don't want to limit the index creation by MTI used.
-- 5) P_AVERAGE_QUERY_ESTIMATE - The average estimated number of seconds needed to execute the query
-- which drove the index advice.
-- Pass in 1 if you don't want to limit the index creation by average query estimate.
--
-- Other columns which might be useful parameters to gauge index advisor consumption are:
-- LAST_ADVISED
-- ESTIMATED_CREATION_TIME
-- MOST_EXPENSIVE_QUERY
-- TABLE_SIZE
-- MTI_CREATED
-- LAST_MTI_USED
--
-- QSYS2.SYSIXADV documentation can be found here:
-- http://publib.boulder.ibm.com/infocenter/iserics/v6r1m0/topic/rzajq/rzajqindexcols.htm
--
-- Note: This procedure is hard-coded to work against index advice with Sort Sequence = '*HEX';
-- If you want it to work against index advice with sort sequence tables, search for *HEX and replace
-- with the NLS5 schema and library. This restriction is necessary because the procedure should be
-- running with a sort sequence which matches the sort sequence of the index advice.
--
-- DECLARE V_DYNSTMT VARCHAR (30000) ;
-- DECLARE V_INDEXNAME VARCHAR (128) ;
-- DECLARE V_COUNT INTEGER DEFAULT 0 ;
-- DECLARE V1 INT DEFAULT 0 ;
```

The IBM maintenance of SYSTOOLS includes periodically dropping and recreating the IBM supplied objects. Customers are allowed to create their own objects within SYSTOOLS. However, if your user created objects conflict with the IBM supplied objects, your objects might be deleted. The tools and examples within SYSTOOLS are considered ready for use. However, they are not subject to IBM Service and Support as they are not considered part of any IBM product.

## SYSTOOLS Services

The following documented services exist in the SYSTOOLS schema.

- Audit journal entry services: [“Audit journal entry services” on page 664](#)
- ACT\_ON\_INDEX\_ADVICE procedure: [“ACT\\_ON\\_INDEX\\_ADVICE procedure” on page 338](#)
- ADD\_VALIDATION\_LIST\_ENTRY scalar function: [“ADD\\_VALIDATION\\_LIST\\_ENTRY scalar function” on page 895](#)

- [CHANGE\\_USER\\_PROFILE table function: “CHANGE\\_USER\\_PROFILE table function” on page 903](#)
- [CHANGE\\_VALIDATION\\_LIST\\_ENTRY scalar function: “CHANGE\\_VALIDATION\\_LIST\\_ENTRY scalar function” on page 906](#)
- [CHECK\\_PRODUCT\\_OPTIONS table function: “CHECK\\_PRODUCT\\_OPTIONS table function” on page 870](#)
- [CHECK\\_SYSCST procedure: “CHECK\\_SYSCST procedure” on page 369](#)
- [CHECK\\_SYSROUTINE procedure: “CHECK\\_SYSROUTINE procedure” on page 371](#)
- [CONFIGURATION\\_STATUS view: “CONFIGURATION\\_STATUS view” on page 604](#)
- [DEFECTIVE\\_PTF\\_CURRENCY view: “DEFECTIVE\\_PTF\\_CURRENCY view” on page 879](#)
- [DELETE\\_OLD\\_SPOOLED\\_FILES procedure: “DELETE\\_OLD\\_SPOOLED\\_FILES procedure” on page 944](#)
- [END\\_JOBS procedure: “END\\_JOBS procedure” on page 1045](#)
- [ENDED\\_JOB\\_INFO table function: “ENDED\\_JOB\\_INFO table function” on page 1048](#)
- [ERRNO\\_INFO scalar function: “ERRNO\\_INFO scalar function” on page 483](#)
- [FIRMWARE\\_CURRENCY view: “FIRMWARE\\_CURRENCY view” on page 881](#)
- [GENERATE\\_PDF scalar function: “GENERATE\\_PDF scalar function” on page 946](#)

- [SEND\\_EMAIL scalar function: “SEND\\_EMAIL scalar function” on page 513](#)
- [SPECIAL\\_AUTHORITY\\_DATA\\_MART: “SPECIAL\\_AUTHORITY\\_DATA\\_MART table” on page 924](#)
- [SPLIT table function: “SPLIT table function” on page 518](#)
- [SPOOLED\\_FILE\\_DATA table function: “SPOOLED\\_FILE\\_DATA table function” on page 966](#)
- [SQLCODE\\_INFO table function: “SQLCODE\\_INFO table function” on page 334](#)
- [VALIDATE\\_DATA table function: “VALIDATE\\_DATA, VALIDATE\\_DATA\\_FILE, and VALIDATE\\_DATA\\_LIBRARY table functions” on page 418](#)

## HTTP function overview

The HTTP functions in SYSTOOLS are used to make HTTP requests to web services. These functions allow the SQL programmer to use Representational State Transfer (RESTful) via SQL, including Embedded SQL.

An alternate version of the HTTP functions are shipped in QSYS2. These are implemented using the HTTP Transport support provided by the AXISC APIs instead of Java. See [HTTP\\_DELETE](#), [HTTP\\_GET](#), [HTTP\\_POST](#), [HTTP\\_PUT](#), [HTTP\\_DELETE\\_VERBOSE](#), [HTTP\\_GET\\_VERBOSE](#), [HTTP\\_POST\\_VERBOSE](#), [HTTP\\_PUT\\_VERBOSE](#)

### Environmental considerations

Because the HTTP functions use functionality provided by Java, a Java environment is created in the current job. This requires the following conditions.

1. A JVM must not already exist in the job (with the exception of a JVM created by the Java stored procedures support).
2. The job CCSID cannot be 65535.
3. PASE must be installed and operational. The CHKPRDOPT PRDID(5770SS1) OPTION(33) CL command can be used to verify that PASE is installed.

### Foundational HTTP functions

The foundational functions are named according to the three dimensions used when making HTTP requests.

- The first dimension is the HTTP operation. There are 4 different HTTP operations: GET, PUT, POST, and DELETE.
- The second dimension is the data type used for returning data. There are two alternatives: BLOB and CLOB.
- The third dimension is if the verbose version of the function should be used. Non-verbose functions are scalar functions. The VERBOSE functions are table functions that return the return header information that is sent from the HTTP server.

The names of the functions reflect these three dimensions. For example, the HTTPGETCLOBVERBOSE uses the GET operation from the first dimension, the CLOB data type from the second dimension, and the VERBOSE setting from the third dimension.

The following table summarizes the 16 functions that are named according to the three dimensions.

| <b>make HTTP requests<br/>Function</b> | <b>Description</b>                                                     | <b>Documentation link</b>                                                                      |
|----------------------------------------|------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|
| HTTPDELETEBLOB                         | Makes an HTTP DELETE request and return BLOB data.                     | <a href="#">“HTTPDELETEBLOB and HTTPDELETECLOB scalar functions” on page 1165</a>              |
| HTTPDELETEBLOBVERBOSE                  | Makes an HTTP DELETE request and return BLOB data and response header. | <a href="#">“HTTPDELETEBLOBVERBOSE and HTTPDELETECLOBVERBOSE table functions” on page 1165</a> |
| HTTPDELETECLOB                         | Makes an HTTP DELETE request and return CLOB data.                     | <a href="#">“HTTPDELETEBLOB and HTTPDELETECLOB scalar functions” on page 1165</a>              |
| HTTPDELETECLOBVERBOSE                  | Makes an HTTP DELETE request and return CLOB data and response header. | <a href="#">“HTTPDELETEBLOBVERBOSE and HTTPDELETECLOBVERBOSE table functions” on page 1165</a> |

Table 297. Foundational HTTP functions (continued)

| <b>make HTTP requests<br/>Function</b> | <b>Description</b>                                                   | <b>Documentation link</b>                                                                  |
|----------------------------------------|----------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| HTTPGETBLOB                            | Makes an HTTP GET request and return BLOB data.                      | <a href="#">“HTTPGETBLOB and HTTPGETCLOB scalar functions” on page 1166</a>                |

| HTTPPUTBLOB                            | Makes an HTTP PUT request and return BLOB data.                      | <a href="#">“HTTPPUTBLOB and HTTPPUTCLOB scalar functions” on page 1169</a>                |
| HTTPPUTBLOBVERBOSE                     | Makes an HTTP PUT request and return BLOB data and response header.  | <a href="#">“HTTPPUTBLOBVERBOSE and HTTPPUTCLOBVERBOSE table functions” on page 1169</a>   |
| HTTPPUTCLOB                            | Makes an HTTP PUT request and return CLOB data.                      | <a href="#">“HTTPPUTBLOB and HTTPPUTCLOB scalar functions” on page 1169</a>                |
| HTTPPUTCLOBVERBOSE                     | Makes an HTTP PUT request and return CLOB data and response header.  | <a href="#">“HTTPPUTBLOBVERBOSE and HTTPPUTCLOBVERBOSE table functions” on page 1169</a>   |

These HTTP functions are passed parameters that indicate the HTTP server to access, the settings of the HTTP headers, and any data to be sent to the server. The first two parameters are the same for each HTTP function.

- The first parameter is the URL used to access the server.
- The second parameter is an XML document which indicates the HTTP header that is to be presented to the server by the request. This XML document can be provided as either a CLOB or XML value. The HTTP header XML document has the following format:

```
<httpHeader headerAttribute="headerAttributeValue">
 <header name="name" value="value" />
 <header name="Accept" value="text/plain,application/xml,*/*" />
</httpHeader>
```

The XML header document consists of an *httpHeader* element with various attributes, described below. The *httpHeader* element then contains *header* elements that are used to set additional HTTP headers. This is done by specifying the name of the header and the value that corresponds to the name.

The following attributes can be set in the *httpHeader* element.

Attribute name	Type	Default	Description
connectionTimeout	Integer	SystemDefault	Timeout in milliseconds
readTimeout	Integer	SystemDefault	Timeout in milliseconds
followRedirects	Boolean	true	If true, then redirects are followed. Redirects will only be followed if the protocol does not change. For example, a redirect from "http:" to "https:" will not be followed.
useCaches	Boolean	true	If true, then caches are used.
includeErrorMsg	Boolean	false	If true, then HTTP verbose functions will return error information in the RESPONSEMSG column.

The *header* elements allow various HTTP headers to be set. The following header names are case insensitive: "Content-Type", "Content-Length", "Content-Encoding", "Accept-Encoding", "Authorization", "User-Agent". The remaining headers are sent as specified. To correctly use these headers, consult the appropriate Web server and RFC documentation on the use of HTTP request headers. Examples of RFCs are <https://tools.ietf.org/html/rfc2616> and <https://tools.ietf.org/html/rfc7231>.

For example, using the header

```
<httpHeader><header name="User-Agent" value="IBM i HTTP function"/></httpHeader>
```

will cause "User-Agent": "IBM i HTTP function" to be included in the HTTP header sent to the server.

## Generic HTTP functions

The HTTPBLOB and HTTPCLOB functions can be used to perform any of the non-verbose HTTP functions by passing the operation to perform as an argument: GET, PUT, POST, or DELETE.

Function	Description	Documentation link
HTTPBLOB	Makes an HTTP request and return BLOB data.	<a href="#">"HTTPBLOB and HTTPCLOB scalar functions" on page 1163</a>
HTTPCLOB	Makes an HTTP request and return CLOB data.	<a href="#">"HTTPBLOB and HTTPCLOB scalar functions" on page 1163</a>

## Utility HTTP functions

Some additional HTTP functions are utility functions for working with HTTP requests.

Function	Description	Documentation link
BASE64DECODE	Returns a bit data string that has been Base64 decoded.	<a href="#">“BASE64DECODE scalar function” on page 1162</a>
BASE64ENCODE	Returns the Base64 encoded version of a character string.	<a href="#">“BASE64ENCODE scalar function” on page 1162</a>
HTTPHEAD	Verifies the HTTP header using an HTTP HEAD request.	<a href="#">“HTTPHEAD scalar function” on page 1167</a>
URLDECODE	Decodes a URL encoded string.	<a href="#">“URLDECODE scalar function” on page 1170</a>
URLENCODE	Encodes a string using URL encoding.	<a href="#">“URLENCODE scalar function” on page 1171</a>

## Common errors

When an error occurs, to get additional information about the error consider using the VERBOSE form of the function with `includeErrorMsg="true"`. This will return error information in the RESPONSEMSG column. For example:

```
select * from table(systools.httpgetclobverbose('http://www.w3.org/notfound.html',
 '<httpHeader includeErrorMsg="true"/>'))
```

The following are some common errors that may be encountered when using the HTTP functions.

- If the current system does not have internet access, the following error may be encountered.  
[SQL4302] Java stored procedure or user-defined function SYSTOOLS.HTTPGETCLOB, specific name HTTPG00005 aborted with an exception "java.net.ConnectException:A remote host refused an attempted connect operation. (Connection refused)".
- If DNS is not configured on the system, the following error may be encountered.  
[SQL4302] Java stored procedure or user-defined function SYSTOOLS.HTTPGETCLOB, specific name HTTPG00005 aborted with an exception "java.net.UnknownHostException"
- If the Job CCSID is 65535, the following error may be encountered.  
[SQL0332] Character conversion between CCSID 65535 and CCSID 1200 not valid.
- If https is being used, then the connection uses SSL. In order to work properly, the server must use a certificated signed by a recognized certificate authority. Using a self signed certificate may result in the following error.  
[SQL4302] Java stored procedure or user-defined function SYSTOOLS.HTTPGETCLOB, specific name HTTPG00005 aborted with an exception "com.ibm.jsse2.util.h: PKIX path building failed: java.security.cert.CertPathBuilderException: PKIXCertPathBuilderImpl could not build a valid CertPath.

If you must access a server that uses a self signed certificate, you must add a certificate to the trust store of the JVM being used. If the current JVM is the 32-bit JDK 6, then the following command may be used in QSH after downloading the certificate from the server. The trust store of the JVM may be

refreshed when Java PTFs are applied, causing the loss of local changes. This step needs to be repeated after applying Java PTFs that refresh the trust store.

```
keytool -import -trustcacerts
-keystore /QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit/jre/lib/security/cacerts
-storepass changeit -noprompt -alias myhost -file myhost.crt
```

- Some websites require the use of specific SSL versions. In that case, an error like the following may be encountered.

```
[SQL4302] Java stored procedure or user-defined function
SYSTOOLS.HTTPGETCLOBVERBOSE, specific name HTTPG00007 aborted with an
exception "Received fatal alert: handshake_failure".
```

To force the use of a specific SSL version, the following may be done.

1. Create a user defined function to set a JVM property. This only needs to be done once per system.

```
CREATE FUNCTION SYSTOOLS.setProperty(PROPERTY VARCHAR(80), VALUE VARCHAR(80))
RETURNS VARCHAR(80)
LANGUAGE JAVA
PARAMETER STYLE JAVA
EXTERNAL NAME 'java.lang.System.setProperty'
```

2. Before calling the HTTP function in a job, use the following to set the default SSL protocol.

```
VALUES SYSTOOLS.setProperty('com.ibm.jsse2.overrideDefaultProtocol','TLSv12')
```

## Debugging considerations

Using STRSQL to invoke HTTP functions will not provide useful problem information. Instead, you should use ACS Run SQL Scripts to execute the HTTP functions in order to see error information.

Because the HTTP functions utilize the networking functions provided by Java, any networking problem detected by the Java code may not be exposed to the SQL level with enough detail to diagnose the problem. If the HTTP functions fail with an SQL4302 error and the information is not useful, a Java stored procedure trace may be used to see more information about the exception.

A Java stored procedure trace may be executed and viewed by using the following SQL statements.

- Enable the trace.

```
CALL QSYS2.QCMDEXC('ADDENVVAR ENVVAR(QIBM_COMPONENT_TRACE_LEVEL)
VALUE(''SQJAVA,VERBOSE'')')
```

- Execute the HTTP function.
- Dump the trace to a file in QTEMP.

```
CALL QSYS2.QCMDEXC('DMPUSRTRC')
```

- Copy the trace to the current library.

```
CREATE TABLE MYTRACE AS
(SELECT TRIM(CAST(QAP0ZDMP AS VARCHAR(200) CCSID 37)) LINE FROM QTEMP.QAP0ZDMP)
WITH DATA
```

- View the Java exception in the trace.

```
SELECT * FROM MYTRACE
WHERE LINE LIKE '% at %' OR LINE LIKE '%Except%'
```

## BASE64DECODE scalar function

The BASE64DECODE function returns a character string that has been Base64 decoded. Base64 encoding is widely used to represent binary data as a string.

►► BASE64DECODE — (  *character-string* — ) ►◄

The schema is SYSTOOLS.

***character-string*** A character string in CCSID 1208 that is currently Base64 encoded. The length cannot exceed 4096 characters.

The result of the function is a varying length character for bit data string that contains *character-string* after being Base64 decoded.

### Example

- Decode a binary string that was originally X'1122334455'. The result is the original value.

```
VALUES SYSTOOLS.BASE64DECODE('ESIZRFU=');
```

## BASE64ENCODE scalar function

The BASE64ENCODE function returns the Base64 encoded version of the binary values of a character string.

►► BASE64ENCODE — (  *character-string* — ) ►◄

The schema is SYSTOOLS.

***character-string*** A character expression to be encoded. The maximum length is 2732 characters.

The result of the function is a varying length character string in CCSID 1208 that contains the bytes of *character-string* as a Base64-encoded string.

### Example

- Encode a string that contains the value X'1122334455'.

```
VALUES SYSTOOLS.BASE64ENCODE(X'1122334455');
```

The result is: ESIZRFU=.

- Encode a character string in CCSID 37 that contains the value 'ABC'.

```
VALUES SYSTOOLS.BASE64ENCODE('ABC');
```

The result is: wCLD

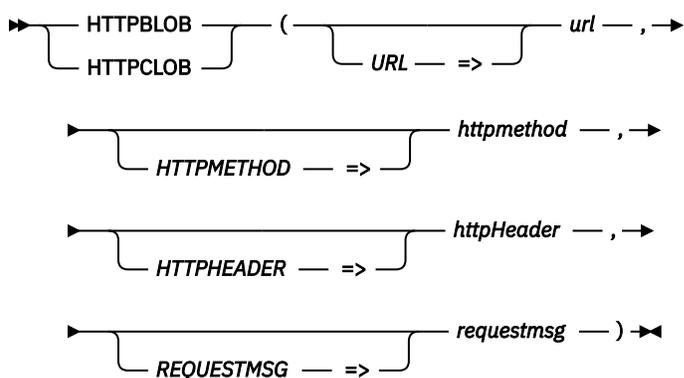

- Encode a UTF-8 string that contains the value 'ABC'.

```
VALUES SYSTOOLS.BASE64ENCODE(CAST('ABC' AS VARCHAR(10) CCSID 1208));
```

The result is: QUJD

## HTTPBLOB and HTTPCLOB scalar functions

The HTTPBLOB and HTTPCLOB REST functions complete an HTTP request with the specified HTTP verb.

The schema is SYSTOOLS.

- url*** Specifies the URL at which to complete the request. This argument is defined as a VARCHAR(2048) CCSID 1208 value.
- httpmethod*** Specifies the HTTP verb to use. Valid values are GET, POST, PUT, and DELETE.
- httpHeader*** Specifies an optional header XML document. To use the default HTTP header, specify NULL or the empty string. This parameter is a CLOB(10K) CCSID 1208 or an XML value. See “[Foundational HTTP functions](#)” on page 1157 for a description of the header content.
- requestmsg*** Specifies the data to update at the specified URL. For the HTTPBLOB function, this argument is defined as BLOB(2G). For the HTTPCLOB function, this argument is defined as CLOB(2G) CCSID 1208. This argument is required for the POST and PUT methods.

For the HTTPBLOB function, the result response message is returned as BLOB(2G). For the HTTPCLOB function, the result response message is returned as CLOB(2G) CCSID 1208.

### Example

- Use HTTPCLOB with the HTTP GET method to retrieve the group PTF information from the IBM PSP website.

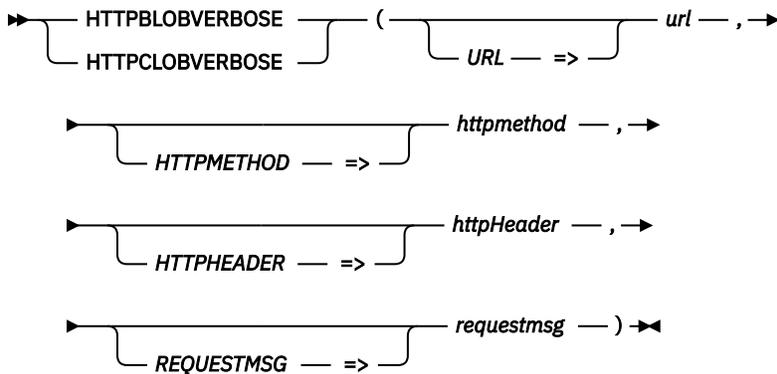

```
VALUES SYSTOOLS.HTTPCLOB(
 XMLDOC.XML',
 URL => 'https://www.ibm.com/support/pages/sites/default/files/inline-files/
 HTTPMETHOD => 'GET',
 HTTPHEADER => NULL,
 REQUESTMSG => NULL);
```

The same operation could be performed using the HTTPGETCLOB function.

```
VALUES SYSTOOLS.HTTPGETCLOB(
 XMLDOC.XML',
 URL => 'https://www.ibm.com/support/pages/sites/default/files/inline-files/
 HTTPHEADER => NULL);
```

## HTTPBLOBVERBOSE and HTTPCLOBVERBOSE table functions

The HTTPBLOBVERBOSE and HTTPCLOBVERBOSE REST table functions complete an HTTP request with the specified HTTP verb. They return a one row table that contains the normal HTTP response for the request and the header information returned from the HTTP request.

The schema is SYSTOOLS.

**url** Specifies the URL at which to complete the request. This argument is defined as a VARCHAR(2048) CCSID 1208 value.

**httpmethod** Specifies the HTTP verb to use. Valid values are GET, POST, PUT, and DELETE.

**httpHeader** Specifies an optional header XML document. To use the default HTTP header, specify NULL or the empty string. This parameter is a CLOB(10K) CCSID 1208 or an XML value. See “Foundational HTTP functions” on page 1157 for a description of the header content.

**requestmsg** Specifies the data to update at the specified URL. For the HTTPBLOBVERBOSE function, this argument is defined as BLOB(2G). For the HTTPCLOBVERBOSE function, this argument is defined as CLOB(2G) CCSID 1208. This argument is required for the POST and PUT methods.

The result of the function is a table containing the following two columns.

Column name	Data type	Description
RESPONSEMSG	BLOB(2G) or CLOB(2G) CCSID 1208 depending on which function is used	The normal HTTP response for the request.
RESPONSEHTTPHEADER	CLOB(1M) CCSID 1208 or XML based on the data type of the <i>httpHeader</i> argument.	Header information returned from the HTTP request.

### Example

- This query returns the error information from using an incorrect URL to request the group PTF information from the IBM PSP website.

```
SELECT * FROM TABLE(SYSTOOLS.HTTPCLOBVERBOSE(
 URL => 'http://www.ibm.com/support/docview.wss?uid=nas4PSPbyNum&aid=1',
```

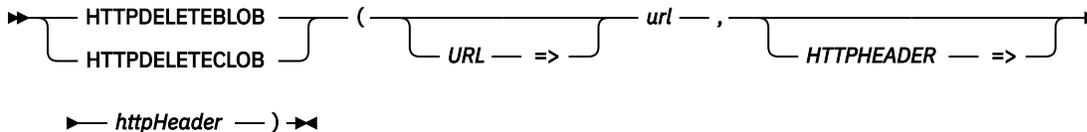

```
HTTPMETHOD => 'GET',
HTTPHEADER => NULL,
REQUESTMSG => NULL));
```

The RESPONSEHTTPHEADER result column contains the following information about the error.

```
<?xml version="1.0" encoding="UTF-8" ?><httpHeader responseCode="301">
 <responseMessage>Moved Permanently....
```

## HTTPDELETEBLOB and HTTPDELETECLOB scalar functions

The HTTPDELETEBLOB and HTTPDELETECLOB REST functions delete a binary or text-based resource from the specified URL through an HTTP DELETE request.

The schema is SYSTOOLS.

**url** Specifies the URL of the resource being accessed. This parameter is a VARCHAR(2048) CCSID 1208 value.

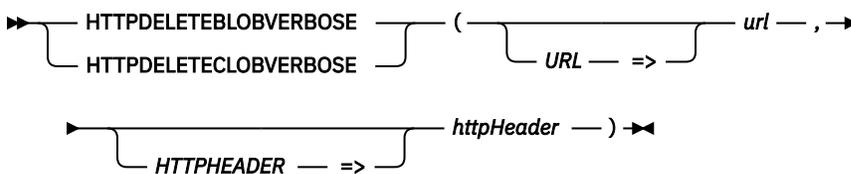

**httpHeader** Specifies an optional header XML document. To use the default HTTP header, specify NULL or the empty string. This parameter is a CLOB(10K) CCSID 1208 or an XML value.

See [“Foundational HTTP functions” on page 1157](#) for a description of the header content.

For the HTTPDELETEBLOB function, the result response message is returned as BLOB(2G). For the HTTPDELETECLOB function, the result response message is returned as CLOB(2G) CCSID 1208.

## HTTPDELETEBLOBVERBOSE and HTTPDELETECLOBVERBOSE table functions

The HTTPDELETEBLOBVERBOSE and HTTPDELETECLOBVERBOSE REST table functions delete a binary or text-based resource from the specified URL through an HTTP DELETE request. They return a one row table that contains the normal HTTP response for the request and the header information returned from the HTTP request.

The schema is SYSTOOLS.

**url** Specifies the URL of the resource being accessed. This parameter is a VARCHAR(2048) CCSID 1208 value.

**httpHeader** Specifies an optional header XML document. To use the default HTTP header, specify NULL or the empty string. This parameter is a CLOB(10K) CCSID 1208 or an XML value.

See [“Foundational HTTP functions” on page 1157](#) for a description of the header content.

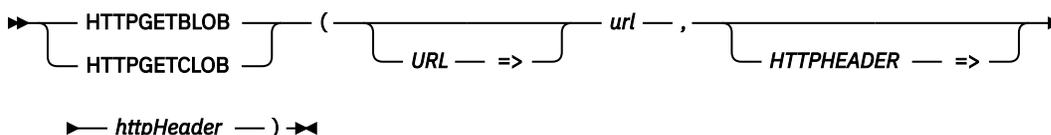

The result of the function is a table containing the following two columns.

Table 302. HTTPDELETEBLOBVERBOSE and HTTPDELETECLOBVERBOSE result table

Column name	Data type	Description
RESPONSEMSG	BLOB(2G) or CLOB(2G) CCSID 1208 depending on which function is used	The normal HTTP response for the request.
RESPONSEHTTPHEADER	CLOB(1M) CCSID 1208 or XML based on the data type of the <i>httpHeader</i> argument.	Header information returned from the HTTP request.

## HTTPGETBLOB and HTTPGETCLOB scalar functions

The HTTPGETBLOB and HTTPGETCLOB REST functions retrieve a binary or text-based resource from the specified URL through an HTTP GET request.

The schema is SYSTOOLS.

**url** Specifies the URL of the resource being accessed. This parameter is a VARCHAR(2048) CCSID 1208 value.

**httpHeader** Specifies an optional header XML document. To use the default HTTP header, specify NULL or the empty string. This parameter is a CLOB(10K) CCSID 1208 or XML value.

See “[Foundational HTTP functions](#)” on page 1157 for a description of the header content.

HTTPGETBLOB returns the resource as BLOB(2G) data. HTTPGETCLOB returns the resource as CLOB(2G) CCSID 1208 data.

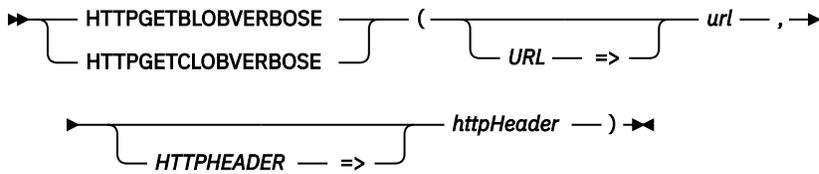

### Example

```
SELECT SYSTOOLS.HTTPGETCLOB(
 URL => CAST('http://ws.geonames.org/countryInfo?lang=' CONCAT
 SYSTOOLS.URLENCODE('en','') CONCAT
 '&country=' CONCAT
 SYSTOOLS.URLENCODE('us','') CONCAT
 '&type=XML' AS VARCHAR(255)),
 HTTPHEADER => CAST(NULL AS CLOB(1K)))
FROM SYSIBM.SYSDUMMY1;
```

## HTTPGETBLOBVERBOSE and HTTPGETCLOBVERBOSE table functions

The HTTPGETBLOBVERBOSE and HTTPGETCLOBVERBOSE REST table functions retrieve a binary or text-based resource from the specified URL through an HTTP GET request. They return a one row table that

contains the normal HTTP response for the request and the header information returned from the HTTP request.

The schema is SYSTOOLS.

**url** Specifies the URL at which to complete the request. This argument is defined as a VARCHAR(2048) CCSID 1208 value.

**httpHeader** Specifies an optional header XML document. To use the default HTTP header, specify NULL or the empty string. This parameter is a CLOB(10K) CCSID 1208 or an XML value. See “[Foundational HTTP functions](#)” on page 1157 for a description of the header content.

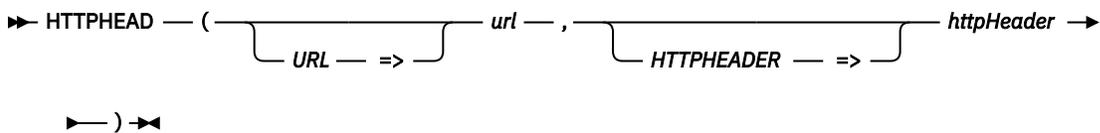

The result of the function is a table containing the following two columns.

Table 303. HTTPGETBLOBVERBOSE and HTTPGETCLOBVERBOSE result table

Column name	Data type	Description
RESPONSEMSG	BLOB(2G) or CLOB(2G) CCSID 1208 depending on which function is used	The normal HTTP response for the request.
RESPONSEHTTPHEADER	CLOB(1M) CCSID 1208 or XML based on the data type of the <i>httpHeader</i> argument.	Header information returned from the HTTP request.

## HTTPHEAD scalar function

The HTTPHEAD REST function verifies the HTTP header for the specified resource through an HTTP HEAD request.

The schema is SYSTOOLS.

**url** Specifies the URL of the resource being accessed. This parameter is a VARCHAR(2048) CCSID 1208 value.

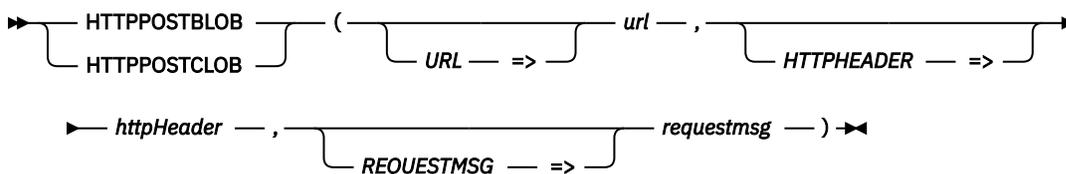

**httpHeader** Specifies an optional header XML document. This parameter is a CLOB(10K) CCSID 1208 or an XML value.

See “[Foundational HTTP functions](#)” on page 1157 for a description of the header content.

The HTTP header is returned as CLOB(10K) CCSID 1208 or XML data based on the data type of the *httpHeader* argument.

## HTTPPOSTBLOB and HTTPPOSTCLOB scalar functions

The HTTPPOSTBLOB and HTTPPOSTCLOB REST functions update a binary or text-based resource under the specified URL through an HTTP POST request.

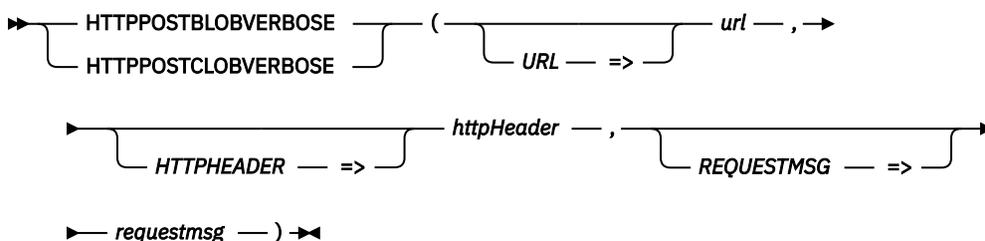

The schema is SYSTOOLS.

- url** Specifies the URL at which to complete the request. This argument is defined as a VARCHAR(2048) CCSID 1208 value.
- httpHeader** Specifies an optional header XML document. To use the default HTTP header, specify NULL or the empty string. This parameter is a CLOB(10K) CCSID 1208 or an XML value. See “Foundational HTTP functions” on page 1157 for a description of the header content.
- requestmsg** Specifies the data to update at the specified URL. For the HTTPPOSTBLOB function, this argument is defined as BLOB(2G). For the HTTPPOSTCLOB function, this argument is defined as CLOB(2G) CCSID 1208.

For the HTTPPOSTBLOB function, the result response message is returned as BLOB(2G). For the HTTPPOSTCLOB function, the result response message is returned as CLOB(2G) CCSID 1208.

## HTTPPOSTBLOBVERBOSE and HTTPPOSTCLOBVERBOSE table functions

The HTTPPOSTBLOBVERBOSE and HTTPPOSTCLOBVERBOSE REST table functions update a binary or text-based resource under the specified URL through an HTTP POST request. They return a one row table that contains the normal HTTP response for the request and the header information returned from the HTTP request.

The schema is SYSTOOLS.

- url** Specifies the URL at which to complete the request. This argument is defined as a VARCHAR(2048) CCSID 1208 value.
- httpHeader** Specifies an optional header XML document. To use the default HTTP header, specify NULL or the empty string. This parameter is a CLOB(10K) CCSID 1208 or an XML value. See “Foundational HTTP functions” on page 1157 for a description of the header content.
- requestmsg** Specifies the data to update at the specified URL. For the HTTPPOSTBLOBVERBOSE function, this argument is defined as BLOB(2G). For the HTTPPOSTCLOBVERBOSE function, this argument is defined as CLOB(2G) CCSID 1208.

The result of the function is a table containing the following two columns.

Table 304. HTTPPOSTBLOBVERBOSE and HTTPPOSTCLOBVERBOSE result table

Column name	Data type	Description
RESPONSEMSG	BLOB(2G) or CLOB(2G) CCSID 1208 depending on which function is used	The normal HTTP response for the request.
RESPONSEHTTPHEADER	CLOB(1M) CCSID 1208 or XML based on the data type of the <i>httpHeader</i> argument.	Header information returned from the HTTP request.

## HTTPPUTBLOB and HTTPPUTCLOB scalar functions

The HTTPPUTBLOB and HTTPPUTCLOB REST functions create or update a binary or text-based resource under the specified URL through an HTTP PUT request.

The schema is SYSTOOLS.

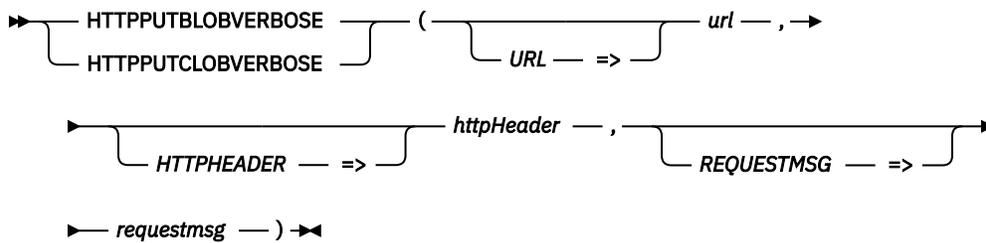

- url** Specifies the URL at which to complete the request. This argument is defined as a VARCHAR(2048) CCSID 1208 value.
- httpHeader** Specifies an optional header XML document. To use the default HTTP header, specify NULL or the empty string. This parameter is a CLOB(10K) CCSID 1208 or an XML value. See “Foundational HTTP functions” on page 1157 for a description of the header content.
- requestmsg** Specifies the data to update at the specified URL. For the HTTPPUTBLOB function, this argument is defined as BLOB(2G). For the HTTPPUTCLOB function, this argument is defined as CLOB(2G) CCSID 1208.

For the HTTPPUTBLOB function, the result response message is returned as BLOB(2G). For the HTTPPUTCLOB function, the result response message is returned as CLOB(2G) CCSID 1208.

## HTTPPUTBLOBVERBOSE and HTTPPUTCLOBVERBOSE table functions

The HTTPPUTBLOBVERBOSE and HTTPPUTCLOBVERBOSE REST table functions create or update a binary or text-based resource under the specified URL through an HTTP PUT request. They return a one row

table that contains the normal HTTP response for the request and the header information returned from the HTTP request.

The schema is SYSTOOLS.

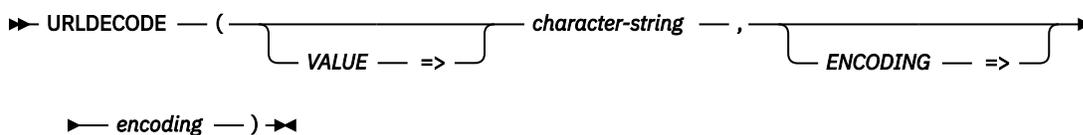

- url** Specifies the URL at which to complete the request. This argument is defined as a VARCHAR(2048) CCSID 1208 value.
- httpHeader** Specifies an optional header XML document. To use the default HTTP header, specify NULL or the empty string. This parameter is a CLOB(10K) CCSID 1208 or an XML value. See “Foundational HTTP functions” on page 1157 for a description of the header content.
- requestmsg** Specifies the data to update at the specified URL. For the HTTPPUTBLOBVERBOSE function, this argument is defined as BLOB(2G). For the HTTPPUTCLOBVERBOSE function, this argument is defined as CLOB(2G) CCSID 1208.

The result of the function is a table containing the following two columns.

Column name	Data type	Description
RESPONSEMSG	BLOB(2G) or CLOB(2G) CCSID 1208 depending on which function is used	The normal HTTP response for the request.
RESPONSEHTTPHEADER	CLOB(1M) CCSID 1208 or XML based on the data type of the <i>httpHeader</i> argument.	Header information returned from the HTTP request.

## URLDECODE scalar function

The URLDECODE function completes URL decoding of the provided text.

The schema is SYSTOOLS.

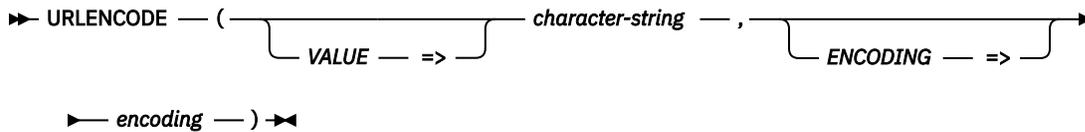

- character-string** A character string that is currently encoded. The length cannot exceed 4096 characters.
- encoding** A character or graphic string that specifies the encoding that was used for encoding characters that are not values in a URL. The default and recommended value is UTF-8.

Otherwise, this is a charset that follows the naming conventions defined in RFC 2278: IANA Charset Registration Procedures.

The result of the function is a varying length character string that contains *character-string* after being decoded.

## URLENCODE scalar function

The URLENCODE function completes URL encoding of the provided text.

The schema is SYSTOOLS.

**character-string** A character or graphic string expression that is to be encoded.

**encoding** A character or graphic string that specifies the encoding used for encoding characters that are not valid in a URL. The default and recommended value is UTF-8. Otherwise, this is a charset that follows the naming conventions defined in RFC 2278: IANA Charset Registration Procedures.

The result of the function is a varying length character string that contains *character-string* after being encoded.

## Database monitor formats

This section contains the formats used to create the database monitor SQL tables and views.

### Database monitor SQL table format

Displays the format used to create the QSYS/QAQQDBMN performance statistics table, that is shipped with the system.

```
CREATE TABLE QSYS.QAQQDBMN (
 QQRID DECIMAL(15, 0) NOT NULL DEFAULT 0 ,
 QQTIME TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ,
 QQJFLD CHAR(46) CCSID 65535 NOT NULL DEFAULT ' ' ,
 QQRDBN CHAR(18) CCSID 37 NOT NULL DEFAULT ' ' ,
 QQSYS CHAR(8) CCSID 37 NOT NULL DEFAULT ' ' ,
 QQJOB CHAR(10) CCSID 37 NOT NULL DEFAULT ' ' ,
 QQUSER CHAR(10) CCSID 37 NOT NULL DEFAULT ' ' ,
 QQJNUM CHAR(6) CCSID 37 NOT NULL DEFAULT ' ' ,
 QQUCNT DECIMAL(15, 0) DEFAULT NULL ,
 QQUDEF VARCHAR(100) CCSID 37 DEFAULT NULL ,
 QQSTN DECIMAL(15, 0) DEFAULT NULL ,
 QQQDTN DECIMAL(15, 0) DEFAULT NULL ,
 QQQDTL DECIMAL(15, 0) DEFAULT NULL ,
 QQMATN DECIMAL(15, 0) DEFAULT NULL ,
 QQMATL DECIMAL(15, 0) DEFAULT NULL ,
 QQTLN CHAR(10) CCSID 37 DEFAULT NULL ,

## Optional database monitor SQL view format

These examples show the different optional SQL view format that you can create with the SQL shown. The column descriptions are explained in the tables following each example. These views are not shipped with the system, and you must create them, if you choose to do so. These views are optional and are not required for analyzing monitor data.

Any rows that have a row identification number (QQRID) of 5000 or greater are for internal database use.

### Database monitor view 1000 - SQL Information

Displays the SQL logical view format for database monitor QQQ1000.

```
CREATE VIEW QQQ1000 AS

View Column Name	Table Column Name	Description
Fast_Delete_Count	QVP151	SQL fast delete count. Possible values are: <ul style="list-style-type: none"> <li>• 0 = *OPTIMIZE or *DEFAULT</li> <li>• 1-999,999,999,999 = User specified value</li> <li>• 'FFFFFFFFFFFFFFFF'x = *NONE</li> </ul>
Statement_Max_Compression	QQF2	SQL statement maximum compression. Possible values are: <ul style="list-style-type: none"> <li>• 1 - *DEFAULT</li> <li>• 1 - User specified queries</li> <li>• 2 - All queries, user, and system</li> <li>• 3 - System generated internal queries</li> </ul>
Current_User_Profile	QVC102	Current user profile name
Expression_Evaluator_Used	QVC1E	<ul style="list-style-type: none"> <li>• N - Not applicable</li> <li>• S - SQL mapping</li> <li>• Y - QQ expression evaluator</li> <li>• O - Expression handled by an Open</li> </ul>
Host_Server_Delta	QVP15A	Time not spent within Host Server
NTS_Lock_Space_Id	QQC301	NTS Lock Space Identifier
IP_Address	QQC183	IP Address
IP_Type	QFC11	IP address type <ul style="list-style-type: none"> <li>• '0' = No client IP address</li> <li>• '1' = IPV4 format</li> <li>• '2' = IPV6 format</li> </ul> Only applicable for database server jobs.
IP_Port_Number	QQSMINT2	IP Port Number
NTS_Transaction_Id	QVC3004	NTS Transaction Identifier
NTS_Format_Id_Length	QQSMINT3	NTS Format Identified length
NTS_Transaction_ID_SubLength	QQSMINT4	NTS Transaction Identifier sublength.
Unique_Refresh_Counter2	QVRCNT	Unique refresh counter
Times_Run	QVP15F	Number of times this Statement was run. If Null, then the statement was run once.  Note: While using an SQL Plan Cache snapshot, this value can be set by the database monitor. This value might be null if the query never completed, or was running when the snapshot was created. If there is not a plan cache snapshot, the value is null.
Full_Opens	QVP15E	Number of runs that were processed as full opens. If Null, then the refresh count (qvrnt) is used to determine if the open was a full open (0) or a pseudo open (>0).  Note: While using an SQL Plan Cache snapshot, this value can be set by the database monitor. This value might be null if the query never completed, or was running when the snapshot was created. If there is not a plan cache snapshot, the value is null.
Proc_In_Cache	QVC1F	Procedure definition was found in an internal cache. (Y/N) Only applicable for CALL statements.
Combined_Operation	QWC1A	Statement was performed with the processing for another statement. (Y/N) Only applicable for OPEN, FETCH, and CLOSE statements.
Client_Applname	QVC3001	Client Special Register - application name

Table 306. QQQ1000 - SQL Information (continued)

View Column Name	Table Column Name	Description
Client_Userid	QVC3002	Client Special Register - userid
Client_Wrkstnname	QVC3003	Client Special Register - work station name
Client_Acctng	QVC3005	Client Special Register - accounting string
Client_Programid	QVC3006	Client Special Register - program name
Interface_Information	QVC5001	Part of the CLIENT special register information. Three types of info are stored in this char500 column, separated by colons. <ul style="list-style-type: none"> <li>• First part, Interface Name, varchar(127);</li> <li>• Second part, Interface Level, varchar(63);</li> <li>• Third part, Interface Type, varchar(63)</li> </ul>
Open_Options	QVC82	Open options appear as a combination of the following characters, representing the actual capability for the cursor. The character values are left-aligned and padded on the right with blanks. Example 'RU ' indicate that the cursor is both read and update capable. <ul style="list-style-type: none"> <li>• R - Read capable</li> <li>• W - Write capable</li> <li>• U - Update capable</li> <li>• D - Delete capable</li> </ul>
Extended_Indicators	QWC1D	An Update or Insert statement was enabled to use extended indicators (Y/N).
DECFLOAT_Rounding_Mode	QWC1C	Rounding mode to use for DECFLOAT computations and conversions. <ul style="list-style-type: none"> <li>• 'E' = ROUND_HALF_EVEN</li> <li>• 'C' = ROUND_CEILING</li> <li>• 'D' = ROUND_DOWN</li> <li>• 'F' = ROUND_FLOOR</li> <li>• 'G' = ROUND_HALF_DOWN</li> <li>• 'H' = ROUND_HALF_UP</li> <li>• 'U' = ROUND_UP</li> </ul>
SQL_DECFLOAT_Warnings	QWC1E	DECFLOAT computations and conversions involving division by 0, overflow, underflow, an invalid operand, an inexact result, or a subnormal number results in a warning (Y/N).
Worst_Time_Micro	QVP15D	If not null, this time is the time for the slowest single run of this query. Note: When monitor files are created when using an SQL Plan Cache snapshot, this time represents the run time for the longest single run of the query. If the value is null, then the longest run information is not available. In that case, QQI6 might be the next best answer. See documentation for QQI6 for the proper use of that field
SQ_Unique_Count	QQINT05	A unique count used to uniquely identify statements which do not have an ODP but do pass in host variables. If QQUCNT is 0 and the statement passes in host variables, this value is non-zero. An example would be a CALL statement.

Table 306. QQQ1000 - SQL Information (continued)

View Column Name	Table Column Name	Description
Concurrent_Access_Res_Used	QFC13	Specifies what method of concurrent access resolution was used. <ul style="list-style-type: none"> <li>'N' = Concurrent access resolution is not applicable. This method applies to read queries with no commit or uncommitted read.</li> <li>'S' = SKIP LOCKED DATA clause was specified and rows with incompatible locks held by other transactions are skipped.</li> <li>'U' = USE CURRENTLY COMMITTED clause was specified and the currently committed version of data being updated or deleted is used. Data being inserted is skipped.</li> <li>'W' = Wait for commit or rollback when data is in the process of being inserted, updated, or deleted. This is the default method when the isolation level does not apply, the query is processed by CQE, or when not specified by the user.</li> </ul>
SQL_UDFs_Not_Inlined	QQSMINT8	Specifies the number of SQL user-defined scalar functions (UDFs) or user-defined table functions (UDTFs) that were not inlined in a SQL query or expression.
Result_Set_Cursor	QVC3007	Result Set Cursor name. Set by Allocate Cursor, Fetch, and Close.
Implicit_XMLPARSE_Option	QFC12	CURRENT IMPLICIT XMLPARSE OPTION special register. This option is used to specify white-space handling for an implicit parse of serialized XML data. <ul style="list-style-type: none"> <li>'S' = STRIP WHITESPACE</li> <li>'P' = PRESERVE WHITESPACE</li> </ul>
SQL_XML_Data_CCSID	QQSMINT7	The CCSID used for XML columns, host variables, parameter markers, and expressions if not explicitly specified.
OPTIMIZER_USE	QQSMINT5	Which optimizer was used for the query. Set to null if the monitor predates this option. <ul style="list-style-type: none"> <li>0 = Does not apply for this statement</li> <li>1 = SQE was used (SQL Query Engine)</li> <li>2 = CQE was used (Classic Query Engine)</li> <li>3 = CQE direct was used (statements like INSERT W/VALUES)</li> </ul>
XML_Schema_In_Cache	QFC14	The XML schema binary used during XMLVALIDATE or decomposition was found in the XML cache. <ul style="list-style-type: none"> <li>'Y' = Yes</li> <li>'N' = No</li> </ul>
Current_User	QQC105	The value of the CURRENT USER special register. The value only appears in the QQC105 column if the SQL statement used CURRENT USER.
Row_Column_Access_Control	QFC15	Type of row or column access applied. <ul style="list-style-type: none"> <li>' ' = Not applicable</li> <li>'C' = Column Access Control</li> <li>'R' = Row Access Control</li> <li>'B' = Both Row and Column Access Control</li> </ul>
Temporal_System_Time	QQTIM12A	The value of the CURRENT TEMPORAL SYSTEM_TIME special register. This TIMESTAMP(12) value is used as a default FOR SYSTEM_TIME period specification when a system-period temporal table is referenced in either static or dynamic SQL statements. This value will only be set when the SQL SYSTIME bind option is set to YES and the CURRENT TEMPORAL SYSTEM_TIME was applied to a system-period temporal table or when CURRENT TEMPORAL SYSTEM_TIME is explicitly used.

Table 306. QQQ1000 - SQL Information (continued)

View Column Name	Table Column Name	Description
SYSTIME_Bind_Option	QFC16	References to system-period temporal tables in both static or dynamic SQL statements are impacted by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. <ul style="list-style-type: none"> <li>'Y' = Yes</li> <li>'N' = No</li> </ul>
Temporal_System_Time_Query	QFC17	A system time period specification was included on a system-period temporal table reference causing both current and historical rows to be queried. <ul style="list-style-type: none"> <li>'Y' = Yes, this is a system time temporal query.</li> <li>'N' = No, this is not a system time temporal query.</li> </ul>
DBCLOB_HOSTVR	QQDBCLOB1	Host variables values in a DBCLOB CCSID 1200 field (max 1MB). Only set if HOSTVAR(*CONDENSED) is used on STRDBMON, otherwise null.
StmtCmpReuseMin	QQSMINT6	SQL statement compression reuse minimum. This only applies to process extended dynamic *SQLPKGs. The minimum number of reuses that a statement must have in order for its access plan information to remain in the package across a compress of the package. <p>Possible values are:</p> <ul style="list-style-type: none"> <li>0 = *DEFAULT</li> <li>1-32767 = User specified value.</li> </ul>
Override_Generated_Values	QFC18	Override system generated values. <ul style="list-style-type: none"> <li>'Y' = Yes. The global variable QSYS2.REPLICATION_OVERRIDE was set to a value that allows all columns defined as GENERATED ALWAYS to be modified for INSERT, UPDATE, and MERGE SQL statements.</li> <li>'N' = No. The global variable QSYS2.REPLICATION_OVERRIDE was not set to a value that allows all columns defined as GENERATED ALWAYS to be modified for INSERT, UPDATE, and MERGE SQL statements.</li> </ul>

Constraint_Name	QQ1000	Constraint name
Table_Name	QVQTBL	Queried table, long name
Table_Schema	QVQLIB	Schema of queried table, long name
Base_Table_Name	QVPTBL	Base table, long name
Base_Table_Schema	QVPLIB	Schema of base table, long name
Index_Name	QVINAM	Name of index (or constraint) used, long name
Index_Schema	QVILIB	Library of index used, long name
Bound	QVBNDY	I/O or CPU bound. Possible values are: <ul style="list-style-type: none"> <li>• I - I/O bound</li> <li>• C - CPU bound</li> </ul>
Unique_Refresh_Counter	QVRCNT	Unique refresh counter
Join_Fanout	QVJFANO	Join fanout. Possible values are: <ul style="list-style-type: none"> <li>• N - Normal join situation where fanout is allowed and each matching row of the join fanout is returned.</li> <li>• D - Distinct fanout. Join fanout is allowed however none of the join fanout rows are returned.</li> <li>• U - Unique fanout. Join fanout is not allowed. Error situation if join fanout occurs.</li> </ul>
Join_Table_Count	QVFILES	Number of tables joined
Parallel_Prefetch	QVPARPF	Parallel Prefetch (Y/N)

Table 308. QQQ3001 - Index Used (continued)

View Column Name	Table Column Name	Description
Parallel_Preload	QVPARPL	Parallel Preload (Y/N)
Parallel_Degree_Requested	QVPARD	Parallel degree requested
Parallel_Degree_Used	QVPARU	Parallel degree used
Parallel_Degree_Reason_Code	QVPARRC	Reason parallel processing was limited
Estimated_Cumulative_Time	QVCTIM	Estimated cumulative time, in seconds
Index_Only_Access	QVC14	Index only access (Y/N)
Index_Fits_In_Memory	QQC12	Index fits in memory (Y/N)
Index_Type	QQC15	Type of Index. Possible values are: <ul style="list-style-type: none"> <li>• B - Binary Radix Index</li> <li>• C - Constraint (Binary Radix)</li> <li>• E - Encoded Vector Index (EVI)</li> <li>• X - Query created temporary index</li> </ul>
Index_Usage	QVC12	Index Usage. Possible values are: <ul style="list-style-type: none"> <li>• P - Primary Index</li> <li>• T - Tertiary (AND or OR) Index</li> </ul>
Index_Entries	QQI4	Number of index entries
Unique_Keys	QQI5	Number of unique key values
Percent_Overflow	QQI6	Percent overflow
Vector_Size	QQI7	Vector size
Index_Size	QQI8	Index size
Index_Page_Size	QQIA	Index page size
Pool_Size	QVP154	Pool size
Pool_Id	QVP155	Pool ID
Table_Size	QVP156	Table size
Skip_Sequential_Table_Scan	QQC16	Skip sequential table scan (Y/N)
Tertiary_Indexes_Exist	QVC13	Tertiary indexes exist (Y/N)
DataSpace_Selection_Columns	QVC3001	Columns used for dataspace selection
Derived_Column_Selection	QQC14	Derived column selection (Y/N)
Derived_Column_Selection_Columns	QVC3002	Columns used for derived column selection
Table_Column_For_Index_Probe	QVC3003	Columns used for index scan-key positioning
Table_Column_For_Index_Scan	QVC3004	Columns used for index scan-key selection
Join_Selection_Columns	QVC3005	Columns used for Join selection
Ordering_Columns	QVC3006	Columns used for Ordering
Grouping_Columns	QVC3007	Columns used for Grouping

Table 308. QQQ3001 - Index Used (continued)

View Column Name	Table Column Name	Description
Read_Trigger	QQC18	Read Trigger (Y/N)
UDTF_Cardinality	QVP157	Cardinality for user-defined table function.
UDTF_Specific_Name	QVC1281	Specific name for user-defined table function.
UDTF_Specific_Schema	QVC1282	Specific schema for user-defined table function.
MQT_Replacement	QQC13	Materialized Query Table replaced queried table (Y/N)
Plan_Iteration_Number	QQSMINTF	AQP Plan iteration number, original optimization = 1
Include_Values	QVC3008	Encoded Vector indexes only.  Aggregates included as part of index creation and predetermined for Grouping query request.
Sparse_Index	QVC15	Index contains sparse selection or Select/Omit selection criteria (Y/N).
Average_Read_Time	QQF1	Average disk I/O time for this object
Distinct_Indicator	QVC11	Distinct Scan or Probe was used (Y/N)

SMP parallel processing is not allowed.</li> <li>• *OPTIMIZE - The optimizer chooses the number of tasks to use for either I/O or SMP parallel processing.</li> <li>• *MAX - The optimizer chooses to use either I/O or SMP parallel processing.</li> <li>• *SYSVAL - Use the current system value to process the query.</li> <li>• *ANY - Has the same meaning as *I/O.</li> <li>• *NBRTASKS - The number of tasks for SMP parallel processing is specified in column QVTASKN.</li> </ul>
Max_Number_of_Tasks	QQI3	Max number of tasks
Apply_CHGQRYA_Remote	QVC17	Apply CHGQRYA remotely (Y/N)
Async_Job_Usage	QVC82	Asynchronous job usage <ul style="list-style-type: none"> <li>• *SAME - Do not change current setting</li> <li>• *DIST - Asynchronous jobs might be used for queries with distributed tables</li> <li>• *LOCAL - Asynchronous jobs might be used for queries with local tables only</li> <li>• *ANY - Asynchronous jobs might be used for any database query</li> <li>• *NONE - No asynchronous jobs are allowed</li> </ul>
Force_Join_Order_Indicator	QVC18	Force join order (Y/N)
Print_Debug_Messages	QVC19	Print debug messages (Y/N)
Parameter_Marker_Conversion	QVC1A	Parameter marker conversion (Y/N)
UDF_Time_Limit	QQI4	User Defined Function time limit
Optimizer_Limitations	QVC1283	Optimizer limitations. Possible values: <ul style="list-style-type: none"> <li>• *PERCENT followed by 2 byte integer containing the percent value</li> <li>• *MAX_NUMBER_OF_RECORDS followed by an integer value that represents the maximum number of rows</li> </ul>

Table 319. QQQ3014 - Generic QQ Information (continued)

View Column Name	Table Column Name	Description
Reoptimize_Requested		<p>Reoptimize access plan requested. Possible values are:</p> <ul style="list-style-type: none"> <li>• O - Only reoptimize the access plan when required. Do not reoptimize for subjective reasons.</li> <li>• Y - Yes, force the access plan to be reoptimized.</li> <li>• N - No, do not reoptimize the access plan, unless optimizer determines that it is necessary. May reoptimize for subjective reasons.</li> </ul>
Optimize_All_Indexes		<p>Optimize all indexes requested</p> <ul style="list-style-type: none"> <li>• *SAME - Do not change current setting</li> <li>• *YES - Examine all indexes</li> <li>• *NO - Allow optimizer to time out</li> <li>• *TIMEOUT - Force optimizer to time out</li> </ul>
Has_Final_Decomposed_QDT	QQC14	Final decomposed QDT built indicator (Y/N)
Is_Final_Decomposed_QDT	QQC15	The final decomposed QDT indicator (Y/N)
Read_Trigger	QQC18	One of the files contains a read trigger (Y/N)
Star_Join	QQC81	<p>Star join optimization requested.</p> <ul style="list-style-type: none"> <li>• *NO - Star join optimization is not performed.</li> <li>• *COST - The optimizer determines if any EVIs can be used for star join optimization.</li> <li>• *FORCE - The optimizer adds any EVIs that can be used for star join optimization.</li> </ul>
Optimization_Goal	QVC23	<p>Byte 1 = Optimization goal. Possible values are:</p> <ul style="list-style-type: none"> <li>• F - First I/O, optimize the query to return the first screen full of rows as quickly as possible.</li> <li>• A - All I/O, optimize the query to return all rows as quickly as possible.</li> </ul>
VE_Diagram_Type	QVC24	<p>Byte 1 = Type of Visual Explain diagram. Possible values are:</p> <ul style="list-style-type: none"> <li>• D - Detail</li> <li>• B - Basic</li> </ul>
Ignore_Like_Redunant_Shifts	QVC24	<p>Byte 2 - Ignore LIKE redundant shifts. Possible values are:</p> <ul style="list-style-type: none"> <li>• O - Optimize, the query optimizer determines which redundant shifts to ignore.</li> <li>• A - All redundant shifts are ignored.</li> </ul>

Table 319. QQQ3014 - Generic QQ Information (continued)

View Column Name	Table Column Name	Description
Union_QDT	QQC23	Byte 1 = This QDT is part of a UNION that is contained within a view (Y/N).  Byte 2 = This QDT is the last subselect of the UNION that is contained within a view (Y/N).
Unicode_Normalization	QQC21	Unicode data normalization requested (Y/N)
Pool_Fair_Share	QVP153	Fair share of the pool size as determined by the optimizer
Force_Join_Order_Requested	QQC82	Force Join Order requested. Possible values are: <ul style="list-style-type: none"> <li>• *NO - The optimizer was allowed to reorder join files</li> <li>• *YES - The optimizer was not allowed to reorder join files as part of its optimization process</li> <li>• *SQL - The optimizer only forced the join order for those queries that used the SQL JOIN syntax</li> <li>• *PRIMARY - The optimizer was only required to force the primary dial for the join.</li> </ul>
Force_Join_Order_Dataspace1	QVP152	Primary dial to force if Force_Join_Order_Indicator is *PRIMARY.
No_Parameter_Marker_Reason_Code	QQI6	Reason code for why Parameter Marker Conversion was not performed: <ol style="list-style-type: none"> <li>1. Argument of function must be a literal</li> <li>2. LOCALTIME or LOCALTIMESTAMP</li> <li>3. Duration literal in arithmetic expression</li> <li>4. UPDATE query with no WHERE clause</li> <li>5. BLOB literal</li> <li>6. Special register in UPDATE or INSERT with values</li> <li>7. Result expression for CASE</li> <li>8. GROUP BY expression</li> <li>9. ESCAPE character</li> <li>10. Double Negative value -(-1)</li> <li>11. INSERT or UPDATE with a mix of literals, parameter markers, and NULLs</li> <li>12. UPDATE with a mix of literals and parameter markers</li> <li>13. INSERT with VALUES containing NULL value and expressions</li> <li>14. UPDATE with list of expressions</li> </ol> <p>99. Parameter marker conversion disabled by QAQQINI</p>
Hash_Join_Reason_Code	QVP151	Reason code why hash join was not used.

Table 319. QQQ3014 - Generic QQ Information (continued)

View Column Name	Table Column Name	Description
MQT_Refresh_Age	QQI7	Value of the MATERIALIZED_QUERY_TABLE_REFRESH_AGE duration. If the QAQQINI parameter value is set to *ANY, the timestamp duration is 9999999999999999.
MQT_Usage	QVC42,1,1	Byte 1 - Contains the MATERIALIZED_QUERY_TABLE_USAGE. Possible values are: <ul style="list-style-type: none"> <li>• N - *NONE - no materialized query tables used in query optimization and implementation</li> <li>• A - *ALL - User-maintained. Refresh-deferred query tables can be used.</li> <li>• U - *USER - Only user-maintained materialized query tables can be used.</li> </ul>
SQE_NotUsed_Reason_Code	QVC43	SQE Not Used Reason Code. Possible values: <ul style="list-style-type: none"> <li>• LF - DDS logical file specified in query definition</li> <li>• DK - An index with derived key or select/omit was found over a queried table</li> <li>• NF - Too many tables in query</li> <li>• NS - Not an SQL query or query not run through an SQL interface</li> <li>• DF - Distributed table in query</li> <li>• RT - Read Trigger defined on queried table</li> <li>• PD - Program described file in query</li> <li>• WC - WHERE CURRENT OF a partition table</li> <li>• IO - Simple INSERT query</li> <li>• CV - Create view statement</li> </ul>
Estimated_IO_Count	QVP156	Estimated I/O count
Estimated_Processing_Cost	QVP157	Estimated processing cost in milliseconds
Estimated_CPU_Cost	QVP158	Estimated CPU cost in milliseconds
Estimated_IO_Cost	QVP159	Estimated I/O cost in milliseconds
Has_Implicit_Numeric_Conversion	QVC44	Byte 1: Implicit numeric conversion (Y/N)
Accumulated_Est_Process_Time	QVCTIM	Accumulated estimated processing time across all subselects, in seconds.
Query_Gov_Storage_Limit	QQINT01	Specified query governor storage limit, in megabytes
Estimated_Storage	QQINT02	Original estimated temporary storage used, in megabytes.
Adjusted_Temp_Storage	QQINT03	Adjusted temporary storage used, in Adjusted megabytes. This value accumulates the actual time and storage it took to create any temporary indexes and temporary tables. Set by CQE only.

Table 319. QQQ3014 - Generic QQ Information (continued)

View Column Name	Table Column Name	Description
Original_Cost_Estimate	QQINT04	Original cost estimate as determined by the CQE query optimizer. Set by CQE only.
Parallel_Degree_Percentage	QQI8	Percentage specified on Parallel_Degree *OPTIMIZE and *MAX.
FieldProc_Encoded_Comparison	QFC12	<p>FIELDPROC_ENCODED_COMPARISON option active for this query. Specifies the amount of optimization that the optimizer might use when queried columns have attached field procedures.</p> <ul style="list-style-type: none"> <li>• 'N' - NONE</li> <li>• 'E' - ALLOW_EQUAL</li> <li>• 'R' - ALLOW_RANGE</li> <li>• 'A' - ALL</li> </ul>
Allow_Array_Change_INI_Opt	QFC13	<p>ALLOW_ARRAY_VALUE_CHANGES QAQQINI option active for this query.</p> <ul style="list-style-type: none"> <li>• 'N' - Do not allow changes to values in arrays referenced in the query to be visible after the query is opened.</li> <li>• 'Y' - Allow changes to values in arrays to be visible to the query while the query is running.</li> </ul>
SQL_Concurrent_Access_Resolution	QFC11	<p>SQL_CONCURRENT_ACCESS_RESOLUTION QAQQINI option active for this query.</p> <ul style="list-style-type: none"> <li>• 'U' - USE CURRENTLY COMMITTED</li> <li>• 'W' - WAIT FOR OUTCOME</li> </ul>
Plan_Iteration_Number	QQSMINTF	AQP Plan iteration number; original optimization = 1
Warm_IO_Requested	QXC11	<p>Warm I/O value that was requested.</p> <ul style="list-style-type: none"> <li>• 'Y' - Yes, use Warm I/O</li> <li>• 'N' - No, do not use Warm I/O</li> <li>• 'D' - Default</li> </ul>
Warm_IO_Used	QXC12	<p>Warm I/O values used to implement the query.</p> <ul style="list-style-type: none"> <li>• 'Y' - Yes, use Warm I/O</li> <li>• 'N' - No, do not use Warm I/O</li> <li>• 'D' - Default</li> </ul>
Optimization_Goal_Override	QXC13	<p>Optimization Goal Override.</p> <ul style="list-style-type: none"> <li>• 'O' - Override the specified Optimize For N Rows value and use Optimize For All Rows.</li> <li>• 'D' - Default, use the specified Optimize For N Rows value.</li> </ul>

Table 319. QQQ3014 - Generic QQ Information (continued)

View Column Name	Table Column Name	Description
Plan_Signature_Match	QXC1E	Plan signature match. <ul style="list-style-type: none"> <li>'Y' - New plan matched old plan it replaced; same plan signature.</li> <li>'N' - New plan different from old plan it replaced; different plan signature.</li> </ul>
Check_HostVars	QXC14	Indicates if this query is enabled for host variable selectivity checking at pseudo-open time. <ul style="list-style-type: none"> <li>'N' – No pseudo-open host variable checking enabled</li> <li>'O' – This query is a candidate for pseudo-open host variable checking and the QAQQINI option was *OPTIMIZE</li> <li>'Y' - This query is a candidate for pseudo-open host variable checking and the QAQQINI option was *YES</li> </ul>
FullOptimization	QXC15	Plan was rebuilt (Y/N)
Pseudo_Open_Replace_Reason	QXC16	Indicates if the plan was replaced due to QAQQINI PSEUDO_OPEN_CHECK_HOST_VARS option <ul style="list-style-type: none"> <li>'0' - Plan was not replaced</li> <li>'1' - Plan was replaced</li> </ul>
WorkloadGroup	QXC17	Workload Group is in effect (Y/N)
Concurrent_Access_Behavior	QXC18	Controls how queries with an isolation level of Cursor Stability (CS) or Read Stability (RS) interact with uncommitted table changes. <ul style="list-style-type: none"> <li>'N' - Not Applicable</li> <li>'O' - OPTIMIZE - Uncommitted changes that delete or update records so that they are no longer selected by the query will not be considered as candidates for query synchronization.</li> <li>'S' - STRICTSCAN - All records referenced by a table scan query access plan will synchronize with any changes that are not yet committed.</li> </ul>
Memory_Pool_Preference	QQINT05	The pool identifier where paging will occur for database operation that supports targeted paging. The pool identifier will be 0 if paging will occur in the same pool as the job is running in.
Longest_Key_Range_Estimate	QQINT06	Number of seconds required to run the longest key range estimate (or EKR) used to optimize this query.

Table 319. QQQ3014 - Generic QQ Information (continued)

View Column Name	Table Column Name	Description
KeyRangeEst_Timeout	QXC19	Indicates whether a key range estimate exceeded the time limit. This limit may be specified in the QAAQINI file. <ul style="list-style-type: none"> <li>'N' - No</li> <li>'Y' - One or more estimates exceeded the time limit. The estimates have been queued for background processing.</li> </ul>
SQE_Used_Indicator	QQC16	Indicator of which optimizer was used <ul style="list-style-type: none"> <li>'Y' - Query ran using SQE</li> <li>'N' - Query ran using CQE</li> </ul>
QRO_HASH	QQC83	For SQE queries, the QRO hash is an internally generated identifier for an SQE query. In general, this identifier will be unique for each SQE query and uses implicit schema qualification among other data to generate the QRO hash. If the SQE optimizer generates multiple plans for the same query, then multiple plans will have the same QRO hash.  The QRO hash for a statement may change on release boundaries or after loading PTFs.
Shared_CTE_Usage	QQSMINT1	For SQE queries, this field describes whether the query uses a common table expression (CTE) that is referenced more than once in the query. This is referred to as a shared CTE and requires special processing by the optimizer. <ul style="list-style-type: none"> <li><b>0</b> Query does not contain CTEs with multiple references.</li> <li><b>1</b> Query contains at least one CTE with multiple references.</li> <li><b>2</b> Query contains at least one CTE with multiple references and at least one of these CTEs is considered complex by the optimizer.</li> <li><b>255</b> Query contains at least one CTE with multiple references, and at least one of these CTEs has been defined as DETERMINISTIC.</li> </ul>

```

Table 321. QQQ3018 - STRDBMON/ENDDBMON

View Column Name	Table Column Name	Description
Row_ID	QQRID	Row identification
Time_Created	QQTIME	Time row was created
Join_Column	QQJFLD	Join column (unique per job)
Relational_Database_Name	QQRDBN	Relational database name
System_Name	QQSYS	System name
Job_Name	QQJOB	Job name
Job_User	QQUSER	Job user
Job_Number	QQJNUM	Job number
Thread_ID	QQI9	Thread identifier
Monitored_Job_type	QQC11	Type of job monitored <ul style="list-style-type: none"> <li>• C - Current</li> <li>• J - Job name</li> <li>• A - All</li> </ul>
Monitor_Command	QQC12	Command type <ul style="list-style-type: none"> <li>• S - STRDBMON</li> <li>• E - ENDDBMON</li> </ul>

Table 321. QQQ3018 - STRDBMON/ENDDBMON (continued)

View Column Name	Table Column Name	Description
Monitor_Job_Information	QQC301	Monitored job information <ul style="list-style-type: none"> <li>• * - Current job</li> <li>• Job number/User/Job name</li> <li>• *ALL - All jobs</li> </ul>
STRDBMON_Command_Text	QQ1000L	STRDBMON command text.
Monitor_ID	QQC101	Monitor ID
Version_Release_Mod	QQC102	Version Release and modification level
Group_PTF	QQC103	Installed Group PTF number and level. For example, 'SF99601 3' indicates that Database Group release V6R1M0, version 3 is installed.
Initial_AQP_Processing	QVC11	Initial AQP processing. Y indicates that the monitor file has already been processed to handle the AQP plan iteration number. All iterations other than the last one have been changed to a negative number. All other values indicate that the monitor file has not been processed.
Current_PC_Threshold	QQSMINT1	Database Plan Cache threshold, a value between 1-100 to represent a percent
Current_PC_Subcaches	QQSMINT2	Number of sub-caches within the database Plan Cache
Num_Active_Queries	QQINT01	Number of queries currently active
Current_PC_Size	QQINT02	Current size of database Plan Cache, in MB
Current_PC_Size_Threshold	QQINT03	Size threshold of database Plan Cache, in MB
Number_of_SMP_Threads	QQINT04	Number of SMP Threads
Current_Number_of_MTIs	QQINT05	Number of temporary indexes
Num_of_Pruning_Monitors	QQINT06	Number of event monitors used to prune the database Plan Cache
Num_of_PC_Prunnings	QQINT07	Number of times plans were pruned from the database Plan Cache
Num_of_Plan_Cache_Naps	QQINT08	Number of times the database Plan Cache became inactive
Num_POpen_Hard_Closed	QQINT09	Number of pseudo-opened queries that were hard closed
Num_of_MTIs_Created	QQINT0A	Number of temporary indexes that were created
Num_of_MTIs_Deleted	QQINT0B	Number of temporary indexes that were deleted
Num_AQP_Active	QQINT0C	Number of times AQP became active, whether a new plan was created or not
Num_AQP_Plans_Replaced	QQINT0D	Number of plans that were rebuilt due to AQP
Num_of_Plans_in_Cache	QVP151	Number of plans in the database Plan Cache
Num_of_ROQs_in_Cache	QVP152	Number of plans with a Read Only Query (ROQ) in the database Plan Cache
Num_of_Temp_ROQs_in_Cache	QVP153	Number of plans with temporary ROQs in the database Plan Cache
Num_of_Reuseable_ROQs	QVP154	Number of plans with reusable ROQs in the database Plan Cache
Size_Temp_Objects_in_Cache	QVP155	Size of temporary objects in the database Plan Cache, in MB
Num_Plans_Built_Since_Start	QVP156	Number of new plans built
Num_Plans_Used_ROQ	QVP157	Number of times a plan with a reusable ROQ was run
Num_Plans_Used_nonROQ	QVP158	Number of times a plan with a non-reusable ROQ was run
Num_Plans_Used_No_ROQ	QVP159	Number of times a plan without a ROQ was run
Num_Plan_Cache_Probes	QVP15A	Number of times the database Plan Cache was probed in hopes of finding a matching plan
Num_Plans_Used_from_Cache	QVP15B	Number of times a matching plan was found in the database Plan Cache

Table 321. QQQ3018 - STRDBMON/ENDDBMON (continued)

View Column Name	Table Column Name	Description
Num_Plan_Cache_No_Matches	QVP15C	Number of times a matching plan was not found in the database Plan Cache
Num_Plans_Pruned	QVP15D	Number of plans that were removed from the database Plan Cache due to size restrictions
Num_Plans_Removed	QVP15E	Number of obsolete plans that were removed from the database Plan Cache
Num_Run_Since_Start	QVP15F	Number of queries that were run
Num_FullOpens_Since_Start	QQI1	Number of queries that performed a full open when they were run
Num_FullOpens_Reused_ROQ	QQI2	Number of queries that performed a full open and reused an existing ROQ when run
Num_Full_Optimizations	QQI3	Number of queries that required a full optimization when run
Num_Valid_Plan_Reopts	QQI4	Number of queries that performed a full optimization even when a valid plan existed
Plan_Cache_Properties	QQDBCLOB1	Plan cache properties in XML format.

Table 322. QQQ3019 - Rows retrieved

<b>View Column Name</b>	<b>Table Column Name</b>	<b>Description</b>
Row_ID	QQRID	Row identification
Time_Created	QQTIME	Time row was created
Join_Column	QQJFLD	Join column (unique per job)
Relational_Database_Name	QQRDBN	Relational database name
System_Name	QQSYS	System name
Job_Name	QQJOB	Job name
Job_User	QQUSER	Job user
Job_Number	QQJNUM	Job number
Thread_ID	QQI9	Thread identifier
Unique_Count	QQUCNT	Unique count (unique per query)
User_Defined	QQUDEF	User defined column
Unique_SubSelect_Number	QQQDTN	Unique subselect number
SubSelect_Nested_Level	QQQDTL	Subselect nested level
Materialized_View_Subselect_Number	QQMATN	Materialized view subselect number
Materialized_View_Nested_Level	QQMATL	Materialized view nested level
Materialized_View_Union_Level	QVP15E	Materialized view union level
Decomposed_Subselect_Number	QVP15A	Decomposed query subselect number, unique across all decomposed subselects
Total_Number_Decomposed_SubSelects	QVP15B	Total number of decomposed subselects
Decomposed_SubSelect_Reason_Code	QVP15C	Decomposed query subselect reason code
Starting_Decomposed_SubSelect	QVP15D	Decomposed query subselect number for the first decomposed subselect
CPU_Time_to_Return_All_Rows	QQI1	CPU time to return all rows, in milliseconds
Clock_Time_to_Return_All_Rows	QQI2	Clock time to return all rows, in milliseconds
Number_Synchronous_Database_Reads	QQI3	Number of synchronous database reads
Number_Asynchronous_Database_Reads	QQI5	Number of asynchronous database reads
Number_Page_Faults	QVP151	Number of page faults
Number_Rows_Returned	QQI7	Number of rows returned
Number_of_Calls_for_Returned_Rows	QQI8	Number of calls to retrieve rows returned
Number_of_Times_Statement_was_Run	QVP15F	Number of times this Statement was run. If Null, then the statement was run once.
Temporary_Storage	QQINT03	Amount of temporary storage used, in megabytes.
DBMON_Temp_Result_Reused	QQC11	Indicates if the query temporary result was reused (Y/N).

Table 322. QQQ3019 - Rows retrieved (continued)

View Column Name	Table Column Name	Description
DBMON_Temp_Reused_RC	QQC21	Reason code why the query temporary result was reused.
DBMON_Temp_Reuse_Count	QQINT01	Number of times the query temporary result was reused.
Skip_Lock_Row_Count	QQIA	Number of locked rows that were skipped.
Skip_Lock_Row_Runs	QQINT05	Number of runs where some rows were skipped.
Skip_Lock_On_Runs	QQINT06	Number of runs where Skip Lock was active.
Adjusted_Average_Run_Time	QQF1	Average runtime for the query, adjusted to not include individual runs that are well outside the norm. Units in microseconds.
Unique_Refresh_Counter	QVRCNT	Unique refresh counter
Committed_Journal_Search_Requests	QVP152	Number of times the database manager searched the journal for the currently committed version of a record.
Committed_Journal_Search_Failures	QVP153	Number of times the database manager failed to find the currently committed version of a record in the journal.
Committed_Journal_Search_Time_Limit	QVP154	Maximum amount of time allowed to search the journal for the currently committed version of a record.

**Related reference**

[Index advisor](#)

The query optimizer analyzes the row selection in the query and determines, based on default values, if creation of a permanent index improves performance. If the optimizer determines that a permanent index might be beneficial, it returns the key columns necessary to create the suggested index.

## Query optimizer messages reference

See the following for query optimizer message reference:

### Query optimization performance information messages

You can evaluate the structure and performance of the SQL statements in a program using informational messages. These messages are put in the job log by the database manager.

The messages are issued for an SQL program or interactive SQL when running in the debug mode. The database manager could send any of the following messages when appropriate. The ampersand variables (&1, &X) are replacement variables that contain either an object name or other substitution value when you see the message in the job log. These messages provide feedback on how a query was run. In some cases, the messages indicate improvements you can make to help the query run faster.

The messages contain message help that provides information about the cause for the message, object name references, and possible user responses.

The time at which the message is sent does not necessarily indicate when the associated function was performed. Some messages are sent altogether at the start of a query run.

<b>CPI4321 - Access path built for &amp;18 &amp;19</b>	
<b>Message Text:</b>	Access path built for &18 &19.

**CPI4321 - Access path built for &18 &19****Cause Text:**

A temporary access path was built to access records from member &6 of &18 &19 in library &5 for reason code &10. This process took &11 minutes and &12 seconds. The access path built contains &15 entries. The access path was built using &16 parallel tasks. A zero for the number of parallel tasks indicates that parallelism was not used. The reason codes and their meanings follow:

- 1 - Perform specified ordering/grouping criteria.
- 2 - Perform specified join criteria.
- 3 - Perform specified record selection to minimize I/O wait time.

The access path was built using the following key fields. The key fields and their corresponding sequence (ASCEND or DESCEND) will be shown:

&17.

A key field of \*MAP indicates the key field is an expression (derived field).

The access path was built using sequence table &13 in library &14.

A sequence table of \*N indicates the access path was built without a sequence table. A sequence table of \*I indicates the table was an internally derived table that is not available to the user.

If &18 &19 in library &5 is a logical file then the access path is built over member &9 of physical file &7 in library &8.

A file name starting with \*QUERY or \*N indicates the access path was built over a temporary file.

**Recovery Text:**

If this query is run frequently, you may want to create an access path (index) similar to this definition for performance reasons. Create the access path using sequence table &13 in library &14, unless the sequence table is \*N. If an access path is created, it is possible the query optimizer may still choose to create a temporary access path to process the query.

If \*MAP is returned for one of the key fields or \*I is returned for the sequence table, then a permanent access path cannot be created. A permanent access path cannot be built with these specifications.

**CPI4322 - Access path built from keyed file &1****Message Text:**

Access path built from keyed file &1.

**CPI4322 - Access path built from keyed file &1**

**Cause Text:** A temporary access path was built using the access path from member &3 of keyed file &1 in library &2 to access records from member &6 of file &4 in library &5 for reason code &10. This process took &11 minutes and &12 seconds. The access path built contains &15 entries. The reason codes and their meanings follow:

- 1 - Perform specified ordering/grouping criteria.
- 2 - Perform specified join criteria.
- 3 - Perform specified record selection to minimize I/O wait time.

The access path was built using the following key fields. The key fields and their corresponding sequence (ASCEND or DESCEND) will be shown:

&17.

A key field of \*MAP indicates the key field is an expression (derived field).

The temporary access path was built using sequence table &13 in library &14.

A sequence table of \*N indicates the access path was built without a sequence table. A sequence table of \*I indicates the table was an internally derived table that is not available to the user.

If file &4 in library &5 is a logical file then the temporary access path is built over member &9 of physical file &7 in library &8. Creating an access path from a keyed file generally results in improved performance.

**Recovery Text:** If this query is run frequently, you may want to create an access path (index) similar to this definition for performance reasons. Create the access path using sequence table &13 in library &14, unless the sequence table is \*N. If an access path is created, it is possible the query optimizer may still choose to create a temporary access path to process the query.

If \*MAP is returned for one of the key fields or \*I is returned for the sequence table, then a permanent access path cannot be created. A permanent access path cannot be built with these specifications.

A temporary access path can only be created using index only access if all of the fields that were used by this temporary access path are also key fields for the access path from the keyed file.

**CPI4323 - The query access plan has been rebuilt**

**Message Text:** The query access plan has been rebuilt.

**CPI4323 - The query access plan has been rebuilt**

<b>Cause Text:</b>	<p>The access plan was rebuilt for reason code &amp;13. The reason codes and their meanings follow:</p> <ul style="list-style-type: none"><li>0 - A new access plan was created.</li><li>1 - A file or member is not the same object as the one referred to in the access plan. Some reasons include the object being recreated, restored, or overridden to a new object.</li><li>2 - Access plan was using a reusable Open Data Path (ODP), and the optimizer chose to use a non-reusable ODP.</li><li>3 - Access plan was using a non-reusable Open Data Path (ODP) and the optimizer chose to use a reusable ODP.</li><li>4 - The number of records in member &amp;3 of file &amp;1 in library &amp;2 has changed by more than 10%.</li><li>5 - A new access path exists over member &amp;6 of file &amp;4 in library &amp;5.</li><li>6 - An access path over member &amp;9 of file &amp;7 in library &amp;8 that was used for this access plan no longer exists or is no longer valid.</li><li>7 - The query access plan had to be rebuilt because of system programming changes.</li><li>8 - The CCSID (Coded Character Set Identifier) of the current job is different than the CCSID used in the access plan.</li><li>9 - The value of one of the following is different in the current job: date format, date separator, time format, or time separator.</li><li>10 - The sort sequence table specified has changed.</li><li>11 - The number of active processors or the size or paging option of the storage pool has changed.</li><li>12 - The system feature DB2 Symmetric Multiprocessing has either been installed or removed.</li><li>13 - The value of the degree query attribute has changed either by the <b>CHGSYSVAL</b> or <b>CHGQRYA</b> CL commands or with the query options file &amp;15 in library &amp;16.</li><li>14 - A view is either being opened by a high level language open, or is being materialized.</li><li>15 - A sequence object or user-defined type or function is not the same object as the one referred to in the access plan; or, the SQL path used to generate the access plan is different than the current SQL path.</li><li>16 - Query attributes have been specified from the query options file &amp;15 in library &amp;16.</li><li>17 - The access plan was generated with a commitment control level that is different in the current job.</li><li>18 - The access plan was generated with a different static cursor answer set size.</li><li>19 - This is the first run of the query since a prepare or compile.</li><li>20 and greater -- View the second level message text of the next message issued (CPI4351) for an explanation of these reason codes.</li></ul> <p>If the reason code is 4, 5, 6, 20, or 21 and the file specified in the reason code explanation is a logical file, then member &amp;12 of physical file &amp;10 in library &amp;11 is the file with the specified change.</p>
<b>Recovery Text:</b>	Excessive rebuilds should be avoided and may indicate an application design problem.

**CPI4324 - Temporary file built for file &1**

<b>Message Text:</b>	Temporary file built for file &1.
----------------------	-----------------------------------

**CPI4324 - Temporary file built for file &1**

<b>Cause Text:</b>	<p>A temporary file was built for member &amp;3 of file &amp;1 in library &amp;2 for reason code &amp;4. This process took &amp;5 minutes and &amp;6 seconds. The temporary file was required in order for the query to be processed. The reason codes and their meanings follow:</p> <p>1 - The file is a join logical file and its join-type (JDFTVAL) does not match the join-type specified in the query.</p> <p>2 - The format specified for the logical file references more than one physical file.</p> <p>3 - The file is a complex SQL view, or nested table expression, or common table expression, or is a data change table reference that requires a temporary file.</p> <p>4 - For an update-capable query, a subselect references a field in this file which matches one of the fields being updated.</p> <p>5 - For an update-capable query, a subselect references SQL view &amp;1, which is based on the file being updated.</p> <p>6 - For a delete-capable query, a subselect references either the file from which records are to be deleted or an SQL view or logical file based on the file from which records are to be deleted.</p> <p>7 - The file is user-defined table function &amp;8 in &amp;2, and all the records were retrieved from the function. The processing time is not returned for this reason code.</p> <p>8 - The file is a partition file requiring a temporary file for processing the grouping or join.</p>
<b>Recovery Text:</b>	You may want to change the query to refer to a file that does not require a temporary file to be built.

**CPI4325 - Temporary result file built for query**

<b>Message Text:</b>	Temporary result file built for query.
----------------------	----------------------------------------

**CPI4325 - Temporary result file built for query**

<b>Cause Text:</b>	<p>A temporary result file was created to contain the results of the query for reason code &amp;4. This process took &amp;5 minutes and &amp;6 seconds. The temporary file created contains &amp;7 records. The reason codes and their meanings follow:</p> <ol style="list-style-type: none"><li>1 - The query contains grouping fields (GROUP BY) from more than one file, or contains grouping fields from a secondary file of a join query that cannot be reordered.</li><li>2 - The query contains ordering fields (ORDER BY) from more than one file, or contains ordering fields from a secondary file of a join query that cannot be reordered.</li><li>3 - The grouping and ordering fields are not compatible.</li><li>4 - DISTINCT was specified for the query.</li><li>5 - Set operator (UNION, EXCEPT, or INTERSECT) was specified for the query.</li><li>6 - The query had to be implemented using a sort. More than 120 key fields specified for ordering.</li><li>7 - The query optimizer chose to use a sort rather than an access path to order the results of the query.</li><li>8 - Perform specified record selection to minimize I/O wait time.</li><li>9 - The query optimizer chose to use a hashing algorithm rather than an access path to perform the grouping for the query.</li><li>10 - The query contains a join condition that requires a temporary file.</li><li>11 - The query optimizer creates a run-time temporary file in order to implement certain correlated group by queries.</li><li>12 - The query contains grouping fields (GROUP BY, MIN/MAX, COUNT, etc.) and there is a read trigger on one or more of the underlying physical files in the query.</li><li>13 - The query involves a static cursor or the SQL FETCH FIRST clause.</li></ol>
<b>Recovery Text:</b>	For more information on why a temporary result was used, refer to <a href="#">“Data access methods”</a> on page 20.

**CPI4325 - Temporary result file built for query**

<b>Message Text:</b>	&12 &13 processed in join position &10.
----------------------	-----------------------------------------

**CPI4325 - Temporary result file built for query**

**Cause Text:** Access path for member &5 of file &3 in library &4 was used to access records in member &2 of file &13 in library &1 for reason code &9. The reason codes and their meanings follow:

- 1 - Perform specified record selection.
- 2 - Perform specified ordering/grouping criteria.
- 3 - Record selection and ordering/grouping criteria.
- 4 - Perform specified join criteria.

If file &13 in library &1 is a logical file then member &8 of physical file &6 in library &7 is the actual file in join position &10.

A file name starting with \*TEMPX for the access path indicates it is a temporary access path built over file &6.

A file name starting with \*N or \*QUERY for the file indicates it is a temporary file.

Index only access was used for this file within the query: &11.

A value of \*YES for index only access processing indicates that all of the fields used from this file for this query can be found within the access path of file &3. A value of \*NO indicates that index only access could not be performed for this access path.

Index only access is generally a performance advantage since all of the data can be extracted from the access path and the data space does not have to be paged into active memory.

**Recovery Text:** Generally, to force a file to be processed in join position 1, specify an order by field from that file only.

If ordering is desired, specifying ORDER BY fields over more than one file forces the creation of a temporary file and allows the optimizer to optimize the join order of all the files. No file is forced to be first.

An access path can only be considered for index only access if all of the fields used within the query for this file are also key fields for that access path.

Refer to the “Data access methods” on page 20 for additional tips on optimizing a query's join order and index only access.

In some cases, creating a temporary result table provides the fastest way to run a query. Other queries that have many rows to be copied into the temporary result table can take a significant amount of time. However, if the query is taking more time and resources than can be allowed, consider changing the query so that a temporary result table is not required.

**CPI4326 - &12 &13 processed in join position &10**

**Message Text:** &12 &13 processed in join position &10.

**CPI4326 - &12 &13 processed in join position &10**

**Cause Text:** Access path for member &5 of file &3 in library &4 was used to access records in member &2 of file &13 in library &1 for reason code &9. The reason codes and their meanings follow:

- 1 - Perform specified record selection.
- 2 - Perform specified ordering/grouping criteria.
- 3 - Record selection and ordering/grouping criteria.
- 4 - Perform specified join criteria.

If file &13 in library &1 is a logical file then member &8 of physical file &6 in library &7 is the actual file in join position &10.

A file name starting with \*TEMPX for the access path indicates it is a temporary access path built over file &6.

A file name starting with \*N or \*QUERY for the file indicates it is a temporary file.

Index only access was used for this file within the query: &11.

A value of \*YES for index only access processing indicates that all of the fields used from this file for this query can be found within the access path of file &3. A value of \*NO indicates that index only access could not be performed for this access path.

Index only access is generally a performance advantage since all of the data can be extracted from the access path and the data space does not have to be paged into active memory.

**Recovery Text:** Generally, to force a file to be processed in join position 1, specify an order by field from that file only.

If ordering is desired, specifying ORDER BY fields over more than one file forces the creation of a temporary file and allows the optimizer to optimize the join order of all the files. No file is forced to be first.

An access path can only be considered for index only access if all of the fields used within the query for this file are also key fields for that access path.

Refer to the “Data access methods” on page 20 for additional tips on optimizing a query's join order and index only access.

In some cases, creating a temporary result table provides the fastest way to run a query. Other queries that have many rows to be copied into the temporary result table can take a significant amount of time. However, if the query is taking more time and resources than can be allowed, consider changing the query so that a temporary result table is not required.

This message provides the join position of the specified table when an index is used to access the table data. **Join position** pertains to the order in which the tables are joined.

**CPI4327 - File &12 &13 processed in join position &10**

**Message Text:** &12 &13 processed in join position &10.

**Cause Text:** Arrival sequence access was used to select records from member &2 of file &13 in library &1.

If file &13 in library &1 is a logical file then member &8 of physical file &6 in library &7 is the actual file in join position &10.

A file name that starts with \*QUERY for the file indicates it is a temporary file.

**CPI4327 - File &12 &13 processed in join position &10****Recovery Text:**

Generally, to force a file to be processed in join position 1, specify an order by field from that file only.

Refer to the [“Data access methods”](#) on page 20 for additional tips on optimizing a query's join order.

**CPI4328 - Access path of file &3 was used by query****Message Text:**

Access path of file &3 was used by query.

**Cause Text:**

Access path for member &5 of file &3 in library &4 was used to access records from member &2 of &12 &13 in library &1 for reason code &9. The reason codes and their meanings follow:

- 1 - Record selection.
- 2 - Ordering/grouping criteria.
- 3 - Record selection and ordering/grouping criteria.

If file &13 in library &1 is a logical file then member &8 of physical file &6 in library &7 is the actual file being accessed.

Index only access was used for this query: &11.

A value of \*YES for index only access processing indicates that all of the fields used for this query can be found within the access path of file &3. A value of \*NO indicates that index only access could not be performed for this access path.

Index only access is generally a performance advantage since all of the data can be extracted from the access path and the data space does not have to be paged into active memory.

**Recovery Text:**

An access path can only be considered for index only access if all of the fields used within the query for this file are also key fields for that access path.

Refer to the [“Data access methods”](#) on page 20. for additional tips on index only access.

**CPI4329 - Arrival sequence access was used for &12 &13****Message Text:**

Arrival sequence access was used for &12 &13.

**Cause Text:**

Arrival sequence access was used to select records from member &2 of file &13 in library &1.

If file &13 in library &1 is a logical file then member &8 of physical file &6 in library &7 is the actual file from which records are being selected.

A file name starting with \*N or \*QUERY for the file indicates it is a temporary file.

**Recovery Text:**

The use of an access path may improve the performance of the query if record selection is specified.

If an access path does not exist, you may want to create one whose left-most key fields match fields in the record selection. Matching more key fields in the access path with fields in the record selection will result in improved performance.

Generally, to force the use of an existing access path, specify order by fields that match the left-most key fields of that access path.

For more information refer to [“Data access methods”](#) on page 20.

<b>CPI432A - Query optimizer timed out for file &amp;1</b>	
<b>Message Text:</b>	Query optimizer timed out for file &1.
<b>Cause Text:</b>	<p>The query optimizer timed out before it could consider all access paths built over member &amp;3 of file &amp;1 in library &amp;2.</p> <p>The list below shows the access paths considered before the optimizer timed out. If file &amp;1 in library &amp;2 is a logical file then the access paths specified are actually built over member &amp;9 of physical file &amp;7 in library &amp;8. Following each access path name in the list is a reason code which explains how the optimizer considered the access path.</p> <p>&amp;11.</p> <p>The reason codes and their meanings follow:</p> <p>0 - The access path was used to implement the query.</p> <p>1 - Access path was not in a valid state. The system invalidated the access path.</p> <p>2 - Access path was not in a valid state. The user requested that the access path be rebuilt.</p> <p>3 - Access path is a temporary access path (resides in library QTEMP) and was not specified as the file to be queried.</p> <p>4 - The cost to use this access path, as determined by the optimizer, was higher than the cost associated with the chosen access method.</p> <p>5 - The keys of the access path did not match the fields specified for the ordering/ grouping criteria.</p> <p>6 - The keys of the access path did not match the fields specified for the join criteria.</p> <p>7 - Use of this access path would not minimize delays when reading records from the file as the user requested.</p> <p>8 - The access path cannot be used for a secondary file of the join query because it contains static select/omit selection criteria. The join-type of the query does not allow the use of select/omit access paths for secondary files.</p> <p>9 - File &amp;1 contains record ID selection. The join-type of the query forces a temporary access path to be built to process the record ID selection.</p> <p>10 and greater - View the second level message text of the next message issued (CPI432D) for an explanation of these reason codes.</p>
<b>Recovery Text:</b>	<p>To ensure an access path is considered for optimization specify that access path to be the queried file. The optimizer will first consider the access path of the file specified on the query. SQL-created indexes cannot be queried but can be deleted and recreated to increase the chance they will be considered during query optimization.</p> <p>The user may want to delete any access paths no longer needed.</p>

<b>CPI432B - Subselects processed as join query</b>	
<b>Message Text:</b>	Subselects processed as join query.
<b>Cause Text:</b>	Two or more SQL subselects were combined together by the query optimizer and processed as a join query. Processing subselects as a join query generally results in improved performance.
<b>Recovery Text:</b>	None — Generally, this method of processing is a good performing option.

**CPI432C - All access paths were considered for file &1**

<b>Message Text:</b>	All access paths were considered for file &1.
<b>Cause Text:</b>	<p>The query optimizer considered all access paths built over member &amp;3 of file &amp;1 in library &amp;2.</p> <p>The list below shows the access paths considered. If file &amp;1 in library &amp;2 is a logical file then the access paths specified are actually built over member &amp;9 of physical file &amp;7 in library &amp;8. Following each access path name in the list is a reason code which explains how the optimizer considered the access path.</p> <p>&amp;11.</p> <p>The reason codes and their meanings follow:</p> <p>0 - The access path was used to implement the query.</p> <p>1 - Access path was not in a valid state. The system invalidated the access path.</p> <p>2 - Access path was not in a valid state. The user requested that the access path be rebuilt.</p> <p>3 - Access path is a temporary access path (resides in library QTEMP) and was not specified as the file to be queried.</p> <p>4 - The cost to use this access path, as determined by the optimizer, was higher than the cost associated with the chosen access method.</p> <p>5 - The keys of the access path did not match the fields specified for the ordering/ grouping criteria. For distributed file queries, the access path keys must exactly match the ordering fields if the access path is to be used when ALWCPYDTA(*YES or *NO) is specified.</p> <p>6 - The keys of the access path did not match the fields specified for the join criteria.</p> <p>7 - Use of this access path would not minimize delays when reading records from the file. The user requested to minimize delays when reading records from the file.</p> <p>8 - The access path cannot be used for a secondary file of the join query because it contains static select/omit selection criteria. The join-type of the query does not allow the use of select/omit access paths for secondary files.</p> <p>9 - File &amp;1 contains record ID selection. The join-type of the query forces a temporary access path to be built to process the record ID selection.</p> <p>10 and greater - View the second level message text of the next message issued (CPI432D) for an explanation of these reason codes.</p>
<b>Recovery Text:</b>	The user may want to delete any access paths no longer needed.

**CPI432D - Additional access path reason codes were used**

<b>Message Text:</b>	Additional access path reason codes were used.
----------------------	------------------------------------------------

<b>CPI432D - Additional access path reason codes were used</b>	
<b>Cause Text:</b>	<p>Message CPI432A or CPI432C was issued immediately before this message. Because of message length restrictions, some of the reason codes used by messages CPI432A and CPI432C are explained below rather than in those messages.</p> <p>The reason codes and their meanings follow:</p> <p>10 - The user specified ignore decimal data errors on the query. This disallows the use of permanent access paths.</p> <p>11 - The access path contains static select/omit selection criteria which is not compatible with the selection in the query.</p> <p>12 - The access path contains static select/omit selection criteria whose compatibility with the selection in the query could not be determined. Either the select/omit criteria or the query selection became too complex during compatibility processing.</p> <p>13 - The access path cannot be used because it contains one or more keys which may be changed by the query during an insert or update.</p> <p>14 - The access path is being deleted or is being created in an uncommitted unit of work in another process.</p> <p>15 - The keys of the access path matched the fields specified for the ordering/grouping criteria. However, the sequence table associated with the access path did not match the sequence table associated with the query.</p> <p>16 - The keys of the access path matched the fields specified for the join criteria. However, the sequence table associated with the access path did not match the sequence table associated with the query.</p> <p>17 - The left-most key of the access path did not match any fields specified for the selection criteria. Therefore, key row positioning could not be performed, making the cost to use this access path higher than the cost associated with the chosen access method.</p> <p>18 - The left-most key of the access path matched a field specified for the selection criteria. However, the sequence table associated with the access path did not match the sequence table associated with the query. Therefore, key row positioning could not be performed, making the cost to use this access path higher than the cost associated with the chosen access method.</p> <p>19 - The access path cannot be used because the secondary file of the join query is a select/omit logical file. The join-type requires that the select/omit access path associated with the secondary file be used or, if dynamic, that an access path be created by the system.</p> <p>99 - The access path was used to gather statistics information for the query optimizer.</p>
<b>Recovery Text:</b>	See prior message CPI432A or CPI432C for more information.

Because of message length restrictions, some of the reason codes used by messages CPI432A and CPI432C are explained in the message help of CPI432D. Use the message help from this message to interpret the information returned from message CPI432A or CPI432C.

<b>CPI432E - Selection fields mapped to different attributes</b>	
<b>Message Text:</b>	Selection fields mapped to different attributes.

**CPI432E - Selection fields mapped to different attributes**

**Cause Text:** The data type, digits, decimal position, or length of each of the following selection fields was changed so that the field could be properly compared to the literal, host variable, or field operand associated with it. Therefore, an access path cannot be used to process that selection, since no key field has attributes that match the new attributes of the field. &1.

The data type of the field may have been changed to match the comparison operand. For a numeric field, the number of total digits or fractional digits of the comparison operand may have exceeded that of the field.

**Recovery Text:** You may want to change each comparison operand as follows:

- 1 - For a literal, change the literal value so that its attributes match the field's attributes. Normally, an attributes mismatch is caused by a numeric literal that has non-significant leading or trailing zeroes.
- 2 - For a host variable, either change the host variable's definition to match the field's definition or define a new host variable that matches the field's definition.
- 3 - For a field, change the attributes of one of the fields to match the other's attributes.

**CPI432F - Access path suggestion for file &1**

**Message Text:** Access path suggestion for file &1.

**Cause Text:** To improve performance the query optimizer is suggesting a permanent access path be built with the key fields it is recommending. The access path will access records from member &3 of file &1 in library &2.

In the list of key fields that follow, the query optimizer is recommending the first &10 key fields as primary key fields. The remaining key fields are considered secondary key fields and are listed in order of expected selectivity based on this query. Primary key fields are fields that significantly reduce the number of keys selected based on the corresponding selection predicate. Secondary key fields are fields that may or may not significantly reduce the number of keys selected. It is up to the user to determine the true selectivity of secondary key fields and to determine whether those key fields should be used when creating the access path.

The query optimizer is able to perform key positioning over any combination of the primary key fields, plus one additional secondary key field. Therefore it is important that the first secondary key field be the most selective secondary key field. The query optimizer will use key selection with any remaining secondary key fields. While key selection is not as fast as key positioning it can still reduce the number of keys selected. Hence, secondary key fields that are fairly selective should be included. When building the access path all primary key fields should be specified first followed by the secondary key fields which are prioritized by selectivity. The following list contains the suggested primary and secondary key fields:

&11.

If file &1 in library &2 is a logical file then the access path should be built over member &9 of physical file &7 in library &8.

**Recovery Text:** If this query is run frequently, you may want to create the suggested access path for performance reasons. It is possible that the query optimizer will choose not to use the access path just created.

For more information, refer to [“Data access methods”](#) on page 20.

<b>CPI4330 - &amp;6 tasks used for parallel &amp;10 scan of file &amp;1</b>	
<b>Message Text:</b>	&6 tasks used for parallel &10 scan of file &1.
<b>Cause Text:</b>	<p>&amp;6 is the average numbers of tasks used for a &amp;10 scan of member &amp;3 of file &amp;1 in library &amp;2.</p> <p>If file &amp;1 in library &amp;2 is a logical file, then member &amp;9 of physical file &amp;7 in library &amp;8 is the actual file from which records are being selected.</p> <p>A file name starting with *QUERY or *N for the file indicates a temporary result file is being used.</p> <p>The query optimizer has calculated that the optimal number of tasks is &amp;5 which was limited for reason code &amp;4. The reason code definitions are:</p> <ol style="list-style-type: none"> <li>1 - The *NBRTASKS parameter value was specified for the DEGREE parameter of the CHGQRYA CL command.</li> <li>2 - The optimizer calculated the number of tasks which would use all of the central processing units (CPU).</li> <li>3 - The optimizer calculated the number of tasks which can efficiently run in this job's share of the memory pool.</li> <li>4 - The optimizer calculated the number of tasks which can efficiently run using the entire memory pool.</li> <li>5 - The optimizer limited the number of tasks to equal the number of disk units which contain the file's data.</li> </ol> <p>The database manager may further limit the number of tasks used if the allocation of the file's data is not evenly distributed across disk units.</p>
<b>Recovery Text:</b>	<p>To disallow usage of parallel &amp;10 scan, specify *NONE on the query attribute degree.</p> <p>A larger number of tasks might further improve performance. The following actions based on the optimizer reason code might allow the optimizer to calculate a larger number:</p> <ol style="list-style-type: none"> <li>1 - Specify a larger number of tasks value for the DEGREE parameter of the CHGQRYA CL command. Start with a value for number of tasks which is a slightly larger than &amp;5.</li> <li>2 - Simplify the query by reducing the number of fields being mapped to the result buffer or by removing expressions. Also, try specifying a number of tasks as described by reason code 1.</li> <li>3 - Specify *MAX for the query attribute DEGREE.</li> <li>4 - Increase the size of the memory pool.</li> <li>5 - Use the CHGPF CL command or the SQL ALTER statement to redistribute the file's data across more disk units.</li> </ol>
<b>CPI4331 - &amp;6 tasks used for parallel index created over file</b>	
<b>Message Text:</b>	&6 tasks used for parallel index created over file &1.

**CPI4331 - &6 tasks used for parallel index created over file**

**Cause Text:** &6 is the average numbers of tasks used for an index created over member &3 of file &1 in library &2.

If file &1 in library &2 is a logical file, then member &9 of physical file &7 in library &8 is the actual file over which the index is being built.

A file name starting with \*QUERY or \*N for the file indicates a temporary result file is being used.

The query optimizer has calculated that the optimal number of tasks is &5 which was limited for reason code &4. The definition of reason codes are:

- 1 - The \*NBRTASKS parameter value was specified for the DEGREE parameter of the CHGQRYA CL command.
- 2 - The optimizer calculated the number of tasks which would use all of the central processing units (CPU).
- 3 - The optimizer calculated the number of tasks which can efficiently run in this job's share of the memory pool.
- 4 - The optimizer calculated the number of tasks which can efficiently run using the entire memory pool.

The database manager may further limit the number of tasks used for the parallel index build if either the allocation of the file's data is not evenly distributed across disk units or the system has too few disk units.

**Recovery Text:** To disallow usage of parallel index build, specify \*NONE on the query attribute degree.

A larger number of tasks might further improve performance. The following actions based on the reason code might allow the optimizer to calculate a larger number:

- 1 - Specify a larger number of tasks value for the DEGREE parameter of the CHGQRYA CL command. Start with a value for number of tasks which is a slightly larger than &5 to see if a performance improvement is achieved.
- 2 - Simplify the query by reducing the number of fields being mapped to the result buffer or by removing expressions. Also, try specifying a number of tasks for the DEGREE parameter of the CHGQRYA CL command as described by reason code 1.
- 3 - Specify \*MAX for the query attribute degree.
- 4 - Increase the size of the memory pool.

**CPI4332 - &1 host variables used in query**

**Message Text:** &1 host variables used in query.

**Cause Text:** There were &1 host variables defined for use in the query. The values used for the host variables for this open of the query follow: &2.

The host variables values displayed above may have been special values. An explanation of the special values follow:

- DBCS data is displayed in hex format.
- \*N denotes a value of NULL.
- \*Z denotes a zero length string.
- \*L denotes a value too long to display in the replacement text.
- \*U denotes a value that could not be displayed.

<b>CPI4332 - &amp;1 host variables used in query</b>	
<b>Recovery Text:</b>	None

<b>CPI4333 - Hashing algorithm used to process join</b>	
<b>Message Text:</b>	Hashing algorithm used to process join.
<b>Cause Text:</b>	<p>The hash join method is typically used for longer running join queries. The original query will be subdivided into hash join steps.</p> <p>Each hash join step will be optimized and processed separately. Debug messages which explain the implementation of each hash join step follow this message in the joblog.</p> <p>The list below shows the names of the files or the table functions used in this query. If the entry is for a file, the format of the entry in this list is the number of the hash join step, the filename as specified in the query, the member name as specified in the query, the filename actually used in the hash join step, and the member name actually used in the hash join step. If the entry is for a table function, the format of the entry in this list is the number of the hash join step and the function name as specified in the query.</p> <p>If there are two or more files or functions listed for the same hash step, then that hash step is implemented with nested loop join.</p>
<b>Recovery Text:</b>	The hash join method is usually a good implementation choice, however, if you want to disallow the use of this method specify ALWCOPYDTA(*YES).

<b>CPI4334 - Query implemented as reusable ODP</b>	
<b>Message Text:</b>	Query implemented as reusable ODP.
<b>Cause Text:</b>	The query optimizer built the access plan for this query such that a reusable open data path (ODP) will be created. This plan will allow the query to be run repeatedly for this job without having to rebuild the ODP each time. This normally improves performance because the ODP is created only once for the job.
<b>Recovery Text:</b>	Generally, reusable ODPs perform better than non-reusable ODPs.

<b>CPI4335 - Optimizer debug messages for hash join step &amp;1 follow</b>	
<b>Message Text:</b>	Optimizer debug messages for hash join step &1 follow:
<b>Cause Text:</b>	This join query is implemented using the hash join algorithm. The optimizer debug messages that follow provide the query optimization information about hash join step &1.
<b>Recovery Text:</b>	Refer to “Data access methods” on <a href="#">page 20</a> for more information about hashing algorithm for join processing.

<b>CPI4336 - Group processing generated</b>	
<b>Message Text:</b>	Group processing generated.
<b>Cause Text:</b>	Group processing (GROUP BY) was added to the query step. Adding the group processing reduced the number of result records which should, in turn, improve the performance of subsequent steps.

<b>CPI4336 - Group processing generated</b>	
<b>Recovery Text:</b>	For more information refer to <a href="#">“Data access methods” on page 20</a>

<b>CPI4337 - Temporary hash table build for hash join step &amp;1</b>	
<b>Message Text:</b>	Temporary hash table built for hash join step &1.
<b>Cause Text:</b>	A temporary hash table was created to contain the results of hash join step &1. This process took &2 minutes and &3 seconds. The temporary hash table created contains &4 records. The total size of the temporary hash table in units of 1024 bytes is &5. A list of the fields which define the hash keys follow:
<b>Recovery Text:</b>	Refer to <a href="#">“Data access methods” on page 20</a> for more information about hashing algorithm for join processing.

<b>CPI4338 - &amp;1 Access path(s) used for bitmap processing of file &amp;2</b>	
<b>Message Text:</b>	&1 Access path(s) used for bitmap processing of file &2.
<b>Cause Text:</b>	<p>Bitmap processing was used to access records from member &amp;4 of file &amp;2 in library &amp;3.</p> <p>Bitmap processing is a method of allowing one or more access path(s) to be used to access the selected records from a file. Using bitmap processing, record selection is applied against each access path, similar to key row positioning, to create a bitmap. The bitmap has marked in it only the records of the file that are to be selected. If more than one access path is used, the resulting bitmaps are merged together using boolean logic. The resulting bitmap is then used to reduce access to just those records actually selected from the file.</p> <p>Bitmap processing is used in conjunction with the two primary access methods: arrival sequence (CPI4327 or CPI4329) or keyed access (CPI4326 or CPI4328). The message that describes the primary access method immediately precedes this message.</p> <p>When the bitmap is used with the keyed access method then it is used to further reduce the number of records selected by the primary access path before retrieving the selected records from the file.</p> <p>When the bitmap is used with arrival sequence then it allows the sequential scan of the file to skip records which are not selected by the bitmap. This is called skip sequential processing.</p> <p>The list below shows the names of the access paths used in the bitmap processing:</p> <p>&amp;8</p> <p>If file &amp;2 in library &amp;3 is a logical file then member &amp;7 of physical file &amp;5 in library &amp;6 is the actual file being accessed.</p>
<b>Recovery Text:</b>	Refer to <a href="#">“Data access methods” on page 20</a> for more information about bitmap processing.

<b>CPI433A - Unable to retrieve query options file</b>	
<b>Message Text:</b>	Unable to retrieve query options file.

<b>CPI433A - Unable to retrieve query options file</b>	
<b>Cause Text:</b>	<p>Unable to retrieve the query options from member &amp;3 in file &amp;2 in library &amp;1 for reason code &amp;4. The reason codes and their meanings follow:</p> <p>1 - Library &amp;1 was not found.</p> <p>2 - File &amp;2 in library &amp;1 was not found.</p> <p>3 - The file was damaged.</p> <p>4 - The file was locked by another process which prevented successful retrieval of the query options.</p> <p>5 - File &amp;2 and the internal query options structures are out of sync.</p> <p>6 - An unexpected error occurred while trying to retrieve the options file.</p> <p>The query options file is used by the Query Optimizer to determine how a query will be implemented.</p>
<b>Recovery Text:</b>	<p>Default query options will be used, unless one of the following actions are taken, based on the reason code above.</p> <p>1 - Either create the library (CRTLIB command) or correct the library name and then try the request again.</p> <p>2 - Either specify the library name that contains the query options file or create a duplicate object (CRTDUPOBJ command) of file &amp;2 from library QSYS into the specified library.</p> <p>4 - Wait for lock on file &amp;2 in library &amp;1 to be released and try the request again.</p> <p>3, 5, or 6 - Delete query options file &amp;2 in library &amp;1 and then duplicate it from QSYS. If the problem still persists, report the problem (ANZPRB command).</p>

<b>CPI433B - Unable to update query options file</b>	
<b>Message Text:</b>	Unable to update query options file.
<b>Cause Text:</b>	<p>An error occurred while trying to update the query options from member &amp;3, file &amp;2, library &amp;1 for reason code &amp;4. The reason codes and their meanings follow:</p> <p>1 - The library &amp;1 was not found.</p> <p>2 - The file &amp;2 in library &amp;1 was not found.</p> <p>3 - The parameter &amp;5 was not found.</p> <p>4 - The value &amp;6 for parameter &amp;5 was not valid.</p> <p>5 - An unexpected error occurred while trying to update the options file.</p>
<b>Recovery Text:</b>	<p>Do one of the following actions based on the reason code above.</p> <p>1 - Either create the library (CRTLIB) command or correct the library name and then try the request again.</p> <p>2 - Either specify the library name that contains the query options file or create duplicate object (CRTDUPOBJ) command of QAQQINI from library QSYS into the specified library.</p> <p>3 - Either specify a valid parameter or correct the parameter name and then try the request again.</p> <p>4 - Either specify a valid parameter value or correct the parameter value and then try the request again. (WRKJOB) command.</p>

<b>CPI433C - Library &amp;1 not found</b>	
<b>Message Text:</b>	Library &1 not found.
<b>Cause Text:</b>	The specified library does not exist, or the name of the library is not spelled correctly.
<b>Recovery Text:</b>	Correct the spelling of the library name, or specify the name of an existing library. Then try the request again.

<b>CPI433D - Query options used to build the query access plan</b>	
<b>Message Text:</b>	Query options used to build the query access plan.
<b>Cause Text:</b>	The access plan that was saved was created with query options retrieved from file &2 in library &1.
<b>Recovery Text:</b>	None

<b>CPI433E - User-defined function &amp;4 found in library &amp;1</b>	
<b>Message Text:</b>	User-defined function &4 found in library &1.
<b>Cause Text:</b>	Function &4 was resolved to library &1. The specific name of the function is &5.  If the function is defined to use an external program, the associated program or service program is &3 in library &2.
<b>Recovery Text:</b>	Refer to the <a href="#">SQL programming</a> topic collection, for more information on user-defined functions.

<b>CPI433F - Multiple join classes used to process join</b>	
<b>Message Text:</b>	Multiple join classes used to process join.
<b>Cause Text:</b>	Multiple join classes are used when join queries are written that have conflicting operations or cannot be implemented as a single query.  Each join class step will be optimized and processed separately. Debug messages detailing the implementation of each join class follow this message in the joblog.  The list below shows the file names of the files used in this query. The format of each entry in this list is the number of the join class step, the number of the join position in the join class step, the file name as specified in the query, the member name as specified in the query, the file name actually used in the join class step, and the member name actually used in the join class step.
<b>Recovery Text:</b>	Refer to <a href="#">“Join optimization”</a> on page 69 for more information about join classes.

<b>CPI4340 - Optimizer debug messages for join class step &amp;1 follow</b>	
<b>Message Text:</b>	Optimizer debug messages for join class step &1 follow:
<b>Cause Text:</b>	This join query is implemented using multiple join classes. The optimizer debug messages that follow provide the query optimization information about join class step &1.

<b>CPI4340 - Optimizer debug messages for join class step &amp;1 follow</b>	
<b>Recovery Text:</b>	Refer to <a href="#">“Join optimization”</a> on page 69 for more information about join classes.

<b>CPI4341 - Performing distributed query</b>	
<b>Message Text:</b>	Performing distributed query.
<b>Cause Text:</b>	Query contains a distributed file. The query was processed in parallel on the following nodes: &1.
<b>Recovery Text:</b>	For more information about processing of distributed files, refer to the <a href="#">Distributed database programming</a> topic collection.

<b>CPI4342 - Performing distributed join for query</b>	
<b>Message Text:</b>	Performing distributed join for query.
<b>Cause Text:</b>	Query contains join criteria over a distributed file and a distributed join was performed, in parallel, on the following nodes: &1.  The library, file and member names of each file involved in the join follow: &2.  A file name beginning with *QQTDF indicates it is a temporary distributed result file created by the query optimizer and it will not contain an associated library or member name.
<b>Recovery Text:</b>	For more information about processing of distributed files, refer to the <a href="#">Distributed database programming</a> .

<b>CPI4343 - Optimizer debug messages for distributed query step &amp;1 of &amp;2 follow</b>	
<b>Message Text:</b>	Optimizer debug messages for distributed query step &1 of &2 follow:
<b>Cause Text:</b>	A distributed file was specified in the query which caused the query to be processed in multiple steps. The optimizer debug messages that follow provide the query optimization information about distributed step &1 of &2 total steps.
<b>Recovery Text:</b>	For more information about processing of distributed files, refer to the <a href="#">Distributed database programming</a> .

<b>CPI4345 - Temporary distributed result file &amp;3 built for query</b>	
<b>Message Text:</b>	Temporary distributed result file &3 built for query.

**CPI4345 - Temporary distributed result file &3 built for query**

**Cause Text:** Temporary distributed result file &3 was created to contain the intermediate results of the query for reason code &6. The reason codes and their meanings follow:

- 1 - Data from member &2 of &7 &8 in library &1 was directed to other nodes.
- 2 - Data from member &2 of &7 &8 in library &1 was broadcast to all nodes.
- 3 - Either the query contains grouping fields (GROUP BY) that do not match the partitioning keys of the distributed file or the query contains grouping criteria but no grouping fields were specified or the query contains a subquery.
- 4 - Query contains join criteria over a distributed file and the query was processed in multiple steps.

A library and member name of \*N indicates the data comes from a query temporary distributed file.

File &3 was built on nodes: &9.

It was built using partitioning keys: &10.

A partitioning key of \*N indicates no partitioning keys were used when building the temporary distributed result file.

**Recovery Text:** If the reason code is:

- 1 - Generally, a file is directed when the join fields do not match the partitioning keys of the distributed file. When a file is directed, the query is processed in multiple steps and processed in parallel. A temporary distributed result file is required to contain the intermediate results for each step.
- 2 - Generally, a file is broadcast when join fields do not match the partitioning keys of either file being joined or the join operator is not an equal operator. When a file is broadcast the query is processed in multiple steps and processed in parallel. A temporary distributed result file is required to contain the intermediate results for each step.
- 3 - Better performance may be achieved if grouping fields are specified that match the partitioning keys.
- 4 - Because the query is processed in multiple steps, a temporary distributed result file is required to contain the intermediate results for each step. See preceding message CPI4342 to determine which files were joined together.

For more information about processing of distributed files, refer to the [Distributed database programming](#)

**CPI4346 - Optimizer debug messages for query join step &1 of &2 follow**

**Message Text:** Optimizer debug messages for query join step &1 of &2 follow:

**Cause Text:** Query processed in multiple steps. The optimizer debug messages that follow provide the query optimization information about join step &1 of &2 total steps.

**Recovery Text:** No recovery necessary.

**CPI4347 - Query being processed in multiple steps**

**Message Text:** Query being processed in multiple steps.

<b>CPI4347 - Query being processed in multiple steps</b>	
<b>Cause Text:</b>	<p>The original query will be subdivided into multiple steps.</p> <p>Each step will be optimized and processed separately. Debug messages which explain the implementation of each step follow this message in the joblog.</p> <p>The list below shows the file names of the files used in this query. The format of each entry in this list is the number of the join step, the filename as specified in the query, the member name as specified in the query, the filename actually used in the step, and the member name actually used in the step.</p>
<b>Recovery Text:</b>	No recovery necessary.

<b>CPI4348 - The ODP associated with the cursor was hard closed</b>	
<b>Message Text:</b>	The ODP associated with the cursor was hard closed.
<b>Cause Text:</b>	<p>The Open Data Path (ODP) for this statement or cursor has been hard closed for reason code &amp;1. The reason codes and their meanings follow:</p> <ol style="list-style-type: none"> <li>1 - Either the length of the new LIKE pattern is zero and the length of the old LIKE pattern is nonzero or the length of the new LIKE pattern is nonzero and the length of the old LIKE pattern is zero.</li> <li>2 - An additional wildcard was specified in the LIKE pattern on this invocation of the cursor.</li> <li>3 - SQL indicated to the query optimizer that the cursor cannot be refreshed.</li> <li>4 - The system code could not obtain a lock on the file being queried.</li> <li>5 - The length of the host variable value is too large for the the host variable as determined by the query optimizer.</li> <li>6 - The size of the ODP to be refreshed is too large.</li> <li>7 - Refresh of the local ODP of a distributed query failed.</li> <li>8 - SQL hard closed the cursor prior to the fast path refresh code.</li> </ol>
<b>Recovery Text:</b>	In order for the cursor to be used in a reusable mode, the cursor cannot be hard closed. Look at the reason why the cursor was hard closed and take the appropriate actions to prevent a hard close from occurring.

<b>CPI4349 - Fast past refresh of the host variables values is not possible</b>	
<b>Message Text:</b>	Fast past refresh of the host variable values is not possible.

**CPI4349 - Fast past refresh of the host variables values is not possible**

<b>Cause Text:</b>	<p>The Open Data Path (ODP) for this statement or cursor could not invoke the fast past refresh code for reason code &amp;1. The reason codes and their meanings follow:</p> <p>1 - The new host variable value is not null and old host variable value is null or the new host variable value is zero length and the old host variable value is not zero length.</p> <p>2 - The attributes of the new host variable value are not the same as the attributes of the old host variable value.</p> <p>3 - The length of the host variable value is either too long or too short. The length difference cannot be handled in the fast path refresh code.</p> <p>4 - The host variable has a data type of IGC ONLY and the the length is not even or is less than 2 bytes.</p> <p>5 - The host variable has a data type of IGC ONLY and the new host variable value does not contain an even number of bytes.</p> <p>6 - A translate table with substitution characters was used.</p> <p>7 - The host variable contains DBCS data and a CCSID translate table with substitution characters is required.</p> <p>8 - The host variable contains DBCS that is not well formed. That is, a shift-in without a shift-out or visa versa.</p> <p>9 - The host variable must be translated with a sort sequence table and the sort sequence table contains substitution characters.</p> <p>10 - The host variable contains DBCS data and must be translated with a sort sequence table that contains substitution characters.</p> <p>11 - The host variable is a Date, Time or Timestamp data type and the length of the host variable value is either too long or too short.</p>
<b>Recovery Text:</b>	Look at the reason why fast path refresh could not be used and take the appropriate actions so that fast path refresh can be used on the next invocation of this statement or cursor.

**CPI434 - Member &3 was opened with fewer open options than were specified**

<b>Message Text:</b>	Member &3 was opened with fewer open options than were specified.
<b>Cause Text:</b>	An INSTEAD OF trigger is being used for some of the open options. However there is an additional INSTEAD OF trigger on an underlying SQL view file whose trigger actions cannot be used. An open request can support INSTEAD OF triggers from only one SQL view file. The member could not be opened with the following open options: &4.
<b>Recovery Text:</b>	When adding an INSTEAD OF trigger, specify trigger actions for all of the requested open options.

**CPI434E - Query could not be run using SQE**

<b>Message Text:</b>	Query could not be run using SQE.
<b>Cause Text:</b>	<p>The query was run using CQE (Current Query Engine). The query could not be run using SQE (SQL Query Engine) for reason code &amp;1. The reason codes and their meanings follow:</p> <p>1 -- Sort sequence table &amp;2 in library &amp;3 is an ICU (International Components of Unicode) sort sequence table that is not supported by SQE.</p>

<b>CPI434E - Query could not be run using SQE</b>	
---------------------------------------------------	--

<b>Recovery Text:</b>	Recovery for reason code 1: To run the query using SQE, specify a version of the ICU sort sequence table that is &4 or later.
-----------------------	-------------------------------------------------------------------------------------------------------------------------------

<b>CPI4350 - Materialized query tables were considered for optimization</b>	
-----------------------------------------------------------------------------	--

<b>Message Text:</b>	Materialized query tables were considered for optimization.
----------------------	-------------------------------------------------------------

**CPI4350 - Materialized query tables were considered for optimization****Cause Text:**

The query optimizer considered usage of materialized query tables for this query.

Following each materialized query table name in the list is a reason code which explains why the materialized query table was not used. A reason code of 0 indicates that the materialized query table was used to implement the query.

The reason codes and their meanings follow:

1 - The cost to use the materialized query table, as determined by the optimizer, was higher than the cost associated with the chosen implementation.

2 - The join specified in the materialized query was not compatible with the query.

3 - The materialized query table had predicates that were not matched in the query.

4 - The grouping or distinct specified in the materialized query table is not compatible with the grouping or distinct specified in the query.

5 - The query specified columns that were not in the select-list of the materialized query table.

6 - The materialized query table query contains functionality that is not supported by the query optimizer.

7 - The materialized query table specified the DISABLE QUERY OPTIMIZATION clause.

8 - The ordering specified in the materialized query table is not compatible with the ordering specified in the query.

9 - The query contains functionality that is not supported by the materialized query table matching algorithm.

10 - Materialized query tables may not be used for this query.

11 - The refresh age of this materialized query table exceeds the duration specified by the MATERIALIZED\_QUERY\_TABLE\_REFRESH\_AGE QAQQINI option.

12 - The commit level of the materialized query table is lower than the commit level specified for the query.

14 - The FETCH FOR FIRST n ROWS clause of the materialized query table is not compatible with the query.

15 - The QAQQINI options used to create the materialized query table are not compatible with the QAQQINI options used to run this query.

16 - The materialized query table is not usable.

17 - The UNION specified in the materialized query table is not compatible with the query.

18 - The constants specified in the materialized query table are not compatible with host variable values specified in the query.

19 - The materialized query table is in Check Pending status and cannot be used.

20 - The UDTF specified in the materialized query table is not compatible with UDTF in the query.

21 - The Values clause specified in the materialized query table is not compatible with Values specified in the query.

**Recovery Text:**

The user may want to delete any materialized query tables that are no longer needed.

<b>CPI4351 - Additional reason codes for query access plan has been rebuilt</b>	
<b>Message Text:</b>	Additional reason codes for query access plan has been rebuilt.
<b>Cause Text:</b>	<p>Message CPI4323 was issued immediately before this message. Because of message length restrictions, some of the reason codes used by message CPI4323 are explained below rather than in that message. The CPI4323 message was issued for reason code &amp;13. The additional reason codes and their meaning follow:</p> <p>20 - Referential or check constraints for member &amp;19 of file &amp;17 in library &amp;18 have changed since the access plan was generated.</p> <p>21 - Materialized query tables for member &amp;22 of file &amp;20 in library &amp;21 have changed since the access plan was generated. If the file is *N then the file name is not available.</p> <p>22 - The value of a host variable changed and the access plan is no longer valid.</p> <p>23 - Adaptive Query Processing (AQP) determined that a new access plan is needed.</p>
<b>Recovery Text:</b>	See the prior message CPI4323 for more information.

<b>CPI436A - Database monitor started for job &amp;1, monitor ID &amp;2</b>	
<b>Message Text:</b>	Database monitor started for job &1, monitor ID &2.
<b>Cause Text:</b>	<p>The database monitor was started for job &amp;1. The system generated monitor ID for this database monitor is &amp;2.</p> <p>If multiple monitors have been started using the same generic job name, the monitor ID is needed to uniquely identify which monitor is to be ended with the ENDDBMON command.</p>
<b>Recovery Text:</b>	If multiple monitors have been started using the same generic job name, remember the monitor ID. The monitor ID will be required when using the ENDDBMON command to end this specific monitor.

## Query optimization performance information messages and open data paths

Several of the following SQL runtime messages refer to open data paths.

An open data path (ODP) definition is an internal object that is created when a cursor is opened or when other SQL statements are run. It provides a direct link to the data so that I/O operations can occur. ODPs are used on OPEN, INSERT, UPDATE, DELETE, and SELECT INTO statements to perform their respective operations on the data.

Even though SQL cursors are closed and SQL statements have run, in many cases, the database manager saves the associated ODPs of the SQL operations. These ODPs are then reused the next time the statement is run. For example, an SQL CLOSE statement could close the SQL cursor, but leave the ODP available to use again the next time the cursor is opened. This technique can significantly reduce the processing and response time in running SQL statements.

The ability to reuse ODPs when SQL statements are run repeatedly is an important consideration in achieving faster performance.

<b>SQL7910 - All SQL cursors closed</b>	
<b>Message Text:</b>	SQL cursors closed.

<b>SQL7910 - All SQL cursors closed</b>	
<b>Cause Text:</b>	SQL cursors have been closed and all Open Data Paths (ODPs) have been deleted, except those that were opened by programs with the CLOSQLCSR(*ENDJOB) option or were opened by modules with the CLOSQLCSR(*ENDACTGRP) option. All SQL programs on the call stack have completed, and the SQL environment has been exited. This process includes the closing of cursors, the deletion of ODPs, the removal of prepared statements, and the release of locks.
<b>Recovery Text:</b>	To keep cursors, ODPs, prepared statements, and locks available after the completion of a program, use the CLOSQLCSR precompile parameter. -- The *ENDJOB option will allow the user to keep the SQL resources active for the duration of the job. -- The *ENDSQL option will allow the user to keep SQL resources active across program calls, provided the SQL environment stays resident. Running an SQL statement in the first program of an application will keep the SQL environment active for the duration of that application. -- The *ENDPGM option, which is the default for non-Integrated Language Environment® (ILE) programs, causes all SQL resources to only be accessible by the same invocation of a program. Once an *ENDPGM program has completed, if it is called again, the SQL resources are no longer active. -- The *ENDMOD option causes all SQL resources to only be accessible by the same invocation of the module. -- The *ENDACTGRP option, which is the default for ILE modules, will allow the user to keep the SQL resources active for the duration of the activation group.

<b>SQL7911 - ODP reused</b>	
<b>Message Text:</b>	ODP reused.
<b>Cause Text:</b>	An ODP that was previously created has been reused. There was a reusable Open Data Path (ODP) found for this SQL statement, and it has been used. The reusable ODP may have been from the same call to a program or a previous call to the program. A reuse of an ODP will not generate an OPEN entry in the journal.
<b>Recovery Text:</b>	None

<b>SQL7912 - ODP created</b>	
<b>Message Text:</b>	ODP created.
<b>Cause Text:</b>	An Open Data Path (ODP) has been created. No reusable ODP could be found. This occurs in the following cases: -- This is the first time the statement has been run. -- A RCLRSC has been issued since the last run of this statement. -- The last run of the statement caused the ODP to be deleted. -- If this is an OPEN statement, the last CLOSE of this cursor caused the ODP to be deleted. -- The Application Server (AS) has been changed by a CONNECT statement.

<b>SQL7912 - ODP created</b>	
<b>Recovery Text:</b>	If a cursor is being opened many times in an application, it is more efficient to use a reusable ODP, and not create an ODP every time. This also applies to repeated runs of INSERT, UPDATE, DELETE, and SELECT INTO statements. If ODPs are being created on every open, see the close message to determine why the ODP is being deleted.

The first time that the statement is run or the cursor is opened for a process, an ODP must always be created. However, if this message appears on every statement run or cursor open, use the tips recommended in “Retaining cursor positions for non-ILE program calls” on page 306 in your application.

<b>SQL7913 - ODP deleted</b>	
<b>Message Text:</b>	ODP deleted.
<b>Cause Text:</b>	The Open Data Path (ODP) for this statement or cursor has been deleted. The ODP was not reusable. This could be caused by using a host variable in a LIKE clause, ordering on a host variable, or because the query optimizer chose to accomplish the query with an ODP that was not reusable.
<b>Recovery Text:</b>	See previous query optimizer messages to determine how the cursor was opened.

<b>SQL7914 - ODP not deleted</b>	
<b>Message Text:</b>	ODP not deleted.
<b>Cause Text:</b>	The Open Data Path (ODP) for this statement or cursor has not been deleted. This ODP can be reused on a subsequent run of the statement. This will not generate an entry in the journal.
<b>Recovery Text:</b>	None

<b>SQL7915 - Access plan for SQL statement has been built</b>	
<b>Message Text:</b>	Access plan for SQL statement has been built.
<b>Cause Text:</b>	SQL had to build the access plan for this statement at run time. This occurs in the following cases: -- The program has been restored from a different release and this is the first time this statement has been run. -- All the files required for the statement did not exist at precompile time, and this is the first time this statement has been run. -- The program was precompiled using SQL naming mode, and the program owner has changed since the last time the program was called.
<b>Recovery Text:</b>	This is normal processing for SQL. Once the access plan is built, it will be used on subsequent runs of the statement.

<b>SQL7916 - Blocking used for query</b>	
<b>Message Text:</b>	Blocking used for query.

**SQL7916 - Blocking used for query**

<b>Cause Text:</b>	Blocking has been used in the implementation of this query. SQL will retrieve a block of records from the database manager on the first FETCH statement. Additional FETCH statements have to be issued by the calling program, but they do not require SQL to request more records, and therefore will run faster.
<b>Recovery Text:</b>	SQL attempts to utilize blocking whenever possible. In cases where the cursor is not update capable, and commitment control is not active, there is a possibility that blocking will be used.

**SQL7917 - Access plan not updated**

<b>Message Text:</b>	Access plan not updated.
<b>Cause Text:</b>	The query optimizer rebuilt the access plan for this statement, but the program could not be updated. Another job may be running the program. The program cannot be updated with the new access plan until a job can obtain an exclusive lock on the program. The exclusive lock cannot be obtained if another job is running the program, if the job does not have proper authority to the program, or if the program is currently being saved. The query will still run, but access plan rebuilds will continue to occur until the program is updated.
<b>Recovery Text:</b>	See previous messages from the query optimizer to determine why the access plan has been rebuilt. To ensure that the program gets updated with the new access plan, run the program when no other active jobs are using it.

**SQL7918 - Reusable ODP deleted**

<b>Message Text:</b>	Reusable ODP deleted. Reason code &1.
----------------------	---------------------------------------

**SQL7918 - Reusable ODP deleted**

<b>Cause Text:</b>	<p>An existing Open Data Path (ODP) was found for this statement, but it could not be reused for reason &amp;1. The statement now refers to different files or uses different override options than are in the ODP. Reason codes and their meanings are:</p> <ul style="list-style-type: none"><li>1 -- Commitment control isolation level is not compatible.</li><li>2 -- The statement contains SQL special register USER, CURRENT DEBUG MODE, CURRENT DECFLOAT ROUNDING MODE, or CURRENT TIMEZONE, and the value for one of these registers has changed.</li><li>3 -- The PATH used to locate an SQL function has changed.</li><li>4 -- The job default CCSID has changed.</li><li>5 -- The library list has changed, such that a file is found in a different library. This only affects statements with unqualified table names, when the table exists in multiple libraries.</li><li>6 -- The file, library, or member for the original ODP was changed with an override.</li><li>7 -- An OVRDBF or DLTOVR command has been issued. A file referred to in the statement now refers to a different file, library, or member.</li><li>8 -- An OVRDBF or DLTOVR command has been issued, causing different override options, such as different SEQONLY or WAITRCD values.</li><li>9 -- An error occurred when attempting to verify the statement override information is compatible with the reusable ODP information.</li><li>10 -- The query optimizer has determined the ODP cannot be reused.</li><li>11 -- The client application requested not to reuse ODPs.</li></ul>
<b>Recovery Text:</b>	Do not change the library list, the override environment, or the values of the special registers if reusable ODPs are to be used.

**SQL7919 - Data conversion required on FETCH or embedded SELECT**

<b>Message Text:</b>	Data conversion required on FETCH or embedded SELECT.
----------------------	-------------------------------------------------------

**SQL7919 - Data conversion required on FETCH or embedded SELECT****Cause Text:**

Host variable &2 requires conversion. The data retrieved for the FETCH or embedded SELECT statement can not be directly moved to the host variables. The statement ran correctly. Performance, however, would be improved if no data conversion was required. The host variable requires conversion for reason &1.

-- Reason 1 - host variable &2 is a character or graphic string of a different length than the value being retrieved.

-- Reason 2 - host variable &2 is a numeric type that is different than the type of the value being retrieved.

-- Reason 3 - host variable &2 is a C character or C graphic string that is NUL-terminated, the program was compiled with option \*CNULRQD specified, and the statement is a multiple-row FETCH.

-- Reason 4 - host variable &2 is a variable length string and the value being retrieved is not.

-- Reason 5 - host variable &2 is not a variable length string and the value being retrieved is.

-- Reason 6 - host variable &2 is a variable length string whose maximum length is different than the maximum length of the variable length value being retrieved.

-- Reason 7 - a data conversion was required on the mapping of the value being retrieved to host variable &2, such as a CCSID conversion.

-- Reason 8 - a DRDA connection was used to get the value being retrieved into host variable &2. The value being retrieved is either null capable or varying-length, is contained in a partial row, or is a derived expression.

-- Reason 10 - the length of host variable &2 is too short to hold a TIME or TIMESTAMP value being retrieved.

-- Reason 11 - host variable &2 is of type DATE, TIME or TIMESTAMP, and the value being retrieved is a character string.

-- Reason 12 - too many host variables were specified and records are blocked. Host variable &2 does not have a corresponding column returned from the query.

-- Reason 13 - a DRDA connection was used for a blocked FETCH and the number of host variables specified in the INTO clause is less than the number of result values in the select list.

-- Reason 14 - a LOB Locator was used and the commitment control level of the process was not \*ALL.

**Recovery Text:**

To get better performance, attempt to use host variables of the same type and length as their corresponding result columns.

**SQL7939 - Data conversion required on INSERT or UPDATE****Message Text:**

Data conversion required on INSERT or UPDATE.

<b>SQL7939 - Data conversion required on INSERT or UPDATE</b>	
<b>Cause Text:</b>	<p>The INSERT or UPDATE values can not be directly moved to the columns because the data type or length of a value is different than one of the columns. The INSERT or UPDATE statement ran correctly. Performance, however, would be improved if no data conversion was required. The reason data conversion is required is &amp;1.</p> <p>-- Reason 1 is that the INSERT or UPDATE value is a character or graphic string of a different length than column &amp;2.</p> <p>-- Reason 2 is that the INSERT or UPDATE value is a numeric type that is different than the type of column &amp;2.</p> <p>-- Reason 3 is that the INSERT or UPDATE value is a variable length string and column &amp;2 is not.</p> <p>-- Reason 4 is that the INSERT or UPDATE value is not a variable length string and column &amp;2 is.</p> <p>-- Reason 5 is that the INSERT or UPDATE value is a variable length string whose maximum length is different than the maximum length of column &amp;2.</p> <p>-- Reason 6 is that a data conversion was required on the mapping of the INSERT or UPDATE value to column &amp;2, such as a CCSID conversion.</p> <p>-- Reason 7 is that the INSERT or UPDATE value is a character string and column &amp;2 is of type DATE, TIME, or TIMESTAMP.</p> <p>-- Reason 8 is that the target table of the INSERT is not a SQL table.</p>
<b>Recovery Text:</b>	To get better performance, try to use values of the same type and length as their corresponding columns.

## PRTSQLINF message reference

The following messages are returned from **PRTSQLINF**.

<b>SQL400A - Temporary distributed result file &amp;1 was created to contain join result</b>	
<b>Message Text:</b>	Temporary distributed result file &1 was created to contain join result. Result file was directed.
<b>Cause Text:</b>	Query contains join criteria over a distributed file and a distributed join was performed in parallel. A temporary distributed result file was created to contain the results of the distributed join.
<b>Recovery Text:</b>	For more information about processing of distributed files, refer to the <a href="#">Distributed database programming</a> topic collection.

<b>SQL400B - Temporary distributed result file &amp;1 was created to contain join result</b>	
<b>Message Text:</b>	Temporary distributed result file &1 was created to contain join result. Result file was broadcast.
<b>Cause Text:</b>	Query contains join criteria over a distributed file and a distributed join was performed in parallel. A temporary distributed result file was created to contain the results of the distributed join.
<b>Recovery Text:</b>	For more information about processing of distributed files, refer to the <a href="#">Distributed database programming</a> topic collection.

<b>SQL400C - Optimizer debug messages for distributed query step &amp;1 and &amp;2 follow</b>	
<b>Message Text:</b>	Optimizer debug messages for distributed query step &1 of &2 follow:
<b>Cause Text:</b>	A distributed file was specified in the query which caused the query to be processed in multiple steps. The optimizer debug messages that follow provide the query optimization information about the current step.
<b>Recovery Text:</b>	For more information about processing of distributed files, refer to the <a href="#">Distributed database programming</a> topic collection.

<b>SQL400D - GROUP BY processing generated</b>	
<b>Message Text:</b>	GROUP BY processing generated.
<b>Cause Text:</b>	GROUP BY processing was added to the query step. Adding the GROUP BY reduced the number of result rows which should, in turn, improve the performance of subsequent steps.
<b>Recovery Text:</b>	For more information refer to the <a href="#">SQL programming</a> topic collection.

<b>SQL400E - Temporary distributed result file &amp;1 was created while processing distributed subquery</b>	
<b>Message Text:</b>	Temporary distributed result file &1 was created while processing distributed subquery.
<b>Cause Text:</b>	A temporary distributed result file was created to contain the intermediate results of the query. The query contains a subquery which requires an intermediate result.
<b>Recovery Text:</b>	Generally, if the fields correlated between the query and subquery do not match the partition keys of the respective files, the query must be processed in multiple steps and a temporary distributed file will be built to contain the intermediate results. For more information about processing of distributed files, refer to the <a href="#">Distributed database programming</a> topic collection.

<b>SQL4001 - Temporary result created</b>	
<b>Message Text:</b>	Temporary result created.
<b>Cause Text:</b>	<p>Conditions exist in the query which cause a temporary result to be created. One of the following reasons may be the cause for the temporary result:</p> <ul style="list-style-type: none"> <li>-- The table is a join logical file and its join type (JDFTVAL) does not match the join-type specified in the query.</li> <li>-- The format specified for the logical file refers to more than one physical table.</li> <li>-- The table is a complex SQL view requiring a temporary table to contain the results of the SQL view.</li> <li>-- The query contains grouping columns (GROUP BY) from more than one table, or contains grouping columns from a secondary table of a join query that cannot be reordered.</li> </ul>
<b>Recovery Text:</b>	Performance may be improved if the query can be changed to avoid temporary results.

<b>SQL4002 - Reusable ODP sort used</b>	
<b>Message Text:</b>	Reusable ODP sort used.
<b>Cause Text:</b>	<p>Conditions exist in the query which cause a sort to be used. This allowed the open data path (ODP) to be reusable. One of the following reasons may be the cause for the sort:</p> <ul style="list-style-type: none"> <li>-- The query contains ordering columns (ORDER BY) from more than one table, or contains ordering columns from a secondary table of a join query that cannot be reordered.</li> <li>-- The grouping and ordering columns are not compatible.</li> <li>-- DISTINCT was specified for the query.</li> <li>-- UNION was specified for the query.</li> <li>-- The query had to be implemented using a sort. Key length of more than 2000 bytes, more than 120 ordering columns, or an ordering column containing a reference to an external user-defined function was specified for ordering.</li> <li>-- The query optimizer chose to use a sort rather than an index to order the results of the query.</li> </ul>
<b>Recovery Text:</b>	A reusable ODP generally results in improved performance when compared to a non-reusable ODP.

<b>SQL4003 - UNION</b>	
<b>Message Text:</b>	UNION, EXCEPT, or INTERSECT.
<b>Cause Text:</b>	A UNION, EXCEPT, or INTERSECT operator was specified in the query. The messages preceding this keyword delimiter correspond to the subselect preceding the UNION, EXCEPT, or INTERSECT operator. The messages following this keyword delimiter correspond to the subselect following the UNION, EXCEPT, or INTERSECT operator.
<b>Recovery Text:</b>	None

<b>SQL4004 - SUBQUERY</b>	
<b>Message Text:</b>	SUBQUERY.
<b>Cause Text:</b>	The SQL statement contains a subquery. The messages preceding the SUBQUERY delimiter correspond to the subselect containing the subquery. The messages following the SUBQUERY delimiter correspond to the subquery.
<b>Recovery Text:</b>	None

<b>SQL4005 - Query optimizer timed out for table &amp;1</b>	
<b>Message Text:</b>	Query optimizer timed out for table &1.
<b>Cause Text:</b>	The query optimizer timed out before it could consider all indexes built over the table. This is not an error condition. The query optimizer may time out in order to minimize optimization time. The query can be run in debug mode (STRDBG) to see the list of indexes which were considered during optimization. The table number refers to the relative position of this table in the query.

**SQL4005 - Query optimizer timed out for table &1**

<b>Recovery Text:</b>	To ensure an index is considered for optimization, specify the logical file of the index as the table to be queried. The optimizer will first consider the index of the logical file specified on the SQL select statement. Note that SQL created indexes cannot be queried. An SQL index can be deleted and recreated to increase the chances it will be considered during query optimization. Consider deleting any indexes no longer needed.
-----------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**SQL4006 - All indexes considered for table &1**

<b>Message Text:</b>	All indexes considered for table &1.
<b>Cause Text:</b>	The query optimizer considered all index built over the table when optimizing the query. The query can be run in debug mode (STRDBG) to see the list of indexes which were considered during optimization. The table number refers to the relative position of this table in the query.
<b>Recovery Text:</b>	None

**SQL4007 - Query implementation for join position &1 table &2**

<b>Message Text:</b>	Query implementation for join position &1 table &2.
<b>Cause Text:</b>	The join position identifies the order in which the tables are joined. A join position of 1 indicates this table is the first, or left-most, table in the join order. The table number refers to the relative position of this table in the query.
<b>Recovery Text:</b>	Join order can be influenced by adding an ORDER BY clause to the query. Refer to “Join optimization” on page 69 for more information about join optimization and tips to influence join order.

**SQL4008 - Index &1 used for table &2**

<b>Message Text:</b>	Index &1 used for table &2.
<b>Cause Text:</b>	The index was used to access rows from the table for one of the following reasons: -- Row selection. -- Join criteria. -- Ordering/grouping criteria. -- Row selection and ordering/grouping criteria.  The table number refers to the relative position of this table in the query.  The query can be run in debug mode (STRDBG) to determine the specific reason the index was used.
<b>Recovery Text:</b>	None

**SQL4009 - Index created for table &1**

<b>Message Text:</b>	Index created for table &1.
----------------------	-----------------------------

<b>SQL4009 - Index created for table &amp;1</b>	
<b>Cause Text:</b>	A temporary index was built to access rows from the table for one of the following reasons:  -- Perform specified ordering/grouping criteria.  -- Perform specified join criteria.  The table number refers to the relative position of this table in the query.
<b>Recovery Text:</b>	To improve performance, consider creating a permanent index if the query is run frequently. The query can be run in debug mode (STRDBG) to determine the specific reason the index was created and the key columns used when creating the index. NOTE: If permanent index is created, it is possible the query optimizer may still choose to create a temporary index to access the rows from the table.

<b>SQL401A - Processing grouping criteria for query containing a distributed table</b>	
<b>Message Text:</b>	Processing grouping criteria for query containing a distributed table.
<b>Cause Text:</b>	Grouping for queries that contain distributed tables can be implemented using either a one or two step method. If the one step method is used, the grouping columns (GROUP BY) match the partitioning keys of the distributed table. If the two step method is used, the grouping columns do not match the partitioning keys of the distributed table or the query contains grouping criteria but no grouping columns were specified. If the two step method is used, message SQL401B will appear followed by another SQL401A message.
<b>Recovery Text:</b>	For more information about processing of distributed tables, refer to the <a href="#">Distributed database programming</a> topic collection.

<b>SQL401B - Temporary distributed result table &amp;1 was created while processing grouping criteria</b>	
<b>Message Text:</b>	Temporary distributed result table &1 was created while processing grouping criteria.
<b>Cause Text:</b>	A temporary distributed result table was created to contain the intermediate results of the query. Either the query contains grouping columns (GROUP BY) that do not match the partitioning keys of the distributed table or the query contains grouping criteria but no grouping columns were specified.
<b>Recovery Text:</b>	For more information about processing of distributed tables, refer to the <a href="#">Distributed database programming</a> topic collection.

<b>SQL401C - Performing distributed join for query</b>	
<b>Message Text:</b>	Performing distributed join for query.
<b>Cause Text:</b>	Query contains join criteria over a distributed table and a distributed join was performed in parallel. See the following SQL401F messages to determine which tables were joined together.
<b>Recovery Text:</b>	For more information about processing of distributed tables, refer to the <a href="#">Distributed database programming</a> topic collection.

<b>SQL401D - Temporary distributed result table &amp;1 was created because table &amp;2 was directed</b>	
<b>Message Text:</b>	Temporary distributed result table &1 was created because table &2 was directed.

<b>SQL401D - Temporary distributed result table &amp;1 was created because table &amp;2 was directed</b>	
<b>Cause Text:</b>	Temporary distributed result table was created to contain the intermediate results of the query. Data from a distributed table in the query was directed to other nodes.
<b>Recovery Text:</b>	Generally, a table is directed when the join columns do not match the partitioning keys of the distributed table. When a table is directed, the query is processed in multiple steps and processed in parallel. A temporary distributed result file is required to contain the intermediate results for each step. For more information about processing of distributed tables, refer to the <a href="#">Distributed database programming</a> topic collection.

<b>SQL401E - Temporary distributed result table &amp;1 was created because table &amp;2 was broadcast</b>	
<b>Message Text:</b>	Temporary distributed result table &1 was created because table &2 was broadcast.
<b>Cause Text:</b>	Temporary distributed result table was created to contain the intermediate results of the query. Data from a distributed table in the query was broadcast to all nodes.
<b>Recovery Text:</b>	Generally, a table is broadcast when join columns do not match the partitioning keys of either table being joined or the join operator is not an equal operator. When a table is broadcast the query is processed in multiple steps and processed in parallel. A temporary distributed result table is required to contain the intermediate results for each step. For more information about processing of distributed tables, refer to the <a href="#">Distributed database programming</a> topic collection.

<b>SQL401F - Table &amp;1 used in distributed join</b>	
<b>Message Text:</b>	Table &1 used in distributed join.
<b>Cause Text:</b>	Query contains join criteria over a distributed table and a distributed join was performed in parallel.
<b>Recovery Text:</b>	For more information about processing of distributed tables, refer to the <a href="#">Distributed database programming</a> topic collection.

<b>SQL4010 - Table scan access for table &amp;1</b>	
<b>Message Text:</b>	Table scan access for table &1.
<b>Cause Text:</b>	Table scan access was used to select rows from the table. The table number refers to the relative position of this table in the query.
<b>Recovery Text:</b>	Table scan is generally a good performing option when selecting a high percentage of rows from the table. The use of an index, however, may improve the performance of the query when selecting a low percentage of rows from the table.

<b>SQL4011 - Index scan-key row positioning used on table &amp;1</b>	
<b>Message Text:</b>	Index scan-key row positioning used on table &1.
<b>Cause Text:</b>	Index scan-key row positioning is defined as applying selection against the index to position directly to ranges of keys that match some or all of the selection criteria. Index scan-key row positioning only processes a subset of the keys in the index and is a good performing option when selecting a small percentage of rows from the table.  The table number refers to the relative position of this table in the query.

<b>SQL4011 - Index scan-key row positioning used on table &amp;1</b>	
<b>Recovery Text:</b>	Refer to <a href="#">“Data access methods”</a> on page 20 for more information about index scan-key row positioning.

<b>SQL4012 - Index created from index &amp;1 for table &amp;2</b>	
<b>Message Text:</b>	Index created from index &1 for table &2.
<b>Cause Text:</b>	<p>A temporary index was created using the specified index to access rows from the queried table for one of the following reasons:</p> <ul style="list-style-type: none"> <li>-- Perform specified ordering/grouping criteria.</li> <li>-- Perform specified join criteria.</li> </ul> <p>The table number refers to the relative position of this table in the query.</p>
<b>Recovery Text:</b>	Creating an index from an index is generally a good performing option. Consider creating a permanent index for frequently run queries. The query can be run in debug mode (STRDBG) to determine the key columns used when creating the index. NOTE: If a permanent index is created, it is possible the query optimizer may still choose to create a temporary index to access the rows from the table.

<b>SQL4013 - Access plan has not been built</b>	
<b>Message Text:</b>	Access plan has not been built.
<b>Cause Text:</b>	<p>An access plan was not created for this query. Possible reasons may include:</p> <ul style="list-style-type: none"> <li>-- Tables were not found when the program was created.</li> <li>-- The query was complex and required a temporary result table.</li> <li>-- Dynamic SQL was specified.</li> </ul>
<b>Recovery Text:</b>	If an access plan was not created, review the possible causes. Attempt to correct the problem if possible.

<b>SQL4014 - &amp;1 join column pair(s) are used for this join position</b>	
<b>Message Text:</b>	&1 join column pair(s) are used for this join position.
<b>Cause Text:</b>	<p>The query optimizer may choose to process join predicates as either join selection or row selection. The join predicates used in join selection are determined by the final join order and the index used. This message indicates how many join column pairs were processed as join selection at this join position. Message SQL4015 provides detail on which columns comprise the join column pairs.</p> <p>If 0 join column pairs were specified then index scan-key row positioning with row selection was used instead of join selection.</p>
<b>Recovery Text:</b>	<p>If fewer join pairs are used at a join position than expected, it is possible no index exists which has keys matching the desired join columns. Try creating an index whose keys match the join predicates.</p> <p>If 0 join column pairs were specified then index scan-key row positioning was used. Index scan-key row positioning is normally a good performing option. Message SQL4011 provides more information on index scan-key row positioning.</p>

<b>SQL4015 - From-column &amp;1.&amp;2, to-column &amp;3.&amp;4, join operator &amp;5, join predicate &amp;6</b>	
<b>Message Text:</b>	From-column &1.&2, to-column &3.&4, join operator &5, join predicate &6.
<b>Cause Text:</b>	<p>Identifies which join predicate was implemented at the current join position. The replacement text parameters are:</p> <p>-- &amp;1: The join 'from table' number. The table number refers to the relative position of this table in the query.</p> <p>-- &amp;2: The join 'from column' name. The column within the join from table which comprises the left half of the join column pair. If the column name is *MAP, the column is an expression (derived field).</p> <p>-- &amp;3: The join 'to table' number. The table number refers to the relative position of this table in the query.</p> <p>-- &amp;4: The join 'to column' name. The column within the join to column which comprises the right half of the join column pair. If the column name is *MAP, the column is an expression (derived field).</p> <p>-- &amp;5: The join operator. Possible values are EQ (equal), NE (not equal), GT (greater than), LT (less than), GE (greater than or equal), LE (less than or equal), and CP (cross join or cartesian product).</p> <p>-- &amp;6: The join predicate number. Identifies the join predicate within this set of join pairs.</p>
<b>Recovery Text:</b>	Refer to <a href="#">"Join optimization"</a> on page 69 for more information about joins.

<b>SQL4016 - Subselects processed as join query</b>	
<b>Message Text:</b>	Subselects processed as join query.
<b>Cause Text:</b>	The query optimizer chose to implement some or all of the subselects with a join query. Implementing subqueries with a join generally improves performance over implementing alternative methods.
<b>Recovery Text:</b>	None

<b>SQL4017 - Host variables implemented as reusable ODP</b>	
<b>Message Text:</b>	Host variables implemented as reusable ODP.
<b>Cause Text:</b>	The query optimizer has built the access plan allowing for the values of the host variables to be supplied when the query is opened. This query can be run with different values being provided for the host variables without requiring the access plan to be rebuilt. This is the normal method of handling host variables in access plans. The open data path (ODP) that will be created from this access plan will be a reusable ODP.
<b>Recovery Text:</b>	Generally, reusable open data paths perform better than non-reusable open data paths.

<b>SQL4018 - Host variables implemented as non-reusable ODP</b>	
<b>Message Text:</b>	Host variables implemented as non-reusable ODP.

<b>SQL4018 - Host variables implemented as non-reusable ODP</b>	
<b>Cause Text:</b>	The query optimizer has implemented the host variables with a non-reusable open data path (ODP).
<b>Recovery Text:</b>	This can be a good performing option in special circumstances, but generally a reusable ODP gives the best performance.

<b>SQL4019 - Host variables implemented as file management row positioning reusable ODP</b>	
<b>Message Text:</b>	Host variables implemented as file management row positioning reusable ODP.
<b>Cause Text:</b>	The query optimizer has implemented the host variables with a reusable open data path (ODP) using file management row positioning.
<b>Recovery Text:</b>	Generally, a reusable ODP performs better than a non-reusable ODP.

<b>SQL402A - Hashing algorithm used to process join</b>	
<b>Message Text:</b>	Hashing algorithm used to process join.
<b>Cause Text:</b>	The hash join algorithm is typically used for longer running join queries. The original query will be subdivided into hash join steps. Each hash join step will be optimized and processed separately. Access plan implementation information for each of the hash join steps is not available because access plans are not saved for the individual hash join dials. Debug messages detailing the implementation of each hash dial can be found in the joblog if the query is run in debug mode using the STRDBG CL command.
<b>Recovery Text:</b>	The hash join method is usually a good implementation choice, however, if you want to disallow the use of this method specify ALWCPYDTA(*YES). Refer to the &qryopt. for more information on hashing algorithm for join processing.

<b>SQL402B - Table &amp;1 used in hash join step &amp;2</b>	
<b>Message Text:</b>	Table &1 used in hash join step &2.
<b>Cause Text:</b>	This message lists the table number used by the hash join steps. The table number refers to the relative position of this table in the query. If there are two or more of these messages for the same hash join step, then that step is a nested loop join. Access plan implementation information for each of the hash join step are not available because access plans are not saved for the individual hash steps. Debug messages detailing the implementation of each hash step can be found in the joblog if the query is run in debug mode using the STRDBG CL command.
<b>Recovery Text:</b>	Refer to <a href="#">“Data access methods”</a> on page 20 for more information about hashing.

<b>SQL402C - Temporary table created for hash join results</b>	
<b>Message Text:</b>	Temporary table created for hash join results.
<b>Cause Text:</b>	The results of the hash join were written to a temporary table so that query processing could be completed. The temporary table was required because the query contained one or more of the following: GROUP BY or summary functions ORDER BY DISTINCT Expression containing columns from more than one table Complex row selection involving columns from more than one table

**SQL402C - Temporary table created for hash join results**

<b>Recovery Text:</b>	Refer to <a href="#">“Data access methods”</a> on page 20 for more information about the hashing algorithm for join processing.
-----------------------	---------------------------------------------------------------------------------------------------------------------------------

**SQL402D - Query attributes overridden from query options file &2 in library &1**

<b>Message Text:</b>	Query attributes overridden from query options file &2 in library &1.
----------------------	-----------------------------------------------------------------------

<b>Cause Text:</b>	None
--------------------	------

<b>Recovery Text:</b>	None
-----------------------	------

**SQL4020 - Estimated query run time is &1 seconds**

<b>Message Text:</b>	Estimated query run time is &1 seconds.
----------------------	-----------------------------------------

<b>Cause Text:</b>	The total estimated time, in seconds, of executing this query.
--------------------	----------------------------------------------------------------

<b>Recovery Text:</b>	None
-----------------------	------

**SQL4021 - Access plan last saved on &1 at &2**

<b>Message Text:</b>	Access plan last saved on &1 at &2.
----------------------	-------------------------------------

<b>Cause Text:</b>	The date and time reflect the last time the access plan was successfully updated in the program object.
--------------------	---------------------------------------------------------------------------------------------------------

<b>Recovery Text:</b>	None
-----------------------	------

**SQL4022 - Access plan was saved with SRVQRY attributes active**

<b>Message Text:</b>	Access plan was saved with SRVQRY attributes active.
----------------------	------------------------------------------------------

<b>Cause Text:</b>	The access plan that was saved was created while SRVQRY was active. Attributes saved in the access plan may be the result of SRVQRY.
--------------------	--------------------------------------------------------------------------------------------------------------------------------------

<b>Recovery Text:</b>	The query will be re-optimized the next time it is run so that SRVQRY attributes will not be permanently saved.
-----------------------	-----------------------------------------------------------------------------------------------------------------

**SQL4023 - Parallel table prefetch used**

<b>Message Text:</b>	Parallel table prefetch used.
----------------------	-------------------------------

<b>Cause Text:</b>	The query optimizer chose to use a parallel prefetch access method to reduce the processing time required for the table scan.
--------------------	-------------------------------------------------------------------------------------------------------------------------------

**SQL4023 - Parallel table prefetch used**

<b>Recovery Text:</b>	<p>Parallel prefetch can improve the performance of queries. Even though the access plan was created to use parallel prefetch, the system will actually run the query only if the following are true:</p> <ul style="list-style-type: none"><li>-- The query attribute degree was specified with an option of *IO or *ANY for the application process.</li><li>-- There is enough main storage available to cache the data being retrieved by multiple I/O streams. Normally, 5 megabytes would be a minimum. Increasing the size of the shared pool may improve performance.</li></ul> <p>For more information about parallel table prefetch, refer to <a href="#">“Data access methods” on page 20.</a></p>
-----------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**SQL4024 - Parallel index preload access method used**

<b>Message Text:</b>	Parallel index preload access method used.
<b>Cause Text:</b>	The query optimizer chose to use a parallel index preload access method to reduce the processing time required for this query. This means that the indexes used by this query will be loaded into active memory when the query is opened.
<b>Recovery Text:</b>	<p>Parallel index preload can improve the performance of queries. Even though the access plan was created to use parallel preload, the system will actually use parallel preload only if the following are true:</p> <ul style="list-style-type: none"><li>-- The query attribute degree was specified with an option of *IO or *ANY for the application process.</li><li>-- There is enough main storage to load all of the index objects used by this query into active memory. Normally, a minimum of 5 megabytes would be a minimum. Increasing the size of the shared pool may improve performance.</li></ul> <p>For more information about parallel table prefetch, refer to <a href="#">“Data access methods” on page 20.</a></p>

**SQL4025 - Parallel table preload access method used**

<b>Message Text:</b>	Parallel table preload access method used.
<b>Cause Text:</b>	The query optimizer chose to use a parallel table preload access method to reduce the processing time required for this query. This means that the data accessed by this query will be loaded into active memory when the query is opened.
<b>Recovery Text:</b>	<p>Parallel table preload can improve the performance of queries. Even though the access plan was created to use parallel preload, the system will actually use parallel preload only if the following are true:</p> <ul style="list-style-type: none"><li>-- The query attribute degree must have been specified with an option of *IO or *ANY for the application process.</li><li>-- There is enough main storage available to load all of the data in the file into active memory. Normally, 5 megabytes would be a minimum. Increasing the size of the shared pool may improve performance.</li></ul> <p>For more information about parallel table prefetch, refer to <a href="#">“Data access methods” on page 20.</a></p>

<b>SQL4026 - Index only access used on table number &amp;1</b>	
<b>Message Text:</b>	Index only access used on table number &1.
<b>Cause Text:</b>	Index only access is primarily used in conjunction with either index scan-key row positioning index scan-key selection. This access method will extract all of the data from the index rather than performing random I/O to the data space. The table number refers to the relative position of this table in the query.
<b>Recovery Text:</b>	Refer to <a href="#">“Data access methods”</a> on page 20 for more information about index only access.

<b>SQL4027 - Access plan was saved with DB2 Symmetric Multiprocessing installed on the system</b>	
<b>Message Text:</b>	Access plan was saved with DB2 Symmetric Multiprocessing installed on the system.
<b>Cause Text:</b>	The access plan saved was created while the system feature DB2 Symmetric Multiprocessing was installed on the system. The access plan may have been influenced by the presence of this system feature. Having this system feature installed may cause the implementation of the query to change.
<b>Recovery Text:</b>	For more information about how the system feature DB2 Symmetric Multiprocessing can influence a query, refer to the <a href="#">“Controlling parallel processing for queries”</a> on page 248

<b>SQL4028 - The query contains a distributed table</b>	
<b>Message Text:</b>	The query contains a distributed table.
<b>Cause Text:</b>	A distributed table was specified in the query which may cause the query to be processed in multiple steps. If the query is processed in multiple steps, additional messages will detail the implementation for each step. Access plan implementation information for each step is not available because access plans are not saved for the individual steps. Debug messages detailing the implementation of each step can be found in the joblog if the query is run in debug mode using the STRDBG CL command.
<b>Recovery Text:</b>	For more information about how a distributed table can influence the query implementation refer to the <a href="#">Distributed database programming</a> topic collection.

<b>SQL4029 - Hashing algorithm used to process the grouping</b>	
<b>Message Text:</b>	Hashing algorithm used to process the grouping.
<b>Cause Text:</b>	The grouping specified within the query was implemented with a hashing algorithm.
<b>Recovery Text:</b>	Implementing the grouping with the hashing algorithm is generally a performance advantage since an index does not have to be created. However, if you want to disallow the use of this method simply specify ALWCPYDTA(*YES). Refer to <a href="#">“Data access methods”</a> on page 20 for more information about the hashing algorithm.

<b>SQL4030 - &amp;1 tasks specified for parallel scan on table &amp;2</b>	
<b>Message Text:</b>	&1 tasks specified for parallel scan on table &2.
<b>Cause Text:</b>	The query optimizer has calculated the optimal number of tasks for this query based on the query attribute degree. The table number refers to the relative position of this table in the query.

<b>SQL4030 - &amp;1 tasks specified for parallel scan on table &amp;2</b>	
<b>Recovery Text:</b>	Parallel table or index scan can improve the performance of queries. Even though the access plan was created to use the specified number of tasks for the parallel scan, the system may alter that number based on the availability of the pool in which this job is running or the allocation of the table's data across the disk units. Refer to <a href="#">“Data access methods”</a> on page 20 for more information about parallel scan.
<b>SQL4031 - &amp;1 tasks specified for parallel index create over table &amp;2</b>	
<b>Message Text:</b>	&1 tasks specified for parallel index create over table &2.
<b>Cause Text:</b>	The query optimizer has calculated the optimal number of tasks for this query based on the query attribute degree. The table number refers to the relative position of this table in the query.
<b>Recovery Text:</b>	Parallel index create can improve the performance of queries. Even though the access plan was created to use the specified number of tasks for the parallel index build, the system may alter that number based on the availability of the pool in which this job is running or the allocation of the table's data across the disk units. Refer to <a href="#">“Data access methods”</a> on page 20 for more information about parallel index create.
<b>SQL4032 - Index &amp;1 used for bitmap processing of table &amp;2</b>	
<b>Message Text:</b>	Index &1 used for bitmap processing of table &2.
<b>Cause Text:</b>	The index was used, in conjunction with query selection, to create a bitmap. The bitmap, in turn, was used to access rows from the table. This message may appear more than once per table. If this occurs, then a bitmap was created from each index of each message. The bitmaps were then combined into one bitmap using boolean logic and the resulting bitmap was used to access rows from the table. The table number refers to the relative position of this table in the query.
<b>Recovery Text:</b>	The query can be run in debug mode (STRDBG) to determine more specific information. Also, refer to <a href="#">“Data access methods”</a> on page 20 for more information about bitmap processing.
<b>SQL4033 - &amp;1 tasks specified for parallel bitmap create using &amp;2</b>	
<b>Message Text:</b>	&1 tasks specified for parallel bitmap create using &2.
<b>Cause Text:</b>	The query optimizer has calculated the optimal number of tasks to use to create the bitmap based on the query attribute degree.
<b>Recovery Text:</b>	Using parallel index scan to create the bitmap can improve the performance of queries. Even though the access plan was created to use the specified number of tasks, the system may alter that number based on the availability of the pool in which this job is running or the allocation of the file's data across the disk units. Refer to <a href="#">“Data access methods”</a> on page 20 for more information about parallel scan.
<b>SQL4034 - Multiple join classes used to process join</b>	
<b>Message Text:</b>	Multiple join classes used to process join.

<b>SQL4034 - Multiple join classes used to process join</b>	
<b>Cause Text:</b>	Multiple join classes are used when join queries are written that have conflicting operations or cannot be implemented as a single query. Each join class will be optimized and processed as a separate step of the query with the results written out to a temporary table. Access plan implementation information for each of the join classes is not available because access plans are not saved for the individual join class dials. Debug messages detailing the implementation of each join dial can be found in the joblog if the query is run in debug mode using the STRDBG CL command.
<b>Recovery Text:</b>	Refer to <a href="#">“Join optimization” on page 69</a> for more information about join classes.

<b>SQL4035 - Table &amp;1 used in join class &amp;2</b>	
<b>Message Text:</b>	Table &1 used in join class &2.
<b>Cause Text:</b>	This message lists the table numbers used by each of the join classes. The table number refers to the relative position of this table in the query. All of the tables listed for the same join class will be processed during the same step of the query. The results from all of the join classes will then be joined together to return the final results for the query. Access plan implementation information for each of the join classes are not available because access plans are not saved for the individual classes. Debug messages detailing the implementation of each join class can be found in the joblog if the query is run in debug mode using the STRDBG CL command.
<b>Recovery Text:</b>	Refer to <a href="#">“Join optimization” on page 69</a> for more information about join classes.

## Code license and disclaimer information

IBM grants you a nonexclusive copyright license to use all programming code examples from which you can generate similar function tailored to your own specific needs.

SUBJECT TO ANY STATUTORY WARRANTIES WHICH CANNOT BE EXCLUDED, IBM, ITS PROGRAM DEVELOPERS AND SUPPLIERS MAKE NO WARRANTIES OR CONDITIONS EITHER EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OR CONDITIONS OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, AND NON-INFRINGEMENT, REGARDING THE PROGRAM OR TECHNICAL SUPPORT, IF ANY.

UNDER NO CIRCUMSTANCES IS IBM, ITS PROGRAM DEVELOPERS OR SUPPLIERS LIABLE FOR ANY OF THE FOLLOWING, EVEN IF INFORMED OF THEIR POSSIBILITY:

1. LOSS OF, OR DAMAGE TO, DATA;
2. DIRECT, SPECIAL, INCIDENTAL, OR INDIRECT DAMAGES, OR FOR ANY ECONOMIC CONSEQUENTIAL DAMAGES; OR
3. LOST PROFITS, BUSINESS, REVENUE, GOODWILL, OR ANTICIPATED SAVINGS.

SOME JURISDICTIONS DO NOT ALLOW THE EXCLUSION OR LIMITATION OF DIRECT, INCIDENTAL, OR CONSEQUENTIAL DAMAGES, SO SOME OR ALL OF THE ABOVE LIMITATIONS OR EXCLUSIONS MAY NOT APPLY TO YOU.

## Notices

---

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing  
IBM Corporation  
North Castle Drive  
Armonk, NY 10504-1785  
U.S.A.

For license inquiries regarding double-byte (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

Intellectual Property Licensing  
Legal and Intellectual Property Law  
IBM Japan Ltd.  
1623-14, Shimotsuruma, Yamato-shi  
Kanagawa 242-8502 Japan

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law: INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some states do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM Web sites are provided for convenience only and do not in any manner serve as an endorsement of those Web sites. The materials at those Web sites are not part of the materials for this IBM product and use of those Web sites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

IBM Corporation  
Software Interoperability Coordinator, Department YBWA  
3605 Highway 52 N  
Rochester, MN 55901  
U.S.A.

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

All IBM prices shown are IBM's suggested retail prices, are current and are subject to change without notice. Dealer prices may vary.

This information is for planning purposes only. The information herein is subject to change before the products described become available.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

#### COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

Each copy or any portion of these sample programs or any derivative work, must include a copyright notice as follows:

© (your company name) (year). Portions of this code are derived from IBM Corp. Sample Programs.

© Copyright IBM Corp. \_enter the year or years\_.

If you are viewing this information softcopy, the photographs and color illustrations may not appear.

## Programming interface information

---

This Database performance and query optimization publication documents intended Programming Interfaces that allow the customer to write programs to obtain the services of IBM i.
