Check pending constraints.....	258
Limiting temporary storage and CPU used by queries.....	258
Creating an index strategy.....	259
Binary radix indexes.....	259
Derived key index.....	260
Sparse indexes.....	260
Optimization.....	261
Matching algorithm.....	261
Sparse index examples.....	263
Specify PAGESIZE.....	266
Index maintenance.....	266
Encoded vector indexes.....	267
How the EVI works.....	268
When to create.....	269
Maintenance.....	270
Recommendations.....	272
Compare radix & EVIs.....	275
Indexes & the optimizer.....	275

Index not used.....	275
Display indexes for a table.....	276
Determine unnecessary indexes.....	280
Reset usage counts.....	281
View index builds.....	281
Manage index rebuilds.....	281
Indexing strategy.....	287
Reactive approach.....	288
Proactive approach.....	288
Coding for effective indexes.....	289
Avoid numeric conversions.....	289
Avoid arithmetic expressions.....	289
Avoid character string padding.....	290
LIKE considerations.....	290
Derived indexes.....	291
Sparse indexes.....	292
Indexes with sort sequence.....	292
Selection, joins, or grouping.....	292
Ordering.....	293
Index examples.....	293
Equal selection, no sort sequence.....	293
Equal selection, unique-weight sort sequence.....	293
Equal selection, shared-weight sort sequence.....	294
Greater than selection, unique-weight sort sequence.....	294
Join selection, unique-weight sort sequence.....	294
Join selection, shared-weight sort sequence.....	294
Order, no sort sequence.....	295
Order, unique-weight sort sequence.....	295
Order, shared-weight sort sequence.....	295
Order, ALWCOPYDTA(*OPTIMIZE), unique-weight sort sequence.....	296
Group, no sort sequence.....	296
Group, unique-weight sort sequence.....	296
Group, shared-weight sort sequence.....	296
Order & group on same columns, unique-weight sort sequence.....	297
Order & group on same columns, ALWCOPYDTA(*OPTIMIZE), unique-weight sort sequence...	297
Order & group on same columns, shared-weight sort sequence.....	298
Order & group on same columns, ALWCOPYDTA(*OPTIMIZE), shared-weight sort sequence...	298
Order & group on different columns, unique-weight sort sequence.....	298
Order & group on different columns, ALWCOPYDTA(*OPTIMIZE), unique-weight sort sequence.....	299
Order & group on different columns, ALWCOPYDTA(*OPTIMIZE), shared-weight sort sequence.....	299
Sparse index examples.....	299
Application design tips.....	302

Database performance and query optimization

The goal of database performance tuning is to minimize the response time of your queries by making the best use of your system resources. The best use of these resources involves minimizing network traffic, disk I/O, and CPU time. This goal can only be achieved by understanding the logical and physical structure of your data, the applications used on your system, and how the conflicting uses of your database might affect performance.

The best way to avoid performance problems is to ensure that performance issues are part of your ongoing development activities. Many of the most significant performance improvements are realized through careful design at the beginning of the database development cycle. To most effectively optimize performance, you must identify the areas that yield the largest performance increases over the widest variety of situations. Focus your analysis on these areas.

Many of the examples within this publication illustrate a query written through either an SQL or an OPNQRYF query interface. The interface chosen for a particular example does not indicate an operation exclusive to that query interface, unless explicitly noted. It is only an illustration of one possible query interface. Most examples can be easily rewritten into whatever query interface that you prefer.

Note: By using the code examples, you agree to the terms of the [“Code license and disclaimer information”](#) on page 1327.

What's new for IBM i 7.4

The following information was added or updated in the initial release of IBM i 7.4:

- Support for managing temporary storage and CPU usage was added : [“Limiting temporary storage and CPU used by queries”](#) on page 258
- Plan cache sizing was updated : [“Plan cache”](#) on page 17
- Plan cache properties was updated : [“SQL plan cache properties”](#) on page 176
- Support for whole table COUNT(*) grouping was added : [“Whole table COUNT\(*\) grouping implementation”](#) on page 83
- Database monitor records that have additions in 7.4:
 - [“Database monitor view 3010 - Host Variable & ODP Implementation”](#) on page 1235
- **New services**
 - ASP_JOB_INFO view: [“ASP_JOB_INFO view”](#) on page 982
 - DATA_AREA_INFO view and table function: [“DATA_AREA_INFO view”](#) on page 452, [“DATA_AREA_INFO table function”](#) on page 451
 - FIRMWARE_CURRENCY view: [“FIRMWARE_CURRENCY view”](#) on page 881
 - MESSAGE_FILE_DATA view: [“MESSAGE_FILE_DATA view”](#) on page 856
 - SPLIT table function: [“SPLIT table function”](#) on page 518
 - SPOOLED_FILE_DATA table function: [“SPOOLED_FILE_DATA table function”](#) on page 966
 - Add, remove, and view Network Time Protocol servers: [“ADD_TIME_SERVER procedure”](#) on page 549, [“REMOVE_TIME_SERVER procedure”](#) on page 593, [“TIME_PROTOCOL_INFO view”](#) on page 604
 - The HTTP functions in SYSTOOLS have been documented: [“HTTP function overview”](#) on page 1157
- **Updated services**
 - The maximum table size has been added as a tracked system limit and as a limit that sends alerts: [“System Health Services”](#) on page 1008, [“System limit alerts”](#) on page 1011
 - ASP_INFO returns the relational database name for SYSBASE: [“ASP_INFO view”](#) on page 973
 - GET_JOB_INFO returns additional columns: [“GET_JOB_INFO table function”](#) on page 1051

- JOB_DESCRIPTION_INFO returns workload group: [“JOB_DESCRIPTION_INFO view” on page 1053](#)
- JOBLIST_INFO table function returns the message key: [“JOBLIST_INFO table function” on page 854](#)
- OBJECT_PRIVILEGES view returns authorization list: [“OBJECT_PRIVILEGES view” on page 916](#)
- OBJECT_STATISTICS table function returns IASP name and the authority collection value: [“OBJECT_STATISTICS table function” on page 841](#)
- PARSE_STATEMENT table function returns information for DROP statements and foreign key constraints: [“PARSE_STATEMENT table function” on page 325](#)
- SET_SERVER_SBS_ROUTING and SERVER_SBS_ROUTING support QDBMSRVR: [“SET_SERVER_SBS_ROUTING procedure” on page 597](#), [“SERVER_SBS_ROUTING view” on page 594](#)
- WLM_SET_CLIENT_INFO procedure uses defaults for unspecified parameters: [“WLM_SET_CLIENT_INFO procedure” on page 336](#)

What's new since the first 7.4 publication

The following revisions or additions have been made to the Performance and query optimization documentation since the first 7.4 publication:

• April 2025 update

- The SQL Error Logging Facility (SELF) can be turned off at the system level: [“SQL Error Logging Facility \(SELF\)” on page 188](#) and [“VALIDATE_SELF scalar function” on page 335](#)
- **Updated services**
 - GROUP_PTF_DETAILS view returns the value for PTF_IPL_REQUIRED based on the live feed: [“GROUP_PTF_DETAILS view” on page 885](#)
 - JOB_INFO table function has a new job name filter: [“JOB_INFO table function” on page 1060](#)
 - SYSDISKSTAT view and table function return additional columns of information: [“SYSDISKSTAT view” on page 999](#) and [“SYSDISKSTAT table function” on page 994](#)

• December 2024 update

- System limit alerting is instrumented for maximum members in a source file and for a maximum sequence number in a journal: [“System limit alerts” on page 1011](#)
- **New services**
 - ADD_VALIDATION_LIST_ENTRY, CHANGE_VALIDATION_LIST_ENTRY, and REMOVE_VALIDATION_LIST_ENTRY scalar functions simplify validation list handling: [“ADD_VALIDATION_LIST_ENTRY scalar function” on page 895](#), [“CHANGE_VALIDATION_LIST_ENTRY scalar function” on page 906](#), and [“REMOVE_VALIDATION_LIST_ENTRY scalar function” on page 919](#)
 - AUDIT_JOURNAL_VP table function returns entry specific data: [“AUDIT_JOURNAL_VP table function” on page 786](#)
 - CONFIGURATION_STATUS view returns the status for each configuration description on the system: [“CONFIGURATION_STATUS view” on page 604](#)
 - END_JOBS procedure simplifies ending a group of jobs: [“END_JOBS procedure” on page 1045](#)
 - IFS_ACCESS scalar function indicates whether a file in the integrated file system can be accessed in the specified way: [“IFS_ACCESS scalar function” on page 619](#)
 - POWER_SCHEDULE_INFO view returns the power on and power off schedule for the next year: [“POWER_SCHEDULE_INFO view” on page 1097](#)
 - SERVICE_TOOLS_SERVER_INFO view returns service tools server configuration information: [“SERVICE_TOOLS_SERVER_INFO view” on page 618](#)
- **Updated services**
 - ACTIVE_JOB_INFO table function returns additional query information: [“ACTIVE_JOB_INFO table function” on page 1020](#)

- AUDIT_JOURNAL_DATA_MART_INFO view and MANAGE_AUDIT_JOURNAL_DATA_MART have been extended with a filter to limit the data added to the data mart table: [“AUDIT_JOURNAL_DATA_MART_INFO view” on page 663](#) and [“MANAGE_AUDIT_JOURNAL_DATA_MART procedure” on page 824](#)
- COMPARE_IFS table function has been extended to compare more attributes for objects in the Integrated File System (IFS): [“COMPARE_IFS table function” on page 621](#)
- FIRMWARE_CURRENCY view includes additional columns with information about the server's firmware fixpack: [“FIRMWARE_CURRENCY view” on page 881](#)
- JOBLOG_INFO table function supports a longer string of message token values: [“JOBLOG_INFO table function” on page 854](#)
- LPRINTF has been modified to print the result using FOR SBCS DATA as part of the data type definition: [“LPRINTF procedure” on page 490](#)
- MTI_INFO returns the table's partition or member name: [“MTI_INFO table function” on page 350](#)
- SEND_EMAIL added a new parameter for the content type of the body: [“SEND_EMAIL scalar function” on page 513](#)
- SYSTEM_STATUS_INFO view, SYSTEM_STATUS_INFO_BASIC view, and SYSTEM_STATUS table function return the enterprise enabled processor count: [“SYSTEM_STATUS_INFO view” on page 1125](#), [“SYSTEM_STATUS_INFO_BASIC view” on page 1133](#), and [“SYSTEM_STATUS table function” on page 1115](#)

• June 2024 update

– New services

- AUDIT_JOURNAL_DATA_MART_INFO view and MANAGE_AUDIT_JOURNAL_DATA_MART provide a way to gather audit journal information for efficient query access: [“AUDIT_JOURNAL_DATA_MART_INFO view” on page 663](#) and [“MANAGE_AUDIT_JOURNAL_DATA_MART procedure” on page 824](#)
- AUDIT_JOURNAL_NA and AUDIT_JOURNAL_PS table functions return entry specific data: [“AUDIT_JOURNAL_NA table function” on page 745](#) and [“AUDIT_JOURNAL_PS table function” on page 763](#)
- CHECK_PRODUCT_OPTIONS table function returns formatted information generated by the Check Product Option (CHKPRDOPT) CL command: [“CHECK_PRODUCT_OPTIONS table function” on page 870](#)
- COMPARE_IFS table function compares objects or directories in the Integrated File System (IFS): [“COMPARE_IFS table function” on page 621](#)
- DB_TRANSACTION_OBJECT_INFO table function returns information about objects under commitment control for a transaction: [“DB_TRANSACTION_OBJECT_INFO table function” on page 479](#)
- DB_TRANSACTION_RECORD_INFO table function returns record level information for a transaction: [“DB_TRANSACTION_RECORD_INFO table function” on page 480](#)
- ERRNO_INFO scalar function returns descriptive text for an errno value: [“ERRNO_INFO scalar function” on page 483](#)
- GETENV and PUTENV scalar functions add, change, retrieve the value of an environment variable: [“GETENV scalar function” on page 489](#) and [“PUTENV scalar function” on page 506](#)
- IFS_UNLINK scalar function deletes an IFS file: [“IFS_UNLINK scalar function” on page 650](#)
- PRINTER_FILE_INFO view returns information about printer files: [“PRINTER_FILE_INFO view” on page 964](#)
- SPECIAL_AUTHORITY_DATA_MART materialized query table can be used to gather all the special authorities for all users: [“SPECIAL_AUTHORITY_DATA_MART table” on page 924](#)
- SYSMEMBERSTAT view returns statistical information for file members, including program described files: [“SYSMEMBERSTAT view” on page 415](#)

- SYSTEM_OBJECT_TYPES table lists all the type values for system objects: [“SYSTEM_OBJECT_TYPES table” on page 848](#)
- **Updated services**
 - ACTIVE_QUERY_INFO has a filter for the job's user: [“ACTIVE_QUERY_INFO table function” on page 339](#)
 - CLEAR_TRACKED_JOB_INFO has additional filters to restrict entries to be removed from the job tracking file: [“CLEAR_TRACKED_JOB_INFO procedure” on page 1041](#)
 - DUMP_PLAN_CACHE has a filter for Independent ASP name: [“DUMP_PLAN_CACHE procedure” on page 358](#)
 - GENERATE_SPREADSHEET generates proportional width columns for xls and xlsx formats: [“GENERATE_SPREADSHEET scalar function” on page 487](#)
 - SEND_EMAIL sends an email to multiple users and can include multiple attachments: [“SEND_EMAIL scalar function” on page 513](#)
 - SYSDISKSTAT view and table function return an indication of whether all the pages for the disk unit have been cleared: [“SYSDISKSTAT view” on page 999](#) and [“SYSDISKSTAT table function” on page 994](#)
- **November 2023 update**
 - SQL Error Logging Facility (SELF) captures thread information for the job: [“SQL_ERROR_LOG view” on page 332](#). Support for logging all errors or all warnings has been added: [“VALIDATE_SELF scalar function” on page 335](#)
 - System limit alerting is instrumented for the maximum number of deleted rows in a partition limit: [“System limit alerts” on page 1011](#)
- **New services**
 - AUDIT_JOURNAL_AU and AUDIT_JOURNAL_LD table functions return entry specific data: [“AUDIT_JOURNAL_AU table function” on page 681](#) and [“AUDIT_JOURNAL_LD table function” on page 728](#)
 - DB_TRANSACTION_JOURNAL_INFO returns information about journal resources for a transaction: [“DB_TRANSACTION_JOURNAL_INFO table function” on page 477](#)
 - ENDED_JOB_INFO returns details about jobs that have ended: [“ENDED_JOB_INFO table function” on page 1048](#)
 - GENERATE_SPREADSHEET generates a spreadsheet from a table or query: [“GENERATE_SPREADSHEET scalar function” on page 487](#)
 - IFS_RENAME renames an IFS file or directory: [“IFS_RENAME scalar function” on page 649](#)
 - JOB_QUEUE_ENTRIES returns a list of entries in a job queue: [“JOB_QUEUE_ENTRIES view” on page 1075](#)
 - PING checks connectivity to another system: [“PING table function” on page 587](#)
 - PTF_COVER_LETTER returns the content of a cover letter: [“PTF_COVER_LETTER table function” on page 890](#)
 - REPLY_INQUIRY_MESSAGES sends a reply to one or more QSYSOPR inquiry messages: [“REPLY_INQUIRY_MESSAGES scalar function” on page 863](#)
 - SEND_EMAIL sends an email to a user: [“SEND_EMAIL scalar function” on page 513](#)
 - SQLCODE_INFO returns message information that corresponds to a specific SQLCODE: [“SQLCODE_INFO table function” on page 334](#)
- **Updated services**
 - CANCEL_SQL allows a user to cancel their own job: [“CANCEL_SQL procedure” on page 369](#)
 - CHANGE_DISK_PATHS selection includes an adapter option: [“CHANGE_DISK_PATHS procedure” on page 985](#)

- CHANGE_USER_PROFILE allows special authorities to be changed: [“CHANGE_USER_PROFILE table function” on page 903](#)
- DB_TRANSACTION_INFO lets users see their own transaction information: [“DB_TRANSACTION_INFO view” on page 459](#)
- DISPLAY_JOURNAL has filters for commit cycle and internal entries: [“DISPLAY_JOURNAL table function” on page 790](#)
- DUMP_PLAN_CACHE has filters for SQL statement text and system queries: [“DUMP_PLAN_CACHE procedure” on page 358](#)
- LPRINTF can print a longer string: [“LPRINTF procedure” on page 490](#)
- NETSTAT_JOB_INFO returns the job name in individual columns: [“NETSTAT_JOB_INFO view” on page 570](#)
- PARSE_STATEMENT table function returns additional details for DDL statements: [“PARSE_STATEMENT table function” on page 325](#)
- PTF_INFO view returns the latest superseding PTF and has new authorization requirement: [“PTF_INFO view” on page 891](#)
- REMOVE_TRACKED_JOB_QUEUE procedure can ignore errors when a job queue cannot be accessed: [“REMOVE_TRACKED_JOB_QUEUE procedure” on page 1105](#)
- SYSTEM_STATUS_INFO view, SYSTEM_STATUS_INFO_BASIC view, and SYSTEM_STATUS table function return both the machine serial number and the virtual serial number: [“SYSTEM_STATUS_INFO view” on page 1125](#), [“SYSTEM_STATUS_INFO_BASIC view” on page 1133](#), and [“SYSTEM_STATUS table function” on page 1115](#)
- SYSTEM_VALUE_INFO returns addition information about system values and a formatted version of the system value: [“SYSTEM_VALUE_INFO view” on page 1140](#)
- USER_INFO_BASIC returns null for the USER_DEFAULT_PASSWORD column. Use the USER_INFO view to access this information: [“USER_INFO_BASIC view” on page 936](#)

- **May 2023 update**

- **New services**

- AUDIT_JOURNAL_AP, AUDIT_JOURNAL_AX, AUDIT_JOURNAL_OR, AUDIT_JOURNAL_PA, AUDIT_JOURNAL_PF, AUDIT_JOURNAL_PU, AUDIT_JOURNAL_RA, AUDIT_JOURNAL_RO, and AUDIT_JOURNAL_RZ table functions return entry specific data: [“AUDIT_JOURNAL_AP table function” on page 680](#), [“AUDIT_JOURNAL_AX table function” on page 682](#), [“AUDIT_JOURNAL_OR table function” on page 748](#), [“AUDIT_JOURNAL_PA table function” on page 752](#), [“AUDIT_JOURNAL_PF table function” on page 754](#), [“AUDIT_JOURNAL_PU table function” on page 765](#), [“AUDIT_JOURNAL_RA table function” on page 768](#), [“AUDIT_JOURNAL_RO table function” on page 770](#), and [“AUDIT_JOURNAL_RZ table function” on page 771](#)
 - DEFECTIVE_PTF_CURRENCY view identifies defective PTFs on the system without the corresponding corrective PTF: [“DEFECTIVE_PTF_CURRENCY view” on page 879](#)
 - DNS_LOOKUP_IP scalar function returns a hostname for a specified IP address: [“DNS_LOOKUP_IP scalar function” on page 554](#)
 - JVM_INFO table function provides a wait time option for accessing JVM information: [“JVM_INFO table function” on page 656](#)
 - NETWORK_ATTRIBUTE_INFO view returns information about the network attributes of the system: [“NETWORK_ATTRIBUTE_INFO view” on page 579](#)
 - RDB_ENTRY_INFO view returns information about RDB directory entries: [“RDB_ENTRY_INFO view” on page 590](#)
 - SAVE_FILE_INFO view returns information about save files: [“SAVE_FILE_INFO view” on page 538](#)
 - SAVE_FILE_OBJECTS view and table function return information about objects within save files: [“SAVE_FILE_OBJECTS view” on page 543](#) and [“SAVE_FILE_OBJECTS table function” on page 540](#)
 - SMAPP_ACCESS_PATHS view returns information about access paths monitored by System-Managed Access Path Protection (SMAPP): [“SMAPP_ACCESS_PATHS view” on page 832](#)

- [TAPE_CARTRIDGE_INFO view](#) returns information about tape cartridges: [“TAPE_CARTRIDGE_INFO view” on page 544](#)
- **Updated services**
 - [ASP_INFO view](#), [SYSTEM_STATUS_INFO view](#), and [SYSTEM_STATUS table function](#) return SMAPP information: [“ASP_INFO view” on page 973](#), [“SYSTEM_STATUS_INFO view” on page 1125](#) and [“SYSTEM_STATUS table function” on page 1115](#)
 - [GROUP_PTF_INFO view](#) has new authorization requirements: [“GROUP_PTF_INFO view” on page 889](#)
 - [JVM_INFO view](#) returns the job name in individual columns: [“JVM_INFO view” on page 658](#)
 - [PROGRAM_INFO view](#) returns copyright strings for ILE programs and service programs: [“PROGRAM_INFO view” on page 492](#)
 - [PTF_INFO view](#) returns additional product option information: [“PTF_INFO view” on page 891](#)
 - [STACK_INFO table function](#) has a new `IGNORE_ERRORS` parameter to allow processing to continue when an error is encountered: [“STACK_INFO table function” on page 519](#)
 - [SYSDISKSTAT view](#) and [table function](#) return a hardware status value: [“SYSDISKSTAT view” on page 999](#) and [“SYSDISKSTAT table function” on page 994](#)
 - [SYSFILES view](#) returns based on file information for logical files and views: [“SYSFILES view” on page 404](#)
- **December 2022 update**
 - [SQL Error Logging Facility \(SELF\)](#): [“SQL Error Logging Facility \(SELF\)” on page 188](#), [“SQL_ERROR_LOG view” on page 332](#), [“SELFCODES global variable” on page 332](#), [“VALIDATE_SELF scalar function” on page 335](#)
- **New services**
 - The [PROCESS_SYSTEM_LIMITS_ALERTS procedure](#) is documented: [“PROCESS_SYSTEM_LIMITS_ALERTS procedure” on page 1019](#)
 - [AUDIT_JOURNAL_AD](#), [AUDIT_JOURNAL_DS](#), [AUDIT_JOURNAL_IM](#), [AUDIT_JOURNAL_PG](#), [AUDIT_JOURNAL_SK](#), [AUDIT_JOURNAL_SM](#), [AUDIT_JOURNAL_ZC](#), and [AUDIT_JOURNAL_ZR table functions](#) return entry specific data: [“AUDIT_JOURNAL_AD table function” on page 668](#), [“AUDIT_JOURNAL_DS table function” on page 703](#), [“AUDIT_JOURNAL_IM table function” on page 721](#), [“AUDIT_JOURNAL_PG table function” on page 759](#), [“AUDIT_JOURNAL_SK table function” on page 773](#), [“AUDIT_JOURNAL_SM table function” on page 774](#), [“AUDIT_JOURNAL_ZC table function” on page 786](#), and [“AUDIT_JOURNAL_ZR table function” on page 788](#)
 - [CHANGE_DISK_PATHS procedure](#): [“CHANGE_DISK_PATHS procedure” on page 985](#)
 - [COMMAND_INFO view](#) returns information about CL commands: [“COMMAND_INFO view” on page 438](#)
 - Hardware resource information: [“HARDWARE_RESOURCE_INFO view” on page 612](#) and [“HARDWARE_RESOURCE_INFO table function” on page 605](#)
 - [OBJECTCONNECT_INFO view](#) and [CHANGE_OBJECTCONNECT procedure](#) provide ObjectConnect over IP information: [“OBJECTCONNECT_INFO view” on page 586](#) and [“CHANGE_OBJECTCONNECT procedure” on page 550](#)
 - Submitted Job Tracker services: [“ADD_TRACKED_JOB_QUEUE procedure” on page 1037](#), [“CLEAR_TRACKED_JOB_INFO procedure” on page 1041](#), [“REMOVE_TRACKED_JOB_QUEUE procedure” on page 1105](#), [“TRACKED_JOB_INFO table function” on page 1141](#), and [“TRACKED_JOB_QUEUES view” on page 1150](#)
 - Support for creating and managing locking policies for NVMe devices: [“ADD_DEVICE_LOCKING_POLICY procedure” on page 972](#), [“CHANGE_DEVICE_LOCKING_POLICY procedure” on page 985](#), [“CREATE_LOCKING_POLICY procedure” on page 988](#), [“DELETE_LOCKING_POLICY procedure” on page 988](#), [“FACTORY_RESET_DEVICE procedure” on page 989](#), [“LOCKING_POLICY_INFO view” on page 989](#), [“REMOVE_DEVICE_LOCKING_POLICY procedure” on page 994](#), and [“UNLOCK_DEVICE procedure” on page 1007](#)

- Updated services

- ACTIVE_DB_CONNECTIONS table function returns information about Db2 Mirror suspend processing: [“ACTIVE_DB_CONNECTIONS table function” on page 546](#)
- ACTIVE_JOB_INFO table function returns the workload group information with the WORK subset of data: [“ACTIVE_JOB_INFO table function” on page 1020](#)
- ASP_INFO returns new geographic mirroring information: [“ASP_INFO view” on page 973](#)
- HISTORY_LOG_INFO returns the job name in individual columns: [“HISTORY_LOG_INFO table function” on page 849](#)
- OUTPUT_QUEUE_ENTRIES view and table function return TOTAL_RECORDS, MAXIMUM_RECORDS, and USER_DEFINED_DATA: [“OUTPUT_QUEUE_ENTRIES view” on page 951](#) and [“OUTPUT_QUEUE_ENTRIES table function” on page 947](#)
- OUTPUT_QUEUE_INFO returns the internet address: [“OUTPUT_QUEUE_INFO view” on page 958](#)
- SYSDISKSTAT returns world wide port number information for certain devices: [“SYSDISKSTAT view” on page 999](#) and [“SYSDISKSTAT table function” on page 994](#)
- SYSTEM_STATUS_INFO and SYSTEM_STATUS return basic summary information: [“SYSTEM_STATUS_INFO view” on page 1125](#) and [“SYSTEM_STATUS table function” on page 1115](#)
- WLM_SET_CLIENT_INFO procedure supports a verbose option: [“WLM_SET_CLIENT_INFO procedure” on page 336](#)

• May 2022 update

- Query Supervisor example exit programs written in CL: [“Query Supervisor example exit programs” on page 217](#)

- New services

- ACTIVATION_GROUP_INFO table function: [“ACTIVATION_GROUP_INFO table function” on page 420](#)
- ASSOCIATE_JOURNAL_RECEIVER table function: [“ASSOCIATE_JOURNAL_RECEIVER table function” on page 660](#)
- AUDIT_JOURNAL_JS, AUDIT_JOURNAL_OM, and AUDIT_JOURNAL_ST table functions return entry specific data: [“AUDIT_JOURNAL_JS table function” on page 724](#), [“AUDIT_JOURNAL_OM table function” on page 746](#), and [“AUDIT_JOURNAL_ST table function” on page 781](#)
- BINDING_DIRECTORY_INFO view: [“BINDING_DIRECTORY_INFO view” on page 423](#)
- DNS_LOOKUP table function: [“DNS_LOOKUP table function” on page 553](#)
- ELECTRONIC_SERVICE_AGENT_INFO view: [“ELECTRONIC_SERVICE_AGENT_INFO view” on page 880](#)
- JOURNAL_RECEIVER_INFO view: [“JOURNAL_RECEIVER_INFO view” on page 813](#)
- MTI_INFO table function: [“MTI_INFO table function” on page 350](#)
- REMOTE_JOURNAL_INFO view: [“REMOTE_JOURNAL_INFO view” on page 827](#)
- SPOOLED_FILE_INFO table function: [“SPOOLED_FILE_INFO table function” on page 968](#)
- SQL_CHECK_FUNCTION_USAGE scalar function: [“SQL_CHECK_FUNCTION_USAGE scalar function” on page 926](#)
- SQL_CHECK_SPECIAL_AUTHORITY scalar function: [“SQL_CHECK_SPECIAL_AUTHORITY scalar function” on page 926](#)
- SYSTEM_ACTIVITY_INFO table function: [“SYSTEM_ACTIVITY_INFO table function” on page 1114](#)
- User space services: [“CREATE_USER_SPACE procedure” on page 448](#), [“CHANGE_USER_SPACE and CHANGE_USER_SPACE_BINARY procedures” on page 434](#), [“CHANGE_USER_SPACE_ATTRIBUTES procedure” on page 435](#)
- User index services: [“CREATE_USER_INDEX procedure” on page 445](#), [“ADD_USER_INDEX_ENTRY and ADD_USER_INDEX_ENTRY_BINARY procedures” on page 422](#),

[“REMOVE_USER_INDEX_ENTRY and REMOVE_USER_INDEX_ENTRY_BINARY table functions” on page 510](#)

– Updated services

- ACTIVE_JOB_INFO table function can return a WORK subset of data: [“ACTIVE_JOB_INFO table function” on page 1020](#)
- GENERATE_PDF scalar function supports *LAST option: [“GENERATE_PDF scalar function” on page 946](#)
- GENERATE_SQL and GENERATE_SQL_OBJECTS procedures have a new option for generating comments for tables: [“GENERATE_SQL procedure” on page 380](#) and [“GENERATE_SQL_OBJECTS procedure” on page 389](#)
- JOBLOG_INFO table function returns the qualified job name: [“JOBLOG_INFO table function” on page 854](#)
- SYSTEM_STATUS table function, SYSTEM_STATUS_INFO view, and SYSTEM_STATUS_INFO_BASIC view no longer return information for the AVERAGE_CPU_RATE, AVERAGE_CPU_UTILIZATION, MINIMUM_CPU_UTILIZATION, and MAXIMUM_CPU_UTILIZATION columns due to performance concerns. This information is now returned through the SYSTEM_ACTIVITY_INFO table function. These columns can be explicitly requested by using an environment variable switch.
ADDENVVAR ENVVAR(QIBM_DB2_SYSTEM_STATUS_INFO) VALUE(FULL) LEVEL(*JOB)
[“SYSTEM_STATUS table function” on page 1115](#), [“SYSTEM_STATUS_INFO view” on page 1125](#), and [“SYSTEM_STATUS_INFO_BASIC view” on page 1133](#)

• September 2021 update

- New system limits global variables provide the ability to remove rows from the system limits table by the age of rows, in days: [“QIBM_SYSTEM_LIMITS global variables” on page 1019](#)

– New services

- ACTIVE_QUERY_INFO table function returns information about active SQL Query Engine (SQE) queries: [“ACTIVE_QUERY_INFO table function” on page 339](#)
- AUDIT_JOURNAL_CD, AUDIT_JOURNAL_CO, AUDIT_JOURNAL_CP, AUDIT_JOURNAL_DO, AUDIT_JOURNAL_EV, AUDIT_JOURNAL_GR, AUDIT_JOURNAL_MO, AUDIT_JOURNAL_M6, AUDIT_JOURNAL_M7, AUDIT_JOURNAL_M8, AUDIT_JOURNAL_M9, AUDIT_JOURNAL_SV table functions return the entry specific data for audit journal entries: [“Audit journal entry services” on page 664](#)
- COLLECTION_SERVICES_INFO returns the configuration properties for Collection Services: [“COLLECTION_SERVICES_INFO view” on page 866](#)
- SYSFILES view returns database file information: [“SYSFILES view” on page 404](#)
- WORKLOAD_GROUP_INFO view returns information about workload groups: [“WORKLOAD_GROUP_INFO view” on page 1151](#)

– Updated services

- ACTIVE_JOB_INFO includes a column for the workload group: [“ACTIVE_JOB_INFO table function” on page 1020](#)
- DISPLAY_JOURNAL table function adds a column with a new name to return the current user value: [“DISPLAY_JOURNAL table function” on page 790](#)
- NVME_INFO view provides more information about NVMe devices: [“NVME_INFO view” on page 990](#)
- PARSE_STATEMENT returns the procedure name for a CALL statement: [“PARSE_STATEMENT table function” on page 325](#)
- SECURITY_INFO view returns additional security-related system values: [“SECURITY_INFO view” on page 920](#)

- SYSDISKSTAT view and SYSDISKSTAT table function return additional information about NVMe devices: [“SYSDISKSTAT view” on page 999](#) and [“SYSDISKSTAT table function” on page 994](#)
- **April 2021 update**
 - The Query Supervisor allows real time monitoring of resources used by queries: [“Query Supervisor” on page 212](#)
 - **New services**
 - AUDIT_JOURNAL_AF, AUDIT_JOURNAL_CA, AUDIT_JOURNAL_OW, AUDIT_JOURNAL_PW table functions return the entry specific data for audit journal entries: [“Audit journal entry services” on page 664](#)
 - CHANGE_USER_PROFILE table function allows some user profile attributes to be changed: [“CHANGE_USER_PROFILE table function” on page 903](#)
 - END_IDLE_SQE_THREADS procedure ends SQE threads not being used by a job: [“END_IDLE_SQE_THREADS procedure” on page 376](#)

Saving PDF files

To save a PDF on your workstation for viewing or printing:

1. Right-click the PDF in your browser (right-click the preceding link).
2. Click the option that saves the PDF locally.
3. Navigate to the directory in which you want to save the PDF.
4. Click **Save**.

Downloading Adobe Reader

You need Adobe Reader installed on your system to view or print these PDF files. You can download a free copy from [Adobe](http://get.adobe.com/reader/) (<http://get.adobe.com/reader/>) .

Query engine overview

IBM Db2 for i provides two query engines to process queries: Classic Query Engine (CQE) and SQL Query Engine (SQE).

SQL-based interfaces, such as ODBC, JDBC, CLI, Query Manager, Net.Data®, RUNSQLSTM, and embedded or interactive SQL, run through SQE. Also some non-SQL based interface such as OPNQRYF and Query/400 will run through SQE. The CQE processes queries originating from non-SQL interfaces: QQQQry API. For ease of use, the routing decision for processing the query by either CQE or SQE is pervasive and under the control of the system. The requesting user or application program cannot control or influence this behavior. However, a better understanding of the engines and process that determines which path a query takes can give you a better understanding of query performance.

Within SQE, several more components were created and other existing components were updated. Additionally, new data access methods are possible with SQE that are not supported under CQE.

SQE and CQE engines

It is important to understand the implementation differences of query management and processing in CQE versus SQE.

The following figure shows an overview of the IBM Db2 for i architecture. It shows the delineation between CQE and SQE, how query processing is directed by the query dispatcher, and where each SQE component fits. The functional separation of each SQE component is clearly evident. This division of responsibility enables IBM to more easily deliver functional enhancements to the individual components of SQE, as and when required. Notice that most of the SQE Optimizer components are implemented below the MI. This implementation translates into enhanced performance efficiency.

As seen in the previous graphic, the query runs from any query interface to the optimizer and the query dispatcher. The query dispatcher determines whether the query is implemented with CQE or SQE.

Query dispatcher

The function of the dispatcher is to route the query request to either CQE or SQE, depending on the attributes of the query. All queries are processed by the dispatcher. It cannot be bypassed.

Currently, the dispatcher routes queries to SQE unless it finds that the query references or contains any of the following:

- INSERT WITH VALUES statement or the target of an INSERT with subselect statement
- Tables with Read triggers
- Read-only queries with more than 1000 dataspace, or updatable queries with more than 256 dataspace.
- Db2 Multisystem tables
- QQQQry API

In earlier releases, for other non-SQL queries, for example Query/400 or OPNQRYF, the routing of the query could be controlled by the QAQQINI SQE_NATIVE_ACCESS option. SQE_NATIVE_ACCESS is no longer supported and a non-SQL query will always run SQE unless it contains one of the conditions listed above.

Related reference

MQT supported function

Although an MQT can contain almost any query, the optimizer only supports a limited set of query functions when matching MQTs to user specified queries. The user-specified query and the MQT query must both be supported by the SQE optimizer.

Statistics manager

In CQE, the retrieval of statistics is a function of the Optimizer. When the Optimizer needs to know information about a table, it looks at the table description to retrieve the row count and table size. If an index is available, the Optimizer might extract information about the data in the table. In SQE, the collection and management of statistics is handled by a separate component called the statistics manager. The statistics manager leverages all the same statistical sources as CQE, but adds more sources and capabilities.

The statistics manager does not actually run or optimize the query. Instead, it controls the access to the metadata and other information that is required to optimize the query. It uses this information to answer questions posed by the query optimizer. The statistics manager always provides answers to the optimizer. In cases where it cannot provide an answer based on actual existing statistics information, it is designed to provide a predefined answer.

The Statistics manager typically gathers and tracks the following information:

Cardinality of values	The number of unique or distinct occurrences of a specific value in a single column or multiple columns of a table.
Selectivity	Also known as a histogram, this information is an indication of how many rows are selected by any given selection predicate or combination of predicates. Using sampling techniques, it describes the selectivity and distribution of values in a given column of the table.
Frequent values	The top <i>nn</i> most frequent values of a column together with a count of how frequently each value occurs. This information is obtained by using statistical sampling techniques. Built-in algorithms eliminate the possibility of data skewing. For example, NULL values and default values that can influence the statistical values are not taken into account.
Metadata information	Includes the total number of rows in the table, indexes that exist over the table, and which indexes are useful for implementing the particular query.
Estimate of IO operation	An estimate of the amount of IO operations that are required to process the table or the identified index.

The Statistics manager uses a hybrid approach to manage database statistics. Most of this information can be obtained from existing indexes. In cases where the required statistics cannot be gathered from existing indexes, statistical information is constructed on single columns of a table and stored internally. By default, this information is collected automatically by the system, but you can manually control the collection of statistics. Unlike indexes, however, statistics are not maintained immediately as data in the tables change.

Related reference

Collecting statistics with the statistics manager

The collection of statistics is handled by a separate component called the statistics manager. Statistical information can be used by the query optimizer to determine the best access plan for a query. Since

the query optimizer bases its choice of access plan on the statistical information found in the table, it is important that this information is current.

Global Statistics Cache

In SQE, the Db2 Statistics Manager stores actual row counts into a Global Statistics Cache. In this manner, the Statistics Manager refines its estimates over time as it learns where estimates have deviated from actual row counts.

Both completed queries and currently executing queries might be inspected by the “[Adaptive Query Processing](#)” on page 110 (AQP) task, which compares estimated row counts to actual row counts. If there are any significant discrepancies, the AQP task notifies the Db2 Statistics Manager (SM). The SM stores this actual row count (also called observed row count) into a Global Statistics Cache (GSC).

If the query which generated the observed statistic in the GSC is reoptimized, the actual row count estimate is used in determining a new query plan. Further, if a different query asks for the same or a similar row count, the SM could return the stored actual row count from the GSC. Faster query plans can be generated by the query optimizer.

Typically, observed statistics are for complex predicates such as with a join. A simple example is a query joining three files A, B, and C. There is a discrepancy between the estimate and actual row count of the join of A and B. The SM stores an observed statistic into the GSC. Later, if a different join query of A, B, and Z is submitted, the SM recalls the observed statistic of the A and B join. The SM considers that observed statistic in its estimate of the A, B, and Z join.

The Global Statistics Cache is an internal Db2 object, and the contents of it are not directly observable.

Plan cache

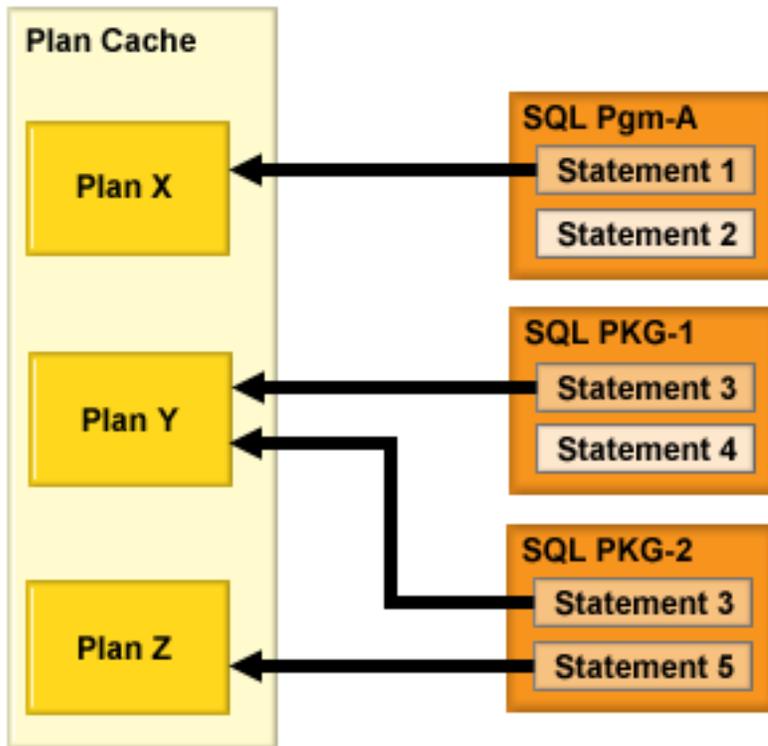

The plan cache is a repository that contains the access plans for queries that were optimized by SQE.

Access plans generated by CQE are not stored in the plan cache; instead, they are stored in SQL packages, the system-wide statement cache, and job cache. The purposes of the plan cache are to:

- Facilitate the reuse of a query access plan when the same query is re-executed
- Store runtime information for subsequent use in future query optimizations
- Provide performance information for analysis and tuning

Once an access plan is created, it is available for use by all users and all queries, regardless of where the query originates. Furthermore, when an access plan is tuned, for example, when creating an index, all queries can benefit from this updated access plan. This updated access plan eliminates the need to re-optimize the query, resulting in greater efficiency.

The following graphic shows the concept of re-usability of the query access plans stored in the plan cache:

As shown in the previous graphic, statements from packages and programs are stored in unique plans in the plan cache. If Statement 3 exists in both SQL package 1 and SQL package 2, the plan is stored once in the plan cache. The plan cache is interrogated each time a query is executed. If an access plan exists that satisfies the requirements of the query, it is used to implement the query. Otherwise a new access plan is created and stored in the plan cache for future use.

The plan cache is automatically updated with new query access plans as they are created. When new statistics or indexes become available, an existing plan is updated the next time the query is run. The plan cache is also automatically updated by the database with runtime information as the queries are run.

Each plan cache entry contains the original query, the optimized query access plan, and cumulative runtime information gathered during the runs of the query. The size of these objects depends largely on the complexity of the SQL statements that are being executed. It is the size of these objects that is counted when calculating the plan cache size.

The size of the plan cache may be controlled by either a system-managed auto-sizing algorithm or by an explicitly set value. By default, the system will use automatic sizing, but this can be disabled by setting the SQL Plan Cache Threshold Size. See the SQL plan cache properties topic for more information: [“SQL plan cache properties” on page 176](#)

When auto-sizing is enabled, the system will begin after each IPL with a default plan cache size of 512 MB. As queries run, the associated plans are placed into the plan cache. Once the plan cache exceeds the current limit set by auto-sizing, the system will evaluate the current hit ratio for the cache. This is the ratio of the number of times a query could re-use a plan from the cache compared to the number of times a query was run. For example, if ten queries were run and nine of the queries used plans from the plan cache while the other one required a full optimization, the hit ratio is 90%. If the current hit ratio equals or exceeds the SQL Plan Cache Target Ratio (see the SQL plan cache properties topic for more information: [“SQL plan cache properties” on page 176](#)), the system considers the plan cache to be operating at an efficient size and will not adjust the size of the cache.

If the current hit ratio is below the target for the plan cache and no other storage constraints exist, the system will automatically increase (up to the Maximum Plan Cache Size for Auto-sizing) the size of the

plan cache. The plan cache will grow incrementally, allowing more plans to be stored, until the current hit ratio meets the target ratio.

Once the target hit ratio has been achieved, the determined size of the cache is maintained by an automatically scheduled background task. The purpose of this task is to go through the plan cache and to remove plans when the cache grows too large. This task will remove access plans based upon age, how frequently it is used, and how much cumulative resources (CPU/IO) were consumed.

Each plan cache entry may also have query runtime objects associated with it. These runtime objects are the real executable objects and temporary storage containers (hash tables, sorts, temporary indexes, and so on) used to run the query. Although these objects are not included in the plan cache size calculation, they may indirectly affect and be affected by the plan cache size. This is because, in addition to honoring the determined plan cache size, the system also seeks to keep the total temporary storage usage for inactive, cached plans within an internally determined threshold. Unlike the plan cache size calculation, this temporary storage calculation considers both the cached plans and the associated runtime objects. If this temporary storage calculation exceeds a system determined percentage of the system auxiliary storage pool (ASP) or if the system storage lower limit (defined by QSTGLOWLMT) is surpassed, the system considers the plan cache to be using excessive temporary storage.

To reduce the excessive temporary storage, the automatically scheduled background task will begin by removing runtime objects from cached plans. This will continue until the plan cache's temporary storage usage is within the system's constraints, and this will happen even if all the cached plan entries themselves fit within the determined plan cache size. If temporary storage usage remains excessive even after the runtime objects are removed, the system will begin a process of incrementally reducing the plan cache size and will continue this reduction until it reaches the minimum value of 512 MB or until the plan cache temporary storage usage is no longer excessive.

Predicting the interaction between plan cache auto-sizing and the temporary storage constraint can be difficult to do. In general, though, these recommendations should be followed:

- Use automatic plan cache sizing unless there is a clear reason to do otherwise.
- Determine and set an acceptable target hit ratio.
- Use an adequately sized system *ASP so that the system has plenty of temporary storage space available.

Multiple access plans for a single SQL statement can be maintained in the plan cache. Although the SQL statement is the primary key into the plan cache, different environmental settings can cause additional access plans to be stored. Examples of these environmental settings include:

- Different SMP Degree settings for the same query
- Different library lists specified for the query tables
- Different settings for the share of available memory for the job in the current pool
- Different ALWCPYDTA settings
- Different selectivity based on changing host variable values used in selection (WHERE clause)

Currently, the plan cache can maintain a maximum of three different access plans for the same SQL statement. As new access plans are created for the same SQL statement, older access plans are discarded to make room for the new access plans. There are, however, certain conditions that can cause an existing access plan to be invalidated. Examples of these conditions include:

- Specifying REOPTIMIZE_ACCESS_PLAN(*YES) or (*FORCE) in the QAQQINI table or in Run SQL Scripts
- Deleting or recreating the table that the access plan refers to
- Deleting an index that is used by the access plan

[Effects of the ALWCPYDTA parameter on database performance](#)

Some complex queries can perform better by using a sort or hashing method to evaluate the query instead of using or creating an index.

[Changing the attributes of your queries](#)

You can modify different types of query attributes for a job with the **Change Query Attributes (CHGQRYA)** CL command. You can also use the System i Navigator Change Query Attributes interface.

Optimizing performance using the Plan Cache

The SQL Plan Cache contains a wealth of information about the SQE queries being run through the database. Its contents are viewable through the System i Navigator GUI interface. Certain portions of the plan cache can also be modified.

Data access methods

Data access methods are used to process queries and access data.

In general, the query engine has two kinds of raw material with which to satisfy a query request:

- The database objects that contain the data to be queried
- The executable instructions or operations to retrieve and transform the data into usable information

There are only two types of permanent database objects that can be used as source material for a query — tables and indexes. Indexes include binary radix and encoded vector indexes.

In addition, the query engine might need to create temporary objects to hold interim results or references during the execution of an access plan. The Db2 Symmetric Multiprocessing feature provides the optimizer with additional methods for retrieving data that include parallel processing. Finally, the optimizer uses certain methods to manipulate these objects.

Permanent objects and access methods

There are three basic types of access methods used to manipulate the permanent and temporary database objects -- Create, Scan, and Probe.

The following table lists each object and the access methods that can be performed against that object. The symbols shown in the table are the icons used by Visual Explain.

Permanent objects	Scan operations	Probe operations
Table	Table scan	Table probe
Radix index	Radix index scan	Radix index probe
Encoded vector index	Encoded vector index symbol table scan	Encoded vector index probe

Table

An SQL table or physical file is the base object for a query. It represents the source of the data used to produce the result set for the query. It is created by the user and specified in the FROM clause (or OPNQRYF FILE parameter).

The optimizer determines the most efficient way to extract the data from the table in order to satisfy the query. These ways could include scanning or probing the table or using an index to extract the data.

Visual explain icon:

Table scan

A table scan is the easiest and simplest operation that can be performed against a table. It sequentially processes all the rows in the table to determine if they satisfy the selection criteria specified in the query. It does this processing in a way to maximize the I/O throughput for the table.

A table scan operation requests large I/Os to bring as many rows as possible into main memory for processing. It also asynchronously pre-fetches the data to make sure that the table scan operation is never waiting for rows to be paged into memory. Table scan however, has a disadvantage in it has to process all the rows in order to satisfy the query. The scan operation itself is efficient if it does not need to perform the I/O synchronously.

Data access method	Table scan
Description	Reads all the rows from the table and applies the selection criteria to each of the rows within the table. The rows in the table are processed in no guaranteed order, but typically they are processed sequentially.
Advantages	<ul style="list-style-type: none">• Minimizes page I/O operations through asynchronous pre-fetching of the rows since the pages are scanned sequentially• Requests a larger I/O to fetch the data efficiently
Considerations	<ul style="list-style-type: none">• All rows in the table are examined regardless of the selectivity of the query• Rows marked as deleted are still paged into memory even though none are selected. You can reorganize the table to remove deleted rows.
Likely to be used	<ul style="list-style-type: none">• When expecting many rows returned from the table• When the number of large I/Os needed to scan is fewer than the number of small I/Os required to probe the table
Example SQL statement	<pre>SELECT * FROM Employee WHERE WorkDept BETWEEN 'A01' AND 'E01' OPTIMIZE FOR ALL ROWS</pre>
Database Monitor and Plan Cache record indicating use	QQRID 3000 - Table Scan
SMP parallel enabled	Yes

[Nested loop join implementation](#)

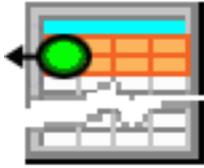

Db2 for i provides a **nested loop** join method. For this method, the processing of the tables in the join are ordered. This order is called the **join order**. The first table in the final join order is called the **primary table**. The other tables are called **secondary tables**. Each join table position is called a **dial**.

Table probe

A table probe operation is used to retrieve a specific row from a table based upon its row number. The row number is provided to the table probe access method by some other operation that generates a row number for the table.

This can include index operations as well as temporary row number lists or bitmaps. The processing for a table probe is typically random. It requests a small I/O to retrieve only the row in question and does not attempt to bring in any extraneous rows. This method leads to efficient processing for smaller result sets because only rows needed to satisfy the query are processed, rather than scanning all rows.

However, since the sequence of the row numbers is not known in advance, little pre-fetching can be performed to bring the data into main memory. This randomness can result in most of the I/Os associated with table probe to be performed synchronously.

<i>Table 3. Table probe attributes</i>	
Data access method	Table probe
Description	Reads a single row from the table based upon a specific row number. A random I/O is performed against the table to extract the row.
Advantages	<ul style="list-style-type: none"> • Requests smaller I/Os to prevent paging rows into memory that are not needed • Can be used with any access method that generates a row number for the table probe to process
Considerations	Because of the synchronous random I/O the probe can perform poorly when many rows are selected
Likely to be used	<ul style="list-style-type: none"> • When row numbers (from indexes or temporary row number lists) are used, but data from the underlying table is required for further processing of the query • When processing any remaining selection or projection of the values
Example SQL statement	<pre>CREATE INDEX X1 ON Employee (LastName) SELECT * FROM Employee WHERE WorkDept BETWEEN 'A01' AND 'E01' AND LastName IN ('Smith', 'Jones', 'Peterson') OPTIMIZE FOR ALL ROWS</pre>
Database Monitor and Plan Cache record indicating use	QQRID 3001 Index Used, where QVC14 (Index_Only_Access) set to 'N' indicates that a table probe was used in conjunction with the index access operation.
SMP parallel enabled	Yes
Also referred to as	Table Probe, Preload
Visual Explain icon	

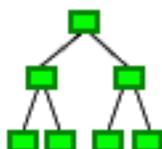

Radix index

An SQL index (or keyed sequence access path) is a permanent object that is created over a table. The index is used by the optimizer to provide a sequenced view of the data for a scan or probe operation.

The rows in the tables are sequenced in the index based upon the key columns specified on the creation of the index. When the optimizer matches a query to index key columns, it can use the index to help satisfy query selection, ordering, grouping, or join requirements.

Typically, using an index also includes a table probe to provide access to columns needed to satisfy the query that cannot be found as index keys. If all the columns necessary to satisfy the query can be found as index keys, then the table probe is not required. The query uses index-only access. Avoiding the table probe can be an important savings for a query. The I/O associated with a table probe is typically the more expensive synchronous random I/O.

Visual Explain icon:

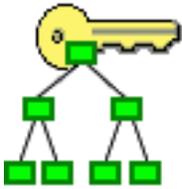

Radix index scan

A radix index scan operation is used to retrieve the rows from a table in a keyed sequence. Like a table scan, all the rows in the index are sequentially processed, but the resulting row numbers are sequenced based upon the key columns.

The sequenced rows can be used by the optimizer to satisfy a portion of the query request (such as ordering or grouping). They can also be used to provide faster throughput by performing selection against the index keys rather than all the rows in the table. Since the index I/Os only contain keys, typically more rows can be paged into memory in one I/O than rows in a table with many columns.

Data access method	Radix index scan
Description	Sequentially scan and process all the keys associated with the index. Any selection is applied to every key value of the index before a table row
Advantages	<ul style="list-style-type: none">• Only those index entries that match any selection continue to be processed• Potential to extract all the data from the index key values, thus eliminating the need for a Table Probe• Returns the rows back in a sequence based upon the keys of the index
Considerations	Generally requires a Table Probe to be performed to extract any remaining columns required to satisfy the query. Can perform poorly when many rows are selected because of the random I/O associated with the Table Probe.

Table 4. Radix index scan attributes (continued)

Data access method	Radix index scan
Likely to be used	<ul style="list-style-type: none"> • When asking for or expecting only a few rows to be returned from the index • When sequencing the rows is required for the query (for example, ordering or grouping) • When the selection columns cannot be matched against the leading key columns of the index
Example SQL statement	<pre>CREATE INDEX X1 ON Employee (LastName, WorkDept) SELECT * FROM Employee WHERE WorkDept BETWEEN 'A01' AND 'E01' ORDER BY LastName OPTIMIZE FOR 30 ROWS</pre>
Database Monitor and Plan Cache record indicating use	<p>QQRID 3001 Index Used, where QQKP (Index_Probe_Used) set to 'N' will indicate an index scan operation. Preload indicated by QVPARPL = 'Y'. Distinct Probe indicated by QVC11 = 'Y'.</p>
SMP parallel enabled	Yes

[Effects of the ALWCPYDTA parameter on database performance](#)

Some complex queries can perform better by using a sort or hashing method to evaluate the query instead of using or creating an index.

Radix index probe

A radix index probe operation is used to retrieve the rows from a table in a keyed sequence. The main difference between the radix index probe and the scan is that the rows returned are first identified by a probe operation to subset them.

The optimizer attempts to match the columns used for some or all the selection against the leading keys of the index. It then rewrites the selection into a series of ranges that can be used to probe directly into the index key values. Only those keys from the series of ranges are paged into main memory.

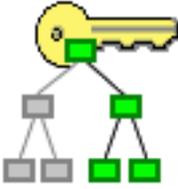

The resulting row numbers generated by the probe can then be further processed by any remaining selection against the index keys or a table probe operation. This method provides for quick access to only the rows of the index that satisfy the selection.

The main function of a radix index probe is to provide quick selection against the index keys. In addition, the row sequencing can be used to satisfy other portions of the query, such as ordering or grouping. Since

the index I/Os are only for rows that match the probe selection, no extraneous processing is performed on rows that do not match. This savings in I/Os against rows that are not a part of the result set is one of the primary advantages for this operation.

<i>Table 5. Radix index probe attributes</i>	
Data access method	Radix index probe
Description	The index is quickly probed based upon the selection criteria that were rewritten into a series of ranges. Only those keys that satisfy the selection are used to generate a table row number.
Advantages	<ul style="list-style-type: none"> • Only those index entries that match any selection continue to be processed • Provides quick access to the selected rows • Potential to extract all the data from the index key values, thus eliminating the need for a Table Probe • Returns the rows back in a sequence based upon the keys of the index
Considerations	Generally requires a Table Probe to be performed to extract any remaining columns required to satisfy the query. Can perform poorly when many rows are selected because of the random I/O associated with the Table Probe.
Likely to be used	<ul style="list-style-type: none"> • When asking for or expecting only a few rows to be returned from the index • When sequencing the rows is required the query (for example, ordering or grouping) • When the selection columns match the leading key columns of the index
Example SQL statement	<pre>CREATE INDEX X1 ON Employee (LastName, WorkDept) SELECT * FROM Employee WHERE WorkDept BETWEEN 'A01' AND 'E01' AND LastName IN ('Smith', 'Jones', 'Peterson') OPTIMIZE FOR ALL ROWS</pre>
Database Monitor and Plan Cache record indicating use	<p>QQRID 3001 Index Used</p> <p>where QQKP (Index_Probe_Used) set to 'Y' will indicate an index probe operation.</p> <p>Preload indicated by QVPARPL = 'Y'</p> <p>Distinct Probe indicated by QVC11 = 'Y'</p>
SMP parallel enabled	Yes
Also referred to as	<p>Index Probe</p> <p>Index Probe, Preload</p> <p>Index Probe, Distinct</p> <p>Index Probe Distinct, Preload</p> <p>Index Probe, Key Positioning</p> <p>Index Scan, Key Row Positioning</p>

Table 5. Radix index probe attributes (continued)

Data access method	Radix index probe
Visual Explain icon	

The following example illustrates a query where the optimizer might choose the radix index probe access method:

```
CREATE INDEX X1 ON Employee (LastName, WorkDept)

SELECT * FROM Employee
WHERE WorkDept BETWEEN 'A01' AND 'E01'
AND LastName IN ('Smith', 'Jones', 'Peterson')
OPTIMIZE FOR ALL ROWS
```

In this example, index X1 is used to position to the first index entry that matches the selection built over both columns LastName and WorkDept. The selection is rewritten into a series of ranges that match all the leading key columns used from the index X1. The probe is then based upon the composite concatenated values for all the leading keys. The pseudo-SQL for this rewritten SQL might look as follows:

```
SELECT * FROM X1
WHERE X1.LeadingKeys BETWEEN 'JonesA01' AND 'JonesE01'
OR X1.LeadingKeys BETWEEN 'PetersonA01' AND 'PetersonE01'
OR X1.LeadingKeys BETWEEN 'SmithA01' AND 'SmithE01'
```

All the key entries that satisfy the probe operation are used to generate a row number for the table associated with the index (for example, Employee). The row number is used by a Table Probe operation to perform random I/O on the table to produce the results for the query. This processing continues until all the rows that satisfy the index probe operation have been processed. In this example, all the index entries processed and rows retrieved met the index probe criteria.

Additional selection might be added that cannot use an index probe, such as selection against columns which are not leading key columns of the index. Then the optimizer performs an index scan operation within the range of probed values. This process still allows for selection to be performed before the Table Probe operation.

Effects of the ALWCPYDTA parameter on database performance

Some complex queries can perform better by using a sort or hashing method to evaluate the query instead of using or creating an index.

Encoded vector index

An encoded vector index is a permanent object that provides access to a table. This access is done by assigning codes to distinct key values and then representing those values in a vector.

The size of the vector matches the number of rows in the underlying table. Each vector entry represents the table row number in the same position. The codes generated to represent the distinct key values can be 1 byte, 2 bytes, or 4 bytes in length. The key length depends upon the number of distinct values that

need to be represented in the vector. Because of their compact size and relative simplicity, the EVI can be used to process large amounts of data efficiently.

An encoded vector index is used to represent the values stored in a table. However, the index itself cannot be used to directly gain access to the table. Instead, the encoded vector index can only be used to generate either a temporary row number list or a temporary row number bitmap. These temporary objects can then be used with a table probe to specify the rows in the table that the query needs to process.

The main difference in the table probe using an encoded vector index vs. a radix index is that the I/O paging can be asynchronous. The I/O can now be scheduled more efficiently to take advantage of groups of selected rows. Large portions of the table can be skipped over where no rows are selected.

Visual explain icon:

Related concepts

Encoded vector indexes

An encoded vector index (EVI) is used to provide fast data access in decision support and query reporting environments.

EVI maintenance

There are unique challenges to maintaining EVIs. The following table shows a progression of how EVIs are maintained, the conditions under which EVIs are most effective, and where EVIs are least effective, based on the EVI maintenance characteristics.

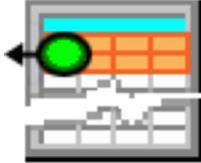

Encoded vector index RRN probe

A table probe operation is used to retrieve a specific row from a table based upon its row number. The row number is provided to the table probe access method by some other operation that generates a row number for the table.

The encoded vector index (EVI) RRN probe is an index only access method that is used to provide selected columns by retrieving the value from the EVI instead of using a table probe to access the table. Retrieving the value from the EVI should provide better I/O characteristics than the random I/Os associated with a table probe operation.

This access method is used in conjunction with a radix index probe, radix index scan, or EVI probe operation. The radix index probe, radix index scan, or EVI probe operation is used to select the rows and then the RRN of the selected row is used to probe into EVIs to retrieve any selected EVI values that were not provided by the index used for selection. The EVI RRN probe can access multiple EVIs to provide selected values.

<i>Table 6. EVI RRN probe attributes</i>	
Data access method	EVI RRN Probe
Description	The encoded vector index (EVI) is quickly probed based upon the RRNs provided by the underlying index access.
Advantages	<ul style="list-style-type: none"> • Potential to extract all the data from the EVI index key values, thus eliminating the need for a Table Probe • Provides better paging characteristics than a Table Probe.

<i>Table 6. EVI RRN probe attributes (continued)</i>	
Data access method	EVI RRN Probe
Considerations	<ul style="list-style-type: none"> • Only single key EVIs are considered for this implementation • All selected columns must have a single column EVI created. • The EVIs must fit in the query's fair share of optimizer memory
Likely to be used	<ul style="list-style-type: none"> • When the table row size is wide, the number of select columns is small compared to the number of columns in the table and the query requires a table probe to retrieve columns
Example SQL statement	<pre>CREATE ENCODED VECTOR INDEX EVI1 ON Employee (WorkDept) CREATE ENCODED VECTOR INDEX EVI2 ON Employee (Salary)WITH 10000 DISTINCT VALUES CREATE ENCODED VECTOR INDEX EVI3 ON Employee (LASTNAME)WITH 100000 DISTINCT VALUES CREATE INDEX IX1 ON Employee (Job) SELECT LASTNAME, WORKDEPT, SALARY FROM EMPLOYEE WHERE JOB = 'ANALYST'</pre>
Database Monitor and Plan Cache record indicating use	A QQRID 3001 Index Used record for each EVI with QQRCD = 'I8'
SMP parallel enabled	Yes
Also referred to as	Table Probe, Preload
Visual Explain icon	

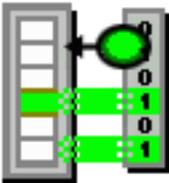

Prior to encoded vector index only access (EOA), the recommendation had been to only create EVIs for column with low cardinality (small number of distinct values). This recommendation has now changed. EVI RRN Probe can be used for columns with high cardinality (large number of distinct values). However, when creating the EVI, the WITH integer DISTINCT VALUES clause should be used to set the initial size of the codes appropriately and to minimize maintenance time if the database manager needs to use a larger code. See the CREATE INDEX statement in the SQL Reference for more details.

Encoded vector index probe

The encoded vector index (EVI) is quickly probed based upon the selection criteria that were rewritten into a series of ranges. It produces either a temporary row number list or bitmap.

<i>Table 7. Encoded vector index probe attributes</i>	
Data access method	Encoded vector index probe
Description	The encoded vector index (EVI) is quickly probed based upon the selection criteria that were rewritten into a series of ranges. It produces either a temporary row number list or bitmap.

Table 7. Encoded vector index probe attributes (continued)

Data access method	Encoded vector index probe
Advantages	<ul style="list-style-type: none"> • Only those index entries that match any selection continue to be processed • Provides quick access to the selected rows • Returns the row numbers in ascending sequence so that the Table Probe can be more aggressive in pre-fetching the rows for its operation
Considerations	EVI's are usually built over a single key. The more distinct the column is and the higher the overflow percentage, the less advantageous the encoded vector index becomes. EVI's always require a Table Probe to be performed on the result of the EVI probe operation.
Likely to be used	<ul style="list-style-type: none"> • When the selection columns match the leading key columns of the index • When an encoded vector index exists and savings in reduced I/O against the table justifies the extra cost. This cost includes probing the EVI and fully populating the temporary row number list.
Example SQL statement	<pre>CREATE ENCODED VECTOR INDEX EVI1 ON Employee (WorkDept) CREATE ENCODED VECTOR INDEX EVI2 ON Employee (Salary) CREATE ENCODED VECTOR INDEX EVI3 ON Employee (Job) SELECT * FROM Employee WHERE WorkDept = 'E01' AND Job = 'CLERK' AND Salary = 5000 OPTIMIZE FOR 99999 ROWS</pre>
Database Monitor and Plan Cache record indicating use	<pre>QQRID 3001 Index Used with QQRCD='I5', QQRID 3021 Bitmap Created and optionally QQRID 3022 Bitmap Merge.</pre>
SMP parallel enabled	Yes
Also referred to as	Encoded Vector Index Probe, Preload
Visual Explain icon	

Using the example above, the optimizer chooses to create a temporary row number bitmap for each of the encoded vector indexes used by this query. Each bitmap only identifies those rows that match the selection on the key columns for that index.

These temporary row number bitmaps are then merged together to determine the intersection of the rows selected from each index. This intersection is used to form a final temporary row number bitmap used to help schedule the I/O paging against the table for the selected rows.

The optimizer might choose to perform an index probe with a binary radix tree index if an index existed over all three columns. The implementation choice is probably decided by the number of rows to be returned and the anticipated cost of the I/O associated with each plan.

If few rows are returned, the optimizer probably chooses the binary radix tree index and performs the random I/O against the table. However, selecting more rows causes the optimizer to use the EVIs, because of the savings from the more efficiently scheduled I/O against the table.

Encoded vector index index-symbol table only access

The encoded vector index can also be used for index-symbol table only access.

The EVI can be used for more than generating a bitmap or row number list to provide an asynchronous I/O map to the desired table rows. The EVI can also be used by two index-only access methods that can be applied specific to the symbol table itself. These two index-only access methods are the EVI symbol table scan and the EVI symbol table probe.

These two methods can be used with GROUP BY or DISTINCT queries that can be satisfied by the symbol table. This symbol table-only access can be further employed in aggregate queries by adding INCLUDE values to the encoded vector index.

The following information is a summary of the symbol table-only scan and probe access methods.

Use the following links to learn in-depth information.

An encoded vector index (EVI) is used to provide fast data access in decision support and query reporting environments.

[How the EVI works](#)

EVI's work in different ways for costing and implementation.

Related reference

[Index grouping implementation](#)

There are two primary ways to implement grouping using an index: Ordered grouping and pre-summarized processing.

Encoded vector index symbol table scan

An encoded vector index symbol table scan operation is used to retrieve the entries from the symbol table portion of the index.

All entries (symbols) in the symbol table are sequentially scanned if a scan is chosen. The symbol table can be used by the optimizer to satisfy GROUP BY or DISTINCT portions of a query request.

Selection is applied to every entry in the symbol table. The selection must be applied to the symbol table keys unless the EVI was created as a sparse index, with a WHERE clause. In that case, a portion of the selection is applied as the symbol table is built and maintained. The query request must include matching predicates to use the sparse EVI.

All entries are retrieved directly from the symbol table portion of the index without any access to the vector portion of the index. There is also no access to the records in the associated table over which the EVI is built.

Encoded vector index INCLUDE aggregates

To enhance the ability of the EVI symbol table to provide aggregate answers, the symbol table can be created to contain additional INCLUDE values. These are ready-made numeric aggregate results, such as SUM, COUNT, AVG, or VARIANCE values requested over non-key data. These aggregates are specified using the INCLUDE keyword on the CREATE ENCODED VECTOR INDEX request.

These included aggregates are maintained in real time as rows are inserted, updated, or deleted from the corresponding table. The symbol table maintains these additional aggregate values in addendum to the EVI keys for each symbol table entry. Because these are numeric results and finite in size, the symbol table is still a desirable compact size.

These included aggregates are over non-key columns in the table where the grouping is over the corresponding EVI symbol table defined keys. The aggregate can be over a single column or a derivation.

Table 8. Encoded vector index symbol table scan attributes

Data access method	Encoded vector index symbol table scan
Description	Sequentially scan and process all the symbol table entries associated with the index. When there is selection (WHERE clause), it is applied to every entry in the symbol table. An exception is made in the case of a sparse EVI, where the selection is applied as the index is created and maintained. Selected entries are retrieved directly without any access to the vector or the associated table.
Advantages	<ul style="list-style-type: none"> • Pre-summarized results are readily available • Only processes the unique values in the symbol table, avoiding processing table records. • Extract all the data from the index unique key values or INCLUDE values, thus eliminating the need for a Table Probe or vector scan. • With INCLUDE, provides ready-made numeric aggregates, eliminating the need to access corresponding table rows to perform the aggregation
Considerations	<p>Dramatic performance improvement for grouping queries where the resulting number of groups is relatively small compared to the number of records in the underlying table. Can perform poorly when there are many groups involved such that the symbol table is large. Poor performance is even more likely if a large portion of the symbol table has been put into the overflow area.</p> <p>Dramatic performance improvement for grouping queries when the aggregate is specified as an INCLUDE value of the symbol table.</p>
Likely to be used	<ul style="list-style-type: none"> • When asking for GROUP BY, DISTINCT, COUNT, or COUNT DISTINCT from a single table and the referenced columns are in the key definition. • When the number of unique values in the columns of the key definition is small relative to the number of records in the underlying table. • When there is no selection (WHERE clause) within the query or the selection does not reduce the result set much. • When the symbol table key satisfies the GROUP BY, and requested aggregates, like SUM or COUNT, are specified as INCLUDE values. • when the query is run with commitment control *NONE or *CHG.

[Index grouping implementation](#)

There are two primary ways to implement grouping using an index: Ordered grouping and pre-summarized processing.

Encoded vector index symbol table probe

An encoded vector index symbol table probe operation is used to retrieve entries from the symbol table portion of the index. Scanning the entire symbol table is not necessary.

The symbol table can be used by the optimizer to satisfy GROUP BY or DISTINCT portions of a query request.

The optimizer attempts to match the columns used for some or all the selection against the leading keys of the EVI index. It then rewrites the selection into a series of ranges that can be used to probe directly into the symbol table. Only those symbol table pages from the series of ranges are paged into main memory.

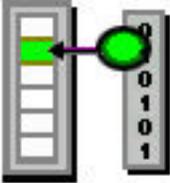

The resulting symbol table entries generated by the probe operation can then be further processed by any remaining selection against EVI keys. This strategy provides for quick access to only the entries of the symbol table that satisfy the selection.

Like an encoded vector symbol table scan, a symbol table probe can return ready-made aggregate results if INCLUDE is specified when the EVI is created.

All entries are retrieved directly from the symbol table portion of the index without any access to the vector portion of the index. In addition, it is unnecessary to access the records in the associated table over which the EVI is built.

<i>Table 9. Encoded vector index symbol table probe attributes</i>	
Data access method	Encoded vector index symbol table probe
Description	
Advantages	Probe the symbol table entries associated with the index. When there is selection (WHERE clause), it is applied to every entry in the symbol table that meets the probe criteria. If there are sparse EVIs, the selection is applied as the EVI is created and maintained. Selected entries are retrieved directly without any access to the vector or the associated table.
Considerations	<ul style="list-style-type: none"> • Pre-summarized results are readily available • Only processes the unique values in the symbol table, avoiding processing table records. • Extracts all the data from the index unique key values or include values, or both, thus eliminating the need for a table probe or vector scan • With INCLUDE, provides ready-made numeric aggregates, eliminating the need to access corresponding table rows to perform the aggregation

Table 9. Encoded vector index symbol table probe attributes (continued)

Data access method	Encoded vector index symbol table probe
Likely to be used	<ul style="list-style-type: none"> • When asking for GROUP BY, DISTINCT, COUNT, or COUNT DISTINCT from a single table and the referenced columns are in the key definition. • When the number of unique values in the columns of the key definition is small relative to the number of records in the underlying table. • When there is selection (WHERE clause) that reduces the selection from the Symbol Table and the WHERE clause involves leading, probable keys. • When the symbol table key satisfies the GROUP BY and the WHERE clause reduces selection to the leading keys, and aggregates are specified as INCLUDE values. • When the query is run with commitment control *NONE or *CHG.
Example SQL statement	<pre>CREATE ENCODED VECTOR INDEX EVI1 ON Sales (Region)</pre> <p>Example 1</p> <pre>SELECT Region, COUNT(*) FROM Sales WHERE Region in ('Quebec', 'Manitoba') GROUP BY Region OPTIMIZE FOR ALL ROWS</pre> <p>Example 2</p> <pre>CREATE ENCODED VECTOR INDEX EVI2 ON Sales(Region) INCLUDE(SUM(SALES))</pre> <pre>SELECT Region, SUM(SALES) FROM Sales WHERE Region = 'PACIFIC' GROUP BY Region</pre>

There are two primary ways to implement grouping using an index: Ordered grouping and pre-summarized processing.

Temporary objects and access methods

Temporary objects are created by the optimizer in order to process a query. In general, these temporary objects are internal objects and cannot be accessed by a user.

<i>Table 10. Temporary object data access methods</i>		
Temporary create objects	Scan operations	Probe operations
Temporary hash table	Hash table scan	Hash table probe
Temporary sorted list	Sorted list scan	Sorted list probe
Temporary distinct sorted list	Sorted list scan	N/A

Temporary buffer	Buffer scan	N/A
Queue	N/A	N/A
Array unnest temporary table	Temporary table scan	N/A
Temporary Indexed List	Temporary Indexed List Scan and Index Merge	N/A
Window	Window scan	N/A

Temporary hash table

The temporary hash table is a temporary object that allows the optimizer to collate the rows based upon a column or set of columns. The hash table can be either scanned or probed by the optimizer to satisfy different operations of the query.

A temporary hash table is an efficient data structure because the rows are organized for quick and easy retrieval after population has occurred. The hash table remains resident within main memory to avoid any I/Os associated with either the scan or probe against the temporary object. The optimizer determines the optimal hash table size based on the number of unique column combinations used as keys for the creation.

Additionally the hash table can be populated with all the necessary columns to satisfy any further processing. This population avoids any random I/Os associated with a table probe operation.

However, the optimizer can selectively include columns in the hash table when the calculated size exceeds the memory pool storage available for the query. In these cases, a table probe operation is required to recollect the missing columns from the hash table before the selected rows can be processed.

The optimizer also can populate the hash table with distinct values. If the query contains grouping or distinct processing, then all the rows with the same key value are not required in the hash table. The rows are still collated, but the distinct processing is performed during the population of the hash table itself. This method allows a simple scan on the result in order to complete the grouping or distinct operation.

A temporary hash table is an internal data structure and can only be created by the database manager

Visual explain icon:

Hash table scan

During a hash table scan operation, the entire temporary hash table is scanned and all the entries contained within the hash table are processed.

The optimizer considers a hash table scan when the data values need to be collated together, but sequencing of the data is not required. A hash table scan allows the optimizer to generate a plan that takes advantage of any non-join selection while creating the temporary hash table.

An additional benefit is that the temporary hash table data structure will typically cause the table data to remain resident within main memory after creation. Resident table data reduces paging on the subsequent hash table scan operation.

<i>Table 11. Hash table scan attributes</i>	
Data access method	Hash table scan
Description	Read all the entries in a temporary hash table. The hash table can perform distinct processing to eliminate duplicates. Or the temporary hash table can collate all the rows with the same value together.
Advantages	<ul style="list-style-type: none"> • Reduces the random I/O to the table associated with longer running queries that might otherwise use an index to collate the data • Selection can be performed before generating the hash table to subset the number of rows in the temporary object
Considerations	Used for distinct or group by processing. Can perform poorly when the entire hash table does not stay resident in memory as it is being processed.
Likely to be used	<ul style="list-style-type: none"> • When the use of temporary results is allowed by the query environmental parameter (ALWCPYDTA) • When the data is required to be collated based upon a column or columns for distinct or grouping

Table 11. Hash table scan attributes (continued)

Data access method	Hash table scan
Visual Explain icon	

Hash table probe

A hash table probe operation is used to retrieve rows from a temporary hash table based upon a probe lookup operation.

The optimizer initially identifies the keys of the temporary hash table from the join criteria specified in the query. When the hash table is probed, the values used to probe into the hash table are extracted from the join-from criteria specified in the selection.

These values are sent through the same hashing algorithm used to populate the temporary hash table. They determine if any rows have a matching equal value. All the matching join rows are then returned to be further processed by the query.

Table 12. Hash table probe attributes

Data access method	Hash table probe
Description	The temporary hash table is quickly probed based upon the join criteria.
Advantages	<ul style="list-style-type: none"> • Provides quick access to the selected rows that match probe criteria • Reduces the random I/O to the table associated with longer running queries that use an index to collate the data • Selection can be performed before generating the hash table to subset the number of rows in the temporary object
Considerations	Used to process equal join criteria. Can perform poorly when the entire hash table does not stay resident in memory as it is being processed.
Likely to be used	<ul style="list-style-type: none"> • When the use of temporary results is allowed by the query environmental parameter (ALWCPYDTA) • When the data is required to be collated based upon a column or columns for join processing • The join criteria was specified using an equals (=) operator
Example SQL statement	<pre>SELECT * FROM Employee XXX, Department YYY WHERE XXX.WorkDept = YYY.DeptNo OPTIMIZE FOR ALL ROWS</pre>

Table 12. Hash table probe attributes (continued)

Data access method	Hash table probe
Visual Explain icon	

The hash table probe access method is considered when determining the implementation for a secondary table of a join. The hash table is created with the key columns that match the equal selection or join criteria for the underlying table.

The hash table probe allows the optimizer to choose the most efficient implementation in selecting rows from the underlying table, without regard for join criteria. This single pass through the underlying table can now use a table scan or existing index to select the rows needed for the hash table population.

Since hash tables are constructed so that most of the hash table remains resident within main memory, the I/O associated with a hash probe is minimal. Additionally, if the hash table was populated with all necessary columns from the underlying table, no additional table probe is required to finish processing this table. This method causes further I/O savings.

Related concepts

Nested loop join implementation

Db2 for i provides a **nested loop** join method. For this method, the processing of the tables in the join are ordered. This order is called the **join order**. The first table in the final join order is called the **primary table**. The other tables are called **secondary tables**. Each join table position is called a **dial**.

Temporary sorted list

The temporary sorted list is a temporary object that allows the optimizer to sequence rows based upon a column or set of columns. The sorted list can be either scanned or probed by the optimizer to satisfy different operations of the query.

A temporary sorted list is a data structure where the rows are organized for quick and easy retrieval after population has occurred. During population, the rows are copied into the temporary object and then a second pass is made through the temporary object to perform the sort.

In order to optimize the creation of this temporary object, minimal data movement is performed while the sort is processed. It is not as efficient to probe a temporary sorted list as it is to probe a temporary hash table.

Additionally, the sorted list can be populated with all the necessary columns to satisfy any further processing. This population avoids any random I/Os associated with a table probe operation.

However, the optimizer can selectively include columns in the sorted list when the calculated size exceeds the memory pool storage available for this query. In those cases, a table probe operation is required to recollect the missing columns from the sorted list before the selected rows can be processed.

A temporary sorted list is an internal data structure and can only be created by the database manager.

Visual explain icon:

Sorted list scan

During a sorted list scan operation, the entire temporary sorted list is scanned and all the entries contained within the sorted list are processed.

A sorted list scan is considered when the data values need to be sequenced. A sorted list scan allows the optimizer to generate a plan that can take advantage of any non-join selection while creating the temporary sorted list.

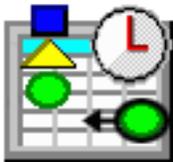

An additional benefit is that the data structure will usually cause the table data within the sorted list to remain resident within main memory after creation. This resident data reduces paging on the subsequent sorted list scan operation.

<i>Table 13. Sorted list scan attributes</i>	
Data access method	Sorted list scan
Description	Read all the entries in a temporary sorted list. The sorted list can perform distinct processing to eliminate duplicate values or take advantage of the temporary sorted list to sequence all the rows.
Advantages	<ul style="list-style-type: none"> • Reduces the random I/O to the table associated with longer running queries that would otherwise use an index to sequence the data. • Selection can be performed prior to generating the sorted list to subset the number of rows in the temporary object

Nested loop join implementation

Db2 for i provides a **nested loop** join method. For this method, the processing of the tables in the join are ordered. This order is called the **join order**. The first table in the final join order is called the **primary table**. The other tables are called **secondary tables**. Each join table position is called a **dial**.

Temporary distinct sorted list

A temporary distinct sorted list combines the features of the temporary hash table and the temporary sorted list.

Like the hash table, the temporary distinct sorted list allows the optimizer to collate the rows based on a column or set of columns. Like the sorted list, the temporary distinct sorted list also allows the optimizer to sequence the rows.

A temporary distinct sorted list contains a hash table data structure set up for efficient access to aggregate rows during population. In addition, a binary tree data structure is maintained over the hash table data structure so that the data can be accessed in sequence. The sorted aspect of the data structure allows for the efficient computation of super-aggregate rows in SQL statements that contain GROUP BY ROLLUP.

A temporary sorted aggregate hash table is an internal data structure and can only be created by the database manager.

Visual explain icon:

Sorted list scan

During the sorted list scan, the entire temporary distinct sorted list is scanned and all the entries contained within the temporary are processed.

The optimizer uses the sorted list scan when the data values need to be aggregated and sequenced. The optimizer generates this plan that can take advantage of any non-join selection while creating the temporary distinct sorted list. The data structure of the temporary distinct sorted list will typically cause the table data to remain resident within main memory after creation. This memory-resident data reduces paging on the subsequent sorted list scan.

<i>Table 15. Sorted list scan attributes</i>	
Data access method	Sorted list scan
Description	Reads all the entries in a temporary distinct sorted list
Advantages	<ul style="list-style-type: none"> • Allows efficient computation of ROLLUP super-aggregate rows. • Reduces the random I/O to the table associated with longer running queries that might otherwise use an index to collate the data. • Selection can be performed before generating the distinct sorted list to subset the number of rows in the temporary object.

Temporary list

The temporary list is a temporary object that allows the optimizer to store intermediate results of a query. The list is an unsorted data structure that is used to simplify the operation of the query. Since the list does not have any keys, the rows within the list can only be retrieved by a sequential scan operation.

The temporary list can be used for various reasons, some of which include an overly complex view or derived table, Symmetric Multiprocessing (SMP) or to prevent a portion of the query from being processed multiple times.

A temporary list is an internal data structure and can only be created by the database manager.

Visual explain icon:

List scan

The list scan operation is used when a portion of the query is processed multiple times, but no key columns can be identified. In these cases, that portion of the query is processed once and its results are stored within the temporary list. The list can then be scanned for only those rows that satisfy any selection or processing contained within the temporary object.

<i>Table 16. List scan attributes</i>	
Data access method	List scan
Description	Sequentially scan and process all the rows in the temporary list.

Table 16. List scan attributes (continued)

Data access method	List scan
Advantages	<ul style="list-style-type: none"> • The temporary list and list scan can be used by the optimizer to minimize repetition of an operation or to simplify the optimizer logic flow. • Selection can be performed before generating the list to subset the number of rows in the temporary object.
Considerations	Used to prevent portions of the query from being processed multiple times when no key columns are required to satisfy the request.
Likely to be used	<ul style="list-style-type: none"> • When the use of temporary results is allowed by the query environmental parameter (ALWCOPYDTA). • When Db2 symmetric multiprocessing is used for the query.
Example SQL statement	<pre>SELECT * FROM Employee XXX, Department YYY WHERE XXX.LastName IN ('Smith', 'Jones', 'Peterson') AND YYY.DeptNo BETWEEN 'A01' AND 'E01' OPTIMIZE FOR ALL ROWS</pre>
Database Monitor and Plan Cache record indicating use	QQRID 3004 Temp Table
SMP parallel enabled	Yes
Also referred to as	List Scan, Preload
Visual Explain icon	

Using the example above, the optimizer chose to create a temporary list to store the selected rows from the DEPARTMENT table. Since there is no join criteria, a Cartesian product join is performed between the two tables. To prevent the join from scanning all the rows of the DEPARTMENT table for each join possibility, the selection against the DEPARTMENT table is performed once. The results are stored in the temporary list. The temporary list is then scanned for the Cartesian product join.

Temporary values list

The temporary values list allows the optimizer to store rows of data specified in a VALUES clause of a SELECT or CREATE VIEW statement.

The list is an unsorted data structure that is used to simplify the operation of the query. Since the list does not have any keys, the rows within the list can only be retrieved by a sequential scan operation.

A temporary values list is an internal data structure and can only be created by the database manager.

Visual explain icon:

Values list scan

During a values list scan operation, the entire temporary values list is scanned and all the rows of data are processed.

Table 17. Values list scan attributes	
Data access method	Values list scan
Description	Sequentially scan and process all the rows of data in the temporary values list.
Advantages	The temporary values list and values list scan can be used by the optimizer to simplify the optimizer logic flow.
Likely to be used	When a VALUES clause is specified in the from-clause of an SQL fullselect
Example SQL statement	<pre>SELECT EMPNO, 'empproject' FROM EMPPROJECT WHERE PROJNO IN('MA2100', 'MA2110', 'MA2112') UNION VALUES ('NEWAAA', 'new'), ('NEWBBB', 'new')</pre>
Database Monitor and Plan Cache record indicating use	QQRID 3000 where QVQTBL = '*VALUES'
SMP parallel enabled	Yes
Visual Explain icon	

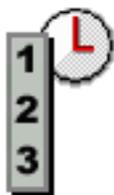

Temporary row number list

The temporary row number list, also referred to as an RRN List, is a temporary object that allows the optimizer to sequence rows based upon their row address (their row number). The row number list can be either scanned or probed by the optimizer to satisfy different operations of the query.

A temporary row number list is a data structure where the rows are organized for quick and efficient retrieval. The row number list only contains the row number for the associated row. Since no table data is present, a table probe operation is typically associated with it in order to retrieve the underlying table data. Because the row numbers are sorted, the random I/O associated with the table probe operation is performed more efficiently. The database manager performs pre-fetch or look-ahead logic to determine if multiple rows are located on adjacent pages. If so, the table probe requests a larger I/O to bring the rows into main memory more efficiently.

A temporary row number list is an internal data structure and can only be created by the database manager.

Visual explain icon:

Row number list scan

The entire temporary row number list is scanned and all the row addresses contained within the row number list are processed. The optimizer considers this plan when there is an applicable encoded vector

index or if the index probe or scan random I/O can be reduced. The random I/O can be reduced by first preprocessing and sorting the row numbers associated with the Table Probe.

The use of a row number list scan allows the optimizer to generate a plan that can take advantage of multiple indexes to match up to different portions of the query.

An additional benefit is that the data structure of the temporary row number list guarantees that the row numbers are sorted. It closely mirrors the row number layout of the table data, ensuring that the table paging never visits the same page of data twice. This results in increased I/O savings for the query.

A row number list scan is identical to a bitmap scan operation. The only difference is that the list scan is over a list of row addresses while the bitmap scan is over a bitmap representing the addresses.

<i>Table 18. Row number list scan</i>	
Data access method	Row number list scan
Description	Sequentially scan and process all the row numbers in the temporary row number list. The sorted row numbers can be merged with other temporary row number lists or can be used as input into a Table Probe operation.
Advantages	<ul style="list-style-type: none"> • The temporary row number list only contains address, no data, so the temporary can be efficiently scanned within memory. • The row numbers contained within the temporary object are sorted to provide efficient I/O processing to access the underlying table. • Selection is performed as the row number list is generated to subset the number of rows in the temporary object.
Considerations	Since the row number list contains only the addresses of the selected rows in the table, a separate Table Probe fetches the table rows.
Likely to be used	<ul style="list-style-type: none"> • When the use of temporary results is allowed by the query environmental parameter (ALWCPYDTA). • When the cost of sorting of the row number is justified by the more efficient I/O that can be performed during the Table Probe operation. • When multiple indexes over the same table need to be combined in order to minimize the number of selected rows.
Example SQL statement	<pre>CREATE INDEX X1 ON Employee (WorkDept) CREATE ENCODED VECTOR INDEX EVI2 ON Employee (Salary) CREATE ENCODED VECTOR INDEX EVI3 ON Employee (Job) SELECT * FROM Employee WHERE WorkDept = 'E01' AND Job = 'CLERK' AND Salary = 5000 OPTIMIZE FOR 99999 ROWS</pre>
Database Monitor and Plan Cache record indicating use	<p>QQRID 3001 and QQRID 3021 records for each index used.</p> <p>The QQC11 field in the 3021 record will be 'L'.</p> <p>A QQRID 3000 record with QQC11 (Skip_Sequential_Table_Scan) = 'Y'.</p> <p>Optionally, QQRID 3022 records if bitmap merging occurred.</p>
SMP parallel enabled	Yes
Also referred to as	Row Number List Scan, Preload; RRN Scan; RRN Scan, Preload

Table 18. Row number list scan (continued)

Data access method	Row number list scan
Visual Explain icon	

Using the example above, the optimizer created a temporary row number list for each of the indexes used by this query. These indexes included a radix index and two encoded vector indexes. Each index row number list was scanned and merged into a final composite row number list representing the intersection of all the index row number lists. The final row number list is then used by the Table Probe to determine which rows are selected and processed for the query results.

Row number list probe

A row number list probe is used to test row numbers generated by a separate operation against the selected rows of a temporary row number list. The row numbers can be generated by any operation that constructs a row number for a table. That row number is then used to probe into a temporary row number list to determine if it matches the selection used to generate the list.

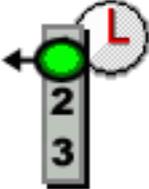

The use of a row number list probe operation allows the optimizer to generate a plan that can take advantage of any sequencing provided by an index, but still use the row number list to perform additional selection before any Table probe operations.

A row number list probe is identical to a bitmap probe operation. The only difference is that the list probe is over a list of row addresses while the bitmap probe is over a bitmap representing the addresses.

Table 19. Row number list probe

Data access method	Row number list probe
Description	The temporary row number list is quickly probed based upon the row number generated by a separate operation.
Advantages	<ul style="list-style-type: none"> • The temporary row number list only contains a row address, no data, so the temporary can be efficiently probed within memory. • The row numbers represented within the row number list are sorted to provide efficient lookup processing to test the underlying table. • Selection is performed as the row number list is generated to subset the number of selected rows in the temporary object.
Considerations	Used when the query contains ordering and additional selection that can be satisfied by additional indexes. Since the row number list contains only the addresses of the selected rows in the table, a separate Table Probe fetches the table rows.
Likely to be used	<ul style="list-style-type: none"> • When the use of temporary results is allowed by the query environmental parameter (ALWCOPYDTA). • When the cost of creating and probing the row number list is justified by reducing the number of Table Probe operations that must be performed. • When multiple indexes over the same table need to be combined in order to minimize the number of selected rows.

Table 19. Row number list probe (continued)

Data access method	Row number list probe
Example SQL statement	<pre>CREATE INDEX X1 ON Employee (WorkDept) CREATE ENCODED VECTOR INDEX EVI2 ON Employee (Salary) CREATE ENCODED VECTOR INDEX EVI3 ON Employee (Job) SELECT * FROM Employee WHERE WorkDept = 'E01' AND Job = 'CLERK' AND Salary = 5000 ORDER BY WorkDept</pre>
Database Monitor and Plan Cache record indicating use	<p>QQRID 3001 and QQRID 3021 records for each index used.</p> <p>The QQC11 field in the 3021 record will be 'L'.</p> <p>Optionally, QQRID 3022 records if bitmap merging occurred.</p>
SMP parallel enabled	Yes
Also referred to as	Row Number List Probe, Preload; RRN Probe; RRN Probe, Preload
Visual Explain icon	

Using the example above, the optimizer created a temporary row number list for each of the encoded vector indexes. Additionally, an index probe operation was performed against the radix index X1 to satisfy the ordering requirement. Since the ORDER BY requires that the resulting rows be sequenced by the WorkDept column, the row number list cannot be scanned for the selected rows.

However, the temporary row number list can be probed using a row address extracted from the index X1 used to satisfy the ordering. By probing the list with the row address extracted from the index probe, the sequencing of the keys in the index X1 is preserved. The row can still be tested against the selected rows within the row number list.

Temporary bitmap

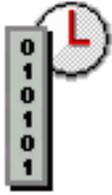

The temporary bitmap is a temporary object that allows the optimizer to sequence rows based upon their row address (their row number). The bitmap can be either scanned or probed by the optimizer to satisfy different operations of the query.

A temporary bitmap is a data structure that uses a bitmap to represent all the row numbers for a table. Since each row is represented by a separate bit, all the rows within a table can be represented in a fairly condensed form. When a row is selected, the bit within the bitmap that corresponds to the selected row is set on. After the temporary bitmap is populated, all the selected rows can be retrieved in a sorted manner for quick and efficient retrieval. The temporary bitmap only represents the row number for the associated selected rows.

No table data is present within the temporary bitmap. A table probe operation is typically associated with the bitmap in order to retrieve the underlying table data. Because the bitmap is by definition sorted, the random I/O associated with the table probe operation can be performed more efficiently. The database manager performs pre-fetch or look-ahead logic to determine if multiple rows are located on adjacent pages. If so, the table probe requests a larger I/O to bring the rows into main memory more efficiently.

A temporary bitmap is an internal data structure and can only be created by the database manager.

Visual explain icon:

Bitmap scan

During a bitmap scan operation, the entire temporary bitmap is scanned and all the row addresses contained within the bitmap are processed. The optimizer considers this plan when there is an applicable encoded vector index or if the index probe or scan random I/O can be reduced. The random I/O can be reduced by first preprocessing and sorting the row numbers associated with the Table Probe.

The use of a bitmap scan allows the optimizer to generate a plan that can take advantage of multiple indexes to match up to different portions of the query.

An additional benefit is that the data structure of the temporary bitmap guarantees that the row numbers are sorted. It closely mirrors the row number layout of the table data, ensuring that the table paging never visits the same page of data twice. This results in increased I/O savings for the query.

A bitmap scan is identical to a row number list scan operation. The only difference is that the list scan is over a list of row addresses while the bitmap scan is over a bitmap representing the addresses.

<i>Table 20. Bitmap scan attributes</i>	
Data access method	Bitmap scan attributes
Description	Sequentially scan and process all the row numbers in the temporary bitmap. The sorted row numbers can be merged with other temporary bitmaps or can be used as input into a Table Probe operation.
Advantages	<ul style="list-style-type: none"> • The temporary bitmap only contains a reference to a row address, no data, so the temporary can be efficiently scanned within memory. • The row numbers represented within the temporary object are sorted to provide efficient I/O processing to access the underlying table. • Selection is performed as the bitmap is generated to subset the number of selected rows in the temporary object.
Considerations	Since the bitmap contains only the addresses of the selected rows in the table, a separate Table Probe fetches the table rows.
Likely to be used	<ul style="list-style-type: none"> • When the use of temporary results is allowed by the query environmental parameter (ALWCOPYDTA). • When the cost of sorting of the row numbers is justified by the more efficient I/O that can be performed during the Table Probe operation. • When multiple indexes over the same table need to be combined in order to minimize the number of selected rows.

Database Monitor and Plan Cache record indicating use	QQRID 3001 and QQRID 3021 records for each index used. The QQC11 field in the 3021 record will be 'B'. A QQRID 3000 record with QQC11 (Skip_Sequential_Table_Scan) = 'Y'. Optionally, QQRID 3022 records if bitmap merging occurred.
SMP parallel enabled	Yes
Also referred to as	Bitmap Scan, Preload Row Number Bitmap Scan Row Number Bitmap Scan, Preload Skip Sequential Scan
Visual Explain icon	

Using the example above, the optimizer created a temporary bitmap for each of the indexes used by this query. These indexes included a radix index and two encoded vector indexes. Each index temporary bitmap was scanned and merged into a final composite bitmap representing the intersection of all the index temporary bitmaps. The final bitmap is then used by the Table Probe operation to determine which rows are selected and processed for the query results.

Bitmap probe

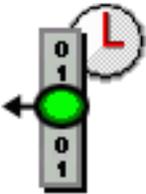

A bitmap probe operation is used to test row numbers generated by a separate operation against the selected rows of a temporary bitmap. The row numbers can be generated by any operation that constructs a row number for a table. That row number is then used to probe into a temporary bitmap to determine if it matches the selection used to generate the bitmap.

The use of a bitmap probe operation allows the optimizer to generate a plan that can take advantage of any sequencing provided by an index, but still use the bitmap to perform additional selection before any Table Probe operations.

A bitmap probe is identical to a row number list probe operation. The only difference is that the list probe is over a list of row addresses while the bitmap probe is over a bitmap representing the addresses.

<i>Table 21. Bitmap probe attributes</i>	
Data access method	Bitmap probe attributes
Description	The temporary bitmap is quickly probed based upon the row number generated by a separate operation.
Advantages	<ul style="list-style-type: none"> • The temporary bitmap only contains a reference to a row address, no data, so the temporary can be efficiently probed within memory. • The row numbers represented within the bitmap are sorted to provide efficient lookup processing to test the underlying table. • Selection is performed as the bitmap is generated to subset the number of selected rows in the temporary object.

Table 21. Bitmap probe attributes (continued)

Data access method	Bitmap probe attributes
Considerations	Since the bitmap contains only the addresses of the selected rows in the table, a separate Table Probe fetches the table rows.
Likely to be used	<ul style="list-style-type: none"> • When the use of temporary results is allowed by the query environmental parameter (ALWCPYDTA). • When the cost of creating and probing the bitmap is justified by reducing the number of Table Probe operations that must be performed. • When multiple indexes over the same table need to be combined in order to minimize the number of selected rows.
Example SQL statement	<pre>CREATE INDEX X1 ON Employee (WorkDept) CREATE ENCODED VECTOR INDEX EVI2 ON Employee (Salary) CREATE ENCODED VECTOR INDEX EVI3 ON Employee (Job) SELECT * FROM Employee WHERE WorkDept = 'E01' AND Job = 'CLERK' AND Salary = 5000 ORDER BY WorkDept</pre>
Database Monitor and Plan Cache record indicating use	<p>QQRID 3001 and QQRID 3021 records for each index used.</p> <p>The QQC11 field in the 3021 record will be 'BL'.</p> <p>Optionally, QQRID 3022 records if bitmap merging occurred.</p>
SMP parallel enabled	Yes
Also referred to as	<p>Bitmap Probe, Preload</p> <p>Row Number Bitmap Probe</p> <p>Row Number Bitmap Probe, Preload</p>
Visual Explain icon	

Using the example above, the optimizer created a temporary bitmap for each of the encoded vector indexes. Additionally, an index probe operation was performed against the radix index X1 to satisfy the ordering requirement. Since the ORDER BY requires that the resulting rows be sequenced by the WorkDept column, the bitmap cannot be scanned for the selected rows.

However, the temporary bitmap can be probed using a row address extracted from the index X1 used to satisfy the ordering. By probing the bitmap with the row address extracted from the index probe, the sequencing of the keys in the index X1 is preserved. The row can still be tested against the selected rows within the bitmap.

Temporary index

A temporary index is a temporary object that allows the optimizer to create and use a radix index for a specific query. The temporary index has all the same attributes and benefits as a radix index created through the CREATE INDEX SQL statement or **Create Logical File (CRTLF)** CL command.

Additionally, the temporary index is optimized for use by the optimizer to satisfy a specific query request. This optimization includes setting the logical page size and applying any selection to the index to speed up its use after creation.

The temporary index can be used to satisfy various query requests:

- Ordering
- Grouping/Distinct
- Joins
- Record selection

Generally a temporary index is a more expensive temporary object to create than other temporary objects. It can be populated by a table scan, or by one or more index scans or probes. The optimizer considers all the methods available when determining which method to use to produce the rows for the index creation. This process is like the costing and selection of the other temporary objects used by the optimizer.

One significant advantage of the temporary index over other temporary objects is that it is the only temporary object maintained if the underlying table changes. The temporary index is identical to a radix index in that any inserts or updates against the table are reflected immediately through normal index maintenance.

SQE usage of temporary indexes is different from CQE usage in that SQE allows reuse. References to temporary indexes created and used by the SQE optimizer are kept in the system Plan Cache. A temporary index is saved for reuse by other instances of the same query or other instances of the same query running in a different job. It is also saved for potential reuse by a different query that can benefit from the use of the same temporary index.

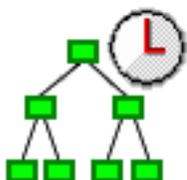

By default, an SQE temporary index persists until the Plan Cache entry for the last referencing query plan is removed. With the SQE Plan Cache auto sizing capability, there is the potential for SQE temporary indexes to persist longer. You can control this behavior by setting the CACHE_RESULTS QAQQINI value. The default for this INI value allows the optimizer to keep temporary indexes around for reuse.

Changing the INI value to '*JOB' prevents the temporary index from being saved in the Plan Cache; the index does not survive a hard close. The *JOB option causes the SQE optimizer use of temporary indexes to behave more like the CQE optimizer. The temporary index has a shorter life, but is still shared as long as there are active queries using it. This behavior can be desirable in cases where there is concern about increased maintenance costs for temporary indexes that persist for reuse.

A SQE temporary index can also be used as a source of statistics.

A temporary index is an internal data structure and can only be created by the database manager.

Visual explain icon:

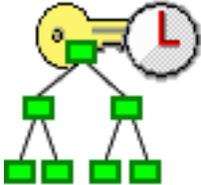

Temporary index scan

A temporary index scan operation is identical to the index scan operation that is performed upon the permanent radix index. It is still used to retrieve the rows from a table in a keyed sequence; however, the

temporary index object must first be created. All the rows in the index are sequentially processed, but the resulting row numbers are sequenced based upon the key columns.

The sequenced rows can be used by the optimizer to satisfy a portion of the query request (such as ordering or grouping).

<i>Table 22. Temporary index scan attributes</i>	
Data access method	Temporary index scan
Description	Sequentially scan and process all the keys associated with the temporary index.
Advantages	<ul style="list-style-type: none"> • Potential to extract all the data from the index key values, thus eliminating the need for a Table Probe • Returns the rows back in a sequence based upon the keys of the index
Considerations	Generally requires a Table Probe to be performed to extract any remaining columns required to satisfy the query. Can perform poorly when many rows are selected because of the random I/O associated with the Table Probe.
Likely to be used	<ul style="list-style-type: none"> • When sequencing the rows is required for the query (for example, ordering or grouping) • When the selection columns cannot be matched against the leading key columns of the index • When the overhead cost associated with the creation of the temporary index can be justified against other alternative methods to implement this query
Example SQL statement	<pre>SELECT * FROM Employee WHERE WorkDept BETWEEN 'A01' AND 'E01' ORDER BY LastName OPTIMIZE FOR ALL ROWS</pre>
Database Monitor and Plan Cache record indicating use	QQRID 3002 record and QQRID 3001 where QQKP(Index_Probe_Used) = 'N'.
SMP parallel enabled	Yes
Also referred to as	Index Scan Index Scan, Preload Index Scan, Distinct Index Scan Distinct, Preload Index Scan, Key Selection
Visual Explain icon	

Using the example above, the optimizer chose to create a temporary index to sequence the rows based upon the LastName column. A temporary index scan might then be performed to satisfy the ORDER BY clause in this query.

The optimizer determines where the selection against the WorkDept column best belongs. It can be performed as the temporary index itself is being created or it can be performed as a part of the temporary index scan. Adding the selection to the temporary index creation has the possibility of making the open data path (ODP) for this query non-reusable. This ODP reuse is considered when determining how selection is performed.

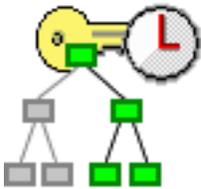

Temporary index probe

A temporary index probe operation is identical to the index probe operation that is performed on the permanent radix index. Its main function is to provide quick access against the index keys of the temporary index. However, it can still be used to retrieve the rows from a table in a keyed sequence.

The temporary index is used by the optimizer to satisfy the join portion of the query request.

<i>Table 23. Temporary index probe attributes</i>	
Data access method	Temporary index probe
Description	The index is quickly probed based upon the selection criteria that were rewritten into a series of ranges. Only those keys that satisfy the selection is used to generate a table row number.
Advantages	<ul style="list-style-type: none"> • Only those index entries that match any selection continue to be processed. Provides quick access to the selected rows • Potential to extract all the data from the index key values, thus eliminating the need for a Table Probe • Returns the rows back in a sequence based upon the keys of the index
Considerations	Generally requires a Table Probe to be performed to extract any remaining columns required to satisfy the query. Can perform poorly when many rows are selected because of the random I/O associated with the Table Probe.
Likely to be used	<ul style="list-style-type: none"> • When the ability to probe the rows required for the query (for example, joins) exists • When the selection columns cannot be matched against the leading key columns of the index • When the overhead cost associated with the creation of the temporary index can be justified against other alternative methods to implement this query
Example SQL statement	<pre>SELECT * FROM Employee XXX, Department YYY WHERE XXX.WorkDept = YYY.DeptNo OPTIMIZE FOR ALL ROWS</pre>
Database Monitor and Plan Cache record indicating use	QQRID 3002 record and QQRID 3001 where QQKP(Index_Probe_Used) = 'Y'.
SMP parallel enabled	Yes

Table 23. Temporary index probe attributes (continued)

Data access method	Temporary index probe
Also referred to as	Index Probe Index Probe, Preload Index Probe, Distinct Index Probe Distinct, Preload Index Probe, Key Selection
Visual Explain icon	

Using the example above, the optimizer chose to create a temporary index over the DeptNo column to help satisfy the join requirement against the DEPARTMENT table. A temporary index probe was then performed against the temporary index to process the join criteria between the two tables. In this particular case, there was no additional selection that might be applied against the DEPARTMENT table while the temporary index was being created.

Temporary buffer

The temporary buffer is a temporary object that is used to help facilitate operations such as parallelism. It is an unsorted data structure that is used to store intermediate rows of a query. The difference between a temporary buffer and a temporary list is that the buffer does not need to be fully populated before its results are processed.

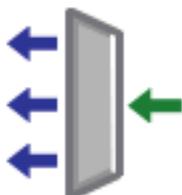

The temporary buffer acts as a serialization point between parallel and non-parallel portions of a query. The operations used to populate the buffer cannot be performed in parallel, whereas the operations that fetch rows from the buffer can be performed in parallel.

The temporary buffer is required for SQE because the index scan and index probe operations are not SMP parallel-enabled for this engine. Unlike CQE, which performs these index operations in parallel, SQE does not subdivide the index operation work to take full advantage of parallel processing.

The buffer is used to allow a query to be processed under parallelism by serializing access to the index operations. Any remaining work within the query is processed in parallel.

A temporary buffer is an internal data structure and can only be created by the database manager.

Visual explain icon:

Buffer scan

The buffer scan is used when a query is processed using Db2 Symmetric Multiprocessing, yet a portion of the query is unable to be parallel processed. The buffer scan acts as a gateway to control access to rows between the parallel enabled portions of the query and the non-parallel portions.

Multiple threads can be used to fetch the selected rows from the buffer, allowing the query to perform any remaining processing in parallel. However, the buffer is populated in a non-parallel manner.

A buffer scan operation is identical to the list scan operation that is performed upon the temporary list object. The main difference is that a buffer does not need to be fully populated before the start of the scan operation. A temporary list requires that the list is fully populated before fetching any rows.

<i>Table 24. Buffer scan attributes</i>	
Data access method	Buffer scan
Description	Sequentially scan and process all the rows in the temporary buffer. Enables SMP parallelism to be performed over a non-parallel portion of the query.
Advantages	<ul style="list-style-type: none"> • The temporary buffer can be used to enable parallelism over a portion of a query that is non-parallel • The temporary buffer does not need to be fully populated in order to start fetching rows
Considerations	Used to prevent portions of the query from being processed multiple times when no key columns are required to satisfy the request.
Likely to be used	<ul style="list-style-type: none"> • When the query is attempting to take advantage of Db2 Symmetric Multiprocessing • When a portion of the query cannot be performed in parallel (for example, index scan or index probe)
Example SQL statement	<pre>CHGQRYA DEGREE(*OPTIMIZE) CREATE INDEX X1 ON Employee (LastName, WorkDept) SELECT * FROM Employee WHERE WorkDept BETWEEN 'A01' AND 'E01' AND LastName IN ('Smith', 'Jones', 'Peterson') OPTIMIZE FOR ALL ROWS</pre>
Database Monitor and Plan Cache record indicating use	QVPARU will be greater than 0 on the associated database monitor record.
SMP parallel enabled	Yes
Also referred to as	Not applicable
Visual Explain icon	

Using the example above, the optimizer chose to use the existing index X1 to perform an index probe operation against the table. In order to speed up the remaining Table Probe operation for this query, Db2 Symmetric Multiprocessing is used to perform the random probe into the table. Since the index probe is not SMP parallel-enabled for SQE, it is placed within a temporary buffer to control access to the selected index entries.

Queue

The Queue is a temporary object that the optimizer uses to feed recursion by putting data values needed for the recursion on it. This data typically includes those values used on the recursive join predicate, and other recursive data accumulated or manipulated during the recursive process.

The Queue has two operations allowed:

- Enqueue: puts data on the queue
- Dequeue: takes data off the queue

A queue is an efficient data structure because it contains only the data needed to feed the recursion or directly modified by the recursion process. Its size is managed by the optimizer.

Unlike other temporary objects created by the optimizer, the queue is not populated all at once by the underlying query node tree. It is a real-time temporary holding area for values feeding the recursion. In this regard, a queue is not considered temporary, as it does not prevent the query from running if ALWCPYDTA(*NO) was specified. The data can flow from the query at the same time the recursive values are inserted into the queue and used to retrieve additional join rows.

A queue is an internal data structure and can only be created by the database manager.

Visual explain icon:

Enqueue

During an enqueue operation, an entry is put on the queue. The entry contains key values used by the recursive join predicates or data manipulated as a part of the recursion process. The optimizer always supplies an enqueue operation to collect the required recursive data on the query node directly above the Union All.

<i>Table 25. Enqueue Attributes</i>	
Data Access Method	Enqueue
Description	Places an entry on the queue needed to cause further recursion
Advantages	<ul style="list-style-type: none"> • Required as a source for the recursion. Only enqueues required values for the recursion process. Each entry has short life span, until it is dequeued. • Each entry on the queue can seed multiple iterative fullselects that are recursive from the same RCTE or view.
Likely to be used	A required access method for recursive queries
Example SQL statement	<pre>WITH RPL (PART, SUBPART, QUANTITY) AS (SELECT ROOT.PART, ROOT.SUBPART, ROOT.QUANTITY FROM PARTLIST ROOT WHERE ROOT.PART = '01' UNION ALL SELECT CHILD.PART, CHILD.SUBPART, CHILD.QUANTITY FROM RPL PARENT, PARTLIST CHILD WHERE PARENT.SUBPART = CHILD.PART) SELECT DISTINCT PART, SUBPART, QUANTITY FROM RPL</pre>
Database Monitor and Plan Cache record indicating use	There are no explicit records that indicate the use of an enqueue
SMP parallel enabled	Yes
Also referred to as	Not applicable

Table 25. Enqueue Attributes (continued)

Data Access Method	Enqueue
Visual Explain icon	

Use the CYCLE option in the definition of the recursive query if the data reflecting the parent-child relationship could be cyclic, causing an infinite recursion loop. CYCLE prevents already visited recursive key values from being put on the queue again for a given set of related (ancestry chain) rows.

Use the SEARCH option in the definition of the recursive query to return the results of the recursion in the specified parent-child hierarchical ordering. The search choices are Depth or Breadth first. Depth first means that all the descendents of each immediate child are returned before the next child is returned. Breadth first means that each child is returned before their children are returned.

SEARCH requires not only the specification of the relationship keys, the columns which make up the parent-child relationship, and the search type of Depth or Breadth. It also requires an ORDER BY clause in the main query on the provided sequence column in order to fully implement the specified ordering.

Dequeue

During a dequeue operation, an entry is taken off the queue. Those values specified by recursive reference are fed back in to the recursive join process.

The optimizer always supplies a corresponding enqueue, dequeue pair of operations for each recursive common table expression or recursive view in the specifying query. Recursion ends when there are no more entries to pull off the queue.

Table 26. Dequeue Attributes

Data Access Method	Dequeue
Description	Removes an entry off the queue. Minimally, provides one side of the recursive join predicate that feeds the recursive join and other data values that are manipulated through the recursive process. The dequeue operation is always on the left side of the inner join with constraint, where the right side is the target child rows.
Advantages	<ul style="list-style-type: none"> • Provides quick access to recursive values • Allows for post selection of local predicate on recursive data values
Likely to be used	<ul style="list-style-type: none"> • A required access method for recursive queries • A single dequeued value can feed the recursion of multiple iterative fullselects that reference the same RCTE or view
Example SQL statement	<pre> WITH RPL (PART, SUBPART, QUANTITY) AS (SELECT ROOT.PART, ROOT.SUBPART, ROOT.QUANTITY FROM PARTLIST ROOT WHERE ROOT.PART = '01' UNION ALL SELECT CHILD.PART, CHILD.SUBPART, CHILD.QUANTITY FROM RPL PARENT, PARTLIST CHILD WHERE PARENT.SUBPART = CHILD.PART) SELECT DISTINCT PART, SUBPART, QUANTITY FROM RPL </pre>

<i>Table 26. Dequeue Attributes (continued)</i>	
Data Access Method	Dequeue
Database Monitor and Plan Cache record indicating use	There are no explicit records that indicate the use of the dequeue operation.
SMP parallel enabled	Yes
Also referred to as	Not applicable
Visual Explain icon	

Array unnest temporary table

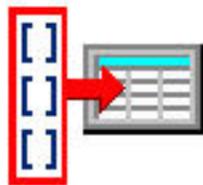

The array unnest temporary table is a temporary object that holds the output of an UNNEST of an array or a list of arrays. It can be viewed vertically, with each column of array values having the same format. The temporary table contains one or more arrays specified by the user in an UNNEST clause of a SELECT statement.

UNNEST creates a temporary table with the arrays specified as columns in the table. If more than one array is specified, the first array provides the first column in the result table. The second array provides the second column, and so on.

The arrays might be of different lengths. Shorter arrays are primed with nulls to match the length of the longest array in the list.

If WITH ORDINALITY is specified, an extra counter column of type BIGINT is appended to the temporary table. The ordinality column contains the index position of the elements in the arrays.

The array unnest temporary table is an internal data structure and can only be created by the database manager.

Visual Explain icon	

Temporary Indexed List

The temporary indexed list is a temporary object that allows the optimizer to sequence rows based upon a column or set of columns. The temporary indexed list can be scanned by the optimizer to satisfy ordering or grouping requirements of the query.

A temporary indexed list is a data structure that contains a radix index object to provide ordering. This object is generally used when a query contains ordering and non-equal predicates and only a partial answer set is fetched. The object is initially populated with a distinct set of values by distinct scanning or probing an existing index. As processing continues and more rows are needed, additional rows will be inserted into the temporary indexed list for additional processing.

If the underlying index used to build the temporary indexed list contains all the necessary columns to satisfy any further processing, then these columns are built into the temporary indexed list. This population avoids any random I/Os associated with a table probe operation. If the underlying index does not contain all the necessary columns, then a table probe operation is required to recollect the missing columns from the temporary indexed list before the selected rows can be processed.

A temporary indexed list is an internal data structure and can only be created by the database manager. The temporary indexed list is always used in conjunction with the temporary indexed list scan and index merge data access methods.

Visual explain icon:

Temporary Indexed List scan and Index Merge

A temporary indexed list scan operation is similar to the index scan operation that is performed upon the permanent radix index. It is still used to retrieve the rows from a table in a keyed sequence; however, the temporary indexed list object must first be created. This operation is often performed in conjunction with an index merge operation. However, for some distinct and grouping queries, the temporary indexed list scan may be used without an associated index merge operation.

This access method is used when there is non-equal selection and is used in conjunction with an existing permanent radix index. A distinct index scan or a distinct index probe operation is performed against the index to get a unique set of rows. The rows are then inserted into the temporary indexed list to provide the appropriate ordering.

In general, for a radix index to be eligible for temporary list scan and Index Merge Ordering, the index should be created as follows:

- Any columns with equal predicates that are not in the ORDER BY list should be first keys in the index.
- Followed by any columns for non-equal predicates that are not in the ORDER BY list. The columns should be arranged so the most selective predicate column is the first column following the equal predicate columns.
- Followed by the ORDER BY columns in the same order as the ORDER BY clause of the query and with the same ASC or DESC attribute.
- Optionally, at the end you may include other selection columns or other selected columns for Index Only Access.

A temporary sorted list is an internal data structure and can only be created by the database manager.

<i>Table 28. Temporary indexed list scan</i>	
Data access method	Temporary indexed list scan
Description	Sequentially scan and process all the keys associated with the temporary indexed list.
Advantages	<ul style="list-style-type: none"> • Provides an alternate implementation to order data when the query contains non-equal where selection. • Returns the rows back in a sequence based upon the keys of the index. • Provides better paging characteristics than a sorted list scan in low memory environments. • Provides better performance characteristics than a Sorted List Scan when only a partial answer set is fetched.
Considerations	Used to process ordering, grouping or distinct processing for a single table query.

Table 28. Temporary indexed list scan (continued)

Data access method	Temporary indexed list scan
Likely to be used	<ul style="list-style-type: none"> • When the use of temporary results is allowed by the query environmental parameter (ALWCPYDTA). • When the data is required to be ordered or grouped based upon a column or columns and the query contains non-equal where selection. • The query is being optimized for FIRST I/O. • The number of distinct values is low.
Example SQL statement	<pre>CREATE INDEX INDEX1 ON EMPLOYEE(SALARY, WORKDEPT) SELECT DISTINCT WORKDEPT FROM EMPLOYEE WHERE SALARY > 30000 OPTIMIZE FOR 30 ROWS</pre>
Database Monitor and Plan Cache record indicating use	QQRID 3001 where QQRCOD = 'I7'
SMP parallel enabled	No
Also referred to as	
Visual Explain icon	

Using the example above, the optimizer chose to create a temporary indexed list of distinct WORKDEPT values from index INDEX1. The selection SALARY > 3000 was applied to the index probe distinct.

Index Merge:

An index merge operation is used to provide ordering in conjunction with a temporary indexed list scan and an index probe distinct or distinct index.

The sequenced rows can be used by the optimizer to satisfy a portion of the query request (such as ordering or grouping).

Table 29. Index Merge

Data access method	Index Merge
Description	Sequentially scan and process all the keys associated with the temporary indexed list.
Advantages	<ul style="list-style-type: none"> • Potential to extract all the data from the index key values, thus eliminating the need for a Table Probe. • Returns the rows back in a sequence based upon the keys of the index.

Table 29. Index Merge (continued)

Data access method	Index Merge
Considerations	Used to process ordering, grouping or distinct processing for a single table query.
Likely to be used	<ul style="list-style-type: none"> • When the use of temporary results is allowed by the query environmental parameter (ALWCPYDTA). • When the data is required to be ordered or grouped based upon a column or columns and the query contains non-equal where selection. • The query is being optimized for FIRST I/O. • The number of distinct values is low.
Example SQL statement	<pre>CREATE INDEX IX1 ON Sales(Sales_date, Region, Sales_person) SELECT * FROM Sales WHERE Sales_date BETWEEN '1996-03-29' AND '1996-04-29' AND Region IN ('Quebec','Manitoba') ORDER BY Sales_person;</pre>

Visual Explain icon	

Window

The window is a temporary object that holds intermediate results needed to determine the result for On-Line Analytical Processing (OLAP) functions. The number of rows in the window may change as the data flows through it.

The window is an internal data structure and can only be created by the database manager.

Visual explain icon:

Window scan

During processing of an OLAP function the window may be processed multiple time in order to determine the result of the OLAP function for each row

Table 30. Window scan attributes	
Data access method	Window scan
Description	Sequentially scan and process all the rows needed to determine the result of the OLAP function.
Advantages	<ul style="list-style-type: none">Allows the database manager to process subsets of the data to calculate the OLAP result without processing the entire result set for each row.
Considerations	Required for OLAP specifications that require intermediate results to determine the value of the OLAP expression. The OLAP specifications that require a window include any of the aggregate OLAPs, LAG, LEAD, NTILE, and CUME_DIST.
Likely to be used	Required for OLAP specifications that require intermediate results to determine the value of the OLAP expression.
Example SQL statement	<pre>SELECT workdept, empno, salary, decimal(avg(salary) over(partition by workdept order by salary), 10,2) FROM employee</pre>
Database Monitor and Plan Cache record indicating use	QQRID 3004 where QQRCD = 'H8'.
SMP parallel enabled	No
Also referred to as	
Visual Explain icon	

Objects processed in parallel

The Db2 Symmetric multiprocessing feature provides the optimizer with additional methods for retrieving data that include parallel processing. Symmetrical multiprocessing is a form of parallelism achieved on a single system where multiple CPU and I/O processors sharing memory and disk work simultaneously toward a single result.

This parallel processing means that the database manager can have more than one (or all) of the system processors working on a single query simultaneously. The performance of a CPU-bound query can be improved with this feature on multiple-processor systems by distributing the processor load across more than one processor.

The preceding tables indicate what data access methods are enabled to take advantage of the Db2 Symmetric Multiprocessing feature. An important thing to note, however, is that the parallel implementation differs for both the SQL Query Engine and the Classic Query Engine.

Processing requirements

Parallelism requires that SMP parallel processing must be enabled by one of the following methods:

- System value QQRDEGREE

- Query option file
- DEGREE parameter on the **Change Query Attributes (CHGQRYA)** command
- SQL SET CURRENT DEGREE statement

Once parallelism has been enabled, a set of database system tasks or threads is created at system startup for use by the database manager. The database manager uses the tasks to process and retrieve data from different disk devices. Since these tasks can be run on multiple processors simultaneously, the elapsed time of a query can be reduced. Even though the tasks do much of the parallel I/O and CPU processing, the I/O and CPU resource accounting is transferred to the application job. The summarized I/O and CPU resources for this type of application continue to be accurately displayed by the **Work with Active Jobs (WRKACTJOB)** command.

The job must be run in a shared storage pool with the *CALC paging option, as this method causes more efficient use of active memory.

Related concepts

[Nested loop join implementation](#)

Db2 for i provides a **nested loop** join method. For this method, the processing of the tables in the join are ordered. This order is called the **join order**. The first table in the final join order is called the **primary table**. The other tables are called **secondary tables**. Each join table position is called a **dial**.

Spreading data automatically

Db2 for i automatically spreads the data across the disk devices available in the auxiliary storage pool (ASP) where the data is allocated. This process ensures that the data is spread without user intervention.

The spreading allows the database manager to easily process the blocks of rows on different disk devices in parallel. Even though Db2 for i spreads data across disk devices within an ASP, sometimes the allocation of the data extents (contiguous sets of data) might not be spread evenly. This unevenness occurs when there is uneven allocation of space on the devices, or when a new device is added to the ASP. The allocation of the table data space could be spread again by saving, deleting, and then restoring the table.

Maintaining an even distribution of data across all the disk devices can lead to better throughput on query processing. The number of disk devices used and how the data is spread across them is considered by the optimizer while costing the different plan permutations.

Processing queries: Overview

This overview of the query optimizer provides guidelines for designing queries that perform and use system resources more efficiently.

This overview covers queries that are optimized by the query optimizer and includes interfaces such as SQL, OPNQRYF, APIs (QQQRY), ODBC, and Query/400 queries. Whether you apply the guidelines, the query results are still correct.

Note: The information in this overview is complex. You might find it helpful to experiment with an IBM i product as you read this information to gain a better understanding of the concepts.

When you understand how Db2 for i processes queries, it is easier to understand the performance impacts of the guidelines discussed in this overview. There are two major components of Db2 for i query processing:

- How the system accesses data.

These methods are the algorithms that are used to retrieve data from the disk. The methods include index usage and row selection techniques. In addition, parallel access methods are available with the Db2 Symmetric Multiprocessing operating system feature.

- Query optimizer

The query optimizer identifies the valid techniques which can be used to implement the query and selects the most efficient technique.

How the query optimizer makes your queries more efficient

Data manipulation statements such as SELECT specify only what data the user wants, not how to retrieve that data. This path to the data is chosen by the optimizer and stored in the access plan. Understand the techniques employed by the query optimizer for performing this task.

The optimizer is an important part of Db2 for i because the optimizer:

- Makes the key decisions which affect database performance.
- Identifies the techniques which can be used to implement the query.
- Selects the most efficient technique.

General query optimization tips

Here are some tips to help your queries run as fast as possible.

- Create indexes whose leftmost key columns match your selection predicates to help supply the optimizer with selectivity values (key range estimates).
- For join queries, create indexes that match your join columns to help the optimizer determine the average number of matching rows.
- Minimize extraneous mapping by specifying only columns of interest on the query. For example, specify only the columns you need to query on the SQL SELECT statement instead of specifying SELECT *. Also, specify FOR FETCH ONLY if the columns do not need to be updated.
- If your queries often use table scan, use the **Reorganize Physical File Member (RGZPFM)** command to remove deleted rows from tables, or the **Change Physical File (CHGPF) REUSEDLT (*YES)** command to reuse deleted rows.

Consider using the following options:

- Specify ALWCOPYDTA(*OPTIMIZE) to allow the query optimizer to create temporary copies of data so better performance can be obtained. The IBM i Access ODBC driver and Query Management driver always use this mode. If ALWCOPYDTA(*YES) is specified, the query optimizer attempts to implement the query without copies of the data, but might create copies if required. If ALWCOPYDTA(*NO) is specified, copies of the data are not allowed. If the query optimizer cannot find a plan that does not use a temporary, then the query cannot be run.
- For SQL, use CLOSQLCSR(*ENDJOB) or CLOSQLCSR(*ENDACTGRP) to allow open data paths to remain open for future invocations.
- Specify DLYPRP(*YES) to delay SQL statement validation until an OPEN, EXECUTE, or DESCRIBE statement is run. This option improves performance by eliminating redundant validation.
- Use ALWBLK(*ALLREAD) to allow row blocking for read-only cursors.

Related information

[Reorganize Physical File Member \(RGZPFM\) command](#)

Access plan validation

An access plan is a control structure that describes the actions necessary to satisfy each query request. It contains information about the data and how to extract it. For any query, whenever optimization occurs, the query optimizer develops an optimized plan of how to access the requested data.

To improve performance, an access plan is saved once it is built (see following exceptions), to be available for potentially future runs of the query. However, the optimizer has dynamic replan capability. This means that even if a previously built (and saved) plan is found, the optimizer could rebuild it if a more optimal plan is possible. This process allows for maximum flexibility while still taking advantage of saved plans.

- For dynamic SQL, an access plan is created at prepare or open time. However, optimization uses the host variable values to determine an optimal plan. Therefore, a plan built at prepare time could be rebuilt the first time the query is opened (when the host variable values are present).
- For an IBM i program that contains static embedded SQL, an access plan is initially created at compile time. Again, since optimization uses the host variable values to determine an optimal plan, the compile-time plan could be rebuilt the first time the query is opened.
- For Open Query File (OPNQRYF), an access plan is created but is not saved. A new access plan is created each time the OPNQRYF command is processed.
- For Query/400, an access plan is saved as part of the query definition object.

In all the preceding cases where a plan is saved, including static SQL, dynamic replan can still apply as the queries are run over time.

The access plan is validated when the query is opened. Validation includes the following:

- Verifying that the same tables are referenced in the query as in the access plan. For example, the tables were not deleted and recreated or that the tables resolved by using *LIBL have not changed.
- Verifying that the indexes used to implement the query, still exist.
- Verifying that the table size or predicate selectivity has not changed significantly.
- Verifying that QAQQINI options have not changed.

Single table optimization

At run time, the optimizer chooses an optimal access method for a query by calculating an *implementation cost* based on the current state of the database. The optimizer uses two costs in its decision: an I/O cost and a CPU cost. The goal of the optimizer is to minimize both I/O and CPU cost.

Improved query optimization I/O cost estimates

The time it takes to perform a disk I/O operation can vary according to the connecting infrastructure, the external or internal nature of the media and media type, spinning disk or Solid State Disk. Consequently, the total I/O cost associated with a particular query access method may vary from system to system.

In order to more accurately estimate these costs, the optimizer considers the performance of each disk unit individually. It does this by measuring the time it takes for read operations to complete across a sample of pages across the disk. This analysis is done at each IPL for disks in the system and user ASPs and at vary-on time for independent ASPs. With this information and with the additional knowledge about how database objects are spread across various disk units, the optimizer can make a reasonable estimate about the time it takes to perform I/O against a given database object. This means that no matter where your data resides, and even as it moves around, the optimizer can choose the most efficient plan to execute your queries.

Optimizing Access to each table

The optimizer uses a general set of guidelines to choose the best method for accessing data in each table. The optimizer:

- Determines the default filter factor for each predicate in the selection clause.
- Determines the true filter factor of the predicates by key range estimate when the selection predicates match the index left-most keys, or by available column statistics.
- Determines the cost of table scan processing if an index is not required.
- Determines the cost of creating an index over a table if an index is required. This index is created by performing either a table scan or creating an index-from-index.
- Determines the cost of using a sort routine or hashing method if appropriate.
- Determines the cost of using existing indexes using Index Probe or Index Scan
 - Orders the indexes. For SQE, the indexes are ordered in general such that the indexes that access the smallest number of entries are examined first. For CQE, the indexes are ordered from mostly recently created to oldest.
 - For each index available, the optimizer does the following:
 - Determines if the index meets the selection criteria.
 - Determines the cost of using the index by estimating the number of I/Os and CPU needed to Index Probe or Index Scan, and possible Table Probes.
 - Compares the cost of using this index with the previous cost (current best).
 - Picks the cheaper one.
 - Continues to search for best index until the optimizer decides to look at no more indexes.

SQE orders the indexes so that the best indexes are examined first. Once an index is found that is more expensive than the previously chosen best index, the search is ended.

For CQE, the *time limit* controls how much time the optimizer spends choosing an implementation. The time limit is based on how much time was spent so far and the current best implementation cost found. The idea is to prevent the optimizer from spending more time optimizing the query than it takes to actually execute the query. Dynamic SQL queries are subject to the optimizer time restrictions. Static SQL query optimization time is not limited. For OPNQRYF, if you specify OPTALLAP(*YES), the optimization time is not limited.

For small tables, the query optimizer spends little time in query optimization. For large tables, the query optimizer considers more indexes. For CQE, the optimizer generally considers five or six indexes for each table of a join before running out of optimization time. Because of this processing, it is normal for the optimizer to spend longer lengths of time analyzing queries against the tables.

- Determines the cost of using a temporary bitmap
 - Order the indexes that can be used for bit mapping. In general the indexes that select the smallest number of entries are examined first.
 - Determine the cost of using this index for bit mapping and the cost of merging this bitmap with any previously generated bitmaps.
 - If the cost of this bitmap plan is cheaper than the previous bitmap plan, continue searching for bitmap plans.
- After examining the possible methods of access the data for the table, the optimizer chooses the best plan from all the plans examined.

Solid State Drives

Solid State Drives (SSDs) offer a number of advantages over traditional hard disk drives (HDDs)

Solid State Drives

Solid State Drives (SSDs) offer a number of advantages over traditional hard disk drives (HDDs). With no seek time or rotational delays, SSDs can deliver substantially better I/O performance than HDDs. Capable of driving tens of thousands of I/O operations per second as opposed to hundreds for HDDs, SSDs break through performance bottlenecks of I/O-bound applications. Applications that require dozens and dozens

of “extra” HDDs for performance can meet their I/O performance requirements with far fewer SSDs, resulting in energy, space, and cost savings.

As IBM i has its own storage manager and Db2 for i built in, the integration of SSDs on IBM i is a fairly simple task. The functions provided for management of SSDs and adjusting their impact on Applications and Database are very simple and easy to use.

There are three basic methodologies to place data on SSD.

- ASP Balancer – Enhanced for SSDs
- Library and SSD Integration
- Db2 and SSD Integration

To allow you to specify what data should be allocated on SSD, Db2 has provided the capability to specify a “media preference” as an attribute of a database table, partition, or index. It should be noted that this attribute specifies that storage allocations on SSD are preferred, but if no SSD disks are available or if the SSD disks do not have enough space left to allocate the entire object, at least some part of the object will be allocated on traditional disks. See the **UNIT** parameter on **CRTPF** and **CRTL** or the **UNIT** clause on the **CREATE TABLE**, **CREATE INDEX** and **ALTER TABLE** SQL statements.

You should consider SSDs if your I/O demands have outpaced the performance capabilities of traditional HDDs, latencies associated with spinning platters and moving arms limit the speed of HDD data access. SSDs’ near instantaneous data access removes this I/O bottleneck, creating a paradigm shift in I/O performance. Applications throttled by poor I/O performance can benefit greatly from SSDs.

Memory preference controls

Memory preference controls can be used as a technique to maximize performance and utilization of resources.

Memory preference controls

Memory preference controls can be used against performance critical database tables, indexes, physical files, and logical files as a technique to maximize performance and utilization of resources. Several approaches are available for controlling the memory preference:

1. **Set Object Access (SETOBJACC)** command

One benefit of **SETOBJACC** is that you can carve out a separate memory pool that is not used by from any running applications or **MEMORY_POOL_PREFERENCE** and those objects will then not get paged out because neither applications nor SQE will be using that pool. If the target objects are primarily accessed using Native database I/O, **SETOBJACC** is the preferred approach. **SETOBJACC** uses a single thread to bring the object into memory.

2. **Change Physical File (CHGPF)** and **Change Logical File (CHGLF)** commands - Keep in memory (**KEEPINMEM**) parameter

When an object is changed to have Keep in memory set to *YES, the database will bring the object into memory and attempt to keep it in memory when it is accessed using SQL via SQE. Native database I/O (for example RPG CHAIN, READ, etc.) does not do this. **KEEPINMEM** has the ability to use parallel I/O to bring the object into memory.

- **CHGPF KEEPINMEM(*YES|*NO)**
- **CHGLF KEEPINMEM(*YES|*NO)**

3. The SQL memory-preference can be used as an alternative to the **KEEPINMEM** command parameter.

The behavior of SQL configured in memory objects matches the behavior described in the **KEEPINMEM** section.

KEEP IN MEMORY <NO/YES> is available on the following SQL statements:

- **ALTER TABLE**
- **CREATE INDEX**

- **CREATE TABLE**
- **DECLARE GLOBAL TEMPORARY TABLE**

Note: The QSYS2/SYSPARTITIONSTAT and SYSPARTITIONINDEXSTAT catalogs can be queried to determine the memory-preference for specific objects. When a memory-preference is specified for an object, the MEMORY_POOL_PREFERENCE QAQQINI option can be used to influence where we attempt to page objects. There is no guarantee that objects will remain in memory.

Join optimization

A join operation is a complex function that requires special attention in order to achieve good performance. This section describes how Db2 for i implements join queries and how optimization choices are made by the query optimizer. It also describes design tips and techniques which help avoid or solve performance problems.

Nested loop join implementation

Db2 for i provides a **nested loop** join method. For this method, the processing of the tables in the join are ordered. This order is called the **join order**. The first table in the final join order is called the **primary table**. The other tables are called **secondary tables**. Each join table position is called a **dial**.

The nested loop is implemented either using an index on secondary tables, a hash table, or a table scan (arrival sequence) on the secondary tables. In general, the join is implemented using either an index or a hash table.

Index nested loop join implementation

During the join, Db2 for i:

1. Accesses the first primary table row selected by the predicates local to the primary table.
2. Builds a key value from the join columns in the primary table.
3. Chooses the access to the first secondary table:
 - If using an index, Radix Index Probe is used to locate the first row satisfying the join condition for the secondary table. The probe uses an index with keys matching the join condition or local row selection columns of the secondary table.
 - Applies bitmap selection, if applicable.

All rows that satisfy the join condition from each secondary dial are located using an index. Rows are retrieved from secondary tables in random sequence. This random disk I/O time often accounts for a large percentage of the processing time of the query. Since a given secondary dial is searched once for each row selected from the primary and the preceding secondary dials that satisfy the join condition for each of the preceding secondary dials, many searches could be against the later dials. Any inefficiencies in the processing of the later dials can significantly inflate the query processing time. This reason is why attention to performance considerations for join queries can reduce the run time of a join query from hours to minutes.

If an efficient index cannot be found, a temporary index could be created. Some join queries build temporary indexes over secondary dials even when an index exists for all the join keys. Because efficiency is important for secondary dials of longer running queries, the optimizer could build a temporary index containing only entries with local row selection for that dial. This preprocessing of row selection allows the database manager to process row selection in one pass instead of each time rows are matched for a dial.

- If using a Hash Table Probe, a hash temporary result table is created containing all rows from local selection against the table on the first probe. The structure of the hash table is such that rows with the same join value are loaded into the same hash table partition (clustered). The location of the rows for any given join value can be found by applying a hashing function to the join value.

A nested loop join using a Hash Table Probe has several advantages over a nested loop join using an Index Probe:

- The structure of a hash temporary result table is simpler than the structure of an index. Less CPU processing is required to build and probe a hash table.
 - The rows in the hash result table contain all the data required by the query. There is no need to access the dataspace of the table with random I/O when probing the hash table.
 - Like join values are clustered, so all matching rows for a given join value can typically be accessed with a single I/O request.
 - The hash temporary result table can be built using SMP parallelism.
 - Unlike indexes, entries in hash tables are not updated to reflect changes of column values in the underlying table. The existence of a hash table does not affect the processing cost of other updating jobs in the system.
 - If using a Sorted List Probe, a sorted list result is created containing all the rows from local selection against the table on the first probe. The structure of the sorted list table is such that rows with the same join value are sorted together in the list. The location of the rows for any given join value can be found by probing using the join value.
 - If using a Table Scan, locate the first row that satisfies the join condition or local row selection columns of the secondary table. The join could be implemented with a table scan when the secondary table is a user-defined table function.
4. Determines if the row is selected by applying any remaining selection local to the first secondary dial. If the secondary dial row is not selected then the next row that satisfies the join condition is located. Steps 1 through 4 are repeated until a row that satisfies both the join condition and any remaining selection is selected from all secondary tables
5. Returns the result join row.
6. Processes the last secondary table again to find the next row that satisfies the join condition in that dial.
- During this processing, when no more rows satisfying the join condition can be selected, the processing backs up to the logical previous dial. It attempts to read the next row that satisfies its join condition.
7. Ends processing when all selected rows from the primary table are processed.

Note the following characteristics of a nested loop join:

- If ordering or grouping is specified, and all the columns are over a single table eligible to be the primary, then the optimizer costs the join with that table as the primary table, performing the grouping and ordering with an index.
- If ordering and grouping is specified on two or more tables or if temporary objects are allowed, Db2 for i breaks the processing of the query into two parts:
 1. Perform the join selection, omitting the ordering or grouping processing, and write the result rows to a temporary work table. This method allows the optimizer to consider any table of the join query as a candidate for the primary table.
 2. Perform the ordering or grouping on the data in the temporary work table.

Queries that cannot use hash join

Hash join cannot be used for queries that:

- Hash join cannot be used for queries involving physical files or tables that have read triggers.
- Require that the cursor position is restored as the result of the SQL ROLLBACK HOLD statement or the ROLLBACK CL command. For SQL applications using commitment control level other than *NONE, this method requires that *ALLREAD be specified as the value for the ALWBLK precompiler parameter.
- Hash join cannot be used for a table in a join query where the join condition something other than an equals operator.
- CQE does not support hash join if the query contains any of the following:

- Subqueries unless all subqueries in the query can be transformed to inner joins.
- UNION or UNION ALL
- Perform left outer or exception join.
- Use a DDS created join logical file.

Related concepts

Objects processed in parallel

The Db2 Symmetric multiprocessing feature provides the optimizer with additional methods for retrieving data that include parallel processing. Symmetrical multiprocessing is a form of parallelism achieved on a single system where multiple CPU and I/O processors sharing memory and disk work simultaneously toward a single result.

Related reference

Table scan

A table scan is the easiest and simplest operation that can be performed against a table. It sequentially processes all the rows in the table to determine if they satisfy the selection criteria specified in the query. It does this processing in a way to maximize the I/O throughput for the table.

Sorted list probe

A sorted list probe operation is used to retrieve rows from a temporary sorted list based upon a probe lookup operation.

Hash table probe

A hash table probe operation is used to retrieve rows from a temporary hash table based upon a probe lookup operation.

Radix index probe

A radix index probe operation is used to retrieve the rows from a table in a keyed sequence. The main difference between the radix index probe and the scan is that the rows returned are first identified by a probe operation to subset them.

Join optimization algorithm

The query optimizer must determine the join columns, join operators, local row selection, dial implementation, and dial ordering for a join query.

The join columns and join operators depend on the following situations:

- Join column specifications of the query
- Join order
- Interaction of join columns with other row selection

Join specifications not implemented for the dial are deferred until a later dial or, if an inner join, processed as row selection.

For a given dial, the only join specifications which are usable as join columns are those being joined to a *previous* dial. For example, the second dial can only use join specifications which reference columns in the primary dial. Likewise, the third dial can only use join specifications which reference columns in the primary and the second dials, and so on. Join specifications which reference later dials are deferred until the referenced dial is processed.

Note: For OPNQRYF, only one type of join operator is allowed for either a left outer or an exception join. That is, the join operator for all join conditions must be the same.

When looking for an existing index to access a secondary dial, the query optimizer looks at the left-most key columns of the index. For a given dial and index, the join specifications which use the left-most key columns can be used. For example:

```

DECLARE BROWSE2 CURSOR FOR
SELECT * FROM EMPLOYEE, EMP_ACT
WHERE EMPLOYEE.EMPNO = EMP_ACT.EMPNO
AND EMPLOYEE.HIREDATE = EMP_ACT.EMSTDATE
OPTIMIZE FOR 99999 ROWS

```

For the index over EMP_ACT with key columns EMPNO, PROJNO, and EMSTDATE, the join operation is performed only on column EMPNO. After the join is performed, index scan-key selection is done using column EMSTDATE.

The query optimizer also uses local row selection when choosing the best use of the index for the secondary dial. If the previous example had been expressed with a local predicate as:

```

DECLARE BROWSE2 CURSOR FOR
SELECT * FROM EMPLOYEE, EMP_ACT
WHERE EMPLOYEE.EMPNO = EMP_ACT.EMPNO
AND EMPLOYEE.HIREDATE = EMP_ACT.EMSTDATE
AND EMP_ACT.PROJNO = '123456'
OPTIMIZE FOR 99999 ROWS

```

The index with key columns EMPNO, PROJNO, and EMSTDATE are fully utilized by combining join and selection into one operation against all three key columns.

When creating a temporary index, the left-most key columns are the usable join columns in that dial position. All local row selection for that dial is processed when selecting entries for inclusion into the temporary index. A temporary index is like the index created for a select/omit keyed logical file. The temporary index for the previous example has key columns of EMPNO and EMSTDATE.

Since the optimizer tries a combination of join and local row selection, you can achieve almost all the advantages of a temporary index by using an existing index. In the preceding example, using either implementation, an existing index could be used or a temporary index could be created. A temporary index is built with the local row selection on PROJNO applied during the index creation. The temporary index has key columns of EMPNO and EMSTDATE to match the join selection.

If, instead, an existing index was used with key columns of EMPNO, PROJNO, EMSTDATE (or PROJNO, EMP_ACT, EMSTDATE), the local row selection can be applied **at the same time** as the join selection. This method contrasts to applying the local selection before the join selection, as happens when the temporary index is created. Or applying the local selection after the join selection, as happens when only the first key column of the index matches the join column.

The existing index implementation is more likely to provide faster performance because join and selection processing are combined without the overhead of building a temporary index. However, the existing index could have slightly slower I/O processing than the temporary index because the local selection is run many times rather than once. In general, create indexes with key columns for the combination of join and equal selection columns as the left-most keys.

Join order optimization

The SQE optimizer allows join reordering for a join logical file. However, the join order is fixed if CQE runs a query that references a join logical file. The join order is also fixed if the OPNQRYF JORDER(*FILE) parameter is specified. In addition, the join order is fixed if the query options file (QAQQINI) FORCE_JOIN_ORDER parameter is *YES

Otherwise, the following join ordering algorithm is used to determine the order of the tables:

1. Determine an access method for each individual table as candidates for the primary dial.
2. Estimate the number of rows returned for each table based on local row selection.

If the join query with ordering or grouping is processed in one step, the table with the ordering or grouping columns is the primary table.

3. Determine an access method, cost, and expected number of rows returned for each join combination of candidate tables as primary and first secondary tables.

The join order combinations estimated for a four table inner join would be:

```

1-2   2-1   1-3   3-1   1-4   4-1   2-3   3-2   2-4   4-2   3-4   4-3

```

4. Choose the combination with the lowest join cost and number of selected rows or both.
5. Determine the cost, access method, and expected number of rows for each remaining table joined to the previous secondary table.

6. Select an access method for each table that has the lowest cost for that table.
7. Choose the secondary table with the lowest join cost and number of selected rows or both.
8. Repeat steps 4 through 7 until the lowest cost join order is determined.

Note: After dial 32, the optimizer uses a different method to determine file join order, which might not be the lowest cost.

When a query contains a left or right outer join or a right exception join, the join order is not fixed. However, all from-columns of the ON clause must occur from dials previous to the left or right outer or exception join. For example:

```
FROM A INNER JOIN B ON A.C1=B.C1
LEFT OUTER JOIN C ON B. C2=C.C2
```

The allowable join order combinations for this query would be:

1-2-3, 2-1-3, or 2-3-1

Right outer or right exception joins are implemented as left outer and left exception, with files flipped. For example:

```
FROM A RIGHT OUTER JOIN B ON A.C1=B.C1
```

is implemented as B LEFT OUTER JOIN A ON B.C1=A.C1. The only allowed join order is 2-1.

[Change Query Attributes \(CHGQRYA\) command](#)

Full outer join

Full outer join is supported by the SQE optimizer. Just as right outer and right exception join are rewritten to the supported join types of inner, left outer or left exception, a full outer join is also rewritten.

A full outer join of A FULL OUTER JOIN B is equivalent to a (A LEFT OUTER JOIN B) UNION ALL (B LEFT EXCEPTION JOIN A). The following example illustrates the rewrite.

```
SELECT EMPNO, LASTNAME, DEPTNAME
FROM CORPDATA.EMPLOYEE XXX
FULL OUTER JOIN CORPDATA.DEPARTMENT YYY
ON XXX.WORKDEPT = YYY.DEPTNO
```

This query is rewritten as the following:

```
SELECT EMPNO, LASTNAME, DEPTNAME
FROM CORPDATA.EMPLOYEE XXX
LEFT OUTER JOIN CORPDATA.DEPARTMENT YYY
ON XXX.WORKDEPT = YYY.DEPTNO
UNION ALL
SELECT EMPNO, LASTNAME, DEPTNAME
FROM CORPDATA.DEPARTMENT YYY
LEFT EXCEPTION JOIN CORPDATA.EMPLOYEE XXX
ON XXX.WORKDEPT = YYY.DEPTNO
```

A query with multiple FULL OUTER JOIN requests, such as A FULL OUTER JOIN B FULL OUTER JOIN C can quickly become complicated in this rewritten state. This complication is illustrated in the following example.

If not running in live data mode, the optimizer could facilitate performance both during optimization and runtime by encapsulating intermediate results in a temporary data object. This object can be optimized once and plugged into both the scanned and probed side of the rewrite. These shared temporary objects eliminate the need to make multiple passes through the specific tables to satisfy the request.

In this example, the result of the (A FULL OUTER JOIN B) is a candidate for encapsulation during its FULL OUTER join with C.

```
A FULL OUTER JOIN B FULL OUTER JOIN C
```

This query is rewritten as the following:

```
((A LEFT OUTER JOIN B) UNION ALL (B LEFT EXCEPTION JOIN A)) LEFT OUTER JOIN C )  
UNION ALL  
(C LEFT EXCEPTION JOIN ((A LEFT OUTER JOIN B) UNION ALL (B LEFT EXCEPTION JOIN A)))
```

FULL OUTER implies that both sides of the join request can generate NULL values in the resulting answer set. Local selection in the WHERE clause of the query could result in the appropriate downgrade of the FULL OUTER to a LEFT OUTER or INNER JOIN.

If you want FULL OUTER JOIN behavior and local selection applied, specify the local selection in the ON clause of the FULL OUTER JOIN, or use common table expressions. For example:

```
WITH TEMPEMP AS (SELECT * FROM CORPDATA.EMPLOYEE XXX WHERE SALARY > 10000)  
SELECT EMPNO, LASTNAME, DEPTNAME  
FROM TEMPEMP XXX  
FULL OUTER JOIN CORPDATA.DEPARTMENT YYY  
ON XXX.WORKDEPT = YYY.DEPTNO
```

Join cost estimation and index selection

As the query optimizer compares the various possible access choices, it must assign a numeric cost value to each candidate. The optimizer uses that value to determine the implementation which consumes the least amount of processing time. This costing value is a combination of CPU and I/O time

In steps 3 and 5 in “Join order optimization” on page 72, the optimizer estimates cost and chooses an access method for a given dial combination. The choices made are like the choices for row selection, except that a plan using a probe must be chosen.

The costing value is based on the following assumptions:

- Table pages and index pages must be retrieved from auxiliary storage. For example, the query optimizer is not aware that an entire table might be loaded into active memory as the result of a **Set Object Access (SETOBJACC)** CL command. Use of this command could significantly improve the performance of a query. However, the optimizer does not change the query implementation to take advantage of the memory resident state of the table.
- The query is the only process running on the system. No allowance is given for system CPU utilization or I/O waits which occur because of other processes using the same resources. CPU-related costs are scaled to the relative processing speed of the system running the query.
- The values in a column are uniformly distributed across the table. For example, if 10% of the table rows have the same value, then on average, every 10th row in the table contains that value.
- The column values are independent from any other column values in a row, unless there is an index available whose key definition is (A, B). Multi-key field indexes allow the optimizer to detect when the values between columns are correlated.

For example, a column named A has a value of 1 in 50% of the rows in a table. A column named B has a value of 2 in 50% of the rows. It is expected that a query which selects rows where $A = 1$, and $B = 2$ selects 25% of the rows in the table.

The main factors in the join cost calculation for secondary dials are:

- the number of rows selected in all previous dials
- the number of rows which match, on average, each of the rows selected from previous dials.

Both of these factors can be derived by estimating the number of matching rows for a given dial.

When the join operator is something other than equal, the expected number of matching rows is based on the following default filter factors:

- 33% for less-than, greater-than, less-than-equal-to, or greater-than-equal-to
- 90% for not equal

- 25% for BETWEEN range (OPNQRYPF %RANGE)
- 10% for each IN list value (OPNQRYPF %VALUES)

For example, when the join operator is less-than, the expected number of matching rows is 0.33 * (number of rows in the dial). If no join specifications are active for the current dial, the Cartesian product is assumed to be the operator. For Cartesian products, the number of matching rows is every row in the dial, unless local row selection can be applied to the index.

When the join operator is equal, the expected number of rows is the average number of duplicate rows for a given value.

Related information

[Set Object Access \(SETOBJACC\) command](#)

Transitive closure predicates

For join queries, the query optimizer could do some special processing to generate additional selection. When the set of predicates that belong to a query logically infer extra predicates, the query optimizer generates additional predicates. The purpose is to provide more information during join optimization.

See the following examples:

```
SELECT * FROM EMPLOYEE, EMP_ACT
WHERE EMPLOYEE.EMPNO = EMP_ACT.EMPNO
AND EMPLOYEE.EMPNO = '000010'
```

The optimizer modifies the query to:

```
SELECT * FROM EMPLOYEE, EMP_ACT
WHERE EMPLOYEE.EMPNO = EMP_ACT.EMPNO
AND EMPLOYEE.EMPNO = '000010'
AND EMP_ACT.EMPNO = '000010'
```

The following rules determine which predicates are added to other join dials:

- The dials affected must have join operators of equal.
- The predicate is **isolatable**, which means that a false condition from this predicate omits the row.
- One operand of the predicate is an equal join column and the other is a constant or host variable.
- The predicate operator is not LIKE (OPNQRYPF %WLDCRD, or *CT).
- The predicate is not connected to other predicates by OR.

The query optimizer generates a new predicate, whether a predicate exists in the WHERE clause (OPNQRYPF QRYSLT parameter).

Some predicates are redundant. Redundant predicates occur when a previous evaluation of other predicates in the query already determines the result that predicate provides. Redundant predicates can be specified by you or generated by the query optimizer during predicate manipulation. Redundant predicates with operators of =, >, >=, <, <=, or BETWEEN (OPNQRYPF *EQ, *GT, *GE, *LT, *LE, or %RANGE) are merged into a single predicate to reflect the most selective range.

Look ahead predicate generation (LPG)

A special type of transitive closure called look ahead predicate generation (LPG) might be costed for joins. In this case, the optimizer tries to minimize the random I/O of a join by pre-applying the query results to a large fact table. LPG is typically used with a class of queries referred to as star join queries. However, it can possibly be used with any join query.

Look at the following query:

```
SELECT * FROM EMPLOYEE, EMP_ACT
WHERE EMPLOYEE.EMPNO = EMP_ACT.EMPNO
AND EMPLOYEE.EMPNO = '000010'
```

The optimizer could decide to internally modify the query to be:

```
WITH HT AS (SELECT *
             FROM EMPLOYEE
             WHERE EMPLOYEE.EMPNO='000010')

SELECT *
FROM HT, EMP_ACT
WHERE HT.EMPNO = EMP_ACT.EMPNO
AND EMP_ACT.EMPNO IN (SELECT DISTINCT EMPNO
                     FROM HT)
```

The optimizer places the results of the "subquery" into a temporary hash table. The hash table of the subquery can be applied in one of two methods against the EMP_ACT (fact) table:

- The distinct values of the hash tables are retrieved. For each distinct value, an index over EMP_ACT is probed to determine which records are returned for that value. Those record identifiers are normally then stored and sorted (sometimes the sorting is omitted, depending on the total number of record ids expected). Once the ids are determined, the subset of EMP_ACT records can be accessed more efficiently than in a traditional nested loop join processing.
- EMP_ACT can be scanned. For each record, the hash table is probed to see if the record joins at all to EMPLOYEE. This method allows for efficient access to EMP_ACT with a more efficient record rejection method than in a traditional nested loop join process.

Note: LPG processing is part of the normal processing in the SQL Query Engine. CQE only considers the first method, requires that the index in question by an EVI and also requires use of the STAR_JOIN and FORCE_JOIN_ORDER QAQQINI options.

Tips for improving performance when selecting data from more than two tables

The following suggestion is only applicable to CQE and is directed specifically to select-statements that access several tables. For joins that involve more than two tables, you might want to provide redundant information about the join columns. The CQE optimizer does not generate transitive closure predicates between two columns. If you give the optimizer extra information to work with when requesting a join, it can determine the best way to do the join. The additional information might seem redundant, but is helpful to the optimizer.

If the select-statement you are considering accesses two or more tables, all the recommendations suggested in [“Creating an index strategy”](#) on page 259 apply. For example, instead of coding:

```
EXEC SQL
  DECLARE EMPACTDATA CURSOR FOR
  SELECT LASTNAME, DEPTNAME, PROJNO, ACTNO
     FROM CORPDATA.DEPARTMENT, CORPDATA.EMPLOYEE,
          CORPDATA.EMP_ACT
     WHERE DEPARTMENT.MGRNO = EMPLOYEE.EMPNO
          AND EMPLOYEE.EMPNO = EMP_ACT.EMPNO
END-EXEC.
```

Provide the optimizer with a little more data and code:

```
EXEC SQL
  DECLARE EMPACTDATA CURSOR FOR
  SELECT LASTNAME, DEPTNAME, PROJNO, ACTNO
     FROM CORPDATA.DEPARTMENT, CORPDATA.EMPLOYEE,
          CORPDATA.EMP_ACT
     WHERE DEPARTMENT.MGRNO = EMPLOYEE.EMPNO
          AND EMPLOYEE.EMPNO = EMP_ACT.EMPNO
          AND DEPARTMENT.MGRNO = EMP_ACT.EMPNO
END-EXEC.
```

Multiple join types for a query

Multiple join types (inner, left outer, right outer, left exception, and right exception) can be specified in the query using the JOIN syntax. However, the Db2 for i can only support one join type of inner, left outer, or

left exception join for the entire query. The optimizer determines the overall join type for the query and reorders the files to achieve the correct semantics.

Note: This section does not apply to SQE or OPNQRYF.

The optimizer evaluates the join criteria, along with any row selection, to determine the join type for each dial and the entire query. Then the optimizer generates additional selection using the relative row number of the tables to simulate the different types of joins that occur within the query.

Null values are returned for any unmatched rows in either a left outer or an exception join. Any isolatable selection specified for that dial, including any additional join criteria specified in the WHERE clause, causes all the unmatched rows to be eliminated. (The exception is when the selection is for an IS NULL predicate.) This elimination causes the dial join type to change to an inner join (or an exception join) if the IS NULL predicate was specified.

In the following example, a left outer join is specified between the tables EMPLOYEE and DEPARTMENT. In the WHERE clause, there are two selection predicates that also apply to the DEPARTMENT table.

```
SELECT EMPNO, LASTNAME, DEPTNAME, PROJNO
FROM CORPDATA.EMPLOYEE XXX LEFT OUTER JOIN CORPDATA.DEPARTMENT YYY
    ON XXX.WORKDEPT = YYY.DEPTNO
LEFT OUTER JOIN CORPDATA.PROJECT ZZZ
    ON XXX.EMPNO = ZZZ.RESPEMP
WHERE XXX.EMPNO = YYY.MGRNO AND
      YYY.DEPTNO IN ('A00', 'D01', 'D11', 'D21', 'E11')
```

The first selection predicate, XXX.EMPNO = YYY.MGRNO, is an additional join condition that is evaluated as an "inner join" condition. The second is an isolatable selection predicate that eliminates any unmatched rows. Either of these predicates can cause the join type for the DEPARTMENT table to change from a left outer join to an inner join.

Even though the join between the EMPLOYEE and DEPARTMENT tables was changed to an inner join, the entire query remains a left outer join to satisfy the join condition for the PROJECT table.

Note: Care must be taken when specifying multiple join types since they are supported by appending selection to the query for any unmatched rows. The number of rows satisfying the join criteria can become large before selection that either selects or omits the unmatched rows based on that individual dial join type is applied.

Sources of join query performance problems

The optimization algorithms described earlier benefit most join queries, but the performance of a few queries might be degraded.

This occurs when:

- An index is not available which provides average number of duplicate values statistics for the potential join columns.
- The optimizer uses default filter factors to estimate the number of rows when applying local selection to the table when indexes or column statistics do not exist over the selection columns.

Creating indexes over the selection columns allows the optimizer to make a more accurate filtering estimate by using key range estimates.

- The particular values selected for the join columns yield a greater number of matching rows than the average number of duplicate values for all values of the join columns in the table. For example, the data is not uniformly distributed.

Join performance tips

If you have a join query performing poorly, or you are creating an application which uses join queries, these tips could be useful.

What to Do	How It Helps
<p>Check the database design. Make sure that there are indexes available over all the join columns and row selection columns or both. The optimizer provides index advice in several places to aid in this process:</p> <ul style="list-style-type: none"> • the index advisor under System i Navigator - Database • the advised information under Visual Explain • the advised information in the 3020 record in the database monitor 	<p>The query optimizer can select an efficient access method because it can determine the average number of duplicate values. Many queries could use the existing index and avoid the cost of creating a temporary index or hash table.</p>
<p>Check the query to see whether some complex predicates could be added to other dials to allow the optimizer to get better selectivity for each dial.</p>	<p>The query optimizer does not add predicates for predicates connected by OR or non-isolatable predicates, or predicate operator LIKE. Modify the query by adding additional predicates to help.</p>
<p>Specify ALWCPYDTA(*OPTIMIZE) or ALWCPYDTA(*YES)</p>	<p>The query is creating a temporary index or hash table, and the processing time could be better if the existing index or hash table was used. Specify ALWCPYDTA(*YES).</p> <p>The query is not creating a temporary index or hash table, and the processing time could be better if a temporary index was created. Specify ALWCPYDTA(*OPTIMIZE).</p> <p>Alternatively, specify OPTIMIZE FOR n ROWS to inform the optimizer that the application reads every resulting row. Set n to a large number. You can also set n to a small number before ending the query.</p>
<p>For OPNQRYF, specify OPTIMIZE(*FIRSTIO) or OPTIMIZE(*ALLIO)</p>	<p>Specify the OPTIMIZE(*FIRSTIO) or OPTIMIZE(*ALLIO) option to accurately reflect your application. Use *FIRSTIO, if you want the optimizer to optimize the query to retrieve the first block of rows most efficiently. This biases the optimizer toward using existing objects. If you want to optimize the retrieval time for the entire answer set, use *ALLIO. This option could cause the optimizer to create temporary indexes or hash tables to minimize I/O.</p>

Table 31. Checklist for Creating an Application that Uses Join Queries (continued)

What to Do	How It Helps
Star join queries	<p>A join in which one table is joined with all secondary tables consecutively is sometimes called a star join. If all secondary join predicates contain a column reference to a particular table, place that table in join position one. In Example A, all tables are joined to table EMPLOYEE. The query optimizer can freely determine the join order. For SQE, the optimizer uses Look Ahead Predicate generation to determine the optimal join order. For CQE, the query could be changed to force EMPLOYEE into join position one by using the query options file (QAQQINI) FORCE_JOIN_ORDER parameter of *YES. In these examples, the join type is a join with no default values returned (an inner join.). The reason for forcing the table into the first position is to avoid random I/O processing. If EMPLOYEE is not in join position one, every row in EMPLOYEE can be examined repeatedly during the join process. If EMPLOYEE is fairly large, considerable random I/O processing occurs resulting in poor performance. By forcing EMPLOYEE to the first position, random I/O processing is minimized.</p> <p>Example A: Star join query</p> <pre> DECLARE C1 CURSOR FOR SELECT * FROM DEPARTMENT, EMP_ACT, EMPLOYEE, PROJECT WHERE DEPARTMENT.DEPTNO=EMPLOYEE.WORKDEPT AND EMP_ACT.EMPNO=EMPLOYEE.EMPNO AND EMPLOYEE.WORKDEPT=PROJECT.DEPTNO </pre> <p>Example B: Star join query with order forced using FORCE_JOIN_ORDER</p> <pre> DECLARE C1 CURSOR FOR SELECT * FROM EMPLOYEE, DEPARTMENT, EMP_ACT, PROJECT WHERE DEPARTMENT.DEPTNO=EMPLOYEE.WORKDEPT AND EMP_ACT.EMPNO=EMPLOYEE.EMPNO AND EMPLOYEE.WORKDEPT=PROJECT.DEPTNO </pre>
Specify ALWCOPYDTA(*OPTIMIZE) to allow the query optimizer to use a sort routine.	Ordering is specified and all key columns are from a single dial. The optimizer can consider all possible join orders with ALWCOPYDTA(*OPTIMIZE).
Specify join predicates to prevent all the rows from one table from being joined to every row in the other table.	Improves performance by reducing the join fan-out. It is best if every secondary table has at least one join predicate that references one of its columns as a 'join-to' column.

Distinct optimization

Distinct is used to compare a value with another value.

There are two methods to write a query that returns distinct values in SQL. One method uses the DISTINCT keyword:

```

SELECT DISTINCT COL1, COL2
FROM TABLE1

```

The second method uses GROUP BY:

```

SELECT COL1, COL2
FROM TABLE1
GROUP BY COL1, COL2

```

All queries that contain a DISTINCT, and are run using SQE, rewritten into queries using GROUP BY. This rewrite enables queries using DISTINCT to take advantage of the many grouping techniques available to the optimizer.

Distinct to Grouping implementation

The following example query has a DISTINCT:

```
SELECT DISTINCT COL1, COL2
FROM T1
WHERE COL2 > 5 AND COL3 = 2
```

The optimizer rewrites it into this query:

```
SELECT COL1, COL2
FROM T1
WHERE COL2 > 5 AND COL3 = 2
GROUP BY COL1, COL2
```

Distinct removal

A query containing a DISTINCT over whole-file aggregation (no grouping or selection) allows the DISTINCT to be removed. For example, look at this query with DISTINCT:

```
SELECT DISTINCT COUNT(C1), SUM(C1)
FROM TABLE1
```

The optimizer rewrites this query as the following:

```
SELECT COUNT(C1), SUM(C1)
FROM TABLE1
```

If the DISTINCT and the GROUP BY fields are identical, the DISTINCT can be removed. If the DISTINCT fields are a subset of the GROUP BY fields (and there are no aggregates), the DISTINCTs can be removed.

Grouping optimization

Db2 for i has certain techniques to use when the optimizer encounters grouping. The query optimizer chooses its methods for optimizing your query.

Hash grouping implementation

This technique uses the base hash access method to perform grouping or summarization of the selected table rows. For each selected row, the specified grouping value is run through the hash function. The computed hash value and grouping value are used to quickly find the entry in the hash table corresponding to the grouping value.

If the current grouping value already has a row in the hash table, the hash table entry is retrieved and summarized (updated) with the current table row values based on the requested grouping column operations (such as SUM or COUNT). If a hash table entry is not found for the current grouping value, a new entry is inserted into the hash table and initialized with the current grouping value.

The time required to receive the first group result for this implementation is most likely longer than other grouping implementations because the hash table must be built and populated first. Once the hash table is populated, the database manager uses the table to start returning the grouping results. Before returning any results, the database manager must apply any specified grouping selection criteria or ordering to the summary entries in the hash table.

Where the hash grouping method is most effective

The hash grouping method is most effective when the consolidation ratio is high. The **consolidation ratio** is the ratio of the selected table rows to the computed grouping results. If every database table row has

its own unique grouping value, then the hash table becomes too large. The size in turn slows down the hashing access method.

The optimizer estimates the consolidation ratio by first determining the number of unique values in the specified grouping columns (that is, the expected number of groups in the database table). The optimizer then examines the total number of rows in the table and the specified selection criteria and uses the result of this examination to estimate the consolidation ratio.

Indexes over the grouping columns can help make the ratio estimate of the optimizer more accurate. Indexes improve the accuracy because they contain statistics that include the average number of duplicate values for the key columns.

The optimizer also uses the expected number of groups estimate to compute the number of partitions in the hash table. As mentioned earlier, the hashing access method is more effective when the hash table is well-balanced. The number of hash table partitions directly affects how entries are distributed across the hash table and the uniformity of this distribution.

The hash function performs better when the grouping values consist of columns that have non-numeric data types, except for the integer (binary) data type. In addition, specifying grouping value columns that are not associated with the variable length and null column attributes allows the hash function to perform more effectively.

Index grouping implementation

There are two primary ways to implement grouping using an index: Ordered grouping and pre-summarized processing.

Ordered grouping

This implementation uses the Radix Index Scan or the Radix Index Probe access methods to perform the grouping. An index is required that contains all the grouping columns as contiguous leftmost key columns. The database manager accesses the individual groups through the index and performs the requested summary functions.

Since the index, by definition, already has all the key values grouped, the first group result can be returned in less time than the hashing method. This index performance is faster because the hashing method requires a temporary result. This implementation can be beneficial if an application does not need to retrieve all the group results, or if an index exists that matches the grouping columns.

When the grouping is implemented with an index and a permanent index does not exist that satisfies grouping columns, a temporary index is created. The grouping columns specified within the query are used as the key columns for this index.

Pre-summarized processing

This SQE-only implementation uses an Encoded Vector Index to extract the summary information already in the symbol table of the index. The EVI symbol table contains the unique key values and a count of the number of table records that have that unique value. The grouping for the columns of the index key is already performed. If the query references a single table and performs simple aggregation, the EVI might be used for quick access to the grouping results. For example, consider the following query:

```
SELECT COUNT(*), col1
FROM t1
GROUP BY col1
```

If an EVI exists over t1 with a key of col1, the optimizer can rewrite the query to access the precomputed grouping answer in the EVI symbol table.

This rewrite can result in dramatic improvements when the number of table records is large and the number of resulting groups is small, relative to the size of the table.

This method is also possible with selection (WHERE clause), as long as the reference columns are in the key definition of the EVI.

For example, consider the following query:

```
SELECT COUNT(*), col1
FROM t1
WHERE col1 > 100
GROUP BY col1
```

This query can be rewritten by the optimizer to use the EVI. This pre-summarized processing works for DISTINCT processing, GROUP BY and for column function COUNT. All columns of the table referenced in the query must also be in the key definition of the EVI.

So, for example, the following query can be made to use the EVI:

```
SELECT DISTINCT col1
FROM t1
```

However, this query cannot:

```
SELECT DISTINCT col1
FROM t1
WHERE col2 > 1
```

This query cannot use the EVI because it references col2 of the table, which is not in the key definition of the EVI. If multiple columns are defined in the EVI key, for example, col1 and col2, it is important to use the left-most columns of the key. For example, if an EVI existed with a key definition of (col1, col2), but the query referenced only col2, it is unlikely the EVI is used.

EVI INCLUDE aggregates

A more powerful example of pre-summarized processing can be facilitated by the use of the INCLUDE keyword on the index create. By default, COUNT(*) is implied on the creation of an EVI. Additional numeric aggregates specified over non-key data can further facilitate pre-determined or ready-made aggregate results during query optimization.

For example, suppose the following query is a frequently requested result set, queried in whole or as part of a subquery comparison.

```
SELECT AVG(col2)
FROM t1
GROUP BY col1
```

Create the following EVI to predetermine the value of AVG(col2).

```
CREATE ENCODED VECTOR INDEX eviT1 ON t1(col1) INCLUDE(AVG(col2))
```

eviT1 delivers distinct values for col1 and COUNT(*) specific to the group by of col1. eviT1 can be used to generate an asynchronous bitmap or RRN list for accessing the table rows for specific col1 values. In addition, eviT1 computes an additional aggregate, AVG(col2), over the same group by column (col1) by specifying the INCLUDE aggregate.

INCLUDE aggregates are limited to those aggregates that result in numeric values: SUM, COUNT, AVG, STDDEV, and so on. These values can be readily maintained as records are inserted, deleted, or updated in the base table.

MIN or MAX are two aggregates that are not supported as INCLUDE aggregates. Deleting the current row contributing to the MIN or MAX value would result in the need to recalculate, potentially accessing many rows, and reducing performance.

INCLUDE values can also contain aggregates over derivations. For example, if you have a couple of columns that contribute to an aggregate, that derivation can be specified, for example, as SUM(col1+col2+col3).

It is recommended that EVIs with INCLUDE aggregates only contain references to columns or column-specific derivations, for example, SUM(salary+bonus).

In many environments, queries that contain derivations using constants convert those constants to parameter markers. This conversion allows a much higher degree of ODP reuse. However, it can be more difficult to match the parameter value to a literal in the index definition.

The optimizer does attempt to match constants in the EVI with parameter markers or host variable values in the query. However, in some complex cases this support is limited and could result in the EVI not matching the query.

Pre-summarized processing can also take advantage of EVIs with INCLUDE in a JOIN situation.

For example, see the following aggregate query over the join of two tables.

EVI INCLUDE aggregate example

```
SELECT deptname, sum(salary)
FROM DEPARTMENT, EMPLOYEE
WHERE deptno=workdept
GROUP BY deptname
```

By providing an EVI with INCLUDE index, as follows, and with optimizer support to push down aggregates to the table level when possible, the resulting implementation takes advantage of the ready-made aggregates already supplied by EVI employeeSumByDept. The implementation never needs to touch or aggregate rows in the Employee table.

```
CREATE ENCODED VECTOR INDEX employeeSumByDept ON employee(workdept)
INCLUDE(sum(salary))
```

Aggregate pushdown results in a rewrite with EVI INCLUDE implementation, conceptually like the following query.

```
SELECT deptname, sum(sum(salary))
FROM department,
  (SELECT workdept, sum(salary) FROM employee group by workdept) employee_2
WHERE deptno=workdept
```

Instead of department joining to all the rows in the employee table, it now has the opportunity to join to the predetermined aggregates, the sum of salary by department number, in the EVI symbol table. This results in significant reduction in processing and IO.

[Encoded vector index symbol table scan](#)

An encoded vector index symbol table scan operation is used to retrieve the entries from the symbol table portion of the index.

Whole table COUNT(*) grouping implementation

A special access method is available for handling grouping queries that only use COUNT(*).

For queries that meet all of the following criteria, a special access method of retrieving the record count from the dataspace is used.

- the only aggregate function specified is COUNT(*) or COUNT of a non-null capable expression
- only one table is referenced
- no WHERE clause is specified
- no GROUP BY clause is specified
- the commitment control level is *NONE or Uncommitted Read

This appears as a TableScan in Visual Explain.

Optimizing grouping by eliminating grouping columns

All the grouping columns are evaluated to determine if they can be removed from the list of grouping columns. Only those grouping columns that have isolatable selection predicates with an equal operator specified can be considered. This guarantees that the column can only match a single value and does not help determine a unique group.

This processing allows the optimizer to consider more indexes to implement the query. It also reduces the number of columns that are added as key columns to a temporary index or hash table.

The following example illustrates a query where the optimizer might eliminate a grouping column.

```
DECLARE DEPTEMP CURSOR FOR
SELECT EMPNO, LASTNAME, WORKDEPT
FROM CORPDATA.EMPLOYEE
WHERE EMPNO = '000190'
GROUP BY EMPNO, LASTNAME, WORKDEPT
```

OPNQRYF example:

```
OPNQRYF FILE(EMPLOYEE) FORMAT(FORMAT1)
QRYSLT('EMPNO *EQ ''000190''')
GRPFLD(EMPNO LASTNAME WORKDEPT)
```

In this example, the optimizer can remove EMPNO from the list of grouping columns because of the EMPNO = '000190' selection predicate. An index that only has LASTNAME and WORKDEPT specified as key columns could implement the query. If a temporary index or hash is required then EMPNO is not used.

Note: Even though EMPNO can be removed from the list of grouping columns, the optimizer might use a permanent index that exists with all three grouping columns.

Optimizing grouping by adding additional grouping columns

The same logic that is applied to removing grouping columns can also be used to add additional grouping columns to the query. Additional grouping columns are added only when you are trying to determine if an index can be used to implement the grouping.

The following example illustrates a query where the optimizer might add an additional grouping column.

```
CREATE INDEX X1 ON EMPLOYEE
(LASTNAME, EMPNO, WORKDEPT)

DECLARE DEPTEMP CURSOR FOR
SELECT LASTNAME, WORKDEPT
FROM CORPDATA.EMPLOYEE
WHERE EMPNO = '000190'
GROUP BY LASTNAME, WORKDEPT
```

For this query request, the optimizer can add EMPNO as an additional grouping column when considering X1 for the query.

Optimizing grouping by using index skip key processing

Index Skip Key processing can be used when grouping with the keyed sequence implementation algorithm which uses an existing index. It is a specialized version of ordered grouping that processes few records in each group rather than all records in each group.

The index skip key processing algorithm:

1. Uses the index to position to a group and
2. finds the first row matching the selection criteria for the group, and if specified the first non-null MIN or MAX value in the group
3. Returns the group to the user
4. "Skip" to the next group and repeat processing

This algorithm improves performance by potentially not processing all index key values for a group.

Index skip key processing can be used:

- For single table queries using the keyed sequence grouping implementation when:
 - There are no column functions in the query, or
 - There is only a single MIN or MAX column function and the MIN or MAX operand is the next index key column after the grouping columns. There can be no other grouping functions in the query. For the MIN function, the key column must be an ascending key; for the MAX function, the key column must be a descending key. If the query is whole table grouping, the operand of the MIN or MAX must be the first key column.

Example 1, using SQL:

```
CREATE INDEX IX1 ON EMPLOYEE (SALARY DESC)  
DECLARE C1 CURSOR FOR  
SELECT MAX(SALARY) FROM EMPLOYEE;
```

The query optimizer chooses to use the index IX1. The SLIC runtime code scans the index until it finds the first non-null value for SALARY. Assuming that SALARY is not null, the runtime code positions to the first index key and return that key value as the MAX of salary. No more index keys are processed.

Example 2, using SQL:

```
CREATE INDEX IX2 ON EMPLOYEE (WORKDEPT, JOB, SALARY)  
DECLARE C1 CURSOR FOR  
SELECT WORKDEPT, MIN(SALARY)  
FROM EMPLOYEE  
WHERE JOB='CLERK'  
GROUP BY WORKDEPT
```

The query optimizer chooses to use Index IX2. The database manager positions to the first group for DEPT where JOB equals 'CLERK' and returns the SALARY. The code then skips to the next DEPT group where JOB equals 'CLERK'.

- For join queries:
 - All grouping columns must be from a single table.
 - For each dial, there can be at most one MIN or MAX column function operand that references the dial. No other column functions can exist in the query.
 - If the MIN or MAX function operand is from the same dial as the grouping columns, then it uses the same rules as single table queries.
 - If the MIN or MAX function operand is from a different dial, then the join column for that dial must join to one of the grouping columns. The index for that dial must contain the join columns followed by the MIN or MAX operand.

Example 1, using SQL:

```
CREATE INDEX IX1 ON DEPARTMENT(DEPTNAME)  
CREATE INDEX IX2 ON EMPLOYEE(WORKDEPT, SALARY)  
DECLARE C1 CURSOR FOR  
SELECT DEPARTMENT.DEPTNO, MIN(SALARY)  
FROM DEPARTMENT, EMPLOYEE  
WHERE DEPARTMENT.DEPTNO=EMPLOYEE.WORKDEPT  
GROUP BY DEPARTMENT.DEPTNO;
```

Optimizing grouping by removing read triggers

For queries involving physical files or tables with read triggers, group by triggers always involve a temporary file before the group by processing. Therefore, these queries slow down.

Note: Read triggers are added when the **Add Physical File Trigger (ADDPFTRG)** command has been used on the table with TRGTIME (*AFTER) and TRGEVENT (*READ).

The query runs faster if the read trigger is removed (RMVPFTRG TRGTIME (*AFTER) TRGEVENT (*READ)).

Related information

[Add Physical File Trigger \(ADDPFTRG\) command](#)

Grouping set optimization

The optimizer uses all the previously mentioned grouping optimizations for individual grouping sets specified in the query.

If multiple temporary result sets are needed to implement all the grouping sets, they can all be populated using one pass through the data. This one-pass population occurs even if different types of temporary result sets are used to implement various grouping sets.

A temporary result type called sorted distinct list is used specifically for ROLLUP implementations. This temporary result set is used to compute the aggregate rows: the grouping set that includes all expressions listed in the ROLLUP clause. Hash grouping is used internally to quickly find the current grouping value. The entries in the temporary result sets are also sorted. This sorting allows the aggregate results to be used to compute the super-aggregate rows in the rollup result set without creating additional temporary result sets.

ROLLUPS can also be implemented using a radix index over the columns in the rollup without creating a temporary result set.

The optimizer can compute all the grouping sets in a given ROLLUP using at most one temporary result set. Therefore, it is advantageous for the optimizer to look for the rollup pattern in grouping set queries.

The optimizer tries to find the ROLLUP pattern in a list of individual grouping sets. For example, the following GROUP BY clause:

```
GROUP BY GROUPING SETS ((A, B, C), (B, D), (A, B), (A), ( ))
```

is rewritten to:

```
GROUP BY GROUPING SETS ((ROLLUP(A, B, C)), (B, D))
```

This rewrite allows the query to be implemented using at most two temporary results sets rather than 4.

Queries containing a CUBE clause is broken down into a union of ROLLUPS and grouping sets. For example:

```
CUBE(A, B, C)
```

is equivalent to:

```
(ROLLUP(A, B, C)), (ROLLUP'(B, C)), (ROLLUP'(C, A))
```

The ROLLUP' notation is an internal representation of a ROLLUP operation that does not include a grand total row in its result set. So, ROLLUP'(B, C) is equivalent to GROUP BY GROUPING SETS ((B,C), (B)). This CUBE rewrite implements at most three temporary result sets, rather than the 8 that might be needed had the query not been rewritten.

Ordering optimization

This section describes how Db2 for i implements ordering techniques, and how optimization choices are made by the query optimizer. The query optimizer can use either index ordering or a sort to implement ordering.

Sort Ordering implementation

The sort algorithm reads the rows into a sort space and sorts the rows based on the specified ordering keys. The rows are then returned to the user from the ordered sort space.

Index Ordering implementation

The index ordering implementation requires an index that contains all the ordering columns as contiguous leftmost key columns. The database manager accesses the individual rows through the index in index order, which results in the rows being returned in order to the requester.

This implementation can be beneficial if an application does not need to retrieve all the ordered results, or if an index exists that matches the ordering columns. When the ordering is implemented with an index, and a permanent index does not exist that satisfies ordering columns, a temporary index is created. The ordering columns specified within the query are used as the key columns for this index.

Index Merge Ordering Implementation

Index Merge Ordering takes some of the features of both index and sorted ordering by using an index to apply the selection and then using an indexed list to sort the rows. This optimization is primarily aimed at queries that have an optimization goal of *FIRSTIO and the WHERE clause selection contains non-equal predicates.

Optimizing ordering by eliminating ordering columns

All the ordering columns are evaluated to determine if they can be removed from the list of ordering columns. Only those ordering columns that have isolatable selection predicates with an equal operator specified can be considered. This guarantees that the column can match only a single value, and does not help determine in the order.

In general, for an index to be eligible for Index Merge Ordering, the index should be created as follows:

- Any columns with equal predicates that are not in the ORDER BY list should be first keys in the index.
- Followed by any columns for non-equal predicates that are not in the ORDER BY list. The columns should be arranged so the most selective predicate column is the first column following the equal predicate columns.
- Followed by the ORDER BY columns in the same order as the ORDER BY clause of the query and with the same ASC or DESC attribute.
- Optionally, at the end you may include other selection columns or other selected columns for Index Only Access.

For example:

```
SELECT * FROM SALES
WHERE SALES_DATE BETWEEN '1996-03-29' AND '1996-04-29'
AND REGION IN ('Quebec','Manitoba')
ORDER BY SALES_PERSON
```

The Index to create would be with keys:

```
SALES_DATE, REGION, SALES_PERSON
```

In order to allow a more general indexing scheme, it is possible to use an index for index merge ordering even if there are leading keys not used in the query. The above index could also be used for the following query:

```
SELECT SALES_DATE, REGION, SALES_PERSON, SALES
FROM SALES
WHERE REGION IN ('Quebec','Manitoba')
ORDER BY SALES_PERSON
```

If SALES was added as a trailing key, then Index Only Access would be used for both queries.

```
CREATE INDEX SALES_IMOX ON SALES (SALES_DATE, REGION, SALES_PERSON, SALES)
```

The optimizer can now consider more indexes as it implements the query. The number of columns that are added as key columns to a temporary index is also reduced. The following SQL example illustrates a query where the optimizer might eliminate an ordering column.

```
DECLARE DEPTEMP CURSOR FOR
SELECT EMPNO, LASTNAME, WORKDEPT
FROM CORPDATA.EMPLOYEE
WHERE EMPNO = '000190'
ORDER BY EMPNO, LASTNAME, WORKDEPT
```

Optimizing ordering by adding additional ordering columns

The same logic that is applied to removing ordering columns can also be used to add additional grouping columns to the query. This logic is done only when you are trying to determine if an index can be used to implement the ordering.

The following example illustrates a query where the optimizer might add an additional ordering column.

```
CREATE INDEX X1 ON EMPLOYEE (LASTNAME, EMPNO, WORKDEPT)

DECLARE DEPTEMP CURSOR FOR
SELECT LASTNAME, WORKDEPT
FROM CORPDATA.EMPLOYEE
WHERE EMPNO = '000190'
ORDER BY LASTNAME, WORKDEPT
```

For this query request, the optimizer can add EMPNO as an additional ordering column when considering X1 for the query.

Index Ordering Implementation Using Reverse Ordered Indexes

It is also possible to use reverse ordered indexes to provide ordering. In that case, the index keys for all ORDER BY columns must be reversed. The database manager will process the index in reverse order by starting at the end and reading through the index backwards.

The following index and query illustrates an example where the optimizer could use a reversed ordered index.

```
CREATE INDEX CORPDATA.INDEX1 ON CORPDATA.EMPLOYEE (SALARY ASC, LASTNAME DESC)

SELECT EMPNO, LASTNAME, WORKDEPT, SALARY
FROM CORPDATA.EMPLOYEE
ORDER BY SALARY DESC, LASTNAME ASC
```

View implementation

Views, derived tables (nested table expressions or NTEs), and common table expressions (CTEs) are implemented by the query optimizer using one of two methods.

These methods are:

- The optimizer combines the query select statement with the select statement of the view.
- The optimizer places the results of the view in a temporary table and then replaces the view reference in the query with the temporary table.

View composite implementation

The view composite implementation takes the query select statement and combines it with the select statement of the view to generate a new query. The new, combined select statement query is then run directly against the underlying base tables.

This single, composite statement is the preferred implementation for queries containing views, since it requires only a single pass of the data.

See the following examples:

```
CREATE VIEW D21EMPL AS
SELECT * FROM CORPDATA.EMPLOYEE
WHERE WORKDEPT='D21'
```

Using SQL:

```
SELECT LASTNAME, FIRSTNME, SALARY
FROM D21EMPL
WHERE JOB='CLERK'
```

The query optimizer generates a new query that looks like the following example:

```
SELECT LASTNAME, FIRSTNME, SALARY
FROM CORPDATA.EMPLOYEE
WHERE WORKDEPT='D21' AND JOB='CLERK'
```

The query contains the columns selected by the user query, the base tables referenced in the query, and the selection from both the view and the user query.

Note: The new composite query that the query optimizer generates is not visible to users. Only the original query against the view is seen by users and database performance tools.

View materialization implementation

The view materialization implementation runs the query of the view and places the results in a temporary result. The view reference in the user query is then replaced with the temporary, and the query is run against the temporary result.

View materialization is done whenever it is not possible to create a view composite. For SQE, view materialization is optional. The following types of queries require view materialization:

- The outermost view select contains grouping, the query contains grouping, and refers to a column derived from a column function in the view HAVING or select-list.
- The query is a join and the outermost select of the view contains grouping or DISTINCT.
- The outermost select of the view contains DISTINCT, and the query has UNION, grouping, or DISTINCT and one of the following:
 - Only the query has a shared weight NLSS table
 - Only the view has a shared weight NLSS table
 - Both the query and the view have a shared weight NLSS table, but the tables are different.
- The query contains a column function and the outermost select of the view contains a DISTINCT
- The view does not contain an access plan. Occurs when a view references a view, and a view composite cannot be created because of one of the previous listed reasons. Does not apply to nested table expressions and common table expressions.
- The Common table expression (CTE) is referenced more than once in the query FROM clause. Also, the CTE SELECT clause references a MODIFIES or EXTERNAL ACTION UDF.

When a temporary result table is created, access methods that are allowed with ALWCPYDTA(*OPTIMIZE) could be used to implement the query. These methods include hash grouping, hash join, and bitmaps.

See the following examples:

```
CREATE VIEW AVGSALVW AS
SELECT WORKDEPT, AVG(SALARY) AS AVGSAL
FROM CORPDATA.EMPLOYEE
GROUP BY WORKDEPT
```

SQL example:

```
SELECT D.DEPTNAME, A.AVGSAL
FROM CORPDATA.DEPARTMENT D, AVGSALVW A
WHERE D.DEPTNO=A.WORKDEPT
```

In this case, a view composite cannot be created since a join query references a grouping view. The results of AVGSALVW are placed in a temporary result table (*QUERY0001). The view reference AVGSALVW is replaced with the temporary result table. The new query is then run. The generated query looks like the following:

```
SELECT D.DEPTNAME, A.AVGSAL
FROM CORPDATA.DEPARTMENT D, *QUERY0001 A
WHERE D.DEPTNO=A.WORKDEPT
```

Note: The new query that the query optimizer generates is not visible to users. Only the original query against the view is seen by users and database performance tools.

Whenever possible, isolatable selection from the query, except subquery predicates, is added to the view materialization process. This results in smaller temporary result tables and allows existing indexes to be used when materializing the view. This process is not done if there is more than one reference to the same view or common table expression in the query. The following is an example where isolatable selection is added to the view materialization:

```
SELECT D.DEPTNAME, A.AVGSAL
FROM CORPDATA.DEPARTMENT D, AVGSALVW A
WHERE D.DEPTNO=A.WORKDEPT AND
A.WORKDEPT LIKE 'D%' AND AVGSAL>10000
```

The isolatable selection from the query is added to the view resulting in a new query to generate the temporary result table:

```
SELECT WORKDEPT, AVG(SALARY) AS AVGSAL
FROM CORPDATA.EMPLOYEE
WHERE WORKDEPT LIKE 'D%'
GROUP BY WORKDEPT
HAVING AVG(SALARY)>10000
```

Materialized query table optimization

Materialized query tables (MQTs) (also referred to as automatic summary tables or materialized views) can provide performance enhancements for queries.

This performance enhancement is done by precomputing and storing results of a query in the materialized query table. The database engine can use these results instead of recomputing them for a user specified query. The query optimizer looks for any applicable MQTs. The optimizer can implement the query using a given MQT, provided it is a faster implementation choice.

Materialized Query Tables are created using the SQL CREATE TABLE statement. Alternatively, the ALTER TABLE statement could be used to convert an existing table into a materialized query table. The REFRESH TABLE statement is used to recompute the results stored in the MQT. For user-maintained MQTs, the MQTs could also be maintained by the user using INSERT, UPDATE, and DELETE statements.

Related information

[Create Table statement](#)

MQT supported function

Although an MQT can contain almost any query, the optimizer only supports a limited set of query functions when matching MQTs to user specified queries. The user-specified query and the MQT query must both be supported by the SQE optimizer.

The supported function in the MQT query by the MQT matching algorithm includes:

- Single table and join queries
- WHERE clause
- GROUP BY and optional HAVING clauses
- ORDER BY
- FETCH FIRST n ROWS
- Views, common table expressions, and nested table expressions
- UNIONS
- Partitioned tables

There is limited support in the MQT matching algorithm for the following:

- Scalar subselects
- User Defined Functions (UDFs) and user-defined table functions
- Recursive Common Table Expressions (RCTE)
- The following scalar functions:
 - ATAN2
 - DAYNAME
 - DBPARTITIONNAME
 - DECRYPT_BIT
 - DECRYPT_BINARY
 - DECRYPT_CHAR
 - DECRYPT_DB
 - DIFFERENCE
 - DLVALUE
 - DLURLPATH
 - DLURLPATHONLY
 - DLURLSEVER
 - DLURLSCHEME
 - DLURLCOMPLETE
 - ENCRYPT_AES
 - ENCRYPT_RC2
 - ENCRYPT_TDES
 - GENERATE_UNIQUE
 - GETHINT
 - IDENTITY_VAL_LOCAL
 - INSERT
 - MONTHNAME
 - MONTHS_BETWEEN
 - NEXT_DAY
 - RAND

- RAISE_ERROR
- REPEAT
- REPLACE
- ROUND_TIMESTAMP
- SOUNDEX
- TIMESTAMP_FORMAT
- TIMESTAMPDIFF
- TRUNC_TIMESTAMP
- VARCHAR_FORMAT
- WEEK_ISO

It is recommended that the MQT only contain references to columns and column functions. In many environments, queries that contain constants have the constants converted to parameter markers. This conversion allows a much higher degree of ODP reuse. The MQT matching algorithm attempts to match constants in the MQT with parameter markers or host variable values in the query. However, in some complex cases this support is limited and could result in the MQT not matching the query.

Related concepts

Query dispatcher

The function of the dispatcher is to route the query request to either CQE or SQE, depending on the attributes of the query. All queries are processed by the dispatcher. It cannot be bypassed.

Details on the MQT matching algorithm

What follows is a generalized discussion of how the MQT matching algorithm works.

Using MQTs during query optimization

Before using MQTs, you need to consider your environment attributes.

To even consider using MQTs during optimization the following environmental attributes must be true:

- The query must specify ALWCPYDTA(*OPTIMIZE) or INSENSITIVE cursor.
- The query must not be a SENSITIVE cursor.
- The table to be replaced with an MQT must not be update or delete capable for this query.
- The MQT currently has the ENABLE QUERY OPTIMIZATION attribute active
- The MATERIALIZED_QUERY_TABLE_USAGE QAQQINI option must be set to *ALL or *USER to enable use of MQTs. The default setting of MATERIALIZED_QUERY_TABLE_USAGE does not allow usage of MQTs.
- The timestamp of the last REFRESH TABLE for an MQT is within the duration specified by the MATERIALIZED_QUERY_TABLE_REFRESH_AGE QAQQINI option. Or *ANY is specified, which allows MQTs to be considered regardless of the last REFRESH TABLE. The default setting of MATERIALIZED_QUERY_TABLE_REFRESH_AGE does not allow usage of MQTs.
- The query must be run through SQE.
- The following QAQQINI options must match: IGNORE_LIKE_REDUNDANT_SHIFTS, NORMALIZE_DATA, and VARIABLE_LENGTH_OPTIMIZATION. These options are stored at CREATE materialized query table time and must match the options specified at query run time.
- The commit level of the MQT must be greater than or equal to the query commit level. The commit level of the MQT is either specified in the MQT query using the WITH clause. Or it is defaulted to the commit level that the MQT was run under when it was created.
- The field procedure encoded comparison (QAQQINI FIELDPROC_ENCODED_COMPARISON option) level of the MQT must be greater than or equal to the query specified field procedure encoded comparison level.

MQT examples

The following are examples of using MQTs.

Example 1

The first example is a query that returns information about employees whose job is DESIGNER. The original query:

```
SELECT D.deptname, D.location, E.firstnme, E.lastname, E.salary+E.comm+E.bonus as total_sal
FROM Department D, Employee E
WHERE D.deptno=E.workdept
AND E.job = 'DESIGNER'
```

Create a table, MQT1, that uses this query:

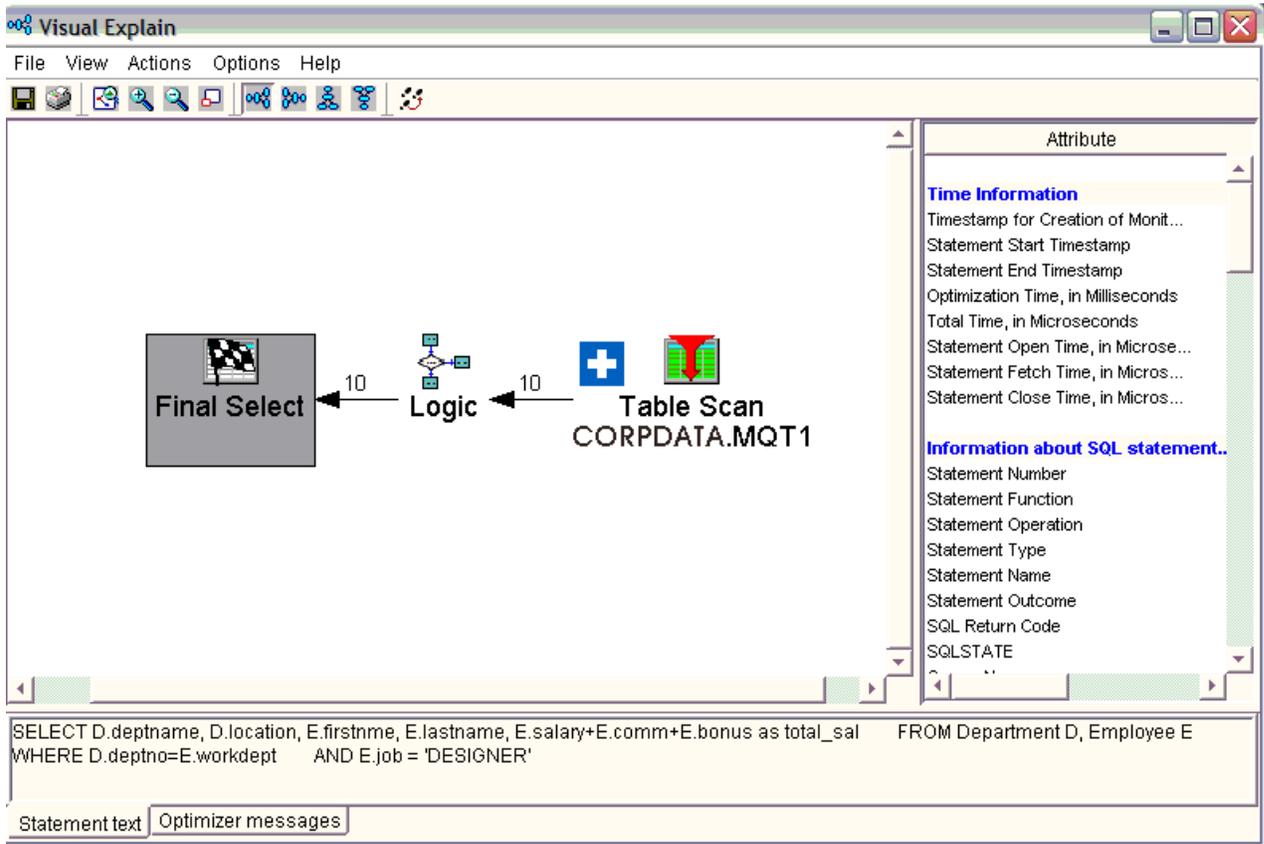

```
CREATE TABLE MQT1
AS (SELECT D.deptname, D.location, E.firstnme, E.lastname, E.salary, E.comm, E.bonus,
E.job
FROM Department D, Employee E
WHERE D.deptno=E.workdept)
DATA INITIALLY IMMEDIATE REFRESH DEFERRED
ENABLE QUERY OPTIMIZATION
MAINTAINED BY USER
```

Resulting new query after replacing the specified tables with the MQT.

```
SELECT M.deptname, M.location, M.firstnme, M.lastname, M.salary+M.comm+M.bonus as total_sal
FROM MQT1 M
WHERE M.job = 'DESIGNER'
```

In this query, the MQT matches part of the user query. The MQT is placed in the FROM clause and replaces tables DEPARTMENT and EMPLOYEE. Any remaining selection not done by the MQT query (M.job= 'DESIGNER') is done to remove the extra rows. The result expression, M.salary+M.comm+M.bonus, is calculated. JOB must be in the select-list of the MQT so that the additional selection can be performed.

Visual Explain diagram of the query when using the MQT:

Example 2

Get the total salary for all departments that are located in 'NY'. The original query:

```
SELECT D.deptname, sum(E.salary)
FROM DEPARTMENT D, EMPLOYEE E
WHERE D.deptno=E.workdept AND D.location = 'NY'
GROUP BY D.deptname
```

Create a table, MQT2, that uses this query:

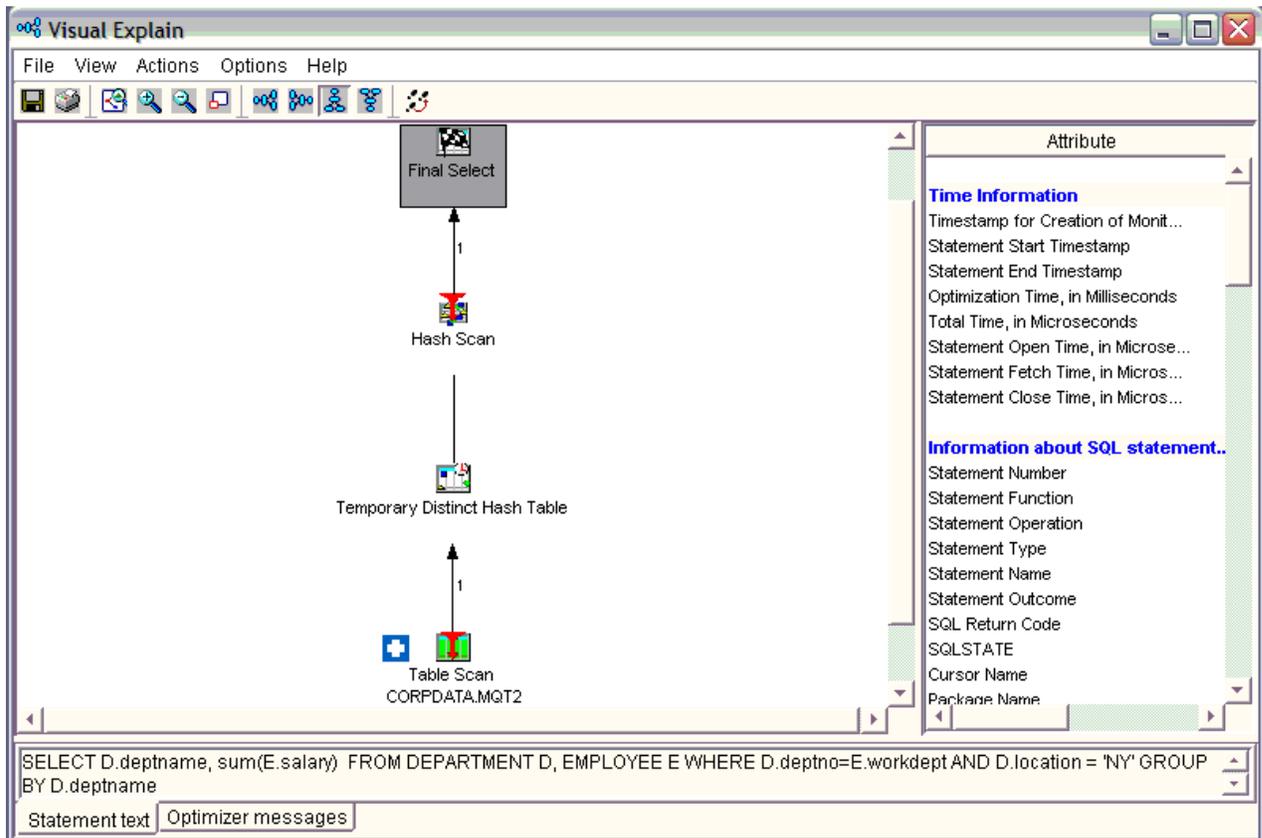

```
CREATE TABLE MQT2
AS (SELECT D.deptname, D.location, sum(E.salary) as sum_sal
FROM DEPARTMENT D, EMPLOYEE E
WHERE D.deptno=E.workdept
GROUP BY D.Deptname, D.location)
DATA INITIALLY IMMEDIATE REFRESH DEFERRED
ENABLE QUERY OPTIMIZATION
MAINTAINED BY USER
```

Resulting new query after replacing the specified tables with the MQT:

```
SELECT M.deptname, sum(M.sum_sal)
FROM MQT2 M
WHERE M.location = 'NY'
GROUP BY M.deptname
```

Since the MQT could potentially produce more groups than the original query, the final resulting query must group again and SUM the results to return the correct answer. Also, the selection M.location='NY' must be part of the new query.

Visual Explain diagram of the query when using the MQT:

Details on the MQT matching algorithm

What follows is a generalized discussion of how the MQT matching algorithm works.

The tables specified in the query and the MQT are examined. If the MQT and the query specify the same tables, then the MQT can potentially be used and matching continues. If the MQT references tables not referenced in the query, then the unreferenced table is examined to determine if it is a parent table in referential integrity constraint. If the foreign key is non-nullable and the two tables are joined using a primary key or foreign key equal predicate, then the MQT can still be potentially used.

Example 3

The MQT contains fewer tables than the query:

```
SELECT D.deptname, p.projname, sum(E.salary)
FROM DEPARTMENT D, EMPLOYEE E, EMPPROJECT EP, PROJECT P
WHERE D.deptno=E.workdept AND E.empno=ep.empno
AND ep.projno=p.projno
GROUP BY D.DEPTNAME, p.projname
```

Create an MQT based on the preceding query:

```
CREATE TABLE MQT3
AS (SELECT D.deptname, sum(E.salary) as sum_sal, e.workdept, e.empno
FROM DEPARTMENT D, EMPLOYEE E
WHERE D.deptno=E.workdept
GROUP BY D.Deptname, e.workdept, e.empno)
DATA INITIALLY IMMEDIATE REFRESH DEFERRED
ENABLE QUERY OPTIMIZATION
MAINTAINED BY USER
```

The rewritten query:

```
SELECT M.deptname, p.projname, SUM(M.sum_sal)
FROM MQT3 M, EMPPROJECT EP, PROJECT P
```

```
WHERE M.Empno=ep.empno AND ep.projno=p.projno
GROUP BY M.deptname, p.projname
```

All predicates specified in the MQT, must also be specified in the query. The query could contain additional predicates. Predicates specified in the MQT must match exactly the predicates in the query. Any additional predicates specified in the query, but not in the MQT must be able to be derived from columns projected from the MQT. See previous example 1.

Example 4

Set the total salary for all departments that are located in 'NY'.

```
SELECT D.deptname, sum(E.salary)
FROM DEPARTMENT D, EMPLOYEE E
WHERE D.deptno=E.workdept AND D.location = ?
GROUP BY D.Deptname
```

Create an MQT based on the preceding query:

```
CREATE TABLE MQT4
AS (SELECT D.deptname, D.location, sum(E.salary) as sum_sal
FROM DEPARTMENT D, EMPLOYEE E
WHERE D.deptno=E.workdept AND D.location = 'NY'
GROUP BY D.deptname, D.location)
DATA INITIALLY IMMEDIATE REFRESH DEFERRED
ENABLE QUERY OPTIMIZATION
MAINTAINED BY USER
```

In this example, the constant 'NY' was replaced by a parameter marker and the MQT also had the local selection of location='NY' applied to it when the MQT was populated. The MQT matching algorithm matches the parameter marker and to the constant 'NY' in the predicate D.Location=?. It verifies that the values of the parameter marker are the same as the constant in the MQT; therefore the MQT can be used.

The MQT matching algorithm also attempts to match where the predicates between the MQT and the query are not the same. For example, if the MQT has a predicate SALARY > 50000, and the query has the predicate SALARY > 70000, the MQT contains the rows necessary to run the query. The MQT is used in the query, but the predicate SALARY > 70000 is left as selection in the query, so SALARY must be a column of the MQT.

Example 5

```
SELECT D.deptname, sum(E.salary)
FROM DEPARTMENT D, EMPLOYEE E
WHERE D.deptno=E.workdept AND D.location = 'NY'
GROUP BY D.deptname
```

Create an MQT based on the preceding query:

```
CREATE TABLE MQT5
AS (SELECT D.deptname, E.salary
FROM DEPARTMENT D, EMPLOYEE E
WHERE D.deptno=E.workdept)
DATA INITIALLY IMMEDIATE REFRESH DEFERRED
ENABLE QUERY OPTIMIZATION
MAINTAINED BY USER
```

In this example, since D.Location is not a column of the MQT, the user query local selection predicate Location='NY' cannot be determined, so the MQT cannot be used.

Example 6

```
SELECT D.deptname, sum(E.salary)
FROM DEPARTMENT D, EMPLOYEE E
WHERE D.deptno=E.workdept
GROUP BY D.deptname
```

Create an MQT based on the preceding query:

```
CREATE TABLE MQT6(workdept, sumSalary)
AS (SELECT workdept, sum(salary)
    FROM EMPLOYEE
    GROUP BY workdept )
DATA INITIALLY IMMEDIATE REFRESH DEFERRED
ENABLE QUERY OPTIMIZATION
MAINTAINED BY USER
```

In this example, the SUM(salary) aggregation is pushed down through the join to the EMPLOYEE table, allowing for a match and substitution of MQT6. A regrouping to (sum(sum(salary))) is defined at the top of the query to compensate for the grouping pushdown.

Instead of department joining to all the rows in the employee table, it now has the opportunity to join to the predetermined aggregates in MQT6. This type of MQT substitution can result in significant reduction of processing and IO.

If the MQT contains grouping, then the query must be a grouping query. The simplest case is where the MQT and the query specify the same list of grouping columns and column functions.

In some cases, if the MQT specifies group by columns that are a superset of query group by columns, the query can be rewritten to do regrouping. This regrouping reaggregates the groups of the MQT into the groups required by the query. When regrouping is required, the column functions need to be recomputed. The following table shows the supported regroup expressions.

The regrouping expression/aggregation rules are:

<i>Table 32. Expression/aggregation rules for MQTs</i>		
Query	MQT	Final query
COUNT(*)	COUNT(*) as cnt	SUM(cnt)
COUNT(*)	COUNT(C2) as cnt2 (where c2 is non-nullable)	SUM(cnt2)
COUNT(c1)	COUNT(c1) as cnt	SUM(cnt)
COUNT(C1) (where C1 is non-nullable)	COUNT(C2) as cnt2 (where C2 is non-nullable)	SUM(cnt2)
COUNT(distinct C1)	C1 as group_c1 (where C1 is a grouping column)	COUNT(group_C1)
COUNT(distinct C1)	where C1 is not a grouping column	MQT not usable
COUNT(C2) where C2 is from a table not in the MQT	COUNT(*) as cnt	cnt*COUNT(C2)
COUNT(distinct C2) where C2 is from a table not in the MQT	Not applicable	COUNT(distinct C2)
SUM(C1)	SUM(C1) as sm	SUM(sm)
SUM(C1)	C1 as group_c1, COUNT(*) as cnt (where C1 is a grouping column)	SUM(group_c1 * cnt)
SUM(C2) where C2 is from a table not in the MQT	COUNT(*) as cnt	cnt*SUM(C2)
SUM(distinct C1)	C1 as group_c1 (where C1 is a grouping column)	SUM(group_C1)
SUM(distinct C1)	where C1 is not a grouping column	MQT not usable

Table 32. Expression/aggregation rules for MQTs (continued)

Query	MQT	Final query
SUM(distinct C2) where C2 is from a table not in the MQT	Not applicable	SUM(distinct C2)
MAX(C1)	MAX(C1) as mx	MAX(mx)
MAX(C1)	C1 as group_C1 (where C1 is a grouping column)	MAX(group_c1)
MAX(C2) where C2 is from a table not in the MQT	Not applicable	MAX(C2)
MIN(C1)	MIN(C1) as mn	MIN(mn)
MIN(C1)	C1 as group_C1 (where C1 is a grouping column)	MIN(group_c1)
MIN(C2) where C2 is from a table not in the MQT	Not applicable	MIN(C2)
GROUPING(C1)	GROUPING(C1) as grp	grp
GROUPING(C2) where C2 is from a table not in the MQT	Not applicable	GROUPING(C2)

MQT matching does not support ARRAY_AGG, XMLAGG, and XMLGROUP grouping functions. AVG, STDDEV, STDDEV_SAMP, VARIANCE_SAMP and VAR_POP are calculated using combinations of COUNT and SUM. If AVG, STDDEV, or VAR_POP are included in the MQT and regroup requires recalculation of these functions, the MQT cannot be used. It is recommended that the MQT only use COUNT, SUM, MIN, and MAX. If the query contains AVG, STDDEV, or VAR_POP, it can be recalculated using COUNT and SUM.

If FETCH FIRST N ROWS is specified in the MQT, then FETCH FIRST N ROWS must also be specified in the query. Also, the number of rows specified for the MQT must be greater than or equal to the number of rows specified in the query. It is not recommended that an MQT contain the FETCH FIRST N ROWS clause.

The ORDER BY clause on the MQT can be used to order the data in the MQT if a REFRESH TABLE is run. It is ignored during MQT matching and if the query contains an ORDER BY clause, it is part of the rewritten query.

MQT supported function

Although an MQT can contain almost any query, the optimizer only supports a limited set of query functions when matching MQTs to user specified queries. The user-specified query and the MQT query must both be supported by the SQE optimizer.

Determining unnecessary MQTs

You can easily determine which MQTs are being used for query optimization. However, you can now easily find all MQTs and retrieve statistics on MQT usage as a result of System i Navigator and IBM i functionality.

To assist you in tuning your performance, this function produces statistics on MQT usage in a query. To access through the System i Navigator, navigate to: **Database > Schemas > Tables**. Right-click your table and select **Show Materialized Query Tables**. You can also view MQT usage information by right-click on Tables or Views folder and select **Show Materialized Query Tables**. This action displays usage information for MQTs created over all the tables or view in that schema.

Note: You can also view the statistics through an application programming interface (API).

In addition to all existing attributes of an MQT, two fields can help you determine unnecessary MQTs.

These fields are:

Last Query Use States the timestamp when the MQT was last used by the optimizer to replace user specified tables in a query.

Query Use Count Lists the number of instances the MQT was used by the optimizer to replace user specified tables in a query.

The fields start and stop counting based on your situation, or the actions you are currently performing on your system. A save and restore procedure does not reset the statistics counter if the MQT is restored over an existing MQT. If an MQT is restored that does not exist on the system, the statistics are reset.

Summary of MQT query recommendations

Follow these recommendations when using MQT queries.

- Do not include local selection or constants in the MQT because that limits the number of user-specified queries where the optimizer can use the MQT.
- For grouping MQTs, only use the SUM, COUNT, MIN, and MAX grouping functions. The query optimizer can recalculate AVG, STDDEV, and VAR_POP in user specified queries.
- Specifying FETCH FIRST N ROWS in the MQT limits the number of user-specified queries where the query optimizer can use the MQT. Not recommended.
- If the MQT is created with DATA INITIALLY DEFERRED, consider specifying DISABLE QUERY OPTIMIZATION to prevent the optimizer from using the MQT until it has been populated. When the MQT is populated and ready for use, the ALTER TABLE statement with ENABLE QUERY OPTIMIZATION enables the MQT.

In addition, consider using a sparse index or EVI INCLUDE additional aggregates rather than an MQT if you are concerned with stale data.

MQT tables need to be optimized just like non-MQT tables. It is recommended that indexes are created over the MQT columns used for selection, join, and grouping, as appropriate. Column statistics are collected for MQT tables.

The database monitor shows the list of MQTs considered during optimization. This information is in the 3030 record. If MQTs have been enabled through the QAQQINI file, and an MQT exists over at least one of the tables in the query, there is a 3030 record for the query. Each MQT has a reason code indicating that it was used or if it was not used, why it was not used.

[Sparse index optimization](#)

An SQL sparse index is like a select/omit access path. Both the sparse index and the select/omit logical file contain only keys that meet the selection specified. For a sparse index, the selection is specified with a WHERE clause. For a select/omit logical file, the selection is specified in the DDS using the COMP operation.

Recursive query optimization

Certain applications and data are recursive by nature. Examples of such applications are a bill-of-material, reservation, trip planner, or networking planning system. Data in one results row has a natural relationship (call it a parent, child relationship) with data in another row or rows. The kinds of recursion implemented in these systems can be performed by using SQL Stored Procedures and temporary results tables. However, the use of a recursive query to facilitate the access of this hierarchical data can lead to a more elegant and better performing application.

Recursive queries can be implemented by defining either a Recursive Common Table Expression (RCTE) or a Recursive View.

Recursive query example

A recursive query is one that is defined by a Union All with an initialization fullselect that seeds the recursion. The iterative fullselect contains a direct reference to itself in the FROM clause.

There are additional restrictions as to what can be specified in the definition of a recursive query. Those restrictions can be found in SQL Programming topic.

Functions like grouping, aggregation, or distinct require a materialization of all the qualifying records before performing the function. These functions cannot be allowed within the iterative fullselect itself. The functions must be placed in the main query, allowing the recursion to complete.

The following is an example of a recursive query over a table called flights, that contains information about departure and arrival cities. The query returns all the flight destinations available by recursion from the two specified cities (New York and Chicago). It also returns the number of connections and total cost to arrive at that final destination.

This example uses the recursion process to also accumulate information like the running cost and number of connections. Four values are put in the queue entry. These values are:

- The originating departure city (either Chicago or New York) because it remains fixed from the start of the recursion
- The arrival city which is used for subsequent joins
- The incrementing connection count
- The accumulating total cost to reach each destination

Typically the data needed for the queue entry is less than the full record (sometimes much less) although that is not the case for this example.

```
CREATE TABLE flights
(
  departure CHAR (10) NOT NULL WITH DEFAULT,
  arrival CHAR (10) NOT NULL WITH DEFAULT,
  carrier CHAR (15) NOT NULL WITH DEFAULT,
  flight_num CHAR (5) NOT NULL WITH DEFAULT,
  ticket INT NOT NULL WITH DEFAULT)

WITH destinations (departure, arrival, connects, cost ) AS
(
  SELECT f.departure,f.arrival, 0, ticket
  FROM flights f
  WHERE f.departure = 'Chicago' OR
        f.departure = 'New York'
  UNION ALL
  SELECT
    r.departure, b.arrival, r.connects + 1,
    r.cost + b.ticket
  FROM destinations r, flights b
  WHERE r.arrival = b.departure
)
SELECT DISTINCT departure, arrival, connects, cost
FROM destinations
```

The following is the initialization fullselect of the preceding query. It seeds the rows that start the recursion process. It provides the initial destinations (arrival cities) that are a direct flight from Chicago or New York.

```
SELECT f.departure,f.arrival, 0, ticket
FROM flights f
WHERE f.departure='Chicago' OR
      f.departure='New York'
```

The following is the iterative fullselect of the preceding query. It contains a single reference in the FROM clause to the destination recursive common table expression. It also sources further recursive joins to

the same flights table. The arrival values of the parent row (initially direct flights from New York or Chicago) are joined with the departure value of the subsequent child rows. It is important to identify the correct parent/child relationship on the recursive join predicate or infinite recursion can occur. Other local predicates can also be used to limit the recursion. For example, for a limit of at most 3 connecting flights, a local predicate using the accumulating connection count, `r.connects<=3`, can be specified.

```
SELECT
  r.departure, b.arrival, r.connects + 1 ,
  r.cost + b.ticket
FROM destinations r, flights b
WHERE r.arrival=b.departure
```

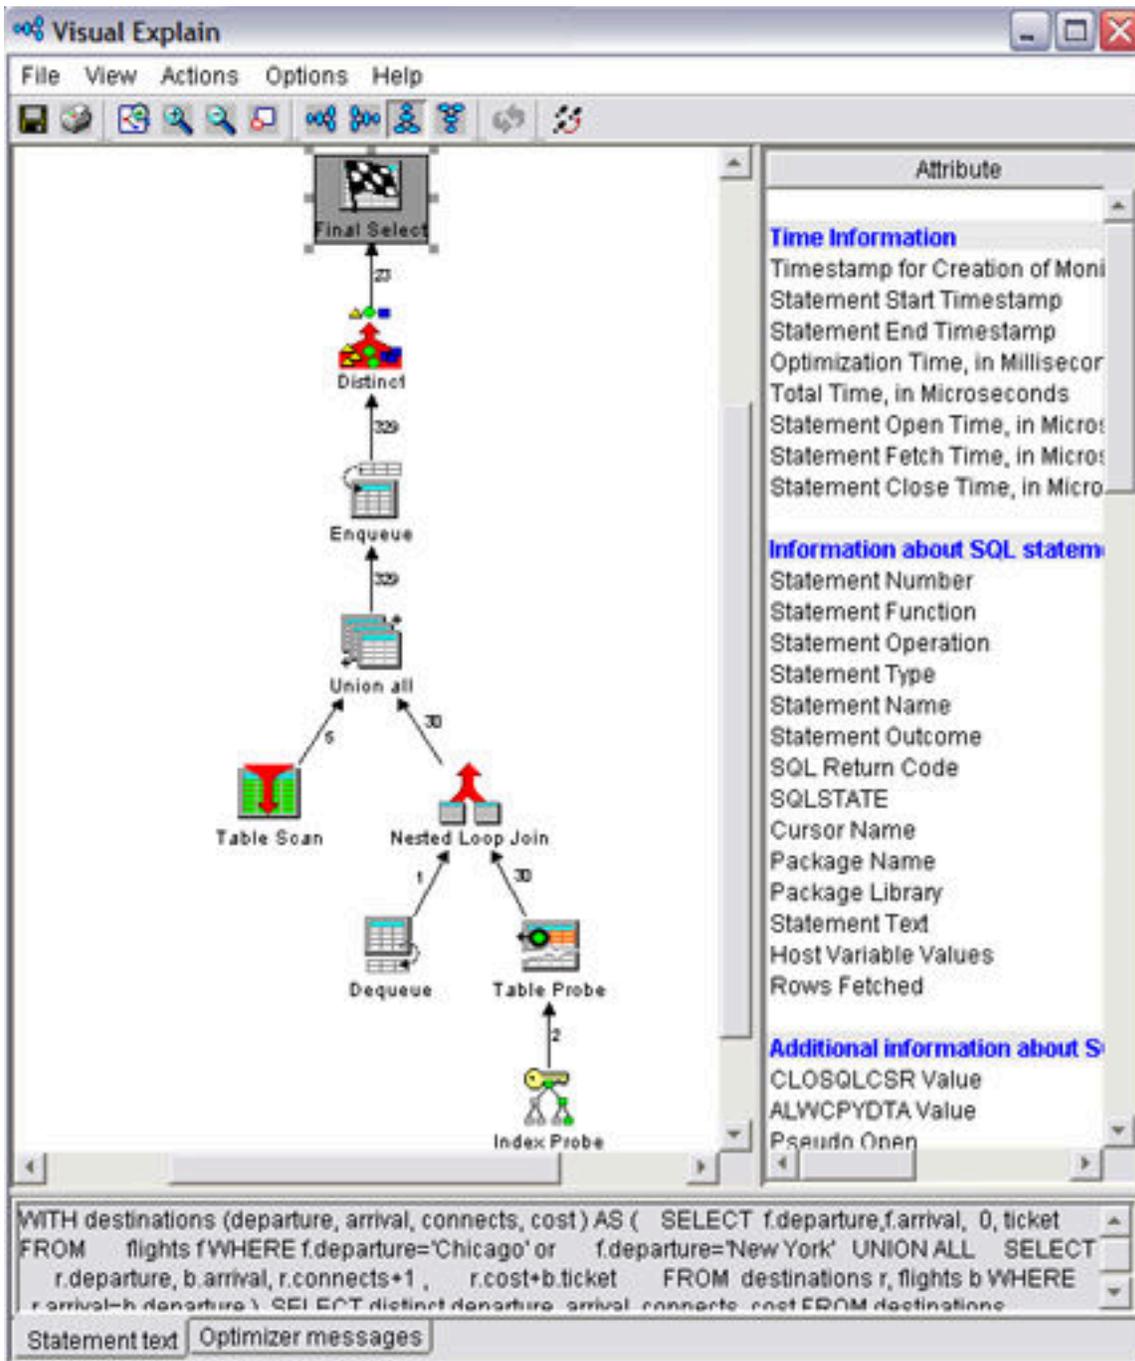

The main query is the query that references the recursive common table expression or view. It is in the main query where requests like grouping, ordering, and distinct are specified.

```
SELECT DISTINCT departure, arrival, connects, cost
FROM destinations
```

Implementation considerations

To implement a source for the recursion, a new temporary data object is provided called a queue. As rows meet the requirements of either the initialization fullselect or the iterative fullselect, they are pulled up through the union all. Values necessary to feed the continuing recursion process are captured and placed in an entry on the queue: an enqueue operation.

At query runtime, the queue data source then takes the place of the recursive reference in the common table expression or view. The iterative fullselect processing ends when the queue is exhausted of entries or a fetch N rows limitation has been met. The recursive queue feeds the recursion process and holds transient data. The join between dequeuing of these queue entries and the rest of the fullselect tables is always a constrained join, with the queue on the left.

Multiple initialization and iterative fullselects

The use of multiple initialization and iterative fullselects specified in the recursive query definition allows for a multitude of data sources and separate selection requirements to feed the recursion process.

For example, the following query allows for final destinations accessible from Chicago by both flight and train travel.

```
WITH destinations (departure, arrival, connects, cost ) AS
(
  SELECT f.departure, f.arrival, 0 , ticket
  FROM flights f
  WHERE f.departure='Chicago'
  UNION ALL
  SELECT t.departure, t.arrival, 0 , ticket
  FROM trains t
  WHERE t.departure='Chicago'
```

Predicate pushing

When processing most queries with non-recursive common table expressions or views, local predicates specified on the main query are pushed down so fewer records need to be materialized. Pushing local predicates from the main query into the defined recursive part of the query (through the Union ALL), however, could considerably alter the process of recursion itself. So as a rule, the Union All specified in a recursive query is currently a predicate fence. Predicates are not pushed down or up, through this fence.

The following is an example of how pushing a predicate in to the recursion limits the recursive results and alter the intent of the query.

The intent of the query is to find all destinations accessible from 'Chicago', not including the final destination of 'Dallas'. Pushing the "arrival<>'Dallas'" predicate into the recursive query alters the output of the intended results. It prevents the output of final destinations where 'Dallas' was an intermediate stop.

```
WITH destinations (departure, arrival, connects, cost ) AS
(
  SELECT f.departure,f.arrival, 0, ticket
  FROM flights f
  WHERE f.departure='Chicago'
  UNION ALL
  SELECT
    r.departure, b.arrival, r.connects + 1 ,
    r.cost + b.ticket
  FROM destinations r, flights b
  WHERE r.arrival=b.departure
)
SELECT departure, arrival, connects, cost
FROM destinations
WHERE arrival != 'Dallas'
```

Conversely, the following is an example where a local predicate applied to all the recursive results is a good predicate to put in the body of the recursive definition because it could greatly decrease the number of rows materialized from the RCTE/View. The better query request here is to specify the r.connects <=3 local predicate with in the RCTE definition, in the iterative fullselect.

```
WITH destinations (departure, arrival, connects, cost ) AS
(
  SELECT f.departure,f.arrival, 0, ticket
  FROM flights f
  WHERE f.departure='Chicago' OR
    f.departure='New York'
  UNION ALL
  SELECT
    r.departure, b.arrival, r.connects + 1 ,
    r.cost + b.ticket
  FROM destinations r, flights b
  WHERE r.arrival=b.departure
)
SELECT departure, arrival, connects, cost
FROM destinations
WHERE r.connects<=3
```

Placement of local predicates is key in recursive queries. They can incorrectly alter the recursive results if pushed into a recursive definition. Or they can cause unnecessary rows to be materialized and then rejected, when a local predicate could legitimately help limit the recursion.

Specifying SEARCH consideration

Certain applications dealing with hierarchical, recursive data could have a requirement in how data is processed: by depth or by breadth.

Using a queuing (First In First Out) mechanism to track the recursive join key values implies the results are retrieved in breadth first order. Breadth first means retrieving all the direct children of a parent row before retrieving any of the grandchildren of that same row. This retrieval is an implementation distinction, however, and not a guarantee.

Applications might want to guarantee how the data is retrieved. Some applications might want to retrieve the hierarchical data in depth first order. Depth first means that all the descendents of each immediate child row are retrieved before the descendents of the next child are retrieved.

The SQL architecture allows for the guaranteed specification of how the application retrieves the resulting data by the use of the SEARCH DEPTH FIRST or BREADTH FIRST keyword. When this option is specified, name the recursive join value, identify a set sequence column, and provide the sequence column in an outer ORDER BY clause. The results are output in depth or breadth first order. Note this ordering is ultimately a relationship sort and not a value-based sort.

Here is the preceding example output in depth first order.

```
WITH destinations (departure, arrival, connects, cost ) AS
(
  SELECT f.departure, f.arrival, 0 , ticket
  FROM flights f
  WHERE f.departure='Chicago' OR f.departure='New York'
  UNION ALL
  SELECT
    r.departure,b.arrival, r.connects+1 ,
    r.cost+b.ticket
  FROM destinations r, flights b
  WHERE r.arrival=b.departure)

SEARCH DEPTH FIRST BY arrival SET depth_sequence

SELECT *
FROM destinations
ORDER BY depth_sequence
```

If the ORDER BY clause is not specified in the main query, the sequencing option is ignored. To facilitate the correct sort there is additional information put on the queue entry during recursion. With BREADTH FIRST, it is the recursion level number and the immediate ancestor join value, so sibling rows can be sorted together. A depth first search is a little more data intensive. With DEPTH FIRST, the query engine needs to represent the entire ancestry of join values leading up to the current row and put that information in a queue entry. Also, because these sort values are not coming from an external data source, the sort implementation is always a temporary sorted list (no indexes possible).

Do not use the SEARCH option if you do not need your data materialized in a depth or breadth first manner. There is additional CPU and memory overhead to manage the sequencing information.

Specifying CYCLE considerations

Recognizing that data in the tables used in a recursive query might be cyclic in nature is important to preventing infinite loops.

The SQL architecture allows for the optional checking for cyclic data and discontinuing the repeating cycles at that point. This additional checking is done by the use of the CYCLE option. The correct join recursion value must be specified on the CYCLE request and a cyclic indicator must be specified. The cyclic indicator could be optionally output in the main query and can be used to help determine and correct errant cyclic data.

```
WITH destinations (departure, arrival, connects, cost , itinerary) AS
(
  SELECT f.departure, f.arrival, 1 , ticket, CAST(f.departure||f.arrival AS VARCHAR(2000))
  FROM flights f
  WHERE f.departure='New York'
  UNION ALL
  SELECT r.departure,b.arrival, r.connects+1 ,
    r.cost+b.ticket, cast(r.itinerary||b.arrival AS varchar(2000))
  FROM destinations r, flights b
  WHERE r.arrival = b.departure)
CYCLE arrival SET cyclic TO '1' DEFAULT '0' USING Cycle_Path

SELECT departure, arrival, itinerary, cyclic
FROM destinations
```

When a cycle is determined to be repeating, the output of that cyclic sequence of rows is stopped. To check for a 'repeated' value however, the query engine needs to represent the entire ancestry of the join

values leading up to the current row in order to look for the repeating join value. This ancestral history is information that is appended to with each recursive cycle and put in a field on the queue entry.

To implement this history field, the query engine uses a compressed representation of the recursion values on the ancestry chain. The query engine can then do a fixed length, quicker scan through the accumulating ancestry to determine if the value has been seen before. This compressed representation is determined by the use of a distinct node in the query tree.

Do not use the CYCLE option unless you know your data is cyclic, or you want to use it specifically to help find the cycles for correction or verification purposes. There is additional CPU and memory overhead to manage and check for repeating cycles before a given row is materialized.

The screenshot shows the Visual Explain tool interface. The main window displays a query execution plan as a tree diagram. The root node is 'Final Select', which connects to 'ListScan', then 'Temporary List', 'Eqseteq', 'Distinct', and 'Union all'. The 'Union all' node branches into 'Table Probe' and 'Nested Loop Join'. 'Table Probe' further branches into 'Index Probe' and 'Deqseteq'. 'Nested Loop Join' connects to 'Table Probe'. The right-hand pane lists various attributes and information about the SQL statement, including time information and statement details. At the bottom, the SQL statement text is visible, showing a query with a recursive CTE and a UNION ALL.

SMP and recursive queries

Recursive queries can benefit as much from symmetric multiprocessing (SMP) as do other queries on the system.

Recursive queries and parallelism, however, present some unique requirements. The initialization fullselect of a recursive query is the fullselect that seeds the initial values of the recursion. It is likely to produce only a small fraction of the ultimate results that cycle through the recursion process. The

query optimizer does not want each of the threads running in parallel to have a unique queue object that feeds only itself. This results in some threads having way too much work to do and others threads quickly depleting their work.

The best way to handle this work is to have all the threads share the same queue. This method allows a thread to enqueue a new recursive key value just as a waiting thread is there to dequeue that request. A shared queue allows all threads to actively contribute to the overall depletion of the queue entries until no thread is able to contribute more results.

Having multiple threads share the same queue, however, requires some management by the Query runtime so that threads do not prematurely end. Some buffering of the initial seed values might be necessary. This buffering is illustrated in the following query, where there are two fullselects that seed the recursion. A buffer is provided so that no thread hits a dequeue state and terminates before the query has seeded enough recursive values to get things going.

The following Visual Explain diagram shows the plan for the following query run with CHGQRYA DEGREE(*NBRTASKS 4). It shows how the results of the multiple initialization fullselects are buffered up. The multiple threads, illustrated by the multiple arrow lines, are acting on the enqueue and dequeue request nodes. As with all SMP queries, the multiple threads, in this case 4, put their results into a Temporary List object which becomes the output for the main query.

```
cl:chgqrya degree(*nbrtasks 4);

System-period temporal tables

Querying a system-period temporal table can return results for a specified point or period in time. These results can include both current values and previous historic values. The following sample queries request policy information from a system-period temporal table (`policy_info`), which also implicitly get information from the associated history table (`hist_policy_info`). See the “Querying system-period temporal data” topic in the Database Administration book for the layout of these tables and more information on how to specify time criteria for a system-period temporal table in a query.

Query with `FOR SYSTEM_TIME AS OF` specified.

```
SELECT policy_id, coverage
FROM policy_info
FOR SYSTEM_TIME AS OF '2011-02-28-09.10.12.649592000000'
```

For this query, the begin column of the period is inclusive, while the end column is exclusive. The history table row(s) with the begin column value less than or equal to '2011-02-28-09.10.12.649592000000' and the end column value greater than '2011-02-28-09.10.12.649592000000' will be included in the result.

As a result Db2 rewrites the query as follows:

```
SELECT policy_id, coverage FROM
  (SELECT policy_id, coverage
   FROM policy_info
   WHERE sys_start <= '2011-02-28-09.10.12.649592000000'
  UNION ALL
   SELECT policy_id, coverage
   FROM hist_policy_info
   WHERE sys_start <= '2011-02-28-09.10.12.649592000000'
   AND sys_end > '2011-02-28-09.10.12.649592000000')
```

Query with `FOR SYSTEM_TIME FROM...TO` specified.

```
SELECT policy_id, coverage, sys_start, sys_end
FROM policy_info
FOR SYSTEM_TIME FROM '0001-01-01-00.00.00.000000'
                    TO '9999-12-30-00.00.00.000000000000'
WHERE policy_id = 'C567'
```

For this query, the begin column and end column of the period are exclusive. The history table row(s) with the begin column value less than '9999-12-30-00.00.00.000000000000' and the end column value greater than '0001-01-01-00.00.00.000000' will be included in the result.

As a result, Db2 rewrites the query as follows:

```
SELECT policy_id, coverage, sys_start, sys_end FROM
  (SELECT policy_id, coverage, sys_start, sys_end
   FROM policy_info
   WHERE sys_start < '9999-12-30-00.00.00.000000000000'
   AND TIMESTAMP('0001-01-01-00.00.00.000000') <
         TIMESTAMP('9999-12-30-00.00.00.000000000000')
  UNION ALL
   SELECT policy_id, coverage, sys_start, sys_end
   FROM hist_policy_info
   WHERE sys_start < '9999-12-30-00.00.00.000000000000'
   AND sys_end > '0001-01-01-00.00.00.000000')
   AND TIMESTAMP('0001-01-01-00.00.00.000000') <
         TIMESTAMP('9999-12-30-00.00.00.000000000000')
WHERE policy_id = 'C567'
```

Query with `FOR SYSTEM_TIME BETWEEN...AND` specified.

```
SELECT policy_id, coverage
FROM policy_info
```

```
FOR SYSTEM_TIME BETWEEN '2011-02-28-09.10.12.649592000000'  
AND '9999-12-30-00.00.00.000000000000'
```

For this query, the begin column of the period is inclusive, while the end column is exclusive. The history table row(s) with the begin column value less than or equal to '9999-12-30-00.00.00.000000000000' and the end column value greater than '2011-02-28-09.10.12.649592000000' will be included in the result.

As a result, Db2 rewrites the query as follows:

```
SELECT policy_id, coverage, sys_start, sys_end FROM  
(SELECT policy_id, coverage, sys_start, sys_end  
FROM policy_info  
WHERE sys_start <= '9999-12-30-00.00.00.000000000000'  
AND TIMESTAMP('2011-02-28-09.10.12.649592000000') <=  
TIMESTAMP('9999-12-30-00.00.00.000000000000')  
UNION ALL  
SELECT policy_id, coverage, sys_start, sys_end  
FROM hist_policy_info  
WHERE sys_start <= '9999-12-30-00.00.00.000000000000'  
AND sys_end > '2011-02-28-09.10.12.649592000000')  
AND TIMESTAMP('2011-02-28-09.10.12.649592000000') <=  
TIMESTAMP('9999-12-30-00.00.00.000000000000')
```

Query with time criteria specified via CURRENT TEMPORAL SYSTEM_TIME special register.

The advantage of using this method is that you can change the time criteria later and not have to modify the SQL. For example, assume that you want to retrieve data from policy_info for a given policy_id of C567 that is from one year ago. If the SYSTIME option is set to YES, you can set the CURRENT TEMPORAL SYSTEM_TIME special register and issue the SELECT statement as follows:

```
SET CURRENT TEMPORAL SYSTEM_TIME = CURRENT TIMESTAMP - 1 YEAR;  
  
SELECT policy_id, coverage FROM policy_info  
WHERE policy_id = 'C567';
```

Db2 interprets the SELECT statement as follows:

```
SELECT policy_id, coverage FROM policy_info  
FOR SYSTEM_TIME AS OF CURRENT TEMPORAL SYSTEM_TIME  
WHERE policy_id = 'C567';
```

For this query, the begin column of the period is inclusive, while the end column is exclusive. The history table row(s) with the begin column value less than or equal to CURRENT TEMPORAL SYSTEM_TIME and the end column value greater than CURRENT TEMPORAL SYSTEM_TIME will be included in the result.

As a result, Db2 rewrites the query as follows:

```
SELECT policy_id, coverage FROM  
(SELECT policy_id, coverage  
FROM policy_info  
WHERE sys_start <= CURRENT TEMPORAL SYSTEM_TIME  
UNION ALL  
SELECT policy_id, coverage  
FROM hist_policy_info  
WHERE sys_start <= CURRENT TEMPORAL SYSTEM_TIME  
AND sys_end > CURRENT TEMPORAL SYSTEM_TIME)  
WHERE policy_id = 'C567';
```

Adaptive Query Processing

Adaptive Query Processing analyzes actual query run time statistics and uses that information for subsequent optimizations.

With rapidly increasing amounts of data, the price of miscalculating complex plans can result in dramatic performance problems. These problems might be measured in minutes or hours instead of seconds or minutes. Traditionally, optimizer architecture has attempted to overcome potential plan problems in

several ways. The most common technique is to increase the amount of time spent optimizing a query, searching for safe alternatives. While additional time reduces the likelihood of a failed plan, it does not fundamentally avoid the problem.

The Db2 optimizer relies on statistical estimates to optimize a query. These estimates can be inaccurate for a number of reasons. The reasons include a lack of statistical metadata for the query tables, complex join conditions, skewed or rapidly changing data within the tables, and others.

The SQE query engine uses a technique called Adaptive Query Processing (AQP). AQP analyzes actual query run time statistics and uses that information to correct previous estimates. These updated estimates can provide better information for subsequent optimizations.

[Adaptive Query Processing in Visual Explain](#)

You can use Visual Explain to request a new plan.

How AQP works

There are three main parts to AQP support.

- **Global Statistics Cache (GSC):** The “[Global Statistics Cache](#)” on page 17 is a system-side repository of statistical information gathered from actual query runs. When the SQE query engine observes a discrepancy between record count estimates and actual observed values, an entry might be made in the GSC. This entry provides the optimizer with more accurate statistical information for subsequent optimizations.
- **AQP Request Support:** This support runs after a query completes. The processing is done in a system task so it does not affect the performance of user applications. Estimated record counts are compared to the actual values. If significant discrepancies are noted, the AQP Request Support stores the observed statistic in the GSC. The AQP Request Support might also make specific recommendations for improving the query plan the next time the query runs.
- **AQP Handler:** The AQP Handler runs in a thread parallel to a running query and observes its progress. The AQP handler wakes up after a query runs for at least 2 seconds without returning any rows. Its job is to analyze the actual statistics from the partial query run, diagnose, and possibly recover from join order problems. These join order problems are due to inaccurate statistical estimates.

The query can be reoptimized using partial observed statistics or specific join order recommendations or both. If this optimization results in a new plan, the old plan is terminated and the query restarted with the new plan, provided the query has not returned any results.

AQP looks for an unexpected starvation join condition when it analyzes join performance. Starvation join is a condition where a table late in the join order eliminates many records from the result set. In general, the query would perform better if the table that eliminates the large number of rows is first in the join order. When AQP identifies a table that causes an unexpected starvation join condition, the table is noted as the 'forced primary table'. The forced primary table is saved for a subsequent optimization of the query.

That subsequent optimization with the forced primary recommendation can be used in two ways:

- The forced primary table is placed first in the join order, overriding the join order implied by the statistical estimates. The rest of the join order is defined using existing techniques.
- The forced primary table can be used for LPG preselection against a large fact table in the join.

[Adaptive Query Processing in Visual Explain](#)

You can use Visual Explain to request a new plan.

AQP example

Here is an example query with an explanation of how AQP could work.

```
SELECT * from t1, t2, t3, t4
WHERE t1.c1=t2.c1 AND t1.c2=t3.c2
AND t1.c3 = CURRENT DATE - t4.c3
```

```
AND t1.c5 < 50 AND t2.c6 > 40  
AND t3.c7 < 100 AND t4.c8 - t4.c9 < 5
```

The WHERE clause of the preceding query contains a predicate, `t1.c3 = CURRENT DATE - t4.c3`, that is difficult to estimate. The estimation difficulty is due to the derivation applied to column `t4.c3` and the derivation involving columns `t4.c8` and `t4.c9`. For the purposes of this example, the predicate `t1.c3 = CURRENT DATE - t4.c3` actually eliminates all or nearly all records in the join.

Due to characteristics of the columns involved in that predicate, the statistical estimate has many rows returned from the join. The optimizer selects join order `t1, t3, t2, t4` based on the following record count estimates.

- Join `t1` to `t3` produces 33,000,000 rows.
- Join `t1, t3` result to `t2` produces 1,300,000 rows.
- Join `t1, t3, t2` result to `t4` (final result set) produces 5 million rows.

The join order is reasonable assuming that the final result set actually produces 5 million rows, but the estimate is incorrect. The query performs poorly since tables `t1, t3, t2` are joined first, producing 1,300,000 rows. These rows are all rejected by table `t4` and the `t1.c3 = CURRENT DATE - t4.c3` predicate (join starvation).

AQP identifies `t4` as the forced primary table. The optimizer would choose `t1` as the second table in the join order since there are no join conditions between `t4` and `t2` or `t3`. Since the join condition between tables `t4` and `t1` selects few rows, this plan is likely many orders of magnitude faster than the original plan.

[Adaptive Query Processing in Visual Explain](#)

You can use Visual Explain to request a new plan.

AQP join order

Adaptive Query Processing analyzes actual query run time join statistics and uses that information for subsequent join optimizations.

The SQE engine implements AQP join order recommendations in the following ways:

Subsequent to run

When each query completes, a fast check is done on key points of the query execution to compare actual selected records with the estimates. If there is a significant discrepancy, then a stand-alone task is notified to do a deeper analysis of the query execution.

The query plan and the execution statistics are passed to the task. A separate task is used for the in-depth analysis so the user job is not impacted while the deep analysis is done. Each step of the join is analyzed, looking for characteristics of starvation join. Starvation join shows a significant reduction in the number of rows produced compared to the previous step. The definition of what is considered significant depends on a number of factors.

If the criteria for starvation join are met, the actual number of records selected at key points of the query are compared to estimates. If there is a significant discrepancy between the actual and estimated record counts, the table at that join position is identified as a 'forced primary table'. This table is saved with the query plan in the system plan cache. When the query runs in the future, the optimizer retrieves the original plan from the system plan cache. The optimizer sees the forced primary table recommendation, and optimizes the query using this recommendation.

The forced primary recommendation is used in two ways by the optimizer:

- The forced primary table is placed first in the join order by the join order optimization strategy.
- The forced primary table is used by the strategy for LPG optimization. The preceding example is a star join since table `T1` is joined to the other tables in the query. `t1.c3` is the column used to join `T1` to `T4`. If an index exists over this join column, then it might be advantageous to do preselection against table `T1`.

using the records selected from table T4. The forced primary table recommendation is used as a hint for the optimizer to consider this technique.

Concurrent to run

The preceding logic to identify starvation join can also run in a thread in parallel to the executing query. The AQP handler thread is created for longer running queries. The thread monitors the query execution and can run the same logic described earlier against partial data from the query execution.

If the partial results show starvation join and significant differences with the record count estimates, the query is reoptimized in the thread. When the new plan is ready, the execution of the original plan is stopped and the new plan started. This scheme for correcting join problems 'on the fly' can only be carried out before any records are selected for the final result set.

Note: AQP can help correct query performance problems, but it is not a substitute for a good database design coupled with a good indexing strategy.

Database Monitor additions for AQP

Additional information is logged in the database monitor when the AQP handler code replaces an executing plan.

A new set of 30xx records is written to the database monitor reflecting the replaced plan. The user needs to be able to distinguish between records produced for the first plan iteration and records produced for subsequent optimization. To distinguish these records, an unused short integer column of the database monitor record is used as a 'plan iteration counter'.

Column QQSMINTF is used for this purpose. For the original optimization of the query, the 30xx records have this field set to 1. Subsequent reoptimization done by AQP processing will increment the value by 1.

The following is an example of how DB monitor output might look like when *a* is replaced 'on the fly'. The example query is the following two-file join with an ORDER BY clause over one of the tables:

```
SELECT a.orderkey,b.orderkey
FROM rvdstar/item_fact3 a, rvdstar/item_fact b
WHERE a.quarter - 8 = b.quarter
ORDER BY b.orderkey
```

Assume that an *order by pushdown* plan is chosen, then replaced using AQP while the query is running. The following is an example of what the DB monitor records might look like. The columns shown for the purposes of explaining the changes are QQRID, QQUCNT, QQSMINTF, and QQRCD. The other fields in the monitor are not affected by AQP processing.

QQRID	QQUCNT	QQSMINTF	QQRCD
3010	14	-	-
3006	14	1	A0
3001	14	1	I2
3000	14	1	T1
3023	14	1	-
3007	14	1	-
3020	14	1	I1
3014	14	1	-

Table 33. Database monitor records for example query (continued)

QQRID	QQUCNT	QQSMINTF	QQRCD
5005	14	1	-
5002	14	1	-
5004	14	1	-
5007	14	1	-
3006	14	2	B6
3000	14	2	T1
3000	14	2	T3
3023	14	2	-
3003	14	2	F7
3007	14	2	-
3020	14	2	I1
3014	14	2	-
5005	14	2	-
5002	14	2	-
5004	14	2	-
1000	14	2	-
5007	14	2	-
3019	14	-	-
1000	14	-	-

Notes on the preceding table:

- There is a full set of optimizer-generated records that reflect the first choice of the optimizer: an *order by pushdown* plan. These records have the QQSMINTF column value set to 1. There is a 3001 record indicating an index was used to provide the ordering. There are 3000 and 3023 records indicating a Table Scan of the second table and a temporary hash table built to aid join performance. The remaining records, including the 3014 and the 500x records, have QQSMINTF set to 1 to reflect their association with the original *order by pushdown* plan.
- There is a second full set of optimizer-generated records that reflect the second choice of the optimizer: a *sorted temporary* plan to implement the ORDER BY. These records have the QQSMINTF column value set to 2. This time there are two 3000 records indicating table scan was used to access both tables. There is a 3023 record indicating a temporary hash table was built and a 3003 record indicating the results were sorted. The remaining records, including the 3014 and the 500x records, have QQSMINTF set to 2 to reflect their association with the replacement plan.
- Both sets of optimizer records have the same unique count (QQUCNT value).
- There is a 3006 (Access Plan Rebuilt) record generated for each replacement plan (QQSMINTF > 0). The QQRCD (reason code) value is set to a new value, 'B6'. The 'B6' value indicates the access plan was rebuilt due to AQP processing. In the example, there is a 3006 record with QQSMINTF = 1 and a QQRCD value of 'A0'. The 1 indicates that the original optimization built the plan for the first time. There might not be a 3006 record associated with the original optimization if the optimizer was able to reuse a plan from the plan cache.
- The 1000, 3010 and 3019 records are produced by XPF at open or close time. These records are not generated by the optimizer so there are no changes due to AQP. There are one set of the records, as in

previous releases, regardless of whether AQP replaced the plan. The QQSMINTF value is *NULL* for these records.

- The replacement plan is the plan that runs to completion and returns the results. To retrieve the DB monitor records from the plan that actually returns the records, it is necessary to query the DB monitor file using a subquery. Retrieve the records where the QQSMINTF value is equal to the maximum QQSMINTF value for a given QQUCNT.

[Database monitor formats](#)

This section contains the formats used to create the database monitor SQL tables and views.

Related reference

[Monitoring your queries using the Database Monitor](#)

Start Database Monitor (STRDBMON) command gathers information about a query in real time and stores this information in an output table. This information can help you determine whether your system and your queries are performing well, or whether they need fine-tuning. Database monitors can generate significant CPU and disk storage overhead when in use.

[Adaptive Query Processing in Visual Explain](#)

You can use Visual Explain to request a new plan.

[QAQQINI query options](#)

There are different options available for parameters in the QAQQINI file.

Row and column access control (RCAC)

Db2 for i introduces row and column access control (RCAC) as an additional layer of data security. RCAC controls access to a table at the row level, column level, or both. RCAC can be used to complement the existing table privileges model.

Indexing Strategy and RCAC

This section focuses on the consequence of RCAC to your SQL query performance when indexing is used.

Row and column access control (RCAC) places access control at the table level around the data itself. SQL rules, which are known as row permissions or column masks, created on rows and columns are the basis of the implementation of this capability.

You can use row and column access control to ensure that your users have access to only the data that is required for their work. For example, tellers in a bank can access customer rows in the CUSTOMER table only from their own branch. All tellers are members of the group user profile TELLER. Customer service representative or telemarketers are members of other groups and allowed to see all rows. A row permission is created by a user who is authorized to the QIBM_DB_SECADM function usage ID.

These SQL rules add additional predicates to any queries or data access requests over tables with defined and activated RCAC permissions. In this example, SQL rules are added to queries over the CUSTOMER table to enforce the following access rules. Depending on the nature of the rules, additional indexes might be advised or existing indexes might need to be enhanced or altered to accommodate the additional predicates enforcing the access. For example, when the TELLER_ROW_ACCESS permission is enabled, additional index advise might include the BRANCH_INFO table and key EMP_ID. In this particular example, index only access can be facilitated by creating an index over BRANCH_INFO that includes EMP_ID and HOME_BRANCH as key fields. The first to facilitate the probe, the second to prevent unnecessary access to the BRANCH_INFO table.

```
CREATE PERMISSION TELLER_ROW_ACCESS ON CUSTOMER
-----
-- Teller information:
-- Group TELLER is allowed to access customer data only
-- in their branch.
-----
FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER, 'TELLER') = 1
AND
BRANCH = (SELECT HOME_BRANCH FROM BRANCH_INFO WHERE EMP_ID = SESSION_USER)
```

```
ENFORCED FOR ALL ACCESS
ENABLE;
```

```
ALTER TABLE CUSTOMER ACTIVATE ROW ACCESS CONTROL;
```

In the example below, not only are you verifying certain user groups for access to particular patient records but also masking certain data based on whether the patient has participated in a clinical trial. Extra security is that physicians can see only patient records for whom they are the primary care provider.

```
CREATE PERMISSION PCP ON patient
-----
-- Primary Care Physician Access
-- Group PCP is allowed to access patient data only
-- AND the Primary Care Physician must be assigned to patient
-- Group RESEARCH are allowed to access patient data for those patients
-- that opted in to a clinical trial
-----
FOR ROWS WHERE
(VERIFY_GROUP_FOR_USER(SESSION_USER, 'PCP') = 1
AND
PCPID = (SELECT PCPID FROM PHYSICIAN WHERE PCPUSER = SESSION_USER) )
OR
(VERIFY_GROUP_FOR_USER(SESSION_USER, 'RESEARCH') = 1
AND
(SELECT 1 FROM PATIENTCHOICE C
WHERE PATIENT.patientid = C.patientid
AND C.CHOICE = 'clinical trial'
AND C.VALUE = 'opt-in')=1
)
ENFORCED FOR ALL ACCESS
ENABLE;
```

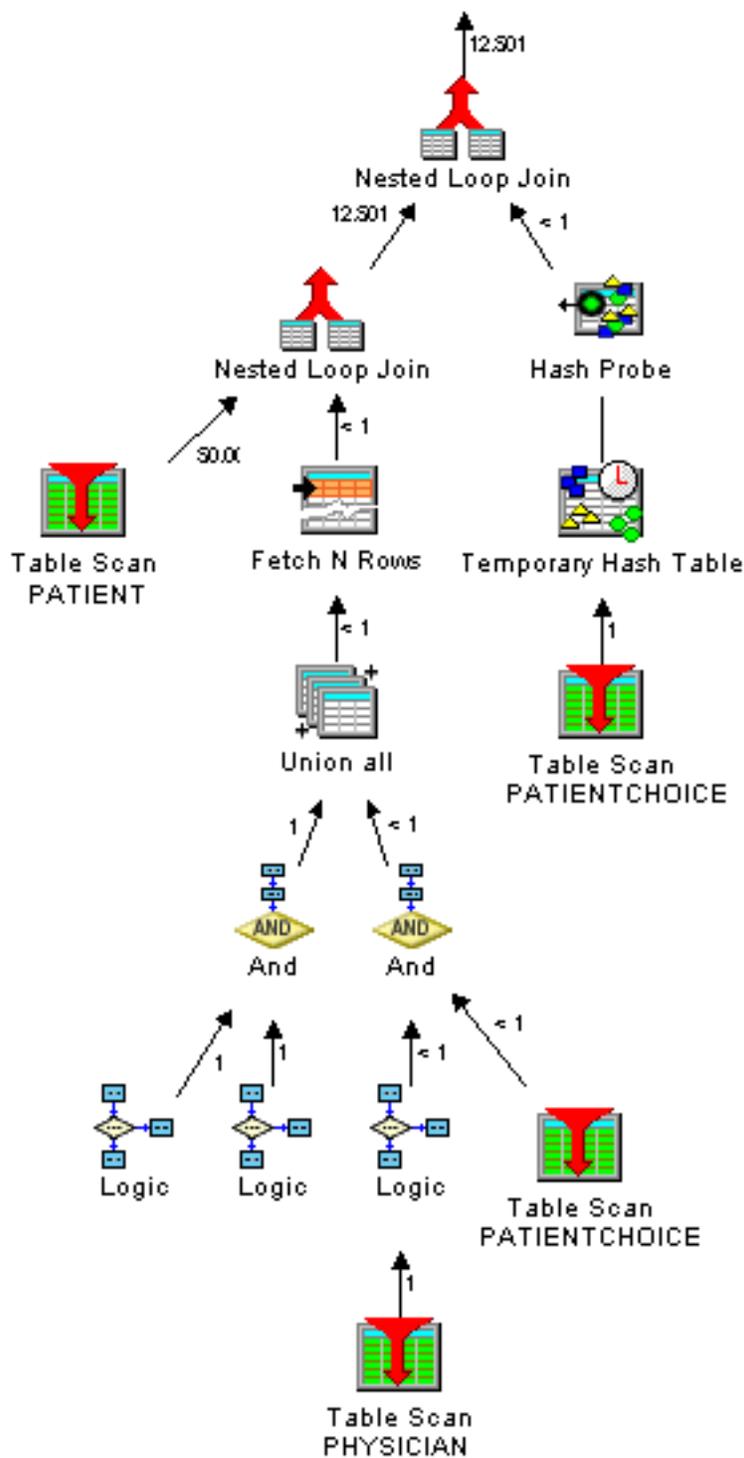

```
CREATE MASK PHARMACY_MASK ON PATIENT FOR
-----
-- Medical information:
-- Group PCP is allowed to access the full information in column PHARMACY.
-- For the purposes of drug research, Role DRUG_RESEARCH can
-- conditionally see a patient's medical information
-- provided that the patient has opted-in.
-- In all other cases, null values are rendered as column
-- values.
-----
COLUMN PHARMACY RETURN
CASE WHEN
    VERIFY_GROUP_FOR_USER(SESSION_USER, 'PCP') = 1 OR
    (VERIFY_GROUP_FOR_USER(SESSION_USER, 'DRUG_RSRCH')=1
    AND
    (SELECT 1 FROM PATIENTCHOICE C
    WHERE PATIENT.patientid = C.patientid
    AND C.CHOICE = 'drug-research'
    AND C.VALUE = 'opt-in')= 1
    )
THEN PHARMACY
ELSE NULL
END
ENABLE;
```

```
ALTER TABLE PATIENT ACTIVATE ROW ACCESS CONTROL ACTIVATE COLUMN ACCESS CONTROL;
```

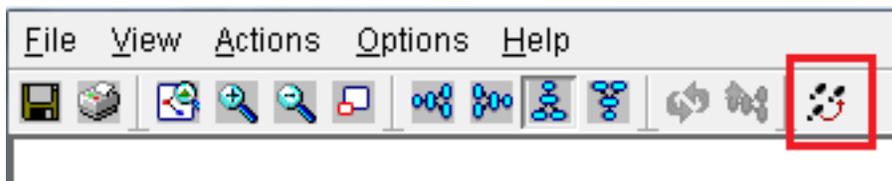

The query in the next example, before the introduction of RCAC policies would have accessed only the PATIENT table. Now it accesses the PATIENT table and the supporting tables that are associated with the row and column permissions.

The next graphic is the Visual Explain for the next example query. As you can see, the PATIENT table is accessed along with any other tables mentioned in the ROW and COLUMN access control.

```
SELECT * FROM PATIENT WHERE PATIENTID = ?
```

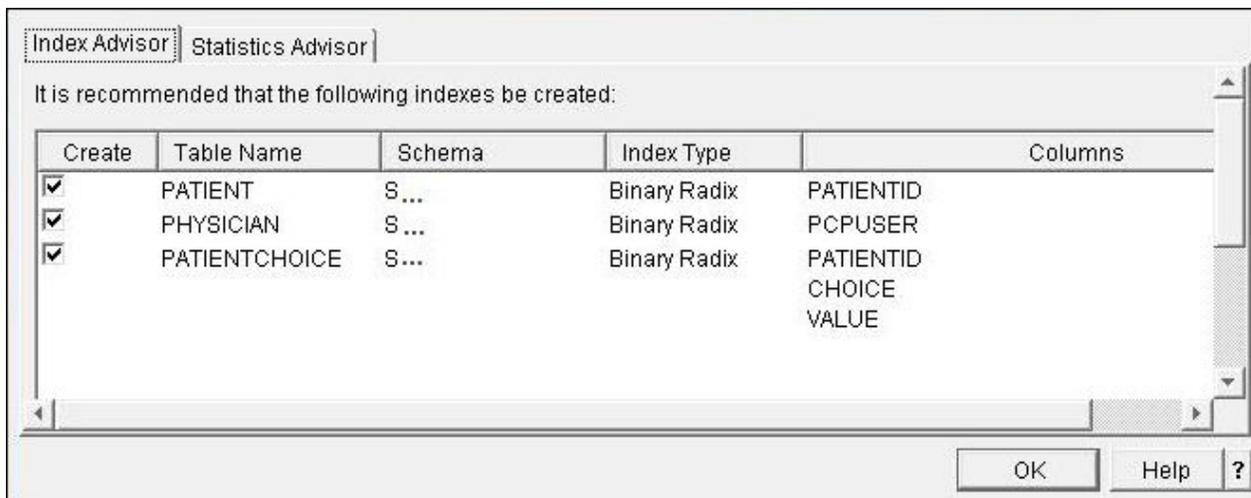

By clicking the index advised icon that is shown in the next graphic:

You get the resulting index advice depicted in the next graphic that shows that it is not only over the PATIENT table that is explicitly specified in the query, but also over the supporting RCAC tables.

Not considering additional advice per the introduction of RCAC SQL rules can affect query performance.

Materialized query tables and RCAC

This section focuses on the consequence of RCAC to your SQL query performance when MQTs are used.

Materialized Query Tables (MQTs) are heavily relied upon by data warehousing applications for better query performance. RCAC and MQTs coexist in harmony. This means:

1. MQTs must continue to provide their added performance benefit to data warehousing applications.
2. MQTs cannot become a means for gaining access to data protected through RCAC rules that are specified in the dependent base tables, either through direct access to the MQT or by MQT matching and substitution.

If a materialized query table that depends on the table (directly or indirectly through a view) for which access control is being activated and that materialized query table does not already have its own access control activated, row level access control is implicitly activated for the materialized query table. This restricts direct access to the contents of the materialized query table. A query that explicitly references the MQT table before such a row permission is defined returns Row Not Found as if there was no data in the table.

In this example MQT:

```
CREATE TABLE MQT1
AS (SELECT patientid, patientname,pcpid,pharmacy
FROM patient
WHERE diagnosis is not null)
DATA INITIALLY IMMEDIATE REFRESH DEFERRED
ENABLE QUERY OPTIMIZATION
MAINTAINED BY USER;
```

To provide access to this materialized query table, an appropriate row permission can be created, or an ALTER TABLE DEACTIVATE ROW ACCESS CONTROL on the materialized query table can be issued to remove the row level protection if that is appropriate. If the query optimizer substitutes one or more tables in a query with this materialized query table via MQT substitution, the row and column access controls on the replaced (base) tables remain in effect, and the access controls, if any, on the materialized query table do not apply.

```
SELECT * FROM MQT1
```

results in no rows because it does not have its own RCAC policy and therefore it cannot expose rows per the PATIENT table.

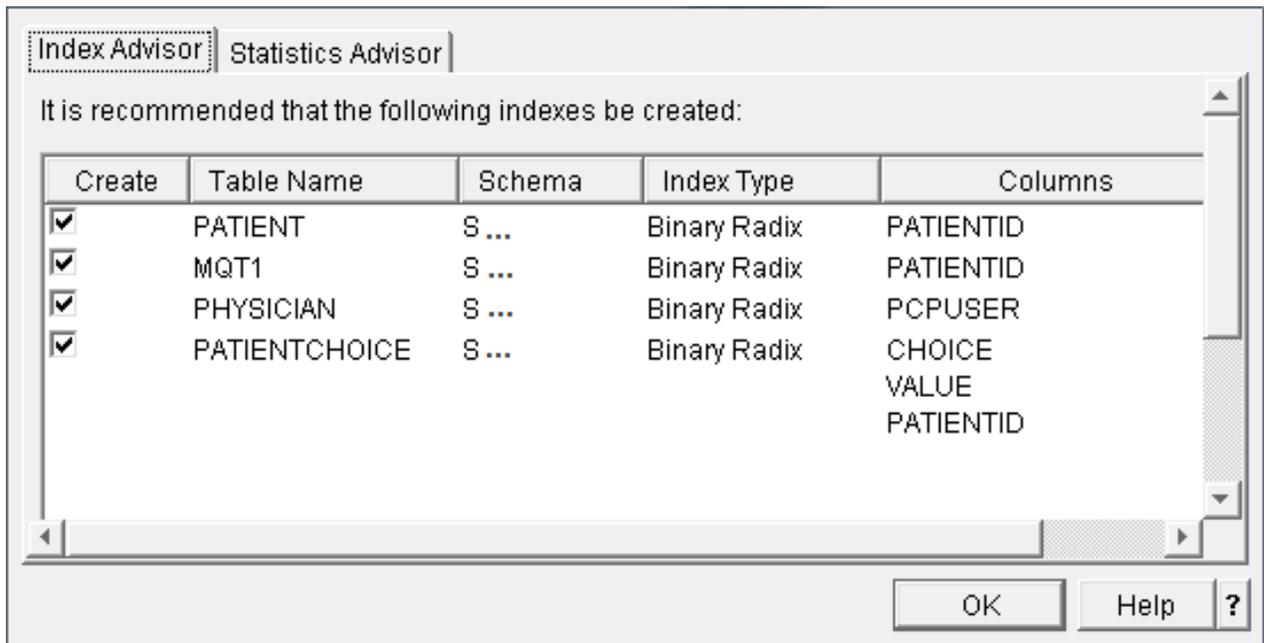

The following query however can be satisfied by the MQT1

```
SELECT patientid, patientname, pharmacy FROM patient WHERE patientid>4 and diagnosis is not null;
```

Row and column level access control does not affect the REFRESH TABLE statement. The table is refreshed as if row and column level access controls do not exist.

```
REFRESH TABLE mqt1;
```

The graphic below shows the Visual Explain that reflects the MQT match and substitution. Note that had the MQT1 not surfaced a required value of PCPID for the existing RCAC SQL Rules, it would not be able to satisfy the query request as an MQT match, even though that field is not in the required select list. In this example Visual Explain, you can see the MQT1 substituted but also inherited the RCAC rules of the base table PATIENT.

As many MQTs, such as the one below, provide ready made aggregation values so aggregating queries in a data warehousing environment perform quickly, these MQTs are now likely not to match query requests with aggregated selection via MQT substitution.

The aggregation is based on the REFRESH TABLE with no RCAC applied and yet the matching is based on the underlying base table and all its RCAC requirements.

```
CREATE TABLE MQT_AGG
AS (SELECT pcpid, count(*) patientcnt
FROM patient group by pcpid
)
DATA INITIALLY IMMEDIATE REFRESH DEFERRED
ENABLE QUERY OPTIMIZATION
MAINTAINED BY USER;
```

The following query, although it appears to be a match for the above MQT_AGG, will not substitute the MQT per RCAC rules.

```
SELECT pcpid, count(*) FROM PATIENT WHERE pcpid in ( 1, ...) GROUP BY pcpid
```

All existing MQTs should be analyzed before deploying RCAC policy on base tables to make sure that performance does not unexpectedly start to suffer because MQTs are no longer available to facilitate the request.

Because most aggregating queries are not dealing with 'details' and so possibly less sensitive to the requirements of RCAC, aggregating MQT over base tables with RCAC might be best deployed by direct substitution in the query and restriction through table privileges and disabling the default RCAC rule, restricting all rows, as follows.

```
ALTER TABLE MQT_AGG DEACTIVATE ROW ACCESS CONTROL;
```

This deactivates the default RCAC applied due to base tables with RCAC and allows direct access to the MQT in a warehousing environment.

Optimizing query performance using query optimization tools

Query optimization is an iterative process. You can gather performance information about your queries and control the processing of your queries.

Db2 for IBM i – Health Center

Use the Db2 for IBM i Health Center to capture information about your database. You can view the total number of objects, the size limits of selected objects, the design limits of selected objects, environmental limits, and activity level.

Navigator view of Health Center

The System i Navigator provides a robust graphical interface to capture, view, and interact with the Health Center.

To start the health center, follow these steps:

1. In the System i Navigator window, expand the system that you want to use.
2. Expand **Databases**.
3. Right-click the database that you want to work with and select **Health Center**.

You can change your preferences by clicking **Change** and entering filter information. Click **Refresh** to update the information.

To save your health center history, do the following:

1. In the System i Navigator window, expand the system you want to use.
2. Expand **Databases**.
3. Right-click the database that you want to work with and select **Health Center**.
4. On the health center dialog, select the area that you want to save. For example, if you want to save the current overview, click **Save** on the Overview tab. Size limits and Design limits are not saved.
5. Specify a schema and table to save the information. You can view the contents of the selected table by clicking **View Contents**. If you select to save information to a table that does not exist, the system creates the table for you.

Health Center SQL procedures

The Health Center is implemented upon several Db2 for i SQL procedures.

IBM i users can call the Health Center SQL procedures directly.

QSYS2.Health_Database_Overview ()

The *QSYS2.Health_Database_Overview()* procedure returns counts of all the different types of Db2 for i objects within the target schema or schemas. The counts are broken down by object type and subtype.

Procedure definition:

```
CREATE PROCEDURE QSYS2.HEALTH_DATABASE_OVERVIEW(  
  IN ARCHIVE_OPTION INTEGER,  
  IN OBJECT_SCHEMA VARCHAR(258),  
  IN NUMBER_OF_ITEMS_ARCHIVE INTEGER,  
  IN OVERVIEW_SCHEMA VARCHAR(258),  
  IN OVERVIEW_TABLE VARCHAR(258))  
  DYNAMIC RESULT SETS 1  
  LANGUAGE C  
  SPECIFIC QSYS2.HEALTH_DATABASE_OVERVIEW  
  NOT DETERMINISTIC  
  MODIFIES SQL DATA  
  CALLED ON NULL INPUT  
  EXTERNAL NAME 'QSYS/QSQHEALTH(OVERVIEW)'  
  PARAMETER STYLE SQL;
```

Service Program Name: QSYS/QSQHEALTH

Default Public Authority: *USE

Threadsafe: Yes

IBM i release

This procedure was added to IBM i in V5R4M0.

Parameters

Archive_Option

(Input) The type of operation to perform for the Db2 for i Health Center overview detail.

The supported values are:

- 1 = Query only, no archive action is taken
- 2 = Archive only
- 3 = Create archive and archive
- 4 = Query the archive

Note: Option 1 produces a new result set. Options 2 and 3 simply use the results from the last Query option. Option 3 fails if the archive exists.

Object_Schema

(Input) The target schema or schemas for this operation. A single schema name can be entered. The '%' character can be used to direct the procedure to process all schemas with names that start with the same characters which appear before the '%'. When this parameter contains only the '%' character, the procedure processes all schemas within the database.

Number_Of_Items_Archive

(Input) The number of rows to archive.

The archive can be used to recognize trends over time. To have meaningful historical comparisons, choose the row count size carefully. This argument is ignored if the Archive_Option is 1.

Overview_Table

(Input) The table that contains the database overview archive.

This argument is ignored if the Archive_Option is 1.

Authorities

To query an existing archive, *USE object authority is required for the Overview_Schema and Overview_Table. To create an archive, *CHANGE object authority is required for the Overview_Schema. To add to an existing archive, *CHANGE object authority is required for the Overview_Table and *USE object authority is required for the Overview_Schema.

Result Set

When Archive_Option is 1 or 4, a single result set is returned.

The format of the result is as follows.

QSYS2.Health_Database_Overview () result set format:

```
"TIMESTAMP" TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ,  
SCHEMAS BIGINT NOT NULL ,  
GRP01 CHAR(1) DEFAULT NULL ,  
TABLES BIGINT NOT NULL ,

Error Messages

Table 34. Error messages	
Message ID	Error Message Text
SQL0462 W	This warning appears in the job log if the procedure encounters objects for which the user does not have *USE object authority. The warning is provided as an indication that the procedure was unable to process all available objects.

Usage Notes

None

Related Information

None

Examples

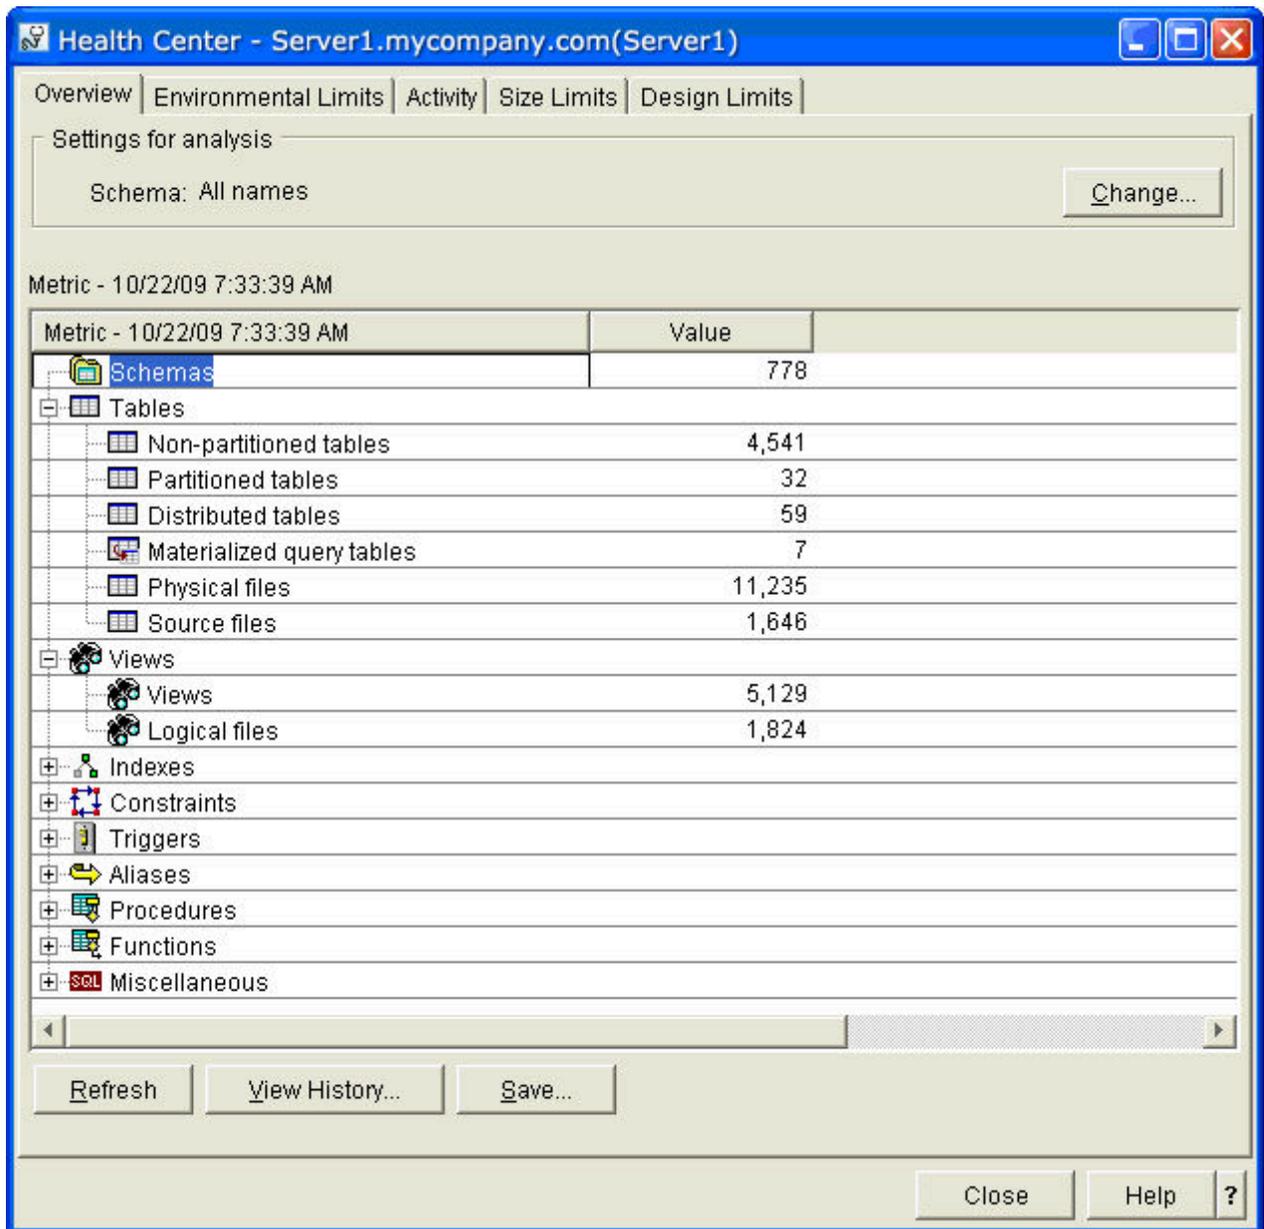

Note: By using the code examples, you agree to the terms of the [“Code license and disclaimer information”](#) on page 1327.

Example 1

Retrieve the overview for the entire database.

```
CALL QSYS2.Health_Database_Overview(1, '%', NULL, NULL, NULL);
```

Example results in System i Navigator:

Example 2

Archive all rows in the overview to an SQL table named MYLIB/ARCHIVE1.

```
CALL QSYS2.Health_Database_Overview(3, '%', 2147483647, 'MYLIB', 'ARCHIVE1')
```

Example 3

Retrieve the overview from MYLIB/ARCHIVE1.

```
CALL QSYS2.Health_Database_Overview(4, '%', NULL, 'MYLIB', 'ARCHIVE1')
```

Example results in System i Navigator:

Metric	Value
Collections	10/22/09 7:58:39 AM
Schemas	778
Tables	4,542
Non-partitioned tables	4,542
Partitioned tables	32
Distributed tables	59
Materialized query tables	7
Physical files	11,235
Source files	1,646
Views	5,129
Views	5,129
Logical files	1,824
Indexes	

QSYS2.Health_Activity ()

The QSYS2.Health_Activity () procedure returns summary counts of database and SQL operations over a set of objects within one or more schemas.

Procedure definition:

```
CREATE PROCEDURE QSYS2.HEALTH_ACTIVITY(
  IN ARCHIVE_OPTION INTEGER,
  IN REFRESH_CURRENT_VALUES INTEGER,
  IN OBJECT_SCHEMA VARCHAR(258),
  IN OBJECT_NAME VARCHAR(258),
  IN NUMBER_OBJECTS_ACTIVITY_TO_ARCHIVE INTEGER,
  IN NUMBER_OF_ACTIVITY_ARCHIVE INTEGER,
  IN ACTIVITY_SCHEMA VARCHAR(258),
  IN ACTIVITY_TABLE VARCHAR(258))
  DYNAMIC RESULT SETS 1
  LANGUAGE C
  SPECIFIC QSYS2.HEALTH_ACTIVITY
  NOT DETERMINISTIC
  MODIFIES SQL DATA
  CALLED ON NULL INPUT
  EXTERNAL NAME 'QSYS/QSQHEALTH(ACTIVITY) '
  PARAMETER STYLE SQL;
```

Service Program Name: QSYS/QSQHEALTH

Default Public Authority: *USE

Threadsafe: Yes

IBM i release

This procedure was added to IBM i 6.1.

Parameters

Archive_Option

(Input) The type of operation to perform for the Db2 for i Health Center overview detail.

The supported values are:

- 1 = Query only, no archive action is taken
- 2 = Archive only
- 3 = Create archive and archive
- 4 = Query the archive

Note: Option 1 produces a new result set. Options 2 and 3 simply use the results from the last Query option. Option 3 fails if the archive exists.

Refresh_Current_Values

(Input) This option directs how the archive operation is done. This option is only valid with archive options 2 and 3.

The supported values are:

- 0 = No. Indicates that we capture the activity on the entire set of specified schemas and objects.
- 1 = Yes. Indicates that we only refresh the activity of the objects previously captured (based on the short names).
- 2 = None. Use the results from the prior call. A call must have been performed in this job before using this option

Object_Schema

(Input) The target schema or schemas for this operation. A single schema name can be entered. The '%' character can be used to direct the procedure to process all schemas with names that start with the same characters which appear before the '%'. When this parameter contains only the '%' character, the procedure processes all schemas within the database.

This name also affects the items refreshed if Refresh_Current_Values = 1.

Object_Name

(Input) The target object name for this operation. Only the '%' character is treated as a wildcard since an underscore is a valid character in a name. The name must be delimited, if necessary, and case sensitive.

This name also affects the items refreshed if Refresh_Current_Values = 1.

Number_Objects_Activity_to_Archive (Input) The number of objects to save for each activity.

Number_Of_Activity_Archive (Input) The number of rows to save per object activity.

The archive can be used to recognize trends over time. To have meaningful historical comparisons, choose the row count size carefully. This argument is ignored if the Archive_Option is 1 or 4.

Activity_Schema

(Input) The table that contains the database activity archive.

This argument is ignored if the Archive_Option is 1.

Activity_Table

The table that contains the database activity archive.

This argument is ignored if the Archive_Option is 1.

Authorities

To query an existing archive, *USE object authority is required for the Activity_Schema and Activity_Table. To create an archive, *CHANGE object authority is required for the Activity_Schema. To add to an existing archive, *CHANGE object authority is required for the Activity_Table and *USE object authority is required for the Activity_Schema.

When Archive_Option is 1 or 3, *USE object authority is required for the Object_Schema and for any objects which are indicated by Object_Name. When an object is encountered and the caller does not have *USE object authority, an SQL0462 warning is placed in the job log. The object is skipped and not included in the procedure result set.

Result Set

When Archive_Option is 1 or 4, a single result set is returned.

The format of the result is as follows. All these items were added for IBM i 6.1.

QSYS2.Health_Activity() result set format:

```
"TIMESTAMP" TIMESTAMP NOT NULL,
ACTIVITY VARCHAR(2000) ALLOCATE(20) DEFAULT NULL,
CURRENT_VALUE FOR COLUMN "VALUE" BIGINT DEFAULT NULL,
OBJECT_SCHEMA FOR COLUMN BSHEMA VARCHAR(128)ALLOCATE(10) DEFAULT NULL,
OBJECT_NAME FOR COLUMN BNAME VARCHAR(128) ALLOCATE(20) DEFAULT NULL,
OBJECT_TYPE FOR COLUMN BTYPE VARCHAR(24) ALLOCATE(10) DEFAULT NULL,
SYSTEM_OBJECT_SCHEMA FOR COLUMN SYS_DNAME VARCHAR(10) ALLOCATE(10)DEFAULT NULL,
SYSTEM_OBJECT_NAME FOR COLUMN SYS_ONAME VARCHAR(10) ALLOCATE(10) DEFAULT NULL,
PARTITION_NAME FOR COLUMN MBRNAME VARCHAR(10) ALLOCATE(10) DEFAULT NULL,
ACTIVITY_ID FOR COLUMN ACTIV00001 INTEGER DEFAULT NULL
```

```
LABEL ON COLUMN <result set>
("TIMESTAMP" IS 'Timestamp',
ACTIVITY IS 'Activity',
CURRENT_VALUE IS 'Current Value',

SYSTEM_OBJECT_NAME IS 'System Object Name',
PARTITION_NAME IS 'Partition Name',
ACTIVITY_ID IS 'Activity ID');
```

Limit Detail

The supported Database Health Center Activity can be seen on any machine by executing this query. The supported value column contains zeros because this category of Health Center information is not tied to a limit.

```
SELECT * FROM QSYS2.SQL_SIZING WHERE SIZING_ID BETWEEN 18000 AND 18199;
```

Note: The **bold** rows were added in IBM i 7.1.

QSYS2.Health_Design_Limits ()

The QSYS2.Health_Design_Limits () procedure returns detailed counts of design limits over a set of objects within one or more schemas. Design limits correspond to architectural constructs, such as 'Maximum number of columns in a table or view'.

Procedure definition:

```
CREATE PROCEDURE QSYS2.HEALTH_DESIGN_LIMITS(  
  ARCHIVE_OPTION INTEGER,  
  IN REFRESH_CURRENT_VALUES INTEGER,  
  IN OBJECT_SCHEMA VARCHAR(258),  
  IN OBJECT_NAME VARCHAR(258),  
  IN NUMBER_OBJECTS_LIMIT_TO_ARCHIVE INTEGER,  
  IN NUMBER_OF_LIMITS_ARCHIVE INTEGER,  
  IN LIMIT_SCHEMA VARCHAR(258),  
  IN LIMIT_TABLE VARCHAR(258),  
  DYNAMIC RESULT SETS 1  
  LANGUAGE C  
  SPECIFIC QSYS2.HEALTH_DESIGN_LIMITS  
  NOT DETERMINISTIC  
  MODIFIES SQL DATA  
  CALLED ON NULL INPUT  
  EXTERNAL NAME 'QSYS/QSQHEALTH(DESIGN)'  
  PARAMETER STYLE SQL;
```

Service Program Name: QSYS/QSQHEALTH

Default Public Authority: *USE

Threadsafe: Yes

IBM i release

This procedure was added to IBM i V5R4M0.

Parameters

Archive_Option

(Input) The type of operation to perform for the Db2 for i Health Center activity detail.

The supported values are:

- 1 = Query only, no archive action is taken
- 2 = Archive only
- 3 = Create archive and archive
- 4 = Query the archive

Note: Option 1 produces a new result set. Options 2 and 3 simply use the results from the last Query option. Option 3 fails if the archive exists.

Refresh_Current_Values

(Input) This option directs how the archive operation is done. This option is only valid with archive options 2 and 3.

The supported values are:

- 0 = No. Indicates that we capture the activity on the entire set of specified schemas and objects.
- 1 = Yes. Indicates that we only refresh the activity of the objects previously captured (based on the short names).
- 2 = None. Use the results from the prior call. A call must have been performed in this job before using this option

Object_Schema	(Input) The target schema or schemas for this operation. A single schema name can be entered. The '%' character can be used to direct the procedure to process all schemas with names that start with the same characters which appear before the '%'. When this parameter contains only the '%' character, the procedure processes all schemas within the database. This name also affects the items refreshed if Refresh_Current_Values = 1.
Object_Name	(Input) The target object name for this operation. Only the '%' character is treated as a wildcard since an underscore is a valid character in a name. The name must be delimited, if necessary, and case sensitive. This name also affects the items refreshed if Refresh_Current_Values = 1.
Number_Objects_Limit_to_Archive	(Input) The number of objects to save for each design limit.
Number_Of_Limits_Archive	(Input) The number of rows to save per object design limit. The archive can be used to recognize trends over time. To have meaningful historical comparisons, choose the row count size carefully. This argument is ignored if the Archive_Option is 1 or 4.
Limit_Schema	(Input) The schema that contains the database limit archive. This argument is ignored if the Archive_Option is 1.
Limit_Table	The table that contains the database limit archive. This argument is ignored if the Archive_Option is 1.

Authorities

To query an existing archive, *USE object authority is required for the Limit_Schema and Limit_Table. To create an archive, *CHANGE object authority is required for the Limit_Schema. To add to an archive, *CHANGE object authority is required for the Limit_Table.

When Archive_Option is 1 or 3, *USE object authority is required for the Object_Schema and for any objects which are indicated by Object_Name. When an object is encountered and the caller does not have *USE object authority, an SQL0462 warning is placed in the job log. The object is skipped and not included in the procedure result set.

Result Set

When Archive_Option is 1 or 4, a single result set is returned.

The format of the result is as follows. All these items were added for IBM i V5R4M0.

QSYS2.Health_Design_Limits() result set format:

```
"TIMESTAMP" TIMESTAMP NOT NULL,
LIMIT VARCHAR(2000) ALLOCATE(20) DEFAULT NULL,
CURRENT_VALUE FOR COLUMN "VALUE" BIGINT DEFAULT NULL,
PERCENT_DECIMAL(5, 2) DEFAULT NULL,
OBJECT_SCHEMA FOR COLUMN BSHEMA VARCHAR(128) ALLOCATE(10) DEFAULT NULL,
OBJECT_NAME FOR COLUMN BNAME VARCHAR(128) ALLOCATE(20) DEFAULT NULL,
OBJECT_TYPE FOR COLUMN BTYPE VARCHAR(24) ALLOCATE(10) DEFAULT NULL,

QSYS2.Health_Size_Limits ()

The QSYS2.Health_Size_Limits () procedure returns detailed size information for database objects within one or more schemas. Size limits help you understand trends towards reaching a database limit such as 'Maximum size of the data in a table partition'.

Procedure definition:

```
CREATE PROCEDURE QSYS2.HEALTH_SIZE_LIMITS(
  IN ARCHIVE_OPTION INTEGER,
  IN REFRESH_CURRENT_VALUES INTEGER,
  IN OBJECT_SCHEMA VARCHAR(258),
  IN OBJECT_NAME VARCHAR(258),
  IN NUMBER_OBJECTS_LIMIT_TO_ARCHIVE INTEGER,
  IN NUMBER_OF_LIMITS_ARCHIVE INTEGER,
  IN LIMIT_SCHEMA VARCHAR(258),
  IN LIMIT_TABLE VARCHAR(258))
  DYNAMIC RESULT SETS 1
  LANGUAGE C
  SPECIFIC QSYS2.HEALTH_SIZE_LIMITS
```

```
NOT DETERMINISTIC
MODIFIES SQL DATA
CALLED ON NULL INPUT
EXTERNAL NAME 'QSYS/QSQHEALTH(SIZE)'
PARAMETER STYLE SQL;
```

Service Program Name: QSYS/QSQHEALTH

Default Public Authority: *USE

Threadsafe: Yes

IBM i release

This procedure was added to IBM i V5R4M0.

Parameters

Archive_Option

(Input) The type of operation to perform for the Db2 for i Health Center activity detail.

The supported values are:

- 1 = Query only, no archive action is taken
- 2 = Archive only
- 3 = Create archive and archive
- 4 = Query the archive

Note: Option 1 produces a new result set. Options 2 and 3 simply use the results from the last Query option. Option 3 fails if the archive exists.

Refresh_Current_Values

(Input) This option directs how the archive operation is done. This option is only valid with archive options 2 and 3.

The supported values are:

- 0 = No. Indicates that we capture the activity on the entire set of specified schemas and objects.
- 1 = Yes. Indicates that we only refresh the activity of the objects previously captured (based on the short names).
- 2 = None. Use the results from the prior call. A call must have been performed in this job before using this option

Object_Schema

(Input) The target schema or schemas for this operation. A single schema name can be entered. The '%' character can be used to direct the procedure to process all schemas with names that start with the same characters which appear before the '%'. When this parameter contains only the '%' character, the procedure processes all schemas within the database.

This name also affects the items refreshed if Refresh_Current_Values = 1.

Object_Name

(Input) The target object name for this operation. Only the '%' character is treated as a wildcard since an underscore is a valid character in a name. The name must be delimited, if necessary, and case sensitive.

This name also affects the items refreshed if Refresh_Current_Values = 1.

Number_Objects_Limit_to_Archive	(Input) The number of objects to save for each size limit.
Number_Of_Limits_Archive	(Input) The number of rows to save per object size limit. The archive can be used to recognize trends over time. To have meaningful historical comparisons, choose the row count size carefully. This argument is ignored if the Archive_Option is 1 or 4.
Limit_Schema	(Input) The schema that contains the database activity archive. This argument is ignored if the Archive_Option is 1.
Limit_Table	The table that contains the database activity archive. This argument is ignored if the Archive_Option is 1.

Authorities

To query an existing archive, *USE object authority is required for the Limit_Schema and Limit_Table. To create an archive, *CHANGE object authority is required for the Limit_Schema. To add to an archive, *CHANGE object authority is required for the Limit_Table.

When Archive_Option is 1 or 3, *USE object authority is required for the Object_Schema and for any objects which are indicated by Object_Name. When an object is encountered and the caller does not have *USE object authority, an SQL0462 warning is placed in the job log. The object is skipped and not included in the procedure result set.

Result Set

When Archive_Option is 1 or 4, a single result set is returned.

The format of the result is as follows.

QSYS2.Health_Size_Limits() result set format:

```
"TIMESTAMP" TIMESTAMP NOT NULL,
LIMIT VARCHAR(2000) ALLOCATE(20) DEFAULT NULL,
CURRENT_VALUE FOR COLUMN "VALUE" BIGINT DEFAULT NULL,
PERCENT_DECIMAL(5, 2) DEFAULT NULL, OBJECT_SCHEMA FOR COLUMN BSHEMA VARCHAR(128) ALLOCATE(10) DEFAULT
NULL,
OBJECT_NAME FOR COLUMN BNAME VARCHAR(128) ALLOCATE(20) DEFAULT NULL,

SYSIBM.SYSDUMMY1 (SYSDUMMY1)	1	0.00	Normal
Maximum number of valid rows in a partition (4,294,967,288)			
Maximum size of the data in a table partition (1.55 TB)			
Total SQL statements			
Total active SQL statements			
Maximum SQL program associated space size (16 MB)			

Buttons at the bottom include Refresh, View History..., Save..., and Change Status Threshold...

QSYS2.Health_Environmental_Limits ()

The QSYS2.Health_Environmental_Limits() procedure returns detail on the top 10 jobs on the system, for different SQL or application limits. The jobs do not have to be in existence. The top 10 information is maintained within Db2 for i and gets reset when the machine is IPLed, the IASP is varied ON, or when the QSYS2.Reset_Environmental_Limits() procedure is called.

Procedure definition:

```
CREATE PROCEDURE QSYS2.HEALTH_ENVIRONMENTAL_LIMITS(  
  IN ARCHIVE_OPTION INTEGER,  
  IN NUMBER_OF_LIMITS_ARCHIVE INTEGER,  
  IN LIMIT_SCHEMA VARCHAR(258),  
  IN LIMIT_TABLE VARCHAR(258))  
  DYNAMIC RESULT SETS 1  
  LANGUAGE C  
  SPECIFIC QSYS2.HEALTH_ENVIRONMENTAL_LIMITS
```

```
NOT DETERMINISTIC
MODIFIES SQL DATA
CALLED ON NULL INPUT
EXTERNAL NAME 'QSYS/QSQHEALTH(ENVIRON)'
PARAMETER STYLE SQL;
```

Service Program Name: QSYS/QSQHEALTH

Default Public Authority: *USE

Threadsafe: Yes

IBM i release

This procedure was added to IBM i 6.1.

Parameters

- Archive_Option** (Input) The type of operation to perform for the Db2 for i Health Center activity detail.
- The supported values are:
- 1 = Query only, no archive action is taken
 - 2 = Archive only
 - 3 = Create archive and archive
 - 4 = Query the archive
- Note:** Option 1 produces a new result set. Options 2 and 3 simply use the results from the last Query option. Option 3 fails if the archive exists.
- Number_Of_Limits_Archive** (Input) The number of rows to save per object health limit.
- The archive can be used to recognize trends over time. To have meaningful historical comparisons, choose the row count size carefully. This argument is ignored if the Archive_Option is 1 or 4.
- Limit_Schema** (Input) The schema that contains the database activity archive.
- This argument is ignored if the Archive_Option is 1.
- Limit_Table** The table that contains the database activity archive.
- This argument is ignored if the Archive_Option is 1.

Authorities

To query an existing archive, *USE object authority is required for the Limit_Schema and Limit_Table. To create an archive, *CHANGE object authority is required for the Limit_Schema. To add to an archive, *CHANGE object authority is required for the Limit_Table.

When Archive_Option is 1 or 3, *USE object authority is required for the Object_Schema and for any objects which are indicated by Object_Name. When an object is encountered and the caller does not have *USE object authority, an SQL0462 warning is placed in the job log. The object is skipped and not included in the procedure result set.

Result Set

When Archive_Option is 1 or 4, a single result set is returned.

The format of the result is as follows. All these items were added for IBM i 6.1.

QSYS2.Health_Environmental_Limits() result set format:

```
"TIMESTAMP" TIMESTAMP NOT NULL,
LIMIT VARCHAR(2000) ALLOCATE(20) DEFAULT NULL,
HIGHWATER_MARK_VALUE FOR COLUMN HIMARK BIGINT DEFAULT NULL,

Threadsafe: Yes

IBM i release

This procedure was added to IBM i 6.1.

Parameters

None.

Authorities

This procedure requires the user to have *JOBCTL user special authority or be authorized to the QIBM_DB_SQLADM Function through Application Administration in System i Navigator. The Change Function Usage (CHGFCNUSG) command can also be used to allow or deny use of the function.

For example:

```
CHGFCNUSG FCNID(QIBM_DB_SQLADM) USER(XXXXX) USAGE(*ALLOWED)
```

Result Set

None.

Error Messages

<i>Table 42. Error messages</i>	
Message ID	Error Message Text
SQL0552	Not authorized to PROCEDURE.

Usage Notes

None

Related Information

None

Example

Note: By using the code examples, you agree to the terms of the [“Code license and disclaimer information”](#) on page 1327.

Reset the SQL environmental limits for the current database.

```
CALL QSYS2.RESET_ENVIRONMENTAL_LIMITS;
```

Monitoring your queries using the Database Monitor

Start Database Monitor (STRDBMON) command gathers information about a query in real time and stores this information in an output table. This information can help you determine whether your system and your queries are performing well, or whether they need fine-tuning. Database monitors can generate significant CPU and disk storage overhead when in use.

You can gather performance information for a specific query, for every query on the system, or for a group of queries on the system. When a job is monitored by multiple monitors, each monitor is logging rows to a different output table. You can identify rows in the output database table by its unique identification number.

When you start a monitor using the **Start Database Monitor (STRDBMON)** command, the monitor is automatically registered with System i Navigator and appears in the System i Navigator monitor list.

Note: Database monitors also contain the SQL statement text and variable values. If the variable values or SQL statements contain sensitive data you should create database monitors in a library that is not publicly authorized to prevent exposure to the sensitive data.

What kinds of statistics you can gather

The database monitor provides the same information that is provided with the query optimizer debug messages (**Start Debug (STRDBG)**) and the **Print SQL information (PRTSQLINF)** command. The following is a sampling of the additional information that is gathered by the database monitors:

- System and job name
- SQL statement and subselect number
- Start and end timestamp
- Estimated processing time
- Total rows in table queried
- Number of rows selected
- Estimated number of rows selected
- Estimated number of joined rows
- Key columns for advised index
- Total optimization time
- Join type and method
- ODP implementation

How you can use performance statistics

You can use these performance statistics to generate various reports. For instance, you can include reports that show queries that:

- Use an abundance of the system resources.
- Take a long time to execute.
- Did not run because of the query governor time limit.
- Create a temporary index during execution

- Use the query sort during execution
- Might perform faster with the creation of a keyed logical file containing keys suggested by the query optimizer.

Note: A query that is canceled by an end request generally does not generate a full set of performance statistics. However, it does contain all the information about how a query was optimized, except for runtime or multi-step query information.

[Start Database Monitor \(STRDBMON\) command](#)

Start Database Monitor (STRDBMON) command

The **Start Database Monitor (STRDBMON)** command starts the collection of database performance statistics for a specified job, for all jobs on the system or for a selected set of jobs. The statistics are placed in a user-specified database table and member. If the table or member do not exist, one is created based on the QAQQDBMN table in library QSYS, with the public authority for the file the same as the create authority specified for the library in which the file is created. If the table and member do exist, the record format of the specified table is verified to ensure it is the same.

For each monitor started using the STRDBMON command, the system generates a monitor ID that can be used to uniquely identify each individual monitor. The monitor ID can be used on the ENDDBMON command to uniquely identify which monitor is to be ended. The monitor ID is returned in the informational message CPI436A which is generated for each occurrence of the STRDBMON command. The monitor ID can also be found in either the column QQC101 of the QQQ3018 database monitor record or in the QSYS2.DATABASE_MONITOR_INFO catalog.

Informally there are two types of monitors. A private monitor is a monitor over one, specific job (or the current job). Only one (1) monitor can be started on a specific job at a time. For example, STRDBMON JOB(*) followed by another STRDBMON JOB(*) within the same job is not allowed. A public monitor is a monitor which collects data across multiple jobs. There can be a maximum of 10 public monitors active at any one time. For example, STRDBMON JOB(*ALL) followed by another STRDBMON JOB(*ALL) is allowed providing the maximum number of public monitors does not exceed 10. You could have 10 public monitors and 1 private monitor active at the same time for any specific job.

If multiple monitors specify the same output file, only one copy of the database statistic records is written to the file for each job. For example, STRDBMON OUTFILE(LIB/TABLE1) JOB(*) and STRDBMON OUTFILE(LIB/TABLE1) JOB(*ALL) target the same output file. For the current job, there are not two copies of the database statistic records—one copy for the private monitor and one copy for the public monitor. There is only one copy of the database statistic records.

If the monitor is started on all jobs (a public monitor), any jobs waiting on queues or started during the monitoring period are included in the monitor data. If the monitor is started on a specific job (a private monitor) that job must be active in the system when the command is issued. Each job in the system can be monitored concurrently by one private monitor and a maximum of 10 public monitors.

The STRDBMON command allows you to collect statistic records for a specific set or subset of the queries running on any job. This filtering can be performed over the job name, user profile, query table names, query estimated run time, TCP/IP address, or any combination of these filters. Specifying a STRDBMON filter helps minimize the number of statistic records captured for any monitor.

Example 1: Starting Public Monitoring

```
STRDBMON  OUTFILE(QGPL/FILE1)  OUTMBR(MEMBER1 *ADD)
JOB(*ALL)  FRCRCD(10)
```

This command starts database monitoring for all jobs on the system. The performance statistics are added to the member named MEMBER1 in the file named FILE1 in the QGPL library. 10 records are held before being written to the file.

Example 2: Starting Private Monitoring

```
STRDBMON  OUTFILE(*LIBL/FILE3)  OUTMBR(MEMBER2)
JOB(134543/QPGMR/DSP01)  FRCRCD(20)
```

This command starts database monitoring for job number 134543. The job name is DSP01 and was started by the user named QPGMR. The performance statistics are added to the member named MEMBER2 in the file named FILE3. 20 records are held before being written to the file.

Example 3: Starting Private Monitoring to a File in a Library in an Independent ASP

```
STRDBMON  OUTFILE(LIB41/DBMONFILE)  JOB(134543/QPGMR/DSP01)
```

This command starts database monitoring for job number 134543. The job name is DSP01 and was started by the user named QPGMR. The performance statistics are added to the member name DBMONFILE (since OUTMBR was not specified) in the file named DBMONFILE in the library named LIB41. This library could exist in more than one independent auxiliary storage pool (ASP); the library in the name space of the originator's job is always used.

Example 4: Starting Public Monitoring For All Jobs That Begin With 'QZDA'

```
STRDBMON  OUTFILE(LIB41/DBMONFILE)  JOB(*ALL/*ALL/QZDA*)
```

This command starts database monitoring for all jobs that whose job name begins with 'QZDA'. The performance statistics (monitor records) are added to member DBMONFILE (since OUTMBR was not specified) in file DBMONFILE in library LIB41. This library could exist in more than one independent auxiliary storage pool (ASP); the library in the name space of the originator's job is always used.

Example 5: Starting Public Monitoring and Filtering SQL Statements That Run Over 10 Seconds

```
STRDBMON  OUTFILE(LIB41/DBMONFILE)  JOB(*ALL)  RUNTHLD(10)
```

This command starts database monitoring for all jobs. Monitor records are created only for those SQL statements whose estimated run time meets or exceeds 10 seconds.

Example 6: Starting Public Monitoring and Filtering SQL Statements That Have an Estimated Temporary Storage Over 200 MB

```
STRDBMON  OUTFILE(LIB41/DBMONFILE)  JOB(*ALL)  STGTHLD(200)
```

This command starts database monitoring for all jobs. Monitor records are created only for those SQL statements whose estimated temporary storage meets or exceeds 200 MB.

Example 7: Starting Private Monitoring and Filtering Over a Specific File

```
STRDBMON  OUTFILE(LIB41/DBMONFILE)  JOB(*)
FTRFILE(LIB41/TABLE1)
```

This command starts database monitoring for the current job. Monitor records are created only for those SQL statements that use file LIB41/TABLE1.

Example 8: Starting Private Monitoring for the Current User

```
STRDBMON  OUTFILE(LIB41/DBMONFILE)  JOB(*)  FTRUSER(*CURRENT)
```

This command starts database monitoring for the current job. Monitor records are created only for those SQL statements that are executed by the current user.

Example 9: Starting Public Monitoring For Jobs Beginning With 'QZDA' and Filtering Over Run Time and File

```
STRDBMON  OUTFILE(LIB41/DBMONFILE)  JOB(*ALL/*ALL/QZDA*)
RUNTHLD(10)  FTRUSER(DEVLPR1)  FTRFILE(LIB41/TTT*)
```

This command starts database monitoring for all jobs whose job name begins with 'QZDA'. Monitor records are created only for those SQL statements that meet all the following conditions:

- The estimated run time, as calculated by the query optimizer, meets, or exceeds 10 seconds
- Was executed by user 'DEVLPR1'.
- Use any file whose name begins with 'TTT' and resides in library LIB41.

Example 10: Starting Public Monitoring and Filtering SQL Statements That Have Internet Address '9.10.111.77'.

```
STRDBMON  OUTFILE(LIB41/DBMONFILE)  JOB(*ALL)
FTRINTNETA('9.10.111.77')
```

This command starts database monitoring for all jobs. Monitor records are created only for TCP/IP database server jobs that are using the client IP version 4 address of '9.10.111.77'.

Example 11: Starting Public Monitoring and Filtering SQL Statements That Have a Port Number of 8471

```
STRDBMON  OUTFILE(LIB41/DBMONFILE)  JOB(*ALL)  FTRLCLPORT(8471)
```

This command starts database monitoring for all jobs. Monitor records are created only for TCP/IP database server jobs that are using the local port number 8471.

Example 12: Starting Public Monitoring Based on Feedback from the Query Governor

```
CHGSYSVAL  QQRYSIMLMT(200)
STRDBMON  OUTFILE(LIB41/DBMONFILE)  JOB(*ALL)  FTRQRYGOVR(*COND)
```

This command starts database monitoring for all jobs whose estimated run time is expected to exceed 200 seconds, based on the response to the query governor. In this example, data is collected only if the query is canceled or a return code of 2 is returned by a query governor exit program. The query can be canceled by a user response to the inquiry message CPA4259, issued because the query exceeded the query governor limits. It can also be canceled by the program logic inside the registered query governor exit program.

Example 13: Collecting database monitor for Interactive SQL use

```
STRDBMON  OUTFILE(QGPL/STRSQLMON1)  OUTMBR(*FIRST *REPLACE)
JOB(*ALL/*ALL/*ALL)  TYPE(*DETAIL)
FTRCLTPGM(STRSQL)
```

This command uses the database monitor pre-filter by Client Special Register Program ID to collect monitor records for all the SQL statements executed by Interactive SQL (STRSQL command) usage.

Example 14: Starting Public Monitoring and Filtering SQL Statements Run From IBM i Access Client Solutions Run SQL Scripts

```
STRDBMON  OUTFILE(LIB41/DBMONFILE)  JOB(*ALL)
FTRCLTAPP('IBM i Access Client Solutions - RUN SQL Scripts')
```

This command starts database monitoring for all jobs. Monitor records are created only for those statements where the client special register CLIENT APPLNAME is IBM i Access Client Solutions - RUN SQL Scripts.

Example 15: Starting Public Monitoring and Filtering SQL Statements Run From IBM System i Access for Windows Run SQL Scripts

```
STRDBMON  OUTFILE(LIB41/DBMONFILE)  JOB(*ALL)
          FTRCLTPGM('cwbunnav.exe')
```

This command starts database monitoring for all jobs. Monitor records are created only for those statements where the client special register CLIENT_PROGRAMID is cwbunnav.exe.

Example 16: Starting Public Monitoring and Filtering for the client user dbmusr1

```
STRDBMON  OUTFILE(LIB41/DBMONFILE)  JOB(*ALL)
          FTRCLTUSR(dbmusr1)
```

This command starts database monitoring for all jobs. Monitor records are created only for those statements where the client special register CLIENT_USERID is dbmusr1.

Example 17: Starting Public Monitoring and Filtering SQL Statements Using FTRUSER

```
STRDBMON  OUTFILE(LIB41/DBMONFILE)  JOB(*ALL)
          FTRUSER((STC* *NE) (S*) (TS*) (TSA* *NE))
```

This command starts database monitoring for all jobs. Monitor records are created only for those statements where the user profile is logically equivalent to: User profile NOT LIKE 'STC%' AND user profile NOT LIKE 'TSA%' AND (user profile LIKE 'S%' OR user profile LIKE 'TS%')

Related information

[Start Database Monitor \(STRDBMON\) command](#)

End Database Monitor (ENDDBMON) command

The **End Database Monitor (ENDDBMON)** command ends the collection of database performance statistics for a specified job, all jobs on the system, or a selected set of jobs (for example, a generic job name).

To end a monitor, you can specify the job or the monitor ID or both. If only the JOB parameter is specified, the monitor that was started using the same exact JOB parameter is ended - if there is only one monitor which matches the specified JOB. If more than one monitor is active which matches the specified JOB, then the user uniquely identifies which monitor is to be ended by use of the MONID parameter.

When only the MONID parameter is specified, the specified MONID is compared to the monitor ID of the monitor for the current job and to the monitor ID of all active public monitors (monitors that are open across multiple jobs). The monitor matching the specified MONID is ended.

The monitor ID is returned in the informational message CPI436A. This message is generated for each occurrence of the STRDBMON command. Look in the job log for message CPI436A to find the system generated monitor ID, if needed. The monitor ID can also be found in column QQC101 of the QQQ3018 database monitor record.

Restrictions

- If a specific job name and number or JOB(*) was specified on the **Start Database Monitor (STRDBMON)** command, the monitor can only be ended by specifying the same job name and number or JOB(*) on the ENDDBMON command.
- If JOB(*ALL) was specified on the **Start Database Monitor (STRDBMON)** command, the monitor can only be ended by specifying ENDDBMON JOB(*ALL). The monitor cannot be ended by specifying ENDDBMON JOB(*).

When monitoring is ended for all jobs, all the jobs on the system are triggered to close the database monitor output table. However, the ENDDBMON command can complete before all the monitored jobs have written their final statistic records to the log. Use the **Work with Object Locks (WRKOBJLCK)**

command to determine that all the monitored jobs no longer hold locks on the database monitor output table before assuming that the monitoring is complete.

Example 1: End Monitoring for a Specific Job

```
ENDDBMON JOB(*)
```

This command ends database monitoring for the current job.

Example 2: End Monitoring for All Jobs

```
ENDDBMON JOB(*ALL)
```

This command ends the monitor open across all jobs on the system. If more than one monitor with JOB(*ALL) is active, then the MONID parameter must also be specified to uniquely identify which specific public monitor to end.

Example 3: End Monitoring for an Individual Public Monitor with MONID Parameter

```
ENDDBMON JOB(*ALL) MONID(061601001)
```

This command ends the monitor that was started with JOB(*ALL) and that has a monitor ID of 061601001. Because there were multiple monitors started with JOB(*ALL), the monitor ID must be specified to uniquely identify which monitor that was started with JOB(*ALL) is to be ended.

Example 4: End Monitoring for an Individual Public Monitor with MONID Parameter

```
ENDDBMON MONID(061601001)
```

This command performs the same function as the previous example. It ends the monitor that was started with JOB(*ALL) or JOB(*) and that has a monitor ID of 061601001.

Example 5: End Monitoring for All JOB(*ALL) Monitors

```
ENDDBMON JOB(*ALL/*ALL/*ALL) MONID(*ALL)
```

This command ends all monitors that are active across multiple jobs. It does not end any monitors open for a specific job or the current job.

Example 6: End Monitoring for a Generic Job

```
ENDDBMON JOB(QZDA*)
```

This command ends the monitor that was started with JOB(QZDA*). If more than one monitor with JOB(QZDA*) is active, then the MONID parameter must also be specified to uniquely identify which individual monitor to end.

Example 7: End Monitoring for an Individual Monitor with a Generic Job

```
ENDDBMON JOB(QZDA*) MONID(061601001)
```

This command ends the monitor that was started with JOB(QZDA*) and has a monitor ID of 061601001. Because there were multiple monitors started with JOB(QZDA*), the monitor ID must be specified to uniquely identify which JOB(QZDA*) monitor is to be ended.

Example 8: End Monitoring for a Group of Generic Jobs

```
ENDDBMON JOB(QZDA*) MONID(*ALL)
```

This command ends all monitors that were started with JOB(QZDA*).

Database monitor performance rows

The rows in the database table are uniquely identified by their row identification number. The information within the file-based monitor (**Start Database Monitor (STRDBMON)**) is written out based upon a set of logical formats which are defined in the database monitor formats. These views correlate closely to the debug messages and the **Print SQL Information (PRSQLINF)** messages.

The database monitor formats section also identifies which physical columns are used for each view and what information it contains. You can use the views to identify the information that can be extracted from the monitor. These rows are defined in several different views which are not shipped with the system and must be created by the user, if wanted. The views can be created with the SQL DDL. The column descriptions are explained in the tables following each figure.

Related concepts

[Database monitor formats](#)

This section contains the formats used to create the database monitor SQL tables and views.

Database monitor examples

The System i Navigator interface provides a powerful tool for gathering and analyzing performance monitor data using database monitor. However, you might want to do your own analysis of the database monitor files.

Suppose you have an application program with SQL statements and you want to analyze and performance tune these queries. The first step in analyzing the performance is collection of data. The following examples show how you might collect and analyze data using **Start Database Monitor (STRDBMON)** and **End Database Monitor (ENDDBMON)** commands. Performance data is collected in LIB/PERFDATA for an application running in your current job. The following sequence collects performance data and prepares to analyze it.

1. **STRDBMON** FILE(LIB/PERFDATA) TYPE(*DETAIL). If this table does not exist, the command creates one from the skeleton table in QSYS/QAQQDBMN.
2. Run your application
3. **ENDDBMON**
4. Create views over LIB/PERFDATA using the SQL DDL. Creating the views is not mandatory. All the information resides in the base table that was specified on the **STRDBMON** command. The views simply provide an easier way to view the data.

You are now ready to analyze the data. The following examples give you a few ideas on how to use this data. You must closely study the physical and logical view formats to understand all the data being collected. Then you can create queries that give the best information for your applications.

Related information

[Start Database Monitor \(STRDBMON\) command](#)

[End Database Monitor \(ENDDBMON\) command](#)

Application with table scans example

Determine which queries in your SQL application are implemented with table scans. The complete information can be obtained by joining two views: QQQ1000, which contains information about the SQL statements, and QQQ3000, which contains data about queries performing table scans.

The following SQL query can be used:

```
SELECT (B.End_Timestamp - B.Start_Timestamp) AS TOT_TIME, A.System_Table_Schema,  
A.System_Table_Name,  
A.Index_Advised, A.Table_Total_Rows, C.Number_Rows_Returned, A.Estimated_Rows_Selected,  
B.Statement_Text_Long
```

```

FROM LIB.QQ3000 A, LIB.QQ1000 B, LIB.QQ3019 C
WHERE A.Join_Column = B.Join_Column
AND A.Join_Column = C.Join_Column

```

Sample output of this query is shown in the following table. Key to this example are the join criteria:

```

WHERE A.Join_Column = B.Join_Column
AND A.Join_Column = C.Join_Column

```

Much data about many queries is contained in multiple rows in table LIB/PERFDATA. It is not uncommon for data about a single query to be contained in 10 or more rows within the table. The combination of defining the logical views and then joining the views together allows you to piece together all the data for a query or set of queries. Column QQJFLD uniquely identifies all queries within a job; column QQUCNT is unique at the query level. The combination of the two, when referenced in the context of the logical views, connects the query implementation to the query statement information.

<i>Table 43. Output for SQL Queries that Performed Table Scans</i>						
Lib Name	Table Name	Total Rows	Index Advised	Rows Returned	TOT_TIME	Statement Text
LIB1	TBL1	20000	Y	10	6.2	SELECT * FROM LIB1/TBL1 WHERE FLD1 = 'A'
LIB1	TBL2	100	N	100	0.9	SELECT * FROM LIB1/TBL2
LIB1	TBL1	20000	Y	32	7.1	SELECT * FROM LIB1/TBL1 WHERE FLD1 = 'B' AND FLD2 > 9000

If the query does not use SQL, the SQL information row (QQQ1000) is not created. Without the SQL information row, it is more difficult to determine which rows in LIB/PERFDATA pertain to which query. When using SQL, row QQQ1000 contains the actual SQL statement text that matches the monitor rows to the corresponding query. Only through SQL is the statement text captured. For queries executed using the OPNQRYF command, the OPNID parameter is captured and can be used to tie the rows to the query. The OPNID is contained in column Open_Id of row QQQ3014.

Queries with table scans example

Like the preceding example that showed which SQL applications were implemented with table scans, the following example shows all queries that are implemented with table scans.

```

SELECT (D.End_Timestamp - D.Start_Timestamp) AS TOT_TIME, A.System_Table_Schema,
A.System_Table_Name,
A.Table_Total_Rows, A.Index_Advised,
B.Open_Id, B.Open_Time,
C.Clock_Time_to_Return_All_Rows, C.Number_Rows_Returned,
D.Result_Rows, D.Statement_Text_Long
FROM LIB.QQ3000 A INNER JOIN LIB.QQ3014 B
ON (A.Join_Column = B.Join_Column)
LEFT OUTER JOIN LIB.QQ3019 C
ON (A.Join_Column = C.Join_Column)
LEFT OUTER JOIN LIB.QQ1000 D
ON (A.Join_Column = D.Join_Column)

```

In this example, the output for all queries that performed table scans are shown in the following table.

Note: The columns selected from table QQQ1000 do return NULL default values if the query was not executed using SQL. For this example assume that the default value for character data is blanks and the default value for numeric data is an asterisk (*).

Table 44. Output for All Queries that Performed Table Scans

Lib Name	Table Name	Total Rows	Index Advised	Query OPNID	ODP Open Time	Clock Time	Recs Rtned	Rows Rtned	TOT_TIME	Statement Text
LIB1	TBL1	20000	Y		1.1	4.7	10	10	6.2	SELECT * FROM LIB1/TBL1 WHERE FLD1 = 'A'
LIB1	TBL2	100	N		0.1	0.7	100	100	0.9	SELECT * FROM LIB1/TBL2
LIB1	TBL1	20000	Y		2.6	4.4	32	32	7.1	SELECT * FROM LIB1/TBL1 WHERE FLD1 = 'A' AND FLD2 > 9000
LIB1	TBL4	4000	N	QRY04	1.2	4.2	724	*	*	*

If the SQL statement text is not needed, joining to table QQQ1000 is not necessary. You can determine the total time and rows selected from data in the QQQ3014 and QQQ3019 rows.

Table scan detail example

Your next step could include further analysis of the table scan data. The previous examples contained a column titled Index Advised. A 'Y' (yes) in this column is a hint from the query optimizer that the query could perform better with an index to access the data. For the queries where an index is advised, the rows selected by the query are low in comparison to the total number of table rows. This selectivity is another indication that a table scan might not be optimal. Finally, a long execution time might highlight queries that could be improved by performance tuning.

The next logical step is to look into the index advised optimizer hint. The following query can be used:

```
SELECT A.System_Table_Schema, A.System_Table_Name,
       A.Index_Advised, A.Index_Advised_Columns,
       A.Index_Advised_Columns_Count, B.Open_Id,
       C.Statement_Text_Long
FROM LIB.QQQ3000 A INNER JOIN LIB.QQQ3014 B
ON (A.Join_Column = B.Join_Column)
LEFT OUTER JOIN LIB.QQQ1000 C
ON (A.Join_Column = C.Join_Column)
WHERE A.Index_Advised = 'Y'
```

There are two slight modifications from the first example. First, the selected columns have been changed. Most important is the selection of Index_Advised_Columns containing a list of possible key columns to use when creating the suggested index. Second, the query selection limits the output to those table scan queries where the optimizer advises that an index is created (A.Index_Advised = 'Y'). The following table shows what the results might look like.

Table 45. Output with Recommended Key Columns

Lib Name	Table Name	Index Advised	Advised Key columns	Advised Primary Key	Query OPNID	Statement Text
LIB1	TBL1	Y	FLD1	1		SELECT * FROM LIB1/TBL1 WHERE FLD1 = 'A'
LIB1	TBL1	Y	FLD1, FLD2	1		SELECT * FROM LIB1/TBL1 WHERE FLD1 = 'B' AND FLD2 > 9000

Table 45. Output with Recommended Key Columns (continued)

Lib Name	Table Name	Index Advised	Advised Key columns	Advised Primary Key	Query OPNID	Statement Text
LIB1	TBL4	Y	FLD1, FLD4	1	QRY04	

Determine whether it makes sense to create a permanent index as advised by the optimizer. In this example, creating one index over LIB1/TBL1 satisfies all three queries since each use a primary or left-most key column of FLD1. By creating one index over LIB1/TBL1 with key columns FLD1, FLD2, there is potential to improve the performance of the second query even more. Consider how often these queries are run and the overhead of maintaining an additional index over the table when deciding whether to create the suggested index.

If you create a permanent index over FLD1, FLD2 the next sequence of steps is as follows:

1. Start the performance monitor again
2. Rerun the application
3. End the performance monitor
4. Re-evaluate the data.

It is likely that the three index-advised queries are no longer performing table scans.

Additional database monitor examples

The following are additional ideas or examples on how to extract information from the performance monitor statistics. All the examples assume that data has been collected in LIB/PERFDATA and the documented views have been created.

1. How many queries are performing dynamic replans?

```
SELECT COUNT(*)
FROM LIB.QQ01000
WHERE Dynamic_Replan_Reason_Code <> 'NA'
```

2. What is the statement text and the reason for the dynamic replans?

```
SELECT Dynamic_Replan_Reason_Code, Statement_Text_Long
FROM LIB.QQ01000
WHERE Dynamic_Replan_Reason_Code <> 'NA'
```

Note: You need to refer to the description of column Dynamic_Replan_Reason_Code for definitions of the dynamic replan reason codes.

3. How many indexes have been created over LIB1/TBL1?

```
SELECT COUNT(*)
FROM LIB.QQ03002
WHERE System_Table_Schema = 'LIB1'
AND System_Table_Name = 'TBL1'
```

4. What key columns are used for all indexes created over LIB1/TBL1 and what is the associated SQL statement text?

```
SELECT A.System_Table_Schema, A.System_Table_Name,
A.Index_Advised_Columns, B.Statement_Text_Long
FROM LIB.QQ03002 A, LIB.QQ01000 B
WHERE A.Join_Column = B.Join_Column
AND A.System_Table_Schema = 'LIB1'
AND A.System_Table_Name = 'TBL1'
```

Note: This query shows key columns only from queries executed using SQL.

5. What key columns are used for all indexes created over LIB1/TBL1 and what was the associated SQL statement text or query open ID?

```

SELECT A.System_Table_Schema, A.System_Table_Name, A.Index_Advised_Columns,
       B.Open_Id, C.Statement_Text_Long
FROM LIB.QQ3002 A INNER JOIN LIB.QQ3014 B
ON (A.Join_Column = B.Join_Column)
LEFT OUTER JOIN LIB.QQ1000 C
ON (A.Join_Column = C.Join_Column)
WHERE A.System_Table_Schema LIKE '%'
AND A.System_Table_Name = '%'

```

Note: This query shows key columns from all queries on the system.

6. What types of SQL statements are being performed? Which are performed most frequently?

```

SELECT CASE Statement_Function
WHEN 'O' THEN 'Other'
WHEN 'S' THEN 'Select'
WHEN 'L' THEN 'DDL'
WHEN 'I' THEN 'Insert'
WHEN 'U' THEN 'Update'
ELSE 'Unknown'
END, COUNT(*)
FROM LIB.QQ1000
GROUP BY Statement_Function
ORDER BY 2 DESC

```

7. Which SQL queries are the most time consuming? Which user is running these queries?

```

SELECT (End_Timestamp - Start_Timestamp), Job_User,
       Current_User_Profile, Statement_Text_Long
FROM LIB.QQ1000
ORDER BY 1 DESC

```

8. Which queries are the most time consuming?

```

SELECT (A.Open_Time + B.Clock_Time_to_Return_All_Rows),
       A.Open_Id, C.Statement_Text_Long
FROM LIB.QQ3014 A LEFT OUTER JOIN LIB.QQ3019 B
ON (A.Join_Column = B.Join_Column)
LEFT OUTER JOIN LIB.QQ1000 C
ON (A.Join_Column = C.Join_Column)
ORDER BY 1 DESC

```

Note: This example assumes that detail data was collected (STRDBMON TYPE(*DETAIL)).

9. Show the data for all SQL queries with the data for each SQL query logically grouped.

```

SELECT A.*
FROM LIB.PERFDATA A, LIB.QQ1000 B
WHERE A.QQJFLD = B.Join_Column

```

Note: This might be used within a report that will format the interesting data into a more readable format. For example, all reason code columns can be expanded by the report to print the definition of the reason code. Physical column QQRCOD = 'T1' means that a table scan was performed because no indexes exist over the queried table.

10. How many queries are implemented with temporary tables because a key length greater than 2000 bytes, or more than 120 key columns was specified for ordering?

```

SELECT COUNT(*)
FROM LIB.QQ3004
WHERE Reason_Code = 'F6'

```

11. Which SQL queries were implemented with nonreusable ODPs?

```

SELECT B.Statement_Text_Long
FROM LIB.QQ3010 A, LIB.QQ1000 B
WHERE A.Join_Column = B.Join_Column
AND A.ODP_Implementation = 'N';

```

12. What is the estimated time for all queries stopped by the query governor?

```

SELECT Estimated_Processing_Time, Open_Id
FROM LIB.QQ3014
WHERE Stopped_By_Query_Governor = 'Y'

```

Note: This example assumes that detail data was collected (STRDBMON TYPE(*DETAIL)).

13. Which queries estimated time exceeds actual time?

```

SELECT A.Estimated_Processing_Time,
       (A.Open_Time + B.Clock_Time_to_Return_All_Rows),
       A.Open_Id, C.Statement_Text_Long
FROM LIB.QQ3014 A LEFT OUTER JOIN LIB.QQ3019 B
ON (A.Join_Column = B.Join_Column)
LEFT OUTER JOIN LIB.QQ1000 C
ON (A.Join_Column = C.Join_Column)
WHERE A.Estimated_Processing_Time/1000 >
      (A.Open_Time + B.Clock_Time_to_Return_All_Rows)

```

Note: This example assumes that detail data was collected (STRDBMON TYPE(*DETAIL)).

14. Should you apply a PTF for queries containing UNIONS? Yes, if any queries are performing UNIONS. Do any of the queries perform this function?

```

SELECT COUNT(*)
FROM QQ3014
WHERE Has_Union = 'Y'

```

Note: If the result is greater than 0, apply the PTF.

15. You are a system administrator and an upgrade to the next release is planned. You want to compare data from the two releases.

- Collect data from your application on the current release and save this data in LIB/CUR_DATA
- Move to the next release
- Collect data from your application on the new release and save this data in a different table: LIB/NEW_DATA
- Write a program to compare the results. You need to compare the statement text between the rows in the two tables to correlate the data.

Using System i Navigator with detailed monitors

You can work with detailed monitors from the System i Navigator interface. The detailed SQL performance monitor is the System i Navigator version of the STRDBMON database monitor, found on the native interface.

You can start this monitor by right-clicking SQL Performance Monitors under the Database portion of the System i Navigator tree and selecting **New > Monitor**. This monitor saves detailed data in real time to a hard disk. It does not need to be paused or ended in order to analyze the results. You can also choose to run a Visual Explain based on the data gathered by the monitor. Since this monitor saves data in real time, it might have a performance impact on your system.

Starting a detailed monitor

You can start a detailed monitor from the System i Navigator interface.

You can start this monitor by right-clicking **SQL Performance Monitors** under the Database portion of the System i Navigator tree and selecting **New > SQL Performance Monitor**.

When you create a detailed monitor, you can filter the information that you want to capture.

Initial number of records: Select to specify the number of records initially allocated for the monitor. The 'Initial number of records' option is used to pre-allocate storage to the database monitor out file. When collecting large amounts of monitor records, this option improves the collection performance by avoiding automatic storage extensions that occur as a file grows in size.

Minimum estimated query runtime:	Select to include queries that exceed a specified amount of time. Select a number and then a unit of time.
Minimum estimated temporary storage:	Select to include queries that exceed a certain amount of temporary storage. Specify a size in MB.
Job name:	Select to filter by a specific job name. Specify a job name in the field. You can specify the entire ID or use a wildcard. For example, 'QZDAS*' finds all jobs where the name starts with 'QZDAS.'
Job user:	Select to filter by a job user. Specify a user ID in the field. You can specify the entire ID or use a wildcard. For example, 'QUSER*' finds all user IDs where the name starts with 'QUSER.'
Current user:	Select to filter by the current user of the job. Specify a user ID in the field. You can specify the entire ID or use a wildcard. For example, 'QSYS*' finds all users where the name starts with 'QSYS.'
Client location:	Select to filter by Internet access. The input needs to be in IPv4 or IPv6 form. <ol style="list-style-type: none"> 1. IP version 4 address in dotted decimal form. Specify an Internet Protocol version 4 address in the form nnn.nnn.nnn.nnn where each nnn is a number in the range 0 through 255. 2. IP version 6 address in colon hexadecimal form. Specify an internet protocol version 6 address in the form xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx, where each xxxx is a hex number in the range 0 through FFFF. IP version 6 includes the IPv4-mapped IPv6 address form (for example, ::FFFF:1.2.3.4). For IP version 6, the compressed form of the address is allowed. 3. IP host domain name. Specify an internet host domain name of up to 254 characters in length.
Local port:	Select to filter by port number. You can select a port from the list or else enter your own port number. <p>Ports in the list include:</p> <ul style="list-style-type: none"> • 446 - DRDA/DDM • 447 - DRDA/DDM • 448 - Secure DRDA/DDM (SSL) • 4402 - QXDAEDRSQL server • 8471 - Database server • 9471 - Secure database server (SSL)
Query Governor limits:	Select to search for queries that have exceeded or are expected to exceed the query governor limits set for the system. Choose from the following options: <ul style="list-style-type: none"> • Always collect information when exceeded • Conditional collection of information when exceeded
Client registers:	Select to filter by the client register information.
Statements that access these objects:	Select to filter by only queries that use certain tables. Click Browse to select tables to include. To remove a table from the list, select the table and click Remove . A maximum of 10 table names can be specified.
Activity to monitor:	Select to collect monitor output for user-generated queries or for both user-generated and system-generated queries.

You can choose which jobs you want to monitor or choose to monitor all jobs. You can have multiple instances of monitors running on your system at one time. You can create up to 10 detailed monitors to monitor all jobs. When collecting information for all jobs, the monitor will collect on previously started jobs or new jobs that are started after the monitor is created. You can edit this list by selecting and removing jobs from the **Selected jobs** list.

Analyzing detailed monitor data

SQL performance monitors provides several predefined reports that you can use to analyze your monitor data.

To view these reports, right-click a monitor and select **Analyze**. The monitor does not need to be ended in order to view this information.

	Value	Summary Available	Statements Available

How much work was requested?			
What options were provided to the optimizer?			

On the Analysis Overview dialog, you can view overview information or else choose one of the following categories:

- How much work was requested?
- What options were provided to the optimizer?
- What implementations did the optimizer use?
- What types of SQL statements were requested?
- Miscellaneous information
- I/O information

From the Actions menu, you can choose one of the following summary predefined reports:

User summary Contains a row of summary information for each user. Each row summarizes all SQL activity for that user.

Job summary	Contains a row of information for each job. Each row summarizes all SQL activity for that job. This information can be used to tell which jobs on the system are the heaviest users of SQL. These jobs are perhaps candidates for performance tuning. You could then start a separate detailed performance monitor on an individual job to get more detailed information without having to monitor the entire system.
Operation summary	Contains a row of summary information for each type of SQL operation. Each row summarizes all SQL activity for that type of SQL operation. This information provides the user with a high-level indication of the type of SQL statements used. For example, are the applications mostly read-only, or is there a large amount of update, delete, or insert activity. This information can then be used to try specific performance tuning techniques. For example, if many INSERTs are occurring, you might use an OVRDBF command to increase the blocking factor or the QDBENCWT API.
Program summary	Contains a row of information for each program that performed SQL operations. Each row summarizes all SQL activity for that program. This information can be used to identify which programs use the most or most expensive SQL statements. Those programs are then potential candidates for performance tuning. A program name is only available if the SQL statements are embedded inside a compiled program. SQL statements that are issued through ODBC, JDBC, or OLE DB have a blank program name unless they result from a procedure, function, or trigger.

In addition, when a green check is displayed under Summary column, you can select that row and click **Summary** to view information about that row type. Click **Help** for more information about the summary report. To view information organized by statements, click **Statements**.

Comparing monitor data

You can use System i Navigator to compare data sets in two or more monitors.

System i Navigator provides you with two types of comparison. The first is a simple compare that provides a high-level comparison of the monitors or snapshots. The second is a detailed comparison. The simple compare provides you with enough data about the monitors or snapshots to help you determine if a detailed comparison is helpful.

To launch a simple compare, go to **System i Navigator > system name > SQL performance monitors**. Right-click one or more monitors and select **Compare**.

To launch a detailed comparison, select the Detailed Comparison tab.

On the Detailed Comparison dialog, you can specify information about the data sets that you want to compare.

Name	The name of the monitors that you want to compare.
Schema mask	Select any names that you want the comparison to ignore. For example, consider the following scenario: You have an application running in a test schema and it is optimized. Now you move it to the production schema and you want to compare how it executes there. The statements in the comparison are identical except that the statements in the test schema use "TEST" and the statements in the production schema use "PROD". You can use the schema mask to ignore "TEST" in the first monitor and "PROD" in the second monitor. Then the statements in the two monitors appear identical.
Statements that ran longer than	The minimum runtime for statements to be compared.
Minimum percent difference	The minimum difference in key attributes of the two statements being compared that determines if the statements are considered equal or not. For example, if you select 25% as the minimum percent different, only matching statements whose key attributes differ by 25% or more are returned.

When you click **Compare**, both monitors are scanned for matching statements. Any matches found are displayed side-by-side for comparison of key attributes of each implementation.

On the Comparison output dialog, you view statements that are included in the monitor by clicking **Show Statements**. You can also run Visual Explain by selecting a statement and clicking **Visual Explain**.

Any matches found are displayed side-by-side for comparison of key attributes of each implementation.

Viewing statements in a monitor

You can view SQL statements that are included in a detailed monitor.

Right-click any detailed monitor in the SQL performance monitor window and select **Show statements**.

The filtering options provide a way to focus in on a particular area of interest:

Minimum runtime for the longest execution of the statement:	Select to include statements that exceed a certain amount of time. Select a number and then a unit of time.
Statements that ran on or after this date and time:	Select to include statements run at a specified date and time. Select a date and time.
Statements that reference the following objects:	Select to include statements that use or reference certain objects. Click Browse to select objects to include.
Statements that contain the following text:	Select to include only those statements that contain a specific type of SQL statement. For example, specify SELECT if you only want to include statements that are using SELECT. The search is case insensitive for ease of use. For example, the string 'SELECT' finds the same entries as the search string 'select'.

Multiple filter options can be specified. In a multi-filter case, the candidate entries for each filter are computed independently. Only those entries that are present in all the candidate lists are shown. For example, if you specified options **Minimum runtime for the longest execution of the statement** and **Statements that ran on or after this date and time**, you will be shown statements with the minimum runtime that ran on or after the specified date and time.

[Index advisor](#)

The query optimizer analyzes the row selection in the query and determines, based on default values, if creation of a permanent index improves performance. If the optimizer determines that a permanent index might be beneficial, it returns the key columns necessary to create the suggested index.

Importing a monitor

You can import monitor data that has been collected using some other interface by using System i Navigator.

Monitors that are created using the **Start Database Monitor (STRDBMON)** command are automatically registered with System i Navigator. They are also included in the list of monitors displayed by System i Navigator.

To import monitor data, right-click **SQL Performance monitors** and select **Import**. Once you have imported a monitor, you can analyze the data.

Index advisor

The query optimizer analyzes the row selection in the query and determines, based on default values, if creation of a permanent index improves performance. If the optimizer determines that a permanent index might be beneficial, it returns the key columns necessary to create the suggested index.

The optimizer is able to perform radix index probe over any combination of the primary key columns, plus one additional secondary key column. Therefore it is important that the first secondary key column is

the most selective secondary key column. The optimizer uses radix index scan with any of the remaining secondary key columns. While radix index scan is not as fast as radix index probe, it can still reduce the number of keys selected. It is recommended that secondary key columns that are fairly selective are included.

Determine the true selectivity of any secondary key columns and whether you include those key columns in the index. When building the index, make the primary key columns the left-most key columns, followed by any of the secondary key columns chosen, prioritized by selectivity.

After creating the suggested index and executing the query again, it is possible that the query optimizer will choose not to use the suggested index. It does not include join, ordering, and grouping criteria. The SQE optimizer includes selection, join, ordering, and grouping criteria when suggesting indexes. Local selection advice can now factor in both AND and OR predicates with the qualifications mentioned below.

You can access index advisor information in many different ways. These ways include:

- The index advisor interface in System i Navigator
- SQL performance monitor Show statements
- Visual Explain interface
- Querying the Database monitor view 3020 - Index advised.

Index advice and OR predicates

Index advice generation to handle OR predicates

Index Advisor has been extended to include queries that OR together local selection (WHERE clause) columns over a single table. OR advice requires two or more indexes to be created as a dependent set.

If any of the OR'd indexes are missing, the optimizer won't be able to cost and choose these dependent indexes for implementation of the OR based query.

This relationship between OR based indexes in the SYSIXADV index advice table is with a new **DEPENDENT_ADVICE_COUNT** column.

Some restrictions with this support:

- OR'd predicate advice appears only if no other advice is generated
- Maximum of 5 predicates OR'd together
- Advised for files with OR'd local selection that get costed in the primary join dial when optimizing a join query

When Index Advisor shows highly dependent advice, use of the exact match capability from Show Statements to find the query in the plan cache is helpful. Once found, use Visual Explain to discover the dependent index advice specific to that query.

Index Or Advice example

- Should advise indexes over all OR'd predicate columns
- All 3 advised indexes will have **DEPENDENT_ADVICE_COUNT>0**
- Execution with indexes should produce bitmap implementation and register no new advice

```
SELECT orderkey, partkey, suppkey,  
linenumber, shipmode orderpriority
```

```
FROM item_fact
WHERE OrderKey <= 10 OR
SuppKey <= 10 OR
PartKey <= 10
OPTIMIZE FOR ALL ROWS
```

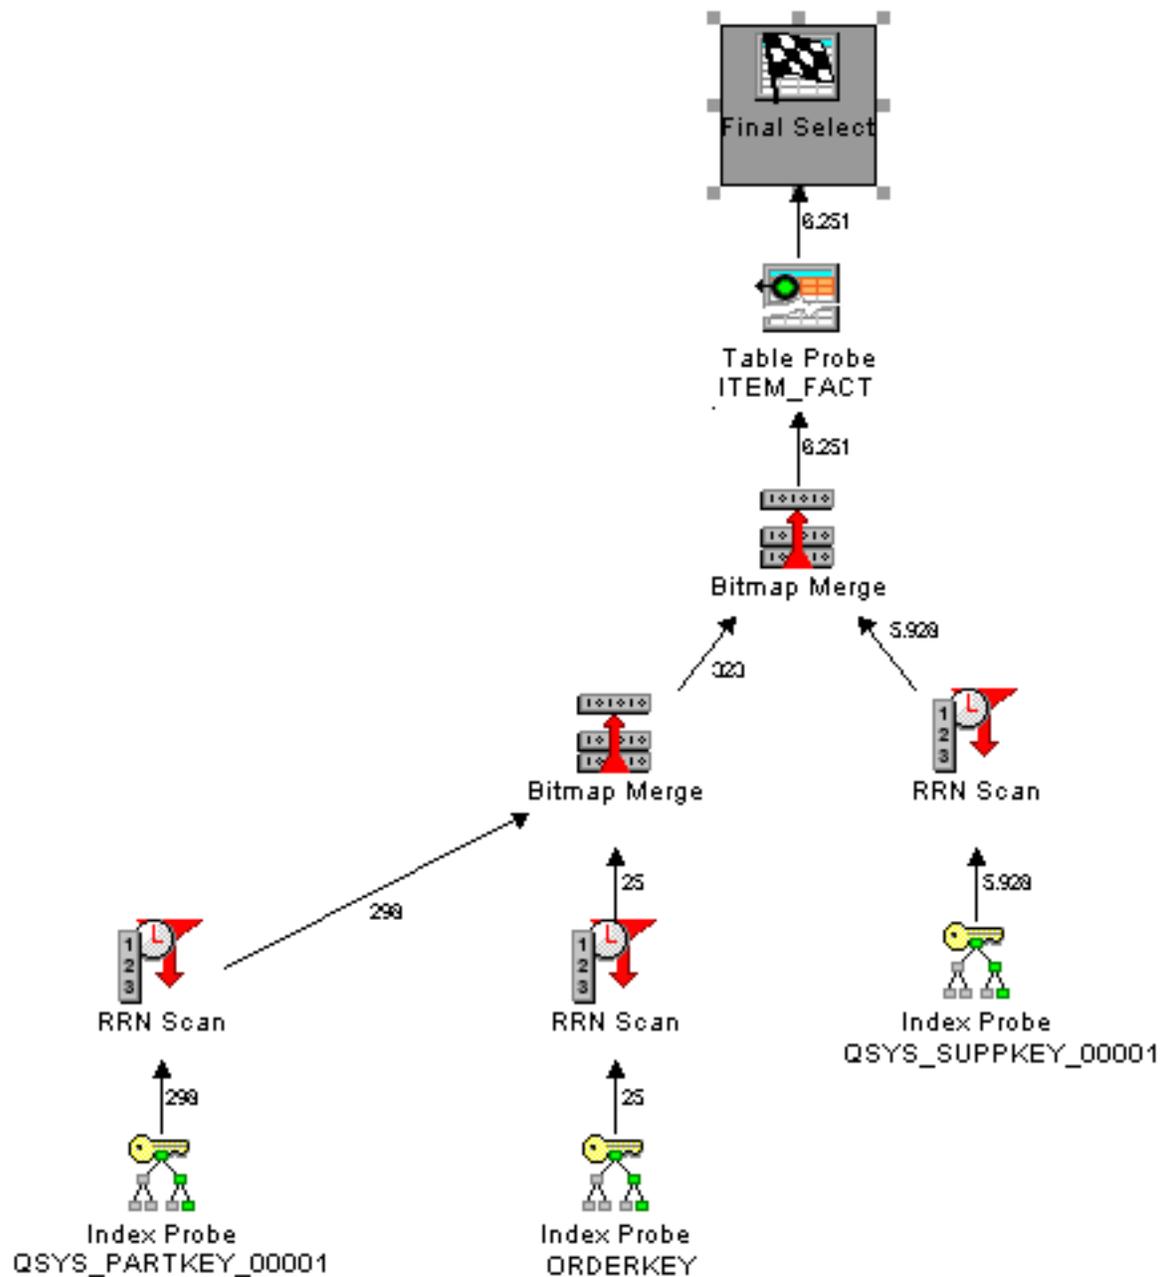

The graphic below shows the Index advice for the OR'd predicate columns:

The screenshot shows the 'Index and Statistics Advisor' window. The 'Index Advisor' tab is active. A message states: 'It is recommended that the following indexes be created:'. Below this is a table with the following data:

Create	Table Name	Schema	Index Type	Columns
<input checked="" type="checkbox"/>	ITEM_FACT	AAA	Binary Radix	SUPPKEY
<input checked="" type="checkbox"/>	ITEM_FACT	AAA	Binary Radix	PARTKEY
<input checked="" type="checkbox"/>	ITEM_FACT	AAA	Binary Radix	ORDERKEY

At the bottom right of the window is a 'Create ...' button.

The graphic below depicts the Visual Explain showing the implementation of merge bitmap representation using the OR'd advice indexes:

Index advice for Encoded Vector Index RRN Probe Plans

- █ Indexes are not advised for use by Encoded Vector Index RRN Probe Plans.
- █ Indexes are not advised for use by Encoded Vector Index RRN Probe Plans.

Displaying index advisor information

You can display index advisor information from the optimizer using System i Navigator. System i Navigator displays information found in the QSYS2/SYSIXADV system table.

To display index advisor information, follow these steps:

1. In the System i Navigator window, expand the system that you want to use.
2. Expand **Databases**.
3. Right-click the database that you want to work with and select **Index Advisor > Index Advisor**.

You can also find index advisor information for a specific schema or a specific table by right-clicking on a schema or table object.

Once you have displayed the information, you have several options. You can create an index from the list, remove the index advised from the list, or clear the list entirely. You can also right-click on an index and select **Show SQL**, launching a Run SQL Scripts session with the index creation statement. Finally, you can right-click on an advised index and select Show Statements. With additional information automatically provided in the advised index filter for the Plan Cache search, the resulting SQL statements shown will be a better match to the original queries that generated that specific index advice.

Depending on if you are viewing the index advice at the database level or the schema level your list could be large. Once you have the list displayed, follow these steps to subset your list:

1. Go to the **View** menu option, and select **Customize this view > Include ...**
2. Enter the information you would like to filter the list by.
3. Press the **OK** button to get the refreshed list of index advice.

Database manager indexes advised system table

This topic describes the indexes advised system table.

<i>Table 46. SYSIXADV system table</i>			
Column name	System column name	Data type	Description
TABLE_NAME	TBNAME	VARCHAR(258)	Table over which an index is advised
TABLE_SCHEMA	DBNAME	VARCHAR(128)	SQL schema containing the table
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System table name on which the index is advised
PARTITION_NAME	TBMEMBER	CHAR(10)	Partition detail for the index
KEY_COLUMNS_ADVISED	KEYSADV	VARCHAR(16000)	Column names for the advised index
LEADING_COLUMN_KEYS	LEADKEYS	VARCHAR(16000)	Leading, Order Independent keys. the keys at the beginning of the KEY_COLUMNS_ADVISED field which could be reordered and still satisfy the index being advised.
INDEX_TYPE	INDEX_TYPE	CHAR(14)	Radix (default) or EVI
LAST_ADVISED	LASTADV	TIMESTAMP	Last time this row was updated
TIMES_ADVISED	TIMESADV	BIGTINT	Number of times this index has been advised
ESTIMATED_CREATION_TIME	ESTTIME	INT	Estimated number of seconds for index creation
REASON_ADVISED	REASON	CHAR(2)	Coded reason why index was advised
LOGICAL_PAGE_SIZE	PAGESIZE	INT	Recommended page size for index
MOST_EXPENSIVE_QUERY	QUERYCOST	INT	Execution time in seconds of the query
AVERAGE_QUERY_ESTIMATE	QUERYEST	INT	Average execution time in seconds of the query
TABLE_SIZE	TABLE_SIZE	BIGINT	Number of rows in table when the index was advised

Table 46. SYSIXADV system table (continued)

Column name	System column name	Data type	Description
NLSS_TABLE_NAME	NLSSNAME	CHAR(10)	NLSS table to use for the index
NLSS_TABLE_SCHEMA	NLSSDBNAME	CHAR(10)	Schema name of the NLSS table
MTI_USED	MTIUSED	BIGINT	The number of times that this specific Maintained Temporary Index (MTI) has been used by the optimizer. The optimizer stops using a matching MTI once a permanent index is created.
MTI_CREATED	MTICREATED	INTEGER	The number of times that this specific Maintained Temporary Index (MTI) has been created by the optimizer. MTIs do not persist across system IPLs.
LAST_MTI_USED	LASTMTIUSE	TIMESTAMP	The timestamp representing the last time this specific Maintained Temporary Index (MTI) was used by the optimizer to improve the performance of a query. The MTI Last Used field can be blank. The blank field indicates that an MTI which exactly matches this advice has never been used by the queries which generated this index advice.
AVERAGE_QUERY_ESTIMATE_MICRO	QRYMICRO	BIGINT	Average execution time in microseconds of the query which drove the index advice
EVI_DISTINCT_VALUES	EVIVALS	INTEGER	Recommended value to use when creating the advised EVI index. This value is <i>n</i> within the WITH <i>n</i> DISTINCT VALUES clause on the CREATE INDEX SQL statement.
INCLUDE_COLUMNS	INCLCOL	CLOB(10000)	EVI INCLUDE expressions for index creation.
FIRST_ADVISED	FIRSTADV	TIMESTAMP	When this row was inserted.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System name of the table schema.
MTI_USED_FOR_STATS	MTISTATS	BIGINT	Number of times Maintained Temporary Index was used as a source for optimizer statistics.
LAST_MTI_USED_FOR_STATS	LASTMTISTA	TIMESTAMP	The timestamp representing the last time this specific Maintained Temporary Index was used as a source of statistics by the optimizer to improve the performance of a query.
DEPENDENT_ADVICE_COUNT	DEPCNT	BIGINT	The number of times this index advice was dependent upon other advice.

Index advisor column descriptions

Displays the columns that are used in the Index advisor window.

<i>Table 47. Columns used in Index advisor window</i>	
Column name	Description
Table for Which Index was Advised	The optimizer is advising creation of a permanent index over this table. This value is the long name for the table. The advice was generated because the table was queried and no existing permanent index could be used to improve the performance of the query.
Schema	Schema or library containing the table.
System Schema	System name of the schema.
System Name	System table name on which the index is advised
Partition	Partition detail for the index. Possible values: <ul style="list-style-type: none"> • <blank>, which means For all partitions • For Each Partition • specific name of the partition
Keys Advised	Column names for the advised index. The order of the column names is important. The names are listed in the same order as in the CREATE INDEX SQL statement. An exception is when the leading, order independent key information indicates that the ordering can be changed.
Leading Keys Order Independent	Leading, Order Independent keys. the keys at the beginning of the KEY_COLUMNS_ADVISED field which could be reordered and still satisfy the index being advised.
Index Type Advised	Radix (default) or EVI
Last Advised for Query Use	The timestamp representing the last time this index was advised for a query.
Times Advised for Query Use	The cumulative number of times this index has been advised. This count ceases to increase once a matching permanent index is created. The row of advice remains in this table until the user removes it
Estimated Index Creation Time	Estimated time in seconds to create this index.
Reason advised	Reason why index was advised. Possible values are: <ul style="list-style-type: none"> Row selection Ordering/Grouping Row selection and Ordering/Grouping
Logical Page Size Advised (KB)	Recommended page size to be used on the PAGESIZE keyword of the CREATE INDEX SQL statement when creating this index.
Most Expensive Query Estimate	Execution time in seconds of the longest running query which generated this index advice.
Average of Query Estimates	Average execution time in seconds of all queries that generated this index advice.

Table 47. Columns used in Index advisor window (continued)

Column name	Description
Rows in Table when Advised	Number of rows in table for the last time this index was advised.
NLSS Table Advised	The sort sequence table in use by the query which generated the index advice. For more detail on sort sequences:
NLSS Schema Advised	The schema of the sort sequence table.
MTI Used	The number of times that this specific Maintained Temporary Index (MTI) has been used by the optimizer.
MTI Created	The number of times that this specific Maintained Temporary Index (MTI) has been created by the optimizer. MTIs do not persist across system IPLs.
MTI Last Used	The timestamp representing the last time this specific Maintained Temporary Index (MTI) was used by the optimizer to improve the performance of a query. The MTI Last Used field can be blank. A blank field indicates that an MTI which exactly matches this advice has never been used by the queries which generated this index advice.
EVI Distinct Values	Recommended value to use when creating the advised EVI index. This value is n within the WITH n DISTINCT VALUES clause on the CREATE INDEX SQL statement.
First Advised	The date/time when a row is first added to the Index Advisor table for this advice.
MTI Used for Stats	The number of times that this specific Maintained Temporary Index (MTI) has been used by the optimizer.
MTI Last Used for Stats	The timestamp representing the last time this specific Maintained Temporary Index (MTI) was used as a source of statistics by the optimizer to improve the performance of a query. The MTI Last Used field can be blank.
Dependent Advice Count	<p>Dependent implies that this advised index is dependent on the creation of other dependent advised indexes and all of the other dependent indexes must be created in order for the index implementation to be costed and utilized.</p> <ul style="list-style-type: none"> • Zero - this advised index stands on its own. • Greater than Zero – Compare this column against the TIMES_ADVISED column to understand how often this advised index has been advised in conjunction with other indexes.

Querying database monitor view 3020 - Index advised

The index advisor information can be found in the Database Monitor view 3020 - Index advised (SQE).

The advisor information is stored in columns QQIDXA, QQIDXK, and QQIDXD. When the QQIDXA column contains a value of 'Y' the optimizer is advising you to create an index using the key columns shown in column QQIDXD. The intention of creating this index is to improve the performance of the query.

In the list of key columns contained in column QQIDXD, the optimizer has listed what it considers the suggested primary and secondary key columns. Primary key columns are columns that can significantly

reduce the number of keys selected based on the corresponding query selection. Secondary key columns are columns that might or might not significantly reduce the number of keys selected.

Column QQIDXK contains the number of suggested primary key columns that are listed in column QQIDXJ. These primary key columns are the left-most suggested key columns. The remaining key columns are considered secondary key columns and are listed in order of expected selectivity based on the query. For example, assuming QQIDXK contains the value of four and QQIDXJ specifies seven key columns, then the first four key columns are the primary key columns. The remaining three key columns are the suggested secondary key columns.

Condensing index advice

Many times, the index advisor advises several different indexes for the same table. You can condense these advised indexes into the best matches for your queries.

1. In the **System i Navigator** window, expand the system you want to use.
2. Expand **Databases**.
3. Right-click the database that you want to work with and select **Index Advisor > Condense Advised Indexes**.

Depending on if you are viewing the condensed index advice at the database level or the schema level your list could be large. Once you have the list displayed, follow these steps to subset your list:

1. Go to the **View** menu option, and select **Customize this view > Include ...**
2. Enter the information you would like to filter the list by.
3. Select **OK** to get the refreshed list of condensed index advice.

Table for Which Index was Advised	Schema	System Schema	System Name	Partition	Keys Advised	Advised Index Type	Last Advised for Query Use	Times Advised for Query Use	Estimated Index Creation	Logical Page Size Advised	Most Expensive Query Estimate	Average of Query Estimates	Rows in Table when Advised	NLS Table Advised	MTI Used	MTI Creat	MTI Last Used

Viewing your queries with Visual Explain

You can use the **Visual Explain** tool with System i Navigator to create a query graph that graphically displays the implementation of an SQL statement. You can use this tool to see information about both static and dynamic SQL statements. Visual Explain supports the following types of SQL statements: SELECT, INSERT, UPDATE, and DELETE.

Queries are displayed using a graph with a series of icons that represent different operations that occur during implementation. This graph is displayed in the main window. In the lower portion of the pane, the SQL statement that the graph is based on is displayed. If Visual Explain is started from Run SQL Scripts, you can view the debug messages issued by the optimizer by clicking the **Optimizer messages** tab. The query attributes are displayed in the right pane.

Visual Explain can be used to graphically display the implementations of queries stored in the detailed SQL performance monitor. However, it does not work with tables resulting from the memory-resident monitor.

Starting Visual Explain

There are two ways to invoke the Visual Explain tool. The first, and most common, is through System i Navigator. The second is through the Visual Explain (QQQVEXPL) API.

You can start Visual Explain from any of the following windows in System i Navigator:

- Enter an SQL statement in the **Run SQL Scripts** window. Select the statement and choose **Explain** or **Run and Explain** from the **Visual Explain** menu.

- Expand the list of available SQL Performance Monitors. Right-click a detailed SQL Performance Monitor and choose the **Show Statements** option. Select filtering information and select the statement in the List of Statements window. Right-click and select **Visual Explain**. You can also start an SQL Performance Monitor from Run SQL Scripts. Select **Start SQL Performance monitor** from the **Monitor** menu.
- Start the SQL Details for Jobs function by right-clicking **Databases** and select **SQL Details for Jobs**. Click **Apply**. Select a job from the list and right-click and select **Show Details**. When the SQL is displayed in the lower pane, you can start Visual Explain by right-clicking on **Statement** and selecting **Visual Explain**.
- Right-click SQL Plan Cache and select **Show Statements**. Select filtering information and select the statement in the List of Statements window. Right-click and select **Visual Explain**.
- Expand the list of available SQL Plan Cache Snapshots. Right-click a snapshot and select **Show Statements**. Select filtering information and select the statement in the List of Statements window. Right-click and select **Visual Explain**.
- Expand the list of SQL Plan Cache Event Monitors. Right-click an event monitor and select **Show Statements**. Select filtering information and select the statement in the List of Statements window. Right-click and select **Visual Explain**.

You have three options when running Visual Explain from Run SQL Scripts.

Visual Explain only	This option allows you to explain the query without actually running it. The data displayed represents the estimate of the query optimizer. Note: Some queries might receive an error code 93 stating that they are too complex for displaying in Visual Explain. You can circumvent this error by selecting the "Run and Explain" option.
Run and Explain	If you select Run and Explain, the query is run by the system before the diagram is displayed. This option might take a significant amount of time, but the information displayed is more complete and accurate.
Explain while running	For long running queries, you can choose to start Visual Explain while the query is running. By refreshing the Visual Explain diagram, you can view the progress of the query.

In addition, a database monitor table that was not created as a result of using System i Navigator can be explained through System i Navigator. First you must import the database monitor table into System i Navigator. To import, right-click the SQL Performance Monitors and choose the **Import** option. Specify a name for the performance monitor (name it is known by within System i Navigator) and the qualified name of the database monitor table. Be sure to select Detailed as the type of monitor. Detailed represents the file-based (STRDBMON) monitor while Summary represents the memory-resident monitor (which is not supported by Visual Explain). Once the monitor has been imported, follow the steps to start Visual Explain from within System i Navigator.

You can save your Visual Explain information as an SQL Performance monitor. This monitor can be useful if you started the query from Run SQL Scripts and want to save the information for later comparison. Select **Save as Performance monitor** from the **File** menu.

[Visual Explain \(QQQVEXPL\) API](#)

Overview of information available from Visual Explain

You can use Visual Explain to view many types of information.

The information includes:

- Information about each operation (icon) in the query graph
- Highlight expensive icons
- The statistics and index advisor

- The predicate implementation of the query
- Basic and detailed information in the graph

Information about each operation (icon) in the query graph

As stated before, the icons in the graph represent operations that occur during the implementation of the query. The order of operations is shown by the arrows connecting the icons. If parallelism was used to process an operation, the arrows are doubled. Occasionally, the optimizer "shares" hash tables with different operations in a query, causing the lines of the query to cross.

You can view information about an operation by selecting the icon. Information is displayed in the **Attributes** table in the right pane. To view information about the environment, click an icon and then select **Display query environment** from the **Action** menu. Finally, you can view more information about the icon by right-clicking the icon and selecting **Help**.

Highlight expensive icons

You can highlight problem areas (expensive icons) in your query using Visual Explain. Visual Explain offers you two types of expensive icons to highlight: by processing time or number of rows. You can highlight icons by selecting **Highlight expensive icons** from the **View** menu.

The statistics and index advisor

During the query implementation, the optimizer can determine if statistics need to be created or refreshed, or if an index might make the query run faster. You can view these recommendations using the Statistics and Index Advisor from Visual Explain. Start the advisor by selecting **Advisor** from the **Action** menu. Additionally, you can begin collecting statistics or create an index directly from the advisor.

The predicate implementation of the query

Visual explain allows you to view the implementation of query predicates. Predicate implementation is represented by a blue plus sign next to an icon. You can expand this view by right-clicking the icon and selecting **Expand**, or open it into another window. Click an icon to view attributes about the operation. To collapse the view, right-click anywhere in the window and select **Collapse**. This function is only available on V5R3 or later systems.

The optimizer can also use the Look Ahead Predicate Generation to minimize the random the I/O costs of a join. To highlight predicates that used this method, select **Highlight LPG** from the **View** menu.

Basic and full information in the graph

Visual Explain also presents information in two different views: basic and full. The basic view only shows those icons that are necessary to understand the implementation of the SQL statement. It excludes some preliminary, or intermediate operations that are not essential for understanding the main flow of query implementation. The full view might show more icons that further depict the flow of the execution tree. You can change the graph detail by select **Graph Detail** from the **Options** menu and selecting either **Basic** or **Full**. The default view is **Basic**. In order to see all the detail for a **Full** view, change the Graph Detail to **Full**, close out Visual Explain, and run the query again. The setting for Graph Detail persists.

For more information about Visual Explain and the different options that are available, see the Visual Explain online help.

Refresh the Visual Explain diagram

For long running queries, you can refresh the visual explain graph with runtime statistical information before the query is complete. Refresh also updates the appropriate information in the attributes section of the icon shown on the right of the screen. In order to use the **Refresh** option, you need to select **Explain while Running** from the Run SQL Scripts window.

To refresh the diagram, select **Refresh** from the **View** menu. Or click the **Refresh** button in the toolbar.

Related reference

Index advisor

The query optimizer analyzes the row selection in the query and determines, based on default values, if creation of a permanent index improves performance. If the optimizer determines that a permanent index might be beneficial, it returns the key columns necessary to create the suggested index.

Adaptive Query Processing in Visual Explain

You can use Visual Explain to request a new plan.

There might be times when you are asked to performance tune a query while the query is still running. For instance, a query might be taking a long time to finish. After viewing the plan in Visual Explain, you decide to create the recommended index to improve the speed of the query. So you create the index and then want to signal the database optimizer to consider a new plan based on the new index.

Here are the steps to request the database engine to consider a new plan while running in Visual Explain:

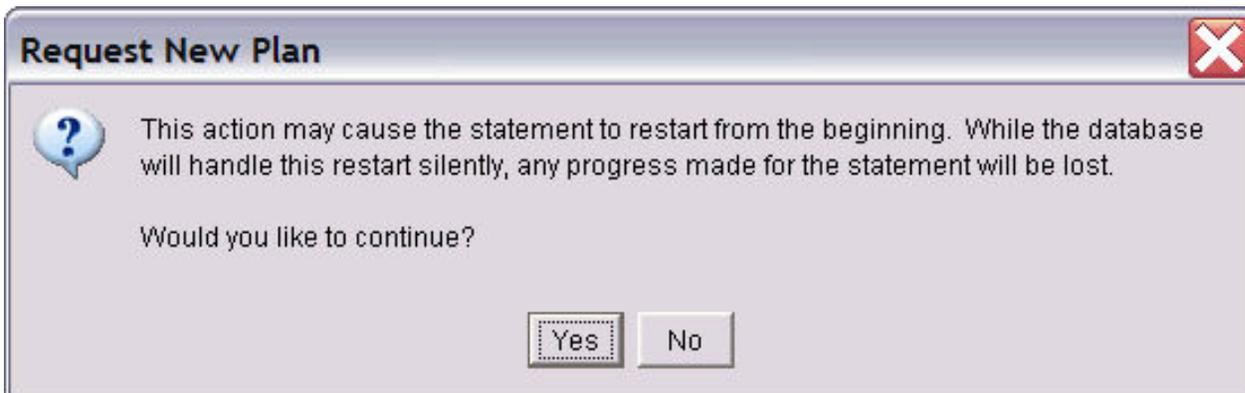

1. Open Run SQL Scripts.
2. Type in a query.
3. Go to the **Visual Explain** menu and select **Explain While Running**.
4. The Visual Explain window is displayed.
5. Next, go to the **Actions** menu and select **Request New Plan**.

The screenshot shows the Visual Explain window for a query on Server1. The query text is: `select * from qsys2.syscolumns where dbname = 'QSYS2'`. The query plan diagram shows a sequence of operations: **Complicated** (1 row) feeds into **Logic** (<1 row), which feeds into **Union all** (2 rows). **Union all** feeds into **Fetch N Rows** (1 row), which feeds into **Nested Loop Join** (2,335 rows). This **Nested Loop Join** feeds into another **Nested Loop Join** (2,335 rows). This second **Nested Loop Join** feeds into **Table Probe** (2,088 rows), which feeds into **Table Probe** (2,635 rows). The **Table Probe** (2,635 rows) feeds into **Index Probe** (2,635 rows). A red box highlights a message box that says: "Request that the database engine consider a new plan for this statement". The right-hand pane shows performance statistics:

Attribute	Value
Time Information	
Timestamp for Creation of Monit...	2009
Statement Start Timestamp	2009
Statement End Timestamp	2009
Total Estimated Run Time (ms)	186.
Actual Runtime Information	
Optimization Time (ms)	88
Run Time (ms)	105
Statement Open Time (ms)	Not.
Statement Fetch Time (ms)	105
Statement Close Time (ms)	Not.
Rows Fetched	51
Total Times Query Was Run	2
Total Time For All Runs (ms)	211
Synchronous Database Reads	4
Asynchronous Database Reads	17
Page Faults	41
Information about SQL stateme...	
Statement Number	34,2
Statement Function	Sele

A message box appears.

Select **Yes** to restart the query.

The database optimizer considers any changes to the query environment, and determines whether it is appropriate to generate a new plan. It might be possible that the database optimizer decides it is better to continue using the existing plan.

Note: This capability could also be available when selecting Visual Explain of a statement in the SQL Details for a Job window, or the SQL Plan Cache Show Statements window.

[Adaptive Query Processing](#)

Adaptive Query Processing analyzes actual query run time statistics and uses that information for subsequent optimizations.

Optimizing performance using the Plan Cache

The SQL Plan Cache contains a wealth of information about the SQE queries being run through the database. Its contents are viewable through the System i Navigator GUI interface. Certain portions of the plan cache can also be modified.

In addition, procedures are provided to allow users to programmatically work with the plan cache. These procedures can be invoked using the SQL CALL statement.

The Plan Cache interface provides a window into the database query operations on the system. The interface to the Plan Cache resides under the **System i Navigator > system name > Database**.

Within the SQL Plan Cache folder are two folders, SQL Plan Cache Snapshots and SQL Plan Cache Event Monitors.

Clicking the SQL Plan Cache Snapshots folder shows a list of any snapshots gathered so far. A snapshot is a database monitor file generated from the plan cache at the time a 'New Snapshot' is requested. It can be treated much the same as the SQL Performance Monitors list. The same analysis capability exists for snapshots as exists for traditional SQL performance monitors.

Clicking the SQL Plan Cache Event Monitors shows a list of any events that have been defined. Plan Cache event monitors, when defined, generate database monitor information from plans as they are being removed from the cache. The list includes currently active events as well as ones that have completed. Like a snapshot, the event monitor is a database monitor file. Consequently, the same analysis capability available to SQL performance monitors and snapshots can be used on the event file.

The plan cache is an actively changing cache. Therefore, it is important to realize that it contains timely information. If information over long periods of time is of interest, an event monitor could be defined to ensure that information is captured on any plans that are removed from the cache over time. Alternatively, you could consider implementing a method of performing periodic snapshots of the plan cache to capture trends and heavy usage periods. See the discussion on IBM supplied, callable SQL procedures later in this section on plan cache.

Related concepts

[Plan cache](#)

The plan cache is a repository that contains the access plans for queries that were optimized by SQE.

SQL Plan Cache - Show Statements

By right-clicking the SQL Plan Cache icon, a series of options are shown which allow different views of current plan cache of the database. The **SQL Plan Cache > Show Statements** option opens a screen with filtering capability. This screen provides a direct view of the current plan cache on the system.

Filters to apply:

- Minimum runtime for the longest execution of the statement: Seconds
- Statements that ran on or after this date and time:
- Top 'n' most frequently run statements:
- Top 'n' statements with the largest total accumulated runtime:
- Statements the following user has ever run:
- Statements that are currently active
- Statements for which an index has been advised
- Statements for which statistics have been advised
- Include statements initiated by the operating system
- Statements that reference the following objects:

Schema	Name
- Statements that contain the following text:

Statements:

Last Time Run	Most Expensive Time (sec)	T
8/27/09 10:12:55 PM	1372.3884	
8/27/09 3:09:42 PM	531.2134	
8/25/09 4:05:10 PM	324.2397	
8/26/09 6:05:33 PM	387.3384	
8/27/09 10:12:55 PM	87.8831	
8/27/09 3:17:07 PM	235.4072	
8/27/09 2:03:42 PM	98.5024	
8/27/09 2:09:28 PM	159.4982	
8/25/09 5:03:47 PM	119.6275	
8/25/09 5:03:47 PM	58.1911

8/27/09 2:24:32 PM	7.9627	
8/27/09 4:22:10 AM	2.7389	
8/26/09 4:13:25 PM	4.7626	
8/25/09 1:01:43 AM	0.6606	
8/25/09 12:47:53 AM	1.0081	
8/25/09 7:16:18 PM	7.4941	
8/27/09 3:01:23 AM	1.0579	
8/27/09 3:01:00 AM	0.8244	

Status: Complete

Buttons: Reset All Filters, Apply, Columns..., Refresh, Close, Help, ?

Press the **Apply** or **Refresh** button to display the current Plan Cache statements. The information shown includes the SQL query text, last time the query ran, most expensive single instance run, total processing time consumed, total number of times run, and information about the user and job that first created the plan entry.

The information also includes several per run averages, including average runtime, average result set size and average temporary storage usage. There is an adjusted average processing time which is the average discounting any anomalous runs.

The display also shows how many times, if any, that the database engine reused the results of a prior run, avoiding rerunning the entire statement. There is also a Save Results button (not shown) that allows you to save the statement list, for example, to a .csv file or spreadsheet.

Finally, the numeric identifier and plan score are also displayed. For more detail on the columns displayed, see [“SQL Plan Cache column descriptions” on page 175](#)

Statement Options

By highlighting one or more plans and right clicking, a menu with several possible actions appears.

Visual Explain Shows a visual depiction of the access plan and provides more detailed performance analysis. Note only one statement can be highlighted when performing this action.

Show Longest Runs Shows details of up to 10 of the longest running instances of that statement. Within the Longest Runs list, you can right click a statement and select **Visual Explain, Work With SQL Statement, Work With SQL Statement and Variables, Save to New...** snapshot or **Remove**. Snapshots are useful for capturing the information for that specific run in Visual Explain. Removing old or superfluous runs makes room to capture future runs. Only one statement can be highlighted when performing these actions. Any runs removed only affect which runs are shown in the list. The total time, total number of runs, and other information for the statement are still calculated including the runs removed from the list.

Show Active Jobs Displays a list of jobs on the system that are currently using that statement or statements.

Show User History Shows a list of all user IDs that have run that statement along with the last time they ran it.

Work with SQL Statement Displays a scripting window containing the SQL statement. The scripting window is useful for working with and tuning the statement directly, or for just viewing the statement in its own window. Only one statement can be highlighted when performing this action.

Work with SQL Statements and Variables Displays a scripting window containing the SQL Statement and any parameter markers entered with their specific values for that run of the SQL statement.

Save to New... Allows you to create a snapshot of the selected statements.

Plan Right-click to show options for modifying the plan:

Change Plan Score allows you to set the score to a specific value. The plan score is used to determine when a plan might be removed from the cache. A lower score plan is removed before a higher score plan. By setting the plan score high, the plan remains in the cache for a longer time. Setting the plan score to a low value causes the plan to be pruned sooner than might otherwise have occurred.

Delete allows you to remove the plan immediately from the cache. Note under normal circumstances there might not be a need to modify the attributes of a plan. Normal database processing ages and prunes plans appropriately. These modifying options are provided mostly as tools for minute analysis and for general interest.

The User and Job Name for each statement on the Statements screen is the user and job that created the initial plan with full optimization. This user is not necessarily the same as the last user to run that statement. The Longest Runs screen, however, does show the particular user and job for that individual run.

Filtering Options

The screen provides filtering options which allow the user to more quickly isolate specific criteria of interest. No filters are required to be specified (the default), though adding filtering shortens the time it takes to show the results. The list of statements that is returned is ordered so that the statement consuming the most total processing time is shown at the top. You can reorder the results by clicking the column heading for which you want the list ordered. Repeated clicking toggles the order from ascending to descending.

The filtering options provide a way to focus in on a particular area of interest:

Minimum runtime for the longest execution of the statement:	Show statements with at least one long individual statement instance runtime.
Statements that ran on or after this date and time:	Show statements that have been run recently.
Top 'n' most frequently run statements:	Show statements run most often.
Top 'n' statements with the largest total accumulated runtime:	Show the top resource consumers. Shows the first 'n' top statements by default when no filtering is given. Specifying a value for 'n' improves the performance of getting the first screen of statements, though the total statements displayed is limited to 'n'.
Statements the following user has ever run:	Show statements a particular user has run. The user and job name shown reflect the originator of the cached statement. This user is not necessarily the same as the user specified on the filter (there could be multiple users running the statement).
Statements that are currently active	Show statements that are still running or are in pseudo-close mode. The user and job name shown reflect the originator of the cached statement. This user is not necessarily the same as the user specified on the filter (there could be multiple users running the statement). Note: An alternative for viewing the active statement for a job is to right-click the Database icon and select SQL Details for Jobs...
Statements for which an index has been advised	Show only those statements where the optimizer advised an index to improve performance.
Statements for which statistics have been advised	Show only those statements where a statistic not yet collected might have been useful to the optimizer. The optimizer automatically collects these statistics in the background. This option is normally not that interesting unless, for whatever reason, you want to control the statistics collection yourself.
Include statements initiated by the operating system	Show the 'hidden' statements initiated by the database to process a request. By default the list only includes user-initiated statements.
Statements that reference the following objects:	Show statements that reference the tables or indexes specified.
Statements that contain the following text:	Show statements that include the text specified. This option is useful for finding particular types of statements. For example, statements with a FETCH FIRST clause can be found by specifying 'fetch'. The search is not case sensitive for ease of use. For example, the string 'FETCH' finds the same statements as the search string 'fetch'. This option provides a wildcard search capability on the SQL text itself.

Multiple filter options can be specified. The candidate statements for each filter are computed independently. Only those statements that are present in all the candidate lists are shown. For example,

you could specify options **Top 'n' most frequently run statements** and **Statements the following user has ever run**. The display shows those most frequently run statements in the cache that have been run by the specified user. It does not show the most frequently run statements by the user (unless those statements are also the most frequently run statements in the entire cache).

SQL Plan Cache column descriptions

Displays the columns that are used in the SQL Plan Cache Statements window.

<i>Table 48. Columns used in SQL Plan Cache Statements window</i>	
Column name	Description
Last Time Run	Displays the last time that this statement was run.
Most Expensive Time (sec)	The time taken for the longest run of this statement.
Total Processing Time (sec)	The sum total time that all runs of this statement took to process in seconds.
Total Times Run	The total number of times that this statement ran.
Average Processing Time (sec)	The average time per run that this statement took to process in seconds.
Statement	The statement text.
Plan Creation User Name	The name of the user id that created the plan.
Job Name	The name of the job that created the plan.
Job User	The name of the user id that owned the job that created the plan.
Job Number	The job number of the job that created the plan.
Adjusted Average Processing Time (sec)	The average time per run that this statement took to process in seconds where anomalous runs are removed from the average calculation. This time provides a realistic average for a statement by ignoring a single (or few) run that was atypical to the normal condition of the statement.
Average Result Set Rows	The average number of result set rows that are returned when this statement is run.
Average Temp Storage Used (MB)	The average amount of temporary storage used when this statement is run.
Plan Score	The rating of this plan relative to other plans in the cache. A plan with a higher rating relative to other plans remains in the cache for a longer time. A plan with a lower rating relative to other plans is removed from the cache sooner than the other plans.
Plan Identifier	A unique numeric identifier of the plan.
Total Cached Results Used	The number of times a result set from a prior run of the statement was reused on a subsequent run of the statement.
Optimization Time (sec)	The amount of time that it took to optimize this statement.
System Name	The system name.
Relational Database name	Relational database name

SQL plan cache properties

The Plan Cache tab of the SQL Performance Center in IBM i Access Client Solutions (ACS) shows high-level information about the SQL plan cache and overall query activity. This information includes cache size, number of plans, number of full opens and pseudo-opens that have occurred.

This information can be used to view overall database activity. If tracked over time, it provides trends to help you better understand the database utilization peaks and valleys throughout the day and week.

Several Plan Cache Properties can be changed by right-clicking a property and selecting Edit Value.

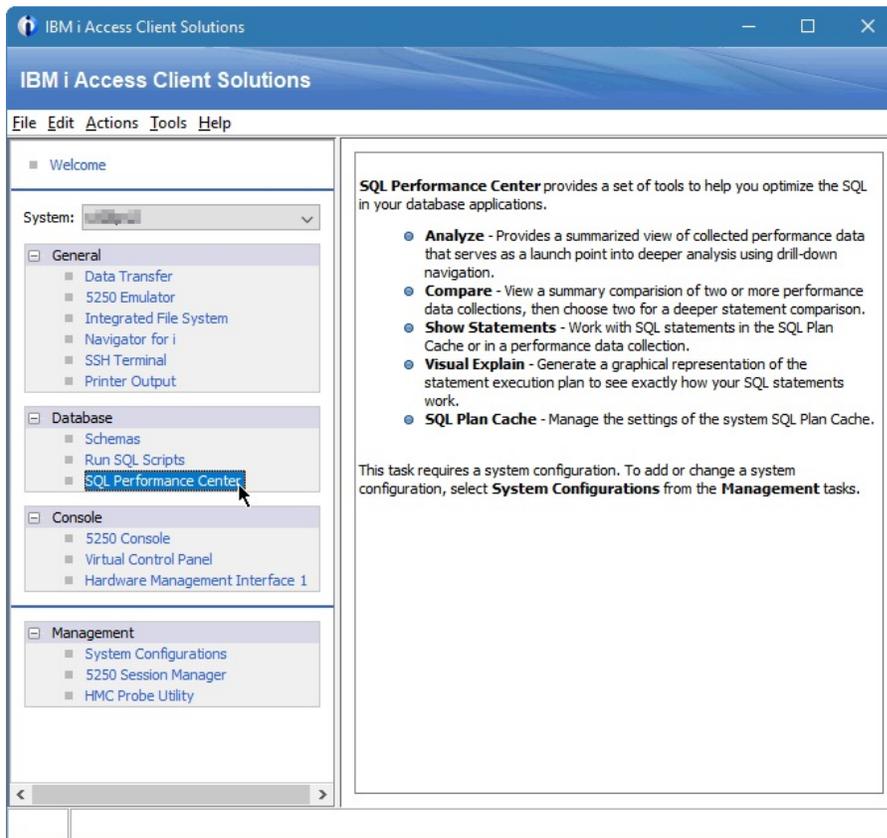

The following terms are used in regards to plan cache properties:

- Active Queries – queries that are currently open or in pseudo close mode.
- Full Open – describes a query run that requires a cursor to be built before the query executes and return rows. A query that reuses a cursor is called a Pseudo Open.
- Unique Queries – unique SQL query statements. For the plan cache, this is uniqueness once tables are resolved to their schemas.
- Hit Ratio – the percentage of time that the query optimizer, when searching the plan cache for a plan, finds an existing plan for the query.
- Target Hit Ratio – the hit ratio percentage that the database tries to achieve by adjusting the plan cache's size. A larger size means plans stay in the cache longer and are therefore more likely to be found and used for future runs of the query.
- Job Scoped – queries that reference tables or indexes that reside in the job's QTEMP library. This includes, for example, global temporary tables. By definition these job scoped plans and runtime objects cannot be reused across jobs.
- Temporary Runtime Objects – the actual runtime executable objects used to process a query. These include the execution tree (ROQ), hash tables, sorted lists, lists, and buffers. A certain number of these objects are cached with the query plan in the cache so they can be reused.
- Longest Runs - information kept about the longest running instances of a query.
- Activity Thresholds – highest or largest values that are tracked by the database.
- ...Since Start – the amount of activity since the cache was created (IPL).

Plan Cache Properties are divided into three main types:

- Summary and Usage – Information about plan usage, query usage and current conditions for the plan cache and queries.
- Configuration – properties that can be adjusted by the user.
- Activity Threshold – tracked 'high water mark' of several key indicators.

To view the Plan Cache properties, select the SQL Performance Center from the main ACS window or from the Tools menu of any ACS window.

The first tab in the SQL Performance Center window that appears will display all of the Plan Cache properties. Changes to configurable properties may be made by clicking the **Change Configuration...** button.

Description	Value	Value Unit
Plan Usage Summary		
Current Number of Plans in Cache	111372	
Total Number of Plans Built Since Start	1404089	
Total Number of SMP Plans Built Since Start	56242

Number of Plans Rebuilt due to AQP	793	
Number of Query Mapping Errors Since Start	12498	

Done: 53 rows retrieved.

Table 49. Plan Cache Properties

Plan Cache Property	Description
Time Of Summary	Timestamp of when the properties were collected.
Plan Cache Creation Time	Timestamp of when the plan cache was created (IPL)
Active Query Summary	
Number of Currently Active Queries	Number of queries that are currently open or in pseudo close mode.
Number of Queries Run Since Start	Shows the total number of SQL queries run since IPL Note: This value includes job scoped queries.
Number of Query Full Opens Since Start	Number of queries run since IPL that required a cursor to be built before the query executed and returned rows.

Table 49. Plan Cache Properties (continued)

Plan Cache Property	Description
Plan Usage Summary	
Current Number of Plans in Cache	Current total number of plans in the plan cache
Total Number of Plans Built Since Start	Number of plans built since IPL. This includes the plans that have been pruned from the plan cache.
Total Number of SMP Plans Built Since Start	The number of plans built since IPL that run with SMP parallel processing.
Total Number of Unique Queries Since Start	This value reflects the total number of unique statements (SQL queries) run since IPL Note: This value includes unique job scoped queries
Current Plan Cache Size	Current size in MB of the plan cache. This does not include the size of cached temporary runtime objects.
Current Plan Cache Size Threshold	<p>The current maximum allowed size of the plan cache.</p> <p>This property is configurable.</p> <ul style="list-style-type: none"> • *AUTO indicates that the database manager will manage the maximum size of the plan cache. • A user specified value between 50 and 51200. Size is specified in MB.
Maximum Plan Cache Size For AutoSizing	<p>If AutoSizing is active, the maximum plan cache size.</p> <p>This property is configurable if the Current Plan Cache Size Threshold is *AUTO.</p> <ul style="list-style-type: none"> • *DEFAULT(nn) - The database manager determines, at IPL, the maximum size that the plan cache can grow to under autosizing. Only applicable if Size Threshold is set to *AUTO. The database determined size is shown in parentheses. • nn – A user specified size between 50 and 51200. Size is specified in MB. While supported, it should rarely be changed from *DEFAULT. • *DISABLED - Indicates that plan cache auto sizing has been disabled.
Current Plan Cache Hit Ratio	<p>The percentage of time the query optimizer found a matching plan in the plan cache.</p> <p>This value indicates the efficiency of the plan cache. The higher the percentage the better.</p>

Table 49. Plan Cache Properties (continued)

Plan Cache Property	Description
Target Plan Cache AutoSize Hit Ratio	<p>This is the target hit ratio percentage that the database manager tries to meet by adjusting the plan cache size.</p> <p>This property is configurable if the Current Plan Cache Size Threshold is *AUTO.</p> <ul style="list-style-type: none"> • DEFAULT(nn) – The database manager sets the target hit ratio. The database determined ratio is shown in parentheses. • nn – percentage from 1 to 99. While supported, it should rarely be changed from *DEFAULT. • *DISABLED - Indicates that plan cache auto sizing has been disabled.
Total Number of Plan Cache Autosizing Adjustments	If autosizing is active, the number of times the plan cache autosized. This includes both plan cache increase and decrease.
Last Plan Cache AutoSizing Adjustment	If autosizing is active, the timestamp when the plan cache was last autosized.
Last Autosizing Limited Due to Temporary Storage	If autosizing is active, the timestamp of when the plan cache last attempted to increase the size of the plan cache but was unable to do so because the temporary storage used on the system exceeded limits.
Current Number of Job Scoped (QTEMP) Plans	Current number of plans in the plan cache that for queries that reference tables or indexes that reside in the job's QTEMP library. This includes, for example, global temporary tables. By definition these job scoped plans and runtime objects cannot be reused across jobs.
Total Number of Job Scoped (QTEMP) Plans Built Since Start	Total number of plans built for queries that reference tables or indexes that reside in the job's QTEMP library.
Total Number of Unique Queries With Job Scoped (QTEMP) References Since Start	This value reflects the total number of unique statements (SQL queries) referencing temporary files that have been run since IPL.
Total Times Plans Used from Cache	Total number of plans that were reused from the plan cache. (i.e. Plans that did not require a reoptimization).

Table 49. Plan Cache Properties (continued)

Plan Cache Property	Description
Total Plans Removed	<p>Number of plans removed from the plan cache during optimization. Reasons that a plan may be removed during optimization include the following, but not limited to:</p> <ul style="list-style-type: none"> • plan no longer valid due to table and index changes • plan out of date due to changes in the number of rows in the table • more than 3 plans for the query exist in the plan cache • internal changes due to PTF applies or other system level changes
Total Plans Pruned	Total number of plans the plan cache pruner task removed.
Number of Times Plan Cache Pruned	Number of times that the plan cache pruner task ran and removed plans from the plan cache.
Time Plan Cache was Last Pruned	The timestamp of when the plan cache pruner task last ran.
Current Number of Temporary Runtime Objects Stored in Cache	Current Number of Temporary Runtime Objects Stored in Cache
Current Total Size of Temporary Runtime Objects stored in Cache	Current Total Size of Temporary Runtime Objects stored in Cache
Maximum Number of Temporary Runtime Objects Stored Per Plan	<p>Maximum number of Temporary Runtime Objects stored per plan.</p> <p>This property is configurable.</p> <ul style="list-style-type: none"> • *DEFAULT(nn) - database determines the maximum number of runtime objects (ROQs) to keep per plan. The database determined number is shown in parentheses. • nn – A user specified value between 1 and 50 that is the maximum number of runtime objects to keep per plan. A runtime ‘object’ is all the runtime constructs (except the cursor) used to execute the query. It includes the ROQ, hash tables, sorts, etc... The database will automatically clear big hash tables and sorts of data contents (leaving only their shell) before storing them with the plan. However, smaller hashes and sorts will retain their contents. Setting this value smaller will lessen the temporary storage usage on the machine. Setting this value higher can improve performance by having more runtime objects ready to go during full opens rather than having to build them.
Total Number of Temporary Indexes Created	Total number of SQE created temporary indexes (MTIs) since IPL.

Table 49. Plan Cache Properties (continued)

Plan Cache Property	Description
Current Number of Temporary Indexes	Current number of SQE created temporary indexes (MTIs) on the system.
Current Total Size of Temporary Indexes	The total size of all SQE created temporary indexes (MTIs) currently on the system.
Number of Plans Rebuilt due to AQP	Number of plans rebuilt to AQP.
Number of Query Mapping Errors Since Start	This is the number of SQE query mapping errors that have occurred since the last IPL. While a number of mapping errors greater than 0 does not indicate a problem, a significant number of mapping errors can negatively affect performance and may require further investigation.
Maximum Number of Longest Runs Allowed Per Plan	<p>The Maximum Number of Longest Runs Allowed Per Plan determines how many longest runs are maintained per plan.</p> <p>This property is configurable.</p> <ul style="list-style-type: none"> • *DEFAULT(nn) - The database manager determines the maximum number of longest run entries to keep per plan. The database determined number is shown in parentheses. • nn – A user specified value between 1 and 50 indicating the maximum number of longest runs information to keep per plan <p>Note: These can be seen by bringing up a show statements of the live cache, right clicking, and selecting Longest Runs</p>
<p>Plan Cache Activity Thresholds</p> <p>The Activity Thresholds group of properties track the upper thresholds of activity for both plans and query activity. The values represent the maximum values achieved since the Threshold Start Time. Each threshold shows both the maximum value and the timestamp of when that maximum was reached.</p>	
Activity Thresholds Start Time	<p>The time from which the tracking started. This value can be reset (to zero) to reset all the thresholds and restart tracking.</p> <p>Note: All thresholds are reset at one time, thresholds cannot be reset individually. Start Time restarts each IPL.</p>
Highest Number of Active Queries at One Time	The highest number of open plus pseudo closed cursors (queries) at a given point in time
Highest Number of Plans in Cache	The largest number of plans in the plan cache at a given point in time

Table 49. Plan Cache Properties (continued)

Plan Cache Property	Description
Highest Number of Temporary Runtime Objects Stored in Cache	The highest number of inactive runtime executable objects stored (cached) away (for future reuse) in the plan cache at a given point in time
Largest Total Size of Temporary Runtime Objects Stored in Cache	The largest amount of temporary storage, in MB, consumed by the inactive runtime executable objects stored (cached) away in the plan cache at a given point in time
Query Supervisor	
The Query Supervisor group of properties provide historical information about the interaction of the Query Supervisor with queries running on the system.	
Number of thresholds reached	The number of Query Supervisor thresholds that have been reached since IPL.
Most recent job to reach a threshold	The name and timestamp of the most recent job to reach a Query Supervisor threshold.
Number of queries terminated	The number of queries that have been terminated since IPL at the request of a Query Supervisor exit program.
Most recent job to have a query terminated	The name and timestamp of the most recent job to have a query terminated at the request of a Query Supervisor exit program.
Most recent exit point program failure	The name and timestamp of the most recent job to encounter an error when using a Query Supervisor exit program.

Creating SQL plan cache snapshots

The **New > Snapshot** option allows for the creation of a snapshot from the plan cache.

Unlike the snapshot option under Show Statements, it allows you to create a snapshot without having to first view the queries.

New SQL Plan Cache Snapshot - Serv...

Name:

Schema:

Include all plan cache entries

Include plan cache entries that meet the following criteria

Filters to apply:

Minimum runtime for the longest execution of the statement:
 Seconds

Statements that ran on or after this date and time:

Top 'n' most frequently run statements:

Top 'n' statements with the largest total accumulated runtime:

Statements the following user has ever run:

Statements that are currently active

Statements for which an index has been advised

Statements for which statistics have been advised

Include statements initiated by the operating system

Statements that reference the following objects:

Schema	Name	
	Schema	

Statements that contain the following text:

The same filtering options are provided here as on the Show Statements screen.

The stored procedure, `qsys2.dump_plan_cache`, provides the simplest, programmatic way to create a database monitor file output (snapshot) from the plan cache. The `dump_plan_cache` procedure takes two parameters, library name and file name, for identifying the resulting database monitor file. If the file does

not exist, it is created. For example, to dump the plan cache to a database performance monitor file in library QGPL:

```
CALL qsys2.dump_plan_cache('QGPL', 'SNAPSHOT1');
```

SQL plan cache event monitor

The SQL plan cache event monitor records changes in your plan cache.

You can access the SQL plan cache event monitor through the System i Navigator interface or by calling the procedures directly.

The SQL plan cache event monitor captures monitor records of plans as they are removed from the plan cache. The event monitor is useful for ensuring that all performance information potentially available in the cache is captured even if plans are removed from the cache. Combining the event monitor output with a plan cache snapshot provides a composite view of the cache from when the event monitor was started until the snapshot is taken.

The event monitor allows the same filtering options as described for **Show statements** and **NewSnapshot**. The exceptions are that the *Top 'n' most frequently run statements* and the *Top 'n' statements with largest total accumulated runtime* are not shown. Once a statement is removed from the cache, it is no longer compared to other plans. Therefore, these two 'Top n' filters do not make sense for pruned plans.

Accessing the SQL plan cache with SQL stored procedures

The System i Navigator provides a visual interface into the plan cache. However, the plan cache is also accessible through stored procedures which can be called using the SQL CALL statement.

See [“Plan Cache Services” on page 356](#) for the descriptions of these procedures.

CLEAR_PLAN_CACHE

The **CLEAR_PLAN_CACHE** procedure is a plan cache clearing alternative to performing a system IPL.

CLEAR_PLAN_CACHE procedure

```
>>-CLEAR_PLAN_CACHE -- ()-----<<
```

The schema is QSYS2.

This procedure is used primarily in performance test and QA environments. It provides database performance analysts with a way to create a consistent environment from which to evaluate potential database performance changes. The procedure will clear all plans in the system SQL Plan Cache that exist at the time the procedure is run. Besides clearing the plan information, any Maintained Temporary Indexes (MTIs) not currently in use by a query will be deleted as part of the clear. SQL queries run while the **CLEAR_PLAN_CACHE** procedure is running may have their plans removed, but the queries themselves will not incur a failure related to plan removal. Any SQL queries run after the clear is complete will begin to repopulate the plan cache.

The time the **CLEAR_PLAN_CACHE** procedure takes to run will vary depending on the plan cache size. To avoid tying up an interactive job, it is recommended to submit the procedure in a background job using a combination of the Submit Job (**SBMJOB**) and Run SQL (**RUNSQL**) CL commands.

Authorization: The **CLEAR_PLAN_CACHE** procedure requires that the authorization ID associated with the statement has *JOBCTL special authority or QIBM_DB_SQLADM function usage.

Errors: The procedure will fail with SQL0443 and SQL0552 if the caller does not have the required authority.

Example:

Verifying the performance of SQL applications

You can verify the performance of an SQL application by using commands.

The commands that can help you verify performance:

- | | |
|--|--|
| Display Job (DSPJOB) | <p>You can use the Display Job (DSPJOB) command with the OPTION(*OPNF) parameter to show the indexes and tables used by an application running in a job.</p> <p>You can also use DSPJOB with the OPTION(*JOBLOCK) parameter to analyze object and row lock contention. It displays the objects and rows that are locked and the name of the job holding the lock.</p> <p>Specify the OPTION(*CMTCTL) parameter on the DSPJOB command to show the isolation level, the number of rows locked during a transaction, and the pending DDL functions. The isolation level displayed is the default isolation level. The actual isolation level, used for any SQL program, is specified on the COMMIT parameter of the CRTSQLxxx command.</p> |
| Print SQL Information (PRTSQLINF) | <p>The Print SQL Information (PRTSQLINF) command lets you print information about the embedded SQL statements in a program, SQL package, or service program. The information includes the SQL statements, access plans used, and the command parameters used to precompile the source member.</p> |
| Start Database Monitor (STRDBMON) | <p>You can use the Start Database Monitor (STRDBMON) command to capture to a file information about every SQL statement that runs.</p> |
| Change Query Attribute (CHGQRYA) | <p>You can use the Change Query Attribute (CHGQRYA) command to change the query attributes for the query optimizer. Among the attributes that can be changed by this command are the predictive query governor, parallelism, and the query options.</p> |
| Start Debug (STRDBG) | <p>You can use the Start Debug (STRDBG) command to put a job into debug mode, and optionally add as many as 20 programs, 20 class files, and 20 service programs to debug mode. It also specifies certain attributes of the debugging session. For example, it can specify whether database files in production libraries can be updated while in debug mode.</p> |

Examining query optimizer debug messages in the job log

Query optimizer debug messages issue informational messages to the job log about the implementation of a query. These messages explain what happened during the query optimization process.

For example, you can learn:

- Why an index was or was not used
- Why a temporary result was required
- Whether joins and blocking are used
- What type of index was advised by the optimizer
- Status of the job queries

- Indexes used
- Status of the cursor

The optimizer automatically logs messages for all queries it optimizes, including SQL, call level interface, ODBC, OPNQRYF, and SQL Query Manager.

Viewing debug messages using STRDBG command:

STRDBG command puts a job into debug mode. It also specifies certain attributes of the debugging session. For example, it can specify whether database files in production schemas can be updated while in debug mode. For example, use the following command:

```
STRDBG PGM(Schema/program) UPDPROD(*YES)
```

STRDBG places in the job log information about all SQL statements that run.

Viewing debug messages using QAQQINI table:

You can also set the QRYOPLIB parameter on the **Change Query Attributes (CHGQRYA)** command to a user schema where the QAQQINI table exists. Set the parameter on the QAQQINI table to MESSAGES_DEBUG, and set the value to *YES. This option places query optimization information in the job log. Changes made to the QAQQINI table are effective immediately and affect all users and queries that use this table. Once you change the MESSAGES_DEBUG parameter, all queries that use this QAQQINI table write debug messages to their respective job logs. Pressing F10 from the command Entry panel displays the message text. To see the second-level text, press F1 (Help). The second-level text sometimes offers hints for improving query performance.

Viewing debug messages in Run SQL Scripts:

To view debug messages in Run SQL Scripts, from the **Options** menu, select **Include Debug Messages in Job Log**. Then from the **View** menu, select **Job Log**. To view detailed messages, double-click a message.

Viewing debug messages in Visual Explain:

In Visual Explain, debug messages are always available. You do not need to turn them on or off. Debug messages appear in the lower portion of the window. You can view detailed messages by double-clicking a message.

Print SQL Information

The **Print SQL Information (PRTSQLINF)** command returns information about the embedded SQL statements in a program, SQL package (used to store the access plan for a remote query), or service program. This information is then stored in a spooled file.

PRTSQLINF provides information about:

- The SQL statements being executed
- The type of access plan used during execution. How the query is implemented, indexes used, join order, whether a sort is used, whether a database scan is used, and whether an index is created.
- A list of the command parameters used to precompile the source member for the object.
- The CREATE PROCEDURE and CREATE FUNCTION statement text used to create external procedures or User Defined Functions.

This output is like the information that you can get from debug messages. However, while query debug messages work at runtime, **PRTSQLINF** works retroactively. You can also see this information in the second-level text of the query governor inquiry message CPA4259.

You can issue **PRTSQLINF** in a couple of ways. First, you can run the **PRTSQLINF** command against a saved access plan. You must execute or at least prepare the query (using the SQL PREPARE statement)

before you use the command. It is best to execute the query because the index created as a result of PREPARE is relatively sparse. It could well change after the first run. **PRTSQLINF**'s requirement of a saved access plan means that the command cannot be used with **OPNQRYF**.

You can also run **PRTSQLINF** against functions, stored procedures, triggers, SQL packages, and programs from System i Navigator. This function is called Explain SQL. To view **PRTSQLINF** information, right-click an object and select **Explain SQL**.

Query optimization tools: Comparison

Use this table to find the information each tool can provide, when it analyzes your queries, and the tasks it can do to improve your queries.

Table 50. Optimization tool comparison

PRTSQLINF	STRDBG or CHGQRYA	File-based monitor (STRDBMON)	Memory-Based Monitor	Visual Explain
Available without running query (after access plan has been created)	Only available when the query is run	Only available when the query is run	Only available when the query is run	Only available when the query is explained
Displayed for all queries in SQL program, whether executed or not	Displayed only for those queries which are executed	Displayed only for those queries which are executed	Displayed only for those queries which are executed	Displayed only for those queries that are explained
Information about host variable implementation	Limited information about the implementation of host variables	All information about host variables, implementation, and values	All information about host variables, implementation, and values	All information about host variables, implementation, and values
Available only to SQL users with programs, packages, or service programs	Available to all query users (OPNQRYF , SQL, QUERY/400)	Available to all query users (OPNQRYF , SQL, QUERY/400)	Available only to SQL interfaces	Available through System i Navigator Database and API interface
Messages are printed to spool file	Messages are displayed in job log	Performance rows are written to database table	Performance information is collected in memory and then written to database table	Information is displayed visually through System i Navigator
Easier to tie messages to query with subqueries or unions	Difficult to tie messages to query with subqueries or unions	Uniquely identifies every query, subquery, and materialized view	Repeated query requests are summarized	Easy to view implementation of the query and associated information

SQL Error Logging Facility (SELF)

The SQL Error Logging Facility (SELF) provides a mechanism that can be used to understand when SQL statements are encountering specific SQL errors or warnings. SELF is built into Db2 for i and can be enabled in specific jobs or system wide.

SELF differs from the Db2 for i SQL Performance Monitoring or Database Monitoring feature in some significant ways:

1. SELF is configured by the client to identify specific SQLCODE values that Db2 for i should use for SELF processing when a user-initiated SQL statement completes with a matching SQLCODE value.
2. SELF collects point-of-failure information which is accessible through the QSYS2.SQL_ERROR_LOG view.
3. SELF runs when an SQL statement completes with an SQLCODE value that matches a list of values in the SYSIBMADM.SELFCODES built-in global variable.
4. SELF is safe to use in production environments. It has no performance impact to SQL statements that complete successfully or for any SQL errors or warnings where the SQLCODE does not match the values listed in the SYSIBMADM.SELFCODES global variable.

By registering the SQLCODE values you are interested in monitoring at either a job or system level, each time one of the SQLCODE values is returned, an entry will be logged in the SELF table. For each SQLCODE, information such as the program name, call stack, and SQL statement text are recorded. This information is collected while the application is running. Logging only happens during SQL error processing, so it has no performance impact on SQL statements that complete successfully. Errors that are issued during a precompile of an embedded SQL program are not recorded. The QSYS2.SQL_ERROR_LOG view can be used to examine the information that has been collected. See [“SQL_ERROR_LOG view” on page 332](#) for the definition of the view.

Registering SQLCODEs with SELF

Users configure the SQLCODEs that should be processed by SELF through the SYSIBMADM.SELFCODES global variable. By default, this global variable is set to NULL for all jobs, which means that SELF is turned off and will not log anything. To enable SELF, the global variable needs to be set, providing one or more SQLCODE values. See [“SELFCODES global variable” on page 332](#) for more information.

The setting of the SELFCODES global variable applies to the SQL session where it is set. An SQL session is equivalent to an activation group. If SELFCODES has a default value, that value applies to all sessions in all user jobs. Changing the default value for the SELFCODES global variable does not affect active jobs. If, however, the user wants to enable SELF only in specific jobs, the SELFCODES global variable value can be changed in those jobs.

A string of SQLCODE values assigned to the SELFCODES global variable must conform to the following rules:

- An error SQLCODE must be preceded by a single minus sign ('-').
- A warning SQLCODE can be preceded by an optional plus sign ('+').
- Multiple SQLCODE values in the string can be separated by any number of blanks and commas between values.
- Up to 32 SQLCODE values can be provided in the string. If more than 32 are specified, only the first 32 are used by SELF. No error is issued.
- If a special value exists in the string, it must be the only entry in the string:
 - The special value of *ERROR specifies all SQLCODEs that are error conditions (negative values).
 - The special value of *WARN specifies all SQLCODEs that are warning conditions (positive values).
 - The special value of *ALL specifies all SQLCODEs that are error or warning conditions.
 - The special value of *NONE turns off SELF processing.
- A string containing the value 0 turns off SELF processing, even if other SQLCODE values are found in the SELFCODES string.
- A value of 100 or +100 is not allowed.
- There is no verification that a specified SQLCODE is used by Db2 for i.
- Any character other than a digit (0-9), minus, plus, blank, or comma is not valid and will remove all SQLCODEs from logging. Using the SYSIBMADM.VALIDATE_SELF scalar function to perform validation of a string to be used for SELFCODES is recommended. See [“VALIDATE_SELF scalar function” on page 335](#) for a description of this function.

Setting SELFCODES within a specific job

To enable SELF only within a specific job, the SELFCODES global variable must be changed within that job.

For example, to set the list of SQLCODEs within a job, use the SQL SET statement. This has no effect on other jobs. Invoke the VALIDATE_SELF function to verify the string is properly formed.

```
SET SYSIBMADM.SELFCODES = SYSIBMADM.VALIDATE_SELF('-514, -204, -501, +30, -199');
```

Each time the SELFCODES global variable is set, the new list of SQLCODE values replaces any SQLCODEs that were previously being used.

Setting SELFCODES for all user jobs

When a job first uses SQL, its value for the SELFCODES global variable is assigned using the default value specified for the SELFCODES global variable. When the default is changed, it applies to jobs that start after the change is made. Changing the default to the special value of *NONE will end SELF processing for all active jobs on the system.

To change the default for the SELFCODES global variable, use the CREATE OR REPLACE VARIABLE SQL statement. Note that the data type of the global variable must remain VARCHAR(256).

```
CREATE OR REPLACE VARIABLE SYSIBMADM.SELFCODES VARCHAR(256)
  DEFAULT '-514, -204, -501, +30, -199';
```

To end SELF for all jobs on the system, set the SELFCODES variable to the special value of *NONE. All jobs currently using SELF will stop recording SQL errors and warnings.

```
CREATE OR REPLACE VARIABLE SYSIBMADM.SELFCODES VARCHAR(256)
  DEFAULT '*NONE';
```

SELF data repository

When an SQL statement completes execution, SELF will determine whether the SQLCODE value matches the list of SQLCODE values specified within the SELFCODES global variable. If the SQLCODE is in the list that is being recorded for the session, information about the failure and the environment is collected and written to the QSYS2.SQL_ERRORRT table.

QSYS2.SQL_ERRORRT - This is the master repository for SELF detail. SELF inserts or updates rows in this table as SQL statements complete with an SQLCODE that matches a value specified within SELFCODES. By default, *PUBLIC is set to *EXCLUDE for SQL_ERRORRT.

QSYS2.SQL_ERROR_LOG - This view is the preferred interface for accessing SELF detail. To access the data within SQL_ERROR_LOG, the caller must have *ALLOBJ special authority or be authorized to the QIBM_DB_SQLADM function usage ID.

There are five details that determine whether SELF will insert a new row or update an existing row in SQL_ERRORRT:

1. Application library name
2. Application program name
3. Application module name
4. Application program type
5. SQLCODE
6. SQL statement text

If these key values are the same as a row that has already been logged, the existing row is updated with information about the new occurrence of the error. The number of times the specific error has been encountered is incremented. Otherwise, a new row is inserted into SQL_ERRORRT.

If any errors occur while attempting to update SQL_ERRORRT, information is not recorded. This includes record lock errors on the SQL_ERRORRT table due to other jobs recording errors.

If SQL_ERRORTEXT does not exist, it will be recreated.

Viewing the SELF log

The QSYS2.SQL_ERROR_LOG view should be used to look at the entries that are recorded by SELF. This view requires the user to be authorized to the QIBM_DB_SQLADM function usage ID or have *ALLOBJ special authority.

To find all entries recorded for a specific application program, the following query can be used.

```
SELECT * FROM QSYS2.SQL_ERROR_LOG
WHERE PROGRAM_LIBRARY = 'PGMLIB' AND PROGRAM_NAME = 'PGM1'
ORDER BY LOGGED_TIME DESC;
```

To find all entries where the same error has occurred for the same statement in the same program, the following query can be used.

```
SELECT * FROM QSYS2.SQL_ERROR_LOG
WHERE NUMBER_OCCURRENCES > 1
ORDER BY NUMBER_OCCURRENCES DESC;
```

Maintaining the SELF log

Similar to the Index Advisor table (QSYS2.SYSIXADV), the database only inserts or updates rows in the SELF log file (QSYS2.SQL_ERRORTEXT). Rows are never deleted.

The user of SELF must decide when and if rows within SQL_ERRORTEXT should be deleted. For example, maybe SELF was being used to review and evaluate SQL application failures before releasing a new version of an application. After an initial set of problems are understood and resolved, the application team could ask for SQL_ERRORTEXT to be cleared of historical SELF detail before another iteration of testing occurs.

To remove rows from the table haven't had a new occurrence logged in the last 30 days:

```
DELETE FROM QSYS2.SQL_ERRORTEXT
WHERE DATE(LOGGED_TIME) < CURRENT DATE - 30 DAYS;
```

SELF example

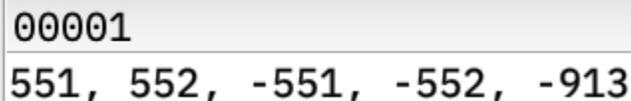

This example shows how SELF can be used to capture point-of-failure detail for SQL statements that are failing because they cannot acquire the necessary locks and for SQL statements that are failing due to lack of authority. The SQLCODEs the example will capture details for are:

- SQLCODE -913 : Row or object &1 in &2 type *&3 in use.
- SQLCODE +551 : Not authorized to object &1 in &2 type *&3.
- SQLCODE -551 : Not authorized to object &1 in &2 type *&3.
- SQLCODE +552 : Not authorized to &1.
- SQLCODE -552 : Not authorized to &1.

Step 1. Build a SELF control string

Use the VALIDATE_SELF scalar function to confirm that the SELF control string is well-formed.

```
VALUES SYSIBMADM.VALIDATE_SELF('-913, -551, -552, +551,+552');
```

```
00001
551, 552, -551, -552, -913
```

Figure 1. Result string from VALIDATE_SELF

Step 2. Set up SELF at the system level

To enable SELF to work across all future user jobs, the SYSIBMADM.SELFCODES global variable needs to be recreated using a DEFAULT string set to the SQLCODE values to log. The string that was returned from step 1 is used, since we know it is a valid string.

```
CREATE OR REPLACE VARIABLE SYSIBMADM.SELFCODES VARCHAR(256)
      DEFAULT '551, 552, -551, -552, -913';
```

Step 3. Monitor results recorded by SELF

After letting SELF run for a user-determined period of time, check the SELF log.

Notice how the SELF log includes deep details on who, what, and when the failure occurred. There's even detail regarding the values of the client special registers at the point of failure.

When a failure occurs multiple times, SELF shows not only the total occurrence count, but also detail about both the first and most recent failure occurrence.

To examine the errors that were set to be captured, run the following query:

```
SELECT *
  FROM QSYS2.SQL_ERROR_LOG
 WHERE LOGGED_SQLCODE IN (551, 552, -551, -552, -913)
 ORDER BY LOGGED_TIME DESC;
```

LOGGED_SQLCODE	LOGGED_SQLSTATE	NUMBER_OCCURRENCES	STATEMENT_TEXT
SQLCODE BEING LOGGED	SQLSTATE CORRESPONDING TO SQLCODE	NUMBER OF OCCURRENCES	SQL STATEMENT TEXT
-55142501			2delete from toystore.employee where empno = '000000'
-55142501			2drop table toystore.employee

Figure 2. SQL_ERROR_LOG result, part 1

Changing the attributes of your queries

You can modify different types of query attributes for a job with the **Change Query Attributes (CHGQRYA)** CL command. You can also use the System i Navigator Change Query Attributes interface.

Related concepts

[Plan cache](#)

The plan cache is a repository that contains the access plans for queries that were optimized by SQE.

[Objects processed in parallel](#)

The Db2 Symmetric multiprocessing feature provides the optimizer with additional methods for retrieving data that include parallel processing. Symmetrical multiprocessing is a form of parallelism achieved on a single system where multiple CPU and I/O processors sharing memory and disk work simultaneously toward a single result.

Controlling queries dynamically with the query options file QAQQINI

The query options file QAQQINI support provides the ability to dynamically modify or override the environment in which queries are executed. This modification is done through the **Change Query Attributes (CHGQRYA)** command and the QAQQINI file. The query options file QAQQINI is used to set some attributes used by the database manager.

For each statement that is run, the query option values are retrieved from the QAQQINI file in the schema specified on the QRYOPTLIB parameter of the CHGQRYA CL command and used to optimize or implement the query. Changes to query option values are only recognized during a full open of a cursor.

Environmental attributes that you can modify through the QAQQINI file include:

- ACTIVE_JOBS
- ALLOW_ADAPTIVE_QUERY_PROCESSING

- ALLOW_ARRAY_VALUE_CHANGES
- ALLOW_DDL_CHANGES_WHILE_OPEN
- ALLOW_EVI_ONLY_ACCESS
- ALLOW_TEMPORARY_INDEXES
- APPLY_REMOTE
- ASYNC_JOB_USAGE
- CACHE_RESULTS
- COLLATE_ERRORS
- COMMITMENT_CONTROL_LOCK_LIMIT
- CONCURRENT_ACCESS_BEHAVIOR
- DETERMINISTIC_UDF_SCOPE
- FIELDPROC_ENCODED_COMPARISON
- FORCE_JOIN_ORDER

- UDF_TIME_OUT
- VARIABLE_LENGTH_OPTIMIZATION

Specifying the QAQQINI file with CHGQRYA

Use the **Change Query Attributes (CHGQRYA)** command with the QRYOPLIB (query options library) parameter to specify which schema currently contains or contains the query options file QAQQINI.

The query options file is retrieved from the schema specified on the QRYOPLIB parameter for each query. It remains in effect for the duration of the job or user session, or until the QRYOPLIB parameter is changed by the **Change Query Attributes (CHGQRYA)** command.

If the **Change Query Attributes (CHGQRYA)** command is not issued, or is issued without the QRYOPLIB parameter specified, QUSRSYS is searched for the QAQQINI file. If a query options file is not found, no attributes are modified. Since the system ships without an INI file in QUSRSYS, you might receive a message indicating that there is no INI file. This message is not an error but an indication that a QAQQINI file that contains all default values is being used. The initial value of the QRYOPLIB parameter for a job is QUSRSYS.

Related information

[Change Query Attributes \(CHGQRYA\) command](#)

Creating the QAQQINI query options file

Each system is shipped with a QAQQINI template file in schema QSYS. The QAQQINI file in QSYS is to be used as a template when creating all user specified QAQQINI files.

To create your own QAQQINI file, use the **Create Duplicate Object (CRTDUPOBJ)** command. Create a copy of the QAQQINI file in the schema specified on the **Change Query Attributes (CHGQRYA)** QRYOPLIB parameter. The file name must remain QAQQINI. For example:

```
CRTDUPOBJ OBJ(QAQQINI)
          FROMLIB(QSYS)
          OBJTYPE(*FILE)
          TOLIB(MYLIB)
          DATA(*YES)
          TRG(*YES)
```

System-supplied triggers are attached to the QAQQINI file in QSYS therefore it is imperative that the only means of copying the QAQQINI file is through the CRTDUPOBJ CL command. If another means is used, such as **CPYF**, then the triggers could be corrupted. An error is signaled that the options file cannot be retrieved or that the options file cannot be updated.

Because of the trigger programs attached to the QAQQINI file, the following CPI321A informational message is displayed six times in the job log when the **CRTDUPOBJ** CL is used to create the file. These messages are not an error; they are only informational messages.

CPI321A Information Message: Trigger QSYS_TRIG_&1__QAQQINI__00000&N in library &1 was added to file QAQQINI in library &1. The ampersand variables (&1, &N) are replacement variables that contain either the library name or a numeric value.

Note: It is highly recommended that the file QAQQINI, in QSYS, not be modified. This file is the original template that is duplicated into QUSRSYS or a user specified library for use.

[Change Query Attributes \(CHGQRYA\) command](#)

[Create Duplicate Object \(CRTDUPOBJ\) command](#)

QAQQINI file override support

If you find working with the QAQQINI query options file cumbersome, consider using the QSYS2.OVERRIDE_QAQQINI procedure. Instead of creating, managing, and using a QAQQINI *FILE object directly, this procedure can be called to work with a temporary version of the INI file. It uses user-specified options and values. The support relies upon the QTEMP library, so any changes affect only the job which calls the procedure.

See [OVERRIDE_QAQQINI procedure](#) for more information.

QAQQINI query options file format

The QAQQINI file is shipped in the schema QSYS. It has a predefined format and has been pre-populated with the default values for the rows.

Query Options File:

A				UNIQUE
A	R	QAQQINI		TEXT('Query options + file')
A		QQPARAM	256A	VARLEN(10) + TEXT('Query+ option parameter') + COLHDG('Parameter')
A		QQVAL	256A	VARLEN(10) + TEXT('Query option + parameter value') + COLHDG('Parameter Value')
A		QQTEXT	1000G	VARLEN(100) + TEXT('Query + option text') + ALWNULL + COLHDG('Query Option' + 'Text') + CCSID(13488) + DFT(*NULL)
A		K	QQPARAM	

Setting the options within the query options file

The QAQQINI file query options can be modified with the INSERT, UPDATE, or DELETE SQL statements.

For the following examples, a QAQQINI file has already been created in library MyLib. To update an existing row in MyLib/QAQQINI use the UPDATE SQL statement. This example sets MESSAGES_DEBUG = *YES so that the query optimizer prints out the optimizer debug messages:

```
UPDATE MyLib/QAQQINI SET QQVAL='*YES'  
WHERE QQPARAM='MESSAGES_DEBUG'
```

To delete an existing row in MyLib/QAQQINI use the DELETE SQL statement. This example removes the QUERY_TIME_LIMIT row from the QAQQINI file:

```
DELETE FROM MyLib/QAQQINI  
WHERE QQPARAM='QUERY_TIME_LIMIT'
```

To insert a new row into MyLib/QAQQINI use the INSERT SQL statement. This example adds the QUERY_TIME_LIMIT row with a value of *NOMAX to the QAQQINI file:

```
INSERT INTO MyLib/QAQQINI  
VALUES('QUERY_TIME_LIMIT','*NOMAX','New time limit set by DBAdmin')
```

QAQQINI query options file authority requirements

QAQQINI is shipped with a *PUBLIC *USE authority. This authority allows users to view the query options file, but not change it. Changing the values of the QAQQINI file affects all queries run on the system. Allow only the system or database administrator to have *CHANGE authority to the QAQQINI query options file.

The query options file, which resides in the library specified on the **Change Query Attributes (CHGQRYA)** CL command QRYOPLIB parameter, is always used by the query optimizer. It is used even if the user has no authority to the query options library and file. This authority provides the system administrator with an additional security mechanism.

When the QAQQINI file resides in the library QUSRSYS the query options affects all the query users on the system. To prevent anyone from inserting, deleting, or updating the query options, the system administrator must remove update authority from *PUBLIC to the file. This update authority prevents users from changing the data in the file.

A copy of the QAQQINI file can also reside in a user library. If that library is specified on the QRYOPLIB parameter of the **Change Query Attributes (CHGQRYA)** command, the query options affect all the queries run for that user job. To prevent the query options from being retrieved from a particular library the system administrator can revoke authority to the **Change Query Attributes (CHGQRYA)** CL command.

QAQQINI file system-supplied triggers

The query options file QAQQINI file uses a system-supplied trigger program in order to process any changes made to the file. A trigger cannot be removed from or added to the file QAQQINI.

If an error occurs on the update of the QAQQINI file (an INSERT, DELETE, or UPDATE operation), the following SQL0443 diagnostic message is issued:

```
Trigger program or external routine detected an error.
```

QAQQINI query options

There are different options available for parameters in the QAQQINI file.

The following table summarizes the query options that can be specified on the QAQQINI command:

Parameter	Value	Description
ACTIVE_JOBS This option specifies what should be used for active jobs during optimization. The number of active jobs is used in determining the optimizer fair share of memory.	*DEFAULT	Average active jobs will be computed based on system information. This is the recommended setting.
	Integer value (1 :: 8192)	The number of active jobs that will be used by the query optimizer to determine fair share. Specify a value between 1 and 8192. Specifying a value other than default means that you may not get all of the performance benefits from the optimizer determining a plan using the memory fair share based on actual system usage. Usage of this setting is intended primarily for debug or modeling query plans based on an optimizer fair share.
ALLOW_ADAPTIVE_QUERY_PROCESSING Specifies whether Adaptive Query Processing (AQP) processing is done for a query. Adaptive query processing uses runtime statistics to look for poor performing queries and potentially replace the poor plan with an improved plan.	*DEFAULT	The default value is set to *YES.
	*YES	Allows Adaptive query processing to occur for this query. The existing QAQQINI options that affect AQP are the following: <ul style="list-style-type: none"> If the REOPTIMIZE_ACCESS_PLAN QAQQINI option is set to *ONLY_REQUIRED, AQP does not reoptimize the original plan. *ONLY_REQUIRED indicates the user does not want the query reoptimized unless there is a functional reason to do so. *ONLY_REQUIRED takes precedence over AQP. Join order requirements specified by the user in the FORCE_JOIN_ORDER QAQQINI option take precedence over AQP. If the user specifies the primary table in the join order, any AQP primary recommendations will be placed after the primary table if they are different.
	*NO	Adaptive query processing cannot be used for this query.

Table 51. Query Options Specified on QAAQINI Command (continued)

Parameter	Value	Description
<p>ALLOW_ARRAY_VALUE_CHANGES Specifies whether changes to the values of array elements are visible to the query while the query is running.</p>	*DEFAULT	The default value is set to *NO.
	*NO	<p>Do not allow changes to values in arrays referenced in the query to be visible after the query is opened.</p> <p>All values which could be referenced in a query are copied during query open processing. Any changes to values in arrays after the query is opened are not visible.</p> <p>Produces queries with predictable and reproducible results, but might have a performance penalty when working with large arrays or large array elements. The penalty is less if all the references to arrays are simple non-column values, for example, :ARRAY[1] or :ARRAY[:hv2].</p> <p>Use of column values from a table to index the ARRAY, or using the UNNEST() function results in copies of the entire array being made. These copies have the largest performance penalty.</p>
	*YES	<p>Allow changes to values in arrays to be visible to the query while the query is running. The arrays are not copied during the open processing of the query. If the array values are changed during the processing of queries, the results of the query might be unpredictable.</p> <p>Performance might be improved for queries which reference large arrays in complex array index lookup operations, such as :Array[column-name], or when using UNNEST. Large arrays include arrays that have thousands of elements, or elements with a large size. Array index lookups using simple index values, such as :ARRAY[1] or :ARRAY[:hv2], see minimal performance improvements.</p> <p>Performance of some queries might be negatively impacted. For example, later queries that could reuse the results if they were cached to avoid recalculation where the cached result is applicable.</p> <p>Procedures that can run with *YES and still expect predictable results have the following characteristics:</p> <ol style="list-style-type: none"> 1. Contain no cursor declarations. 2. Receive arrays as input parameters: <ul style="list-style-type: none"> • and do not contain SET statements which reference arrays on the left side of the SET, and • and have no SQL statements with INTO clauses referencing arrays. 3. Do not contain SET statements which reference arrays on the left side of the set: <ul style="list-style-type: none"> • and have no SQL statements with INTO clauses referencing arrays while a cursor is open for a query which references an array.

Table 51. Query Options Specified on QAQQINI Command (continued)

Parameter	Value	Description
ALLOW_DDL_CHANGES_WHILE_OPEN Specifies whether certain DDL operations against a database file are allowed while another user has the database file (or table) open or a logical file (or view) over a physical file open in another job.	*DEFAULT	The default is set to *NO.
	*YES	The following DDL operations are supported: <ul style="list-style-type: none"> • Trigger operations <ul style="list-style-type: none"> – SQL CREATE TRIGGER, ALTER TRIGGER, and DROP TRIGGER Any open cursors in concurrent jobs that have open cursors over the target table will continue to operate as if the operation was not performed until the cursor is closed. – SQL COMMENT ON TRIGGER and LABEL ON TRIGGER statements – CL ADDPFTRG, RMVPFTRG, and CHGPFTRG commands There is no effect on concurrent jobs. <ul style="list-style-type: none"> – Any open cursors in concurrent jobs that have open cursors over the target table will continue to operate as if the operation was not performed until the cursor is closed. This option is ignored for INSTEAD OF triggers and READ triggers. <ul style="list-style-type: none"> • Grant and revoke operations <ul style="list-style-type: none"> – SQL GRANT and REVOKE for database files Any fully open cursors in concurrent jobs that have open cursors over the target database file will continue to operate as if the operation was not performed until the cursor is closed. If this is not a grant of UPDATE, DELETE, or INSERT, pseudo-closed cursors in other jobs will not be closed. Otherwise, all pseudo-closed cursors will be fully closed. – GRTOBJAUT and RVKOBJAUT CL commands for database files Any fully open cursors in concurrent jobs that have open cursors over the target database file will continue to operate as if the operation was not performed until the cursor is closed. If this is not a grant of *UPD, *DLT, *ADD, or *EXCLUDE, pseudo-closed cursors in other jobs will not be closed. Otherwise, all pseudo-closed cursors will be fully closed.
	*NO	SQL DDL operations can fail to complete, with an SQL0913 error, if an exclusive lock cannot be acquired for the target object.
ALLOW_EVI_ONLY_ACCESS Specifies whether encoded vector index RRN probe can be considered by the optimizer.	*DEFAULT	The default is set to *YES.
	*YES	Specifies whether encoded vector index RRN probe can be considered by the optimizer to replace table accesses. An EVI must exist for every column being accessed in the table.
	*NO	Encoded vector index RRN probes cannot replace table access.
ALLOW_TEMPORARY_INDEXES Specifies whether temporary indexes can be considered by the optimizer. If temporary indexes are not allowed, then any other viable plan is chosen regardless of cost to implement this query.	*DEFAULT	The default value is set to *YES.
	*YES	Allow temporary indexes to be considered.
	*ONLY_REQUIRED	Do not allow any temporary indexes to be considered for this access plan. Choose any other implementation regardless of cost to avoid the creation of a temporary index. Only if no viable plan can be found, is a temporary index allowed.
APPLY_REMOTE Specifies for database queries involving distributed files, whether the CHGQRYA query attributes are applied to the jobs on the remote systems associated with this job.	*DEFAULT	The default value is set to *YES.
	*NO	The CHGQRYA attributes for the job are not applied to the remote jobs. The remote jobs use the attributes associated to them on their systems.
	*YES	The query attributes for the job are applied to the remote jobs used in processing database queries involving distributed tables. For attributes where *SYSVAL is specified, the system value on the remote system is used for the remote job. This option requires that, if CHGQRYA was used for this job, the remote jobs must have authority to use the CHGQRYA command.

Table 51. Query Options Specified on QAQQINI Command (continued)

Parameter	Value	Description
ASYNCH_JOB_USAGE Specifies the circumstances in which asynchronous (temp writer) jobs can be used to help process database queries in the job. The option determines which types of database queries can be used in asynchronous jobs (running in parallel) to help complete the query. An asynchronous job is a separate job that handles query requests from jobs running the database queries on the system. The asynchronous job processes each request and puts the results into a temporary file. This intermediate temporary file is then used by the main job to complete the database query. The advantage of an asynchronous job is that it processes its request at the same time (in parallel) that the main job processes another query step. The disadvantage of using an asynchronous job is that it might encounter a situation that it cannot handle in the same way as the main job. For example, the asynchronous job might receive an inquiry message from which it cancels, whereas the main job can choose to ignore the message and continue. There are two different types of database queries that can run asynchronous jobs: 1. Distributed queries. These are database queries that involve distributed files. Distributed files are provided through the system feature Db2 Multi-System for IBM i. 2. Local queries. There are database queries that involve only files local to the system where the database queries are being run.	*DEFAULT	The default value is set to *LOCAL.
	*LOCAL	Asynchronous jobs might be used for database queries that involve only tables local to the system where the database queries are being run. In addition, this option allows the communications required for queries involving distributed tables to be asynchronous. Each system involved in the query of the distributed tables can run its portion of the query at the same time (in parallel).
	*DIST	Asynchronous jobs might be used for database queries that involve distributed tables.
	*ANY	Asynchronous jobs might be used for any database query.
	*NONE	No asynchronous jobs are allowed to be used for database query processing. In addition, all processing for queries involving distributed tables occurs synchronously. Therefore, no intersystem parallel processing occurs.
CACHE_RESULTS Specifies a way for the user to control the cache results processing. For queries involving temporary results, for example, sorts or hashes, the database manager often saves the results across query pseudo-close or pseudo-open. The results are saved as long as they are not large, with the hope that they can be reused for the next run of the query. Beginning in V5R3, the database manager saves these temporary results even when a job is finished with them. The database manager assumes that another job can later reuse the results. The database manager automatically controls the caching of these results, removing cache results as storage usage becomes large. However, the amount of temporary storage used by the database can be noticeably more than in previous releases.	*DEFAULT	The default value is the same as *SYSTEM.
	*SYSTEM	The database manager might cache a query result set. A subsequent run of the query by the same job can reuse the cached result set. Or, if the ODP for the query has been deleted, any job can reuse the cached result set. In many cases, this option works well. However, you need to consider if the query is doing work outside of the database manager which could affect temporary results. In that case, *JOB or *NONE may be a more appropriate setting. For example, if field procedures that mask data are used or swapping of user profiles in a UDF can occur, this option should specify *NONE.
	*JOB	The database manager might cache a query result set from one run to the next for a job. Caching can occur as long as the query uses a reusable ODP. When the reusable ODP is deleted, the cached result set is destroyed. This value mimics V5R2 processing.
	*NONE	The database does not cache any query results.
COLLATE_ERRORS Specifies how data errors are handled on the GROUP BY and ORDER BY expression during hash or sort processing within queries.	*DEFAULT	The default value is *NO.
	*NO	A value of *NO causes the query to be ended with an error when a grouping or ordering expressions results in an error.
	*YES	A value of *YES indicates that the grouping or sort continues.
COMMITMENT_CONTROL_LOCK_LIMIT Specifies the maximum number of records that can be locked to a commit transaction initiated after setting the new value. The value specified for COMMITMENT_CONTROL_LOCK_LIMIT does not affect transactions running in jobs that have already started commitment control. For the value to be effective, it must be changed before starting commitment control.	*DEFAULT	*DEFAULT is equivalent to 500,000,000. If multiple journals are involved in the transaction, the COMMITMENT_CONTROL_LOCK_LIMIT applies to each journal, not to the transaction as a whole. For example, files F1 to F5 are journaled to journal J1, and files F6 to F10 are journaled to J2. The COMMITMENT_CONTROL_LOCK_LIMIT is set to 100,000. 100,000 record locks can be acquired for files F1 to F5. 100,000 more locks can be acquired for files F6 to F10.
	Integer Value	The maximum number of records that can be locked to a commit transaction initiated after setting the new value. The valid integer value is 1–500,000,000.

Table 51. Query Options Specified on QAAQINI Command (continued)

Parameter	Value	Description
CONCURRENT_ACCESS_BEHAVIOR Controls how queries with an isolation level of Cursor Stability (CS) or Read Stability (RS) interact with uncommitted table changes.	*DEFAULT	The default value is *OPTIMIZE
	*OPTIMIZE	Uncommitted changes that delete or update records so that they are no longer selected by the query will not be considered as candidates for query synchronization.
	*STRICTSCAN	All records referenced by a table scan query access plan will synchronize with any changes that are not yet committed. Serialization behavior depends on the concurrent access resolution used by the query, for example, SKIP LOCKED DATA, USE CURRENTLY COMMITTED, or WAIT FOR OUTCOME (default). Since the table scan attempts to serialize with any pending transactions for deleted and non-selected records, query performance will be reduced, as compared to *OPTIMIZE. Queries may contain many access plan types, but this option is only supported for table scan access. All other plan types will use *OPTIMIZE behavior.
DETERMINISTIC_UDF_SCOPE Specifies the scope or lifetime of the deterministic setting for User Defined Functions (UDFs) and User Defined Table Functions (UDTFs). It is recommended that you specify STATEMENT DETERMINISTIC on any CREATE FUNCTION statement that should be considered deterministic for a single instance of a query open rather than using the *OPEN option. DETERMINISTIC_UDF_SCOPE applies to all deterministic UDFs and UDTFs in every query while this QAAQINI option is in effect.	*DEFAULT	The default value is *ALWAYS.
	*ALWAYS	The UDF is always considered deterministic. Query temporary objects might be shared across query opens and the UDF might not run for a particular query open.
	*OPEN	The UDF is considered deterministic only for a single instance of a query open. Query temporary objects are not shared across query open. The UDF is run at least once in the query for a given set of input parameters.
FIELDPROC_ENCODED_COMPARISON Specifies the amount of optimization that the optimizer might use when queried columns have attached field procedures	*DEFAULT	The default value is *ALLOW_EQUAL.
	*NONE	No optimization to remove field procedure decode option 4 or transformations to optimize field procedure invocations is allowed. For example, the optimizer cannot transform <code>fieldProc(4, column) = 'literal'</code> to <code>column = fieldProc(0, 'literal')</code> . This option is used when the field procedure is not deterministic.
	*ALLOW_EQUAL	Optimization allowed for equal and not equal predicates, GROUP BY, and DISTINCT processing. For example, the optimizer might choose to change the predicate <code>fieldProc(4, column) = 'literal'</code> to <code>column = fieldProc(0, 'literal')</code> in order to facilitate index matching. This option is useful when the field procedure is deterministic but no ordering can be determined based on the result of the field encoding.
	*ALLOW_RANGE	Transformation allowed for MIN, MAX grouping functions, ORDER BY, and all predicates except LIKE in addition to the transformations supported by *ALLOW_EQUAL. This option is useful when the field procedure is deterministic and the encoded value implies ordering
	*ALL	Transformation allowed for all predicates including LIKE, in addition to the transformations supported by *ALLOW_RANGE.
FORCE_JOIN_ORDER Specifies to the query optimizer that the join of files is to occur in the order specified in the query.	*DEFAULT	The default is set to *NO.
	*NO	Allow the optimizer to reorder join tables.
	*SQL	Only force the join order for those queries that use the SQL JOIN syntax. This option mimics the behavior for the optimizer before V4R4M0.
	*PRIMARY nnn	Only force the join position for the file listed by the numeric value nnn into the primary position (or dial) for the join. nnn is optional and defaults to 1. The optimizer then determines the join order for all the remaining files based upon cost.
	*YES	Do not allow the query optimizer to specify the order of join tables as part of its optimization process. The join occurs in the order in which the tables were specified in the query.

Table 51. Query Options Specified on QAAQINI Command (continued)

Parameter	Value	Description
IGNORE_LIKE_REDUNDANT_SHIFTS Specifies whether redundant shift characters are ignored for DBCS-Open operands when processing the SQL LIKE predicate or OPNQRYF command %WLDCRD built-in function.	*DEFAULT	The default value is set to *OPTIMIZE.
	*ALWAYS	When processing the SQL LIKE predicate or OPNQRYF command %WLDCRD built-in function, redundant shift characters are ignored for DBCS-Open operands. The optimizer cannot use an index to perform key row positioning for SQL LIKE or OPNQRYF %WLDCRD predicates involving DBCS-Open, DBCS-Either, or DBCS-Only operands.
	*OPTIMIZE	When processing the SQL LIKE predicate or the OPNQRYF command %WLDCRD built-in function, redundant shift characters might be ignored for DBCS-Open operands. These characters are ignored depending on whether an index is used to perform key row positioning for these predicates. This option enables the query optimizer to consider key row positioning for SQL LIKE or OPNQRYF %WLDCRD predicates involving DBCS-Open, DBCS-Either, or DBCS-Only operands.
KEY_RANGE_ESTIMATE_TIMEOUT Specifies the amount of time the query optimizer may use for any individual key range estimate operation. Key range estimates are used with indexes to approximate the number of rows for a given predicate. This option may help to reduce the time spent waiting for some queries to complete optimization.	*DEFAULT	The default value is *OPTIMIZE.
	*OPTIMIZE	The amount of time used for key range estimate operations is determined by the query optimizer.
	*NONE	No time limit is specified for key range estimate operations, and every estimate will run to completion regardless of the time required. This is the behavior of the query optimizer in releases before IBM i 7.3.
	Integer Value	The number of seconds a key range estimate operation may execute before returning an estimate to the query optimizer. At the end of this time interval, the optimizer will continue optimizing the query, and the estimate operation will continue in a background process. A smaller value may reduce optimization time but may also cause less accurate estimates to be used by the optimizer. Valid values are 1-86400.
LIMIT_PREDICATE_OPTIMIZATION Specifies that the query optimizer can only use simple isolatable predicates (OIF) when performing its index optimization. An OIF is a predicate that can eliminate a record without further evaluation. Any predicate that cannot be classified as an OIF is ignored by the optimizer and needs to be evaluated as a non-key selection predicate. A=10 and (A => 10 AND B=9) are OIFs. A=10 OR B=9 are not OIFs. Note: *YES impairs or limits index optimization.	*DEFAULT	Do not eliminate the predicates that are not simple isolatable predicates (OIF) when doing index optimization. Same as *NO.
	*NO	Do not eliminate the predicates that are not simple isolatable predicates (OIF) when doing index optimization.
	*YES	Eliminate the predicates that are not simple isolatable predicates (OIF) when doing index optimization.
LOB_LOCATOR_THRESHOLD Specifies either *DEFAULT or an Integer Value -- the threshold to free eligible LOB locators that exist within the job.	*DEFAULT	The default value is set to 0. This option indicates that the database does not free locators.
	Integer Value	If the value is 0, then the database does not free locators. For values 1 through 250,000, on a FETCH request, the database compares the SQL current LOB locator count for the job against the threshold value. If the locator count is greater than or equal to the threshold, the database frees host server created locators that have been retrieved. This option applies to all host server jobs (QZDASOINIT) and has no impact to other jobs.
MATERIALIZED_QUERY_TABLE_REFRESH_AGE Specifies the ability to examine which materialized query tables are eligible to be used based on the last time a REFRESH TABLE statement was run.	*DEFAULT	The default value is set to 0.
	0	No materialized query tables can be used.
	*ANY	Any tables indicated by the MATERIALIZED_QUERY_TABLE_USAGE INI parameter can be used.
	Timestamp_duration	Only tables indicated by MATERIALIZED_QUERY_TABLE_USAGE INI option which have a REFRESH TABLE performed within the specified timestamp duration can be used.

Table 51. Query Options Specified on QAQQINI Command (continued)

Parameter	Value	Description
MATERIALIZED_QUERY_TABLE_USAGE Specifies the usage of materialized query tables in query optimization and runtime.	*DEFAULT	The default value is set to *NONE.
	*NONE	Materialized query tables cannot be used in query optimization and implementation.
	*ALL	User-maintained materialized query tables may be used.
	*USER	User-maintained materialized query tables can be used.
MEMORY_POOL_PREFERENCE Specifies the preferred memory pool that database operations uses. This option does not guarantee use of the specified pool, but directs database to perform its paging into this pool when supported by the database operation.	*DEFAULT	The default value is set to *JOB.
	*JOB	Paging is done in the pool of the job. This option is normal paging behavior.
	*BASE	Attempt to page storage into the base pool when paging is needed and a database operation that supports targeted paging occurs.
	nn	Attempt to page storage into pool nn when paging is needed and a database operation that supports targeted paging occurs.
	*NAME PoolName	Attempt to page storage into a named storage pool when paging is needed and a database operation that supports targeted paging occurs.
MESSAGES_DEBUG Specifies whether Query Optimizer debug messages are displayed to the job log. These messages are regularly issued when the job is in debug mode.	*DEFAULT	The default is set to *NO.
	*NO	No debug messages are to be displayed.
	*YES	Issue all debug messages that are generated for STRDBG .
NORMALIZE_DATA Specifies whether normalization is performed on Unicode constants, host variables, parameter markers, and expressions that combine strings.	*DEFAULT	The default is set to *NO.
	*NO	Unicode constants, host variables, parameter markers, and expressions that combine strings is not normalized.
	*YES	Unicode constants, host variables, parameter markers, and expressions that combine strings is normalized
OPEN_CURSOR_CLOSE_COUNT Specifies either *DEFAULT or an Integer Value: the number of cursors to full close when the threshold is encountered.	*DEFAULT	*DEFAULT is equivalent to 0. See Integer Value for details.
	Integer Value	This value determines the number of cursors to be closed. The valid values for this parameter are 1 - 65536. The value for this parameter is less than or equal to the number in the OPEN_CURSOR_THRESHOLD parameter. If the number of open cursors reaches the value specified by the OPEN_CURSOR_THRESHOLD, pseudo-closed cursors are hard (fully) closed. The least recently used cursors are closed first. This value is ignored if OPEN_CURSOR_THRESHOLD is *DEFAULT. If OPEN_CURSOR_THRESHOLD is specified and the value is *DEFAULT, the number of cursors closed is equal to OPEN_CURSOR_THRESHOLD multiplied by 10 percent. The result is rounded up to the next integer value. OPEN_CURSOR_CLOSE_COUNT is used with OPEN_CURSOR_THRESHOLD to manage the number of open cursors within a job. Open cursors include pseudo-closed cursors.
OPEN_CURSOR_THRESHOLD Specifies either *DEFAULT or an Integer Value -- the threshold to start full close of pseudo-closed cursors.	*DEFAULT	*DEFAULT is equivalent to 0. See Integer Value for details.
	Integer Value	This value determines the threshold to start full close of pseudo-closed cursors. When the number of open cursors reaches this threshold value, pseudo-closed cursors are hard (fully) closed with the least recently used cursors being closed first. The number of cursors to be closed is determined by OPEN_CURSOR_CLOSE_COUNT. The valid user-entered values for this parameter are 1 - 65536. A default value of 0 indicates that there is no threshold. Hard closes are not forced based on the number of open cursors within a job. OPEN_CURSOR_THRESHOLD is used with OPEN_CURSOR_CLOSE_COUNT to manage the number of open cursors within a job. Open cursors include pseudo-closed cursors.

Table 51. Query Options Specified on QAAQINI Command (continued)

Parameter	Value	Description
OPTIMIZATION_GOAL Specifies the goal that the query optimizer uses when making costing decisions.	*DEFAULT	Optimization goal is determined by the interface (ODBC, SQL precompiler options, OPTIMIZE FOR nnn ROWS clause).
	*FIRSTIO	All queries are optimized with the goal of returning the first page of output as fast as possible. This option works well when the output is controlled by a user likely to cancel the query after viewing the first page of data. Queries coded with OPTIMIZE FOR nnn ROWS honor the goal specified by the clause.
	*ALLIO	All queries are optimized with the goal of running the entire query to completion in the shortest amount of elapsed time. This option is better when the output of a query is written to a file or report, or the interface is queuing the output data. Queries coded with OPTIMIZE FOR nnn ROWS honor the goal specified by the clause.
OPTIMIZE_STATISTIC_LIMITATION Specifies limitations on the statistics gathering phase of the query optimizer. One of the most time consuming aspects of query optimization is in gathering statistics from indexes associated with the queried tables. Generally, the larger the size of the tables involved in the query, the longer the gathering phase of statistics takes. This option provides the ability to limit the amount of resources spend during this phase of optimization. The more resources spent on statistics gathering, the more accurate (optimal) the optimization plan is.	*DEFAULT	The amount of time spent in gathering index statistics is determined by the query optimizer.
	*NO	No index statistics are gathered by the query optimizer. Default statistics are used for optimization. (Use this option sparingly.)
	*PERCENTAGE integer value	Specifies the maximum percentage of the index that is searched while gathering statistics. Valid values for are 1 - 99.
	*MAX_ NUMBER_OF_ RECORDS_ ALLOWED integer value	Specifies the largest table size, in number of rows, for which gathering statistics is allowed. For tables with more rows than the specified value, the optimizer does not gather statistics and uses default values.

Table 51. Query Options Specified on QAAQINI Command (continued)

Parameter	Value	Description
<p>PARALLEL_DEGREE</p> <p>Specifies the parallel processing option that can be used when running database queries and database file keyed access path builds, rebuilds, and maintenance in the job. The specified parallel processing option determines the types of parallel processing allowed. There are two types of parallel processing:</p> <ol style="list-style-type: none"> 1. Input/Output (I/O) parallel processing. With I/O parallel processing, the database manager uses multiple tasks for each query to do the I/O processing. The central processor unit (CPU) processing is still done serially. 2. Symmetric Multiprocessing (SMP). SMP assigns both CPU and I/O processing to tasks that run the query in parallel. Actual CPU parallelism requires a system with multiple processors. SMP can only be used if the system feature, Db2 Symmetric Multiprocessing, is installed. Use of SMP parallelism can affect the order in which records are returned. 	*DEFAULT	The default value is *SYSVAL.
	*SYSVAL	Set to the current system value QQQYDEGREE.
	*IO	Any number of tasks can be used. SMP parallel processing is not allowed. The SQE optimizer considers I/O parallelism with or without this setting.
	*OPTIMIZE	Any number of tasks for: <ul style="list-style-type: none"> • I/O or SMP parallel processing of the query • database file keyed access path build, rebuild, or maintenance. <p>SMP parallel processing is used only if the system feature, Db2 Symmetric Multiprocessing for IBM i, is installed.</p> <p>Use of parallel processing and the number of tasks used is determined by:</p> <ul style="list-style-type: none"> • the number of processors available in the system • the job share of the amount of active memory available in the pool in which the job is run • whether the expected elapsed time for the query or database file keyed access path build or rebuild is limited by CPU processing or I/O resources. <p>The query optimizer chooses an implementation that minimizes elapsed time based on the job share of the memory in the pool.</p>
	*OPTIMIZE nnn	Like *OPTIMIZE, with the value nnn indicating a percentage from 1 to 200, used to influence the number of tasks. If not specified, 100 is used.
	nnn	The query optimizer chooses to use either I/O or SMP parallel processing to process the query. SMP parallel processing is used only if the system feature, Db2 Symmetric Multiprocessing for IBM i, is installed.
PARALLEL_DEGREE (continued)	*NONE	No parallel processing is allowed for database query processing or database table index build, rebuild, or maintenance.
	*NUMBER_OF_TASKS nnn	Indicates the maximum number of tasks that can be used for a single query. The number of tasks is limited to either this value or the number of disk arms associated with the table. Not recommended if running SQE. The SQE optimizer attempts to use this degree and override many of the normal costing mechanisms. For SQE, use *OPTIMIZE with a percentage.
	*MAX xxx	Like *MAX, with the value xxx indicating the ability to specify an integer percentage value 1 - 200. The query optimizer determines the parallel degree for the query using the same processing as is done for *MAX. Once determined, the optimizer adjusts the actual parallel degree used for the query by the percentage given. This option provides the user the ability to override the parallel degree used to some extent without having to specify a particular parallel degree under *NUMBER_OF_TASKS.

Table 51. Query Options Specified on QAQQINI Command (continued)

Parameter	Value	Description
PARAMETER_MARKER_CONVERSION Specifies whether to allow literals to be implemented as parameter markers in dynamic SQL queries.	*DEFAULT	The default value is set to *YES.
	*NO	Constants cannot be implemented as parameter markers.
	*YES	Constants can be implemented as parameter markers.
PREVENT_ADDITIONAL_CONFLICTING_LOCKS The following SQL DDL statements require an exclusive, no read lock on the target table. If the application activity cannot be quiesced, it can be hard to accomplish these operations. The PREVENT_ADDITIONAL_CONFLICTING_LOCKS QAQQINI option provides a control for customers to use to direct the operating system to favor a request for an exclusive, no read lock over new requests to lock the object for reading.	*DEFAULT	The default value is set to *NO
	*NO	When a job requests an exclusive lock on an object, do not prevent concurrent jobs from acquiring additional locks on the object.
PSEUDO_OPEN_CHECK_HOST_VARS This option can be used to allow SQE to check the selectivity of the host variable values at pseudo open time. If the new set of host variable values require a different plan to perform well, SQE will re-optimize the query. This option is most appropriate when there is considerable variability in the selectivity of host variable in the queries predicates.	*DEFAULT	The default value is set to *NO
	*NO	The optimizer does not check host variables for selectivity changes once in pseudo-open.
	*OPTIMIZE	The optimizer will determine when a host variable selectivity should be checked. In general, the optimizer will monitor the query and if after a certain number of runs it determines that there is no advantage to checking host variable selectivity at pseudo open time, it will stop checking. Full opens do normal plan validation.
QUERY_TIME_LIMIT Specifies a time limit for database queries allowed to be started based on the estimated number of elapsed seconds that the query requires to process.	*YES	The optimizer will always check host variable selectivity at pseudo open time. Note: If the REOPTIMIZE_ACCESS_PLAN INI option is set to *ONLY_REQUIRED then this INI option has no effect.
	*DEFAULT	The default value is set to *SYSVAL.
	*SYSVAL	The query time limit for this job is obtained from the system value, QQRITIMLMT.
	*NOMAX	There is no maximum number of estimated elapsed seconds.
REOPTIMIZE_ACCESS_PLAN Specifies whether the query optimizer reoptimizes a query with a saved access plan. Queries can have a saved access plan stored in the associated storage of an HLL program, or in the plan cache managed by the optimizer itself. Note: If you specify *NO the query could still be revalidated. Some of the reasons this option might be necessary are: <ul style="list-style-type: none"> • The queried file was deleted and recreated. • The query was restored to a different system than the one on which it was created. • An OVRDBF command was used. 	integer value	Specifies the maximum value that is checked against the estimated number of elapsed seconds required to run a query. If the estimated elapsed seconds are greater than this value, the query is not started. Valid values range from 0 to 2,147,352,578.
	*DEFAULT	The default value is set to *NO.
	*NO	Do not force the existing query to be reoptimized. However, if the optimizer determines that optimization is necessary, the query is optimized.
	*YES	Force the existing query to be reoptimized.
	*FORCE	Force the existing query to be reoptimized.
*ONLY_REQUIRED	Do not allow the plan to be reoptimized for any subjective reasons. For these cases, continue to use the existing plan since it is still a valid workable plan. This option could mean that you might not get all the performance benefits that a reoptimization plan might derive. Subjective reasons include file size changes, new indexes, and so on. Non-subjective reasons include deletion of an index used by existing access plan, query file being deleted and recreated, and so on.	

Table 51. Query Options Specified on QAAQINI Command (continued)

Parameter	Value	Description
SQE_NATIVE_ACCESS_POSITION_BEHAVIOR This option controls the positioning behavior of native opens or queries implemented by SQE. By specifying an option other than *DEFAULT, performance benefits may be realized.	*DEFAULT	Normal positioning behavior is performed.
	*NO_ROLLBACK_HOLD	The current cursor position is unchanged by a rollback.
	*NO_KEY_FAILURE_HOLD	If an attempted key positioning operation fails, the cursor position prior to the attempted operation will not be restored. It is assumed that another absolute positioning operation, such as first, last, or key equal, will be attempted before any relative positioning operations, such as next or previous.
	*NO_HOLD	Behavior is the same as defined for *NO_ROLLBACK_HOLD and *NO_KEY_FAILURE_HOLD values.
SQLSTANDARDS_MIXED_CONSTANT Specifies whether to allow IGC constants to always be treated as IGC-OPEN in SQL queries. Note: When *NO is specified, Db2 for i is not compatible with the other Db2 platforms.	*DEFAULT	The default value is set to *YES.
	*YES	SQL IGC constants are treated as IGC-OPEN constants.
	*NO	If the data in the IGC constant only contains shift-out DBCS-data shift-in, then the constant are treated as IGC-ONLY, otherwise it is treated as IGC-OPEN.
SQL_CONCURRENT_ACCESS_RESOLUTION Specifies the concurrent access resolution to use for an SQL query.	*DEFAULT	The default value is set to *WAIT.
	*WAIT	The database manager must wait for the commit or rollback when encountering data in the process of being updated, deleted, or inserted. Rows encountered that are in the process of being inserted are not skipped. This option applies if possible when the isolation level in effect is Cursor Stability or Read Stability and is ignored otherwise.
	*CURCMT	The database manager can use the currently committed version of the data for read-only scans when it is in the process of being updated or deleted. Rows in the process of being inserted can be skipped. This option applies if possible when the isolation level in effect is Cursor Stability and is ignored otherwise.
SQL_DECFLOAT_WARNINGS Specifies the warnings returned for SQL DECFLOAT computations and conversions involving: <ul style="list-style-type: none"> • division by 0. • overflow. • underflow. • an invalid operand. • an inexact result. • 	*DEFAULT	The default value is set to *NO.
	*YES	A warning is returned to the caller for DECFLOAT computations and conversions involving division by 0, overflow, underflow, invalid operand, inexact result, or subnormal number.
	*NO	An error or a mapping error is returned to the caller for DECFLOAT computations and conversions involving division by 0, overflow, underflow, or an invalid operand. A warning or error is not returned for an inexact result or a subnormal number.
SQL_FAST_DELETE_ROW_COUNT Specifies how the delete is implemented by the database manager. This value is used when processing a DELETE FROM table-name SQL statement without a WHERE clause.	*DEFAULT	The default value is set to 0. 0 indicates that the database manager chooses how many rows to consider when determining whether fast delete could be used instead of traditional delete. When using the default value, the database manager will most likely use 1000 as a row count. This means that using the INI option with a value of 1000 results in no operational difference from using 0 for the option.
	*NONE	This value forces the database manager to never attempt to fast delete on the rows.
	*OPTIMIZE	This value is same as using *DEFAULT.
	Integer Value	Specifying a value for this option allows the user to tune the behavior of DELETE. The target table for the DELETE statement must match or exceed the number of rows specified on the option for fast delete to be attempted. A fast delete does not write individual rows into a journal. The valid values are 1 - 999,999,999,999,999.

Table 51. Query Options Specified on QAQQINI Command (continued)

Parameter	Value	Description
SQL_GVAR_BUILD_RULE Determines whether global variables must exist or not when building SQL routines or executing SQL pre-compiles. This option has no affect on dynamic SQL statements.	*DEFAULT	The default value is set to *DEFER
	*DEFER	Global variables do not need to exist when an SQL routine is created or the SQL pre-compiler is run. Since global variables are not required to exist, the create will not fail when an incorrect column name or routine variable is encountered. Incorrect name usage will result in SQL0206 - "Column or global variable &1 not found." failures when the statement is executed.
	*EXIST	Global variables referenced by SQL must exist when the SQL routine is created or the SQL pre-compiler is run. Using this option, an SQL0206 will be issued at create time.
SQL_MODIFIES_SQL_DATA From the SQL Standard, no MODIFIES SQL DATA operations are allowed in an SQL BEFORE trigger. The Informix® database allows MODIFIES SQL DATA operations in SQL BEFORE triggers. Setting the option to *YES allows SQL BEFORE triggers to perform the SQL MODIFIES SQL DATA operations.	*DEFAULT	The default value is set to *NO.
	*NO	No MODIFIES SQL DATA operations are allowed in an SQL BEFORE trigger.
	*YES	MODIFIES SQL DATA operations are allowed in an SQL BEFORE trigger.
SQL_PSEUDO_CLOSE Before V6R1: SQL cursor open processing checks for the presence of a data area named QSQPSCLS1 in the library list of the job. If the data area is found, all reusable cursors are marked as candidates for reuse. They are pseudo-closed the first time rather than the second time the application closes the cursor. Without this data area, a cursor does not become reusable until the second close. Pseudo-closing the first time results in leaving some cursors open that might not be reused. These open cursors can increase the amount of auxiliary and main storage required for the application. The storage can be monitored using the WRKSYSSTS command. For the amount of auxiliary storage used, look at the "% system ASP used." For the amount of main storage, examine the faulting rates on the WRKSYSSTS display. The format and the contents of the data area are not important. The data area can be deleted using the following command: DLTDTAARA DTAARA(QGPL/QSQPSCLS1). The existence of the data area is checked during the first SQL open operation for each job. It is checked only once and the processing mode remains the same for the life of the job. Because the library list is used for the search, the change can be isolated to specific jobs. Create the data area in a library that is included only in the library lists for those jobs.	*DEFAULT	The default behavior depends upon whether the QSQPSCLS1 *DTAARA exists. If the QSQPSCLS1 *DTAARA was found on the first OPEN within the job, then SQL cursors are marked as candidates for reuse. The cursors are pseudo-closed on the first close. If the QSQPSCLS1 *DTAARA was not found on the first OPEN within the job, then SQL cursors are marked as candidates for reuse. The cursors are pseudo-closed on the second close.
	Integer Value	Specifies a value greater than zero that indicates when a cursor is pseudo-closed. The value of this option minus 1 indicates how many times the cursor is hard closed before being marked as candidate for pseudo-close. Valid values are 1 - 65535.
SQL_STMT_COMPRESS_MAX Specifies the compression maximum setting, which is used when statements are prepared into a package.	*DEFAULT	The default value is set to 2. The default indicates that the access plan associated with any statement will be removed after a statement has been compressed twice without being executed.
	Integer Value	The integer value represents the number of times that a statement is compressed before the access plan is removed to create more space in the package. Executing the SQL statement resets the count for that statement to 0. The valid Integer values are 1 - 255.
SQL_STMT_REUSE Specifies the number of times the statement must be prepared in the same connection before the statement is stored in the SQL extended dynamic package. If the number of times the statement has been prepared in the same connection is less than the specified INI option, a temporary copy of the statement is used. Any other job preparing the statement does a complete prepare.	*DEFAULT	The default value is 3. The statement is stored on the third prepare of the statement.
	1::255	The number of times the statement must be prepared in the same connection before the statement is stored in the SQL package.

Table 51. Query Options Specified on QAQQINI Command (continued)

Parameter	Value	Description
SQL_SUPPRESS_MASKED_DATA_DETECTION	*DEFAULT	The default value is set to *NO.
	*YES	If masked data is being used to insert into or update a table, detection of this masked data will not be done and a SQ20478 with reason code 30 will not be sent.
	*NO	If masked data is being used to insert into or update a table with activated column access control directly from an expression involving a column with an active column mask, detection of this masked data will be done and a SQ20478 with reason code 30 will be sent.
SQL_SUPPRESS_WARNINGS For SQL statements, this parameter provides the ability to suppress SQL warnings.	*DEFAULT	The default value is set to *NO.
	*YES	Examine the SQLCODE in the SQLCA after execution of a statement. If the SQLCODE is one of the listed warnings, then alter the SQLCA so that no warning is returned to the caller. Set the SQLCODE to 0, the SQLSTATE to '00000' and SQLWARN to ' '. Warnings: <ul style="list-style-type: none"> • SQL0030 • SQL0335 • SQL0387 • SQL7909 (on a DROP PROCEDURE/ROUTINE/FUNCTION)
	*NO	Specifies that SQL warnings are returned to the caller.
SQL_TRANSLATE_ASCII_TO_JOB Specifies whether to translate SQL statement text on the application server (AS) according to the CCSID of the job. This option applies when using DRDA to connect to an IBM i as the AS where the application requestor (AR) machine is an ASCII-based platform.	*DEFAULT	The default value is set to *NO.
	*YES	Translate ASCII SQL statement text to the CCSID of the IBM i job.
	*NO	Translate ASCII SQL statement text to the EBCDIC CCSID associated with the ASCII CCSID.
SQL_XML_DATA_CCSID Specifies the CCSID to be used for XML columns, host variables, parameter markers, and expressions, if not explicitly specified. See "SQL_XML_DATA_CCSID QAQQINI option" on page 211	*DEFAULT	The default value is set to 1208.
	*JOB	The job CCSID is used for XML columns, host variables, parameter markers, and expressions, if not explicitly specified. If the job CCSID is 65535, the default CCSID of 1208 is used.
	Integer Value	The CCSID used for XML columns, host variables, parameter markers, and expressions, if not explicitly specified. This value must be a valid single-byte or mixed EBCDIC CCSID or Unicode CCSID. The value cannot be 65535.
STAR_JOIN Note: Only modifies the environment for the Classic Query Engine. Specifies enhanced optimization for hash queries where both a hash join table and a Distinct List of values is constructed from the data. This Distinct List of values is appended to the selection against the primary table of the hash join Any EVI indexes built over these foreign key columns can be used to perform bitmap selection against the table before matching the join values. The use of this option does not guarantee that star join is chosen by the optimizer. It only allows the use of this technique if the optimizer has decided to implement the query by using a hash join.	*DEFAULT	The default value is set to *NO
	*NO	The EVI Star Join optimization support is not enabled.
	*COST	Allow query optimization to cost the usage of EVI Star Join support. The optimizer determines whether the Distinct List selection is used based on how much benefit can be derived from using that selection.
STORAGE_LIMIT Specifies a temporary storage limit for database queries. If a query is expected to use more than the specified amount of storage, the query is not allowed to run. The value specified is in megabytes.	*DEFAULT	The default value is set to *NOMAX.
	*NOMAX	Never stop a query from running because of storage concerns.
	Integer Value	The maximum amount of temporary storage in megabytes that can be used by a query. This value is checked against the estimated amount of temporary storage required to run the query as calculated by the query optimizer. If the estimated amount of temporary storage is greater than this value, the query is not started. Valid values range from 0 through 2147352578.

Table 51. Query Options Specified on QAQQINI Command (continued)

Parameter	Value	Description
SUPPRESS_INQUIRY_MESSAGES Specifies that certain inquiry messages will not be issued.	*DEFAULT	The default value is set to *NO.
	*YES	System inquiry message CPA32B2 will not be issued when altering a table.
	*NO	No system inquiry messages will be suppressed.
SYSTEM_SQL_STATEMENT_CACHE Specifies whether to disable the system-wide SQL Statement Cache for SQL queries.	*DEFAULT	The default value is set to *YES.
	*YES	Examine the system-wide SQL Statement Cache when an SQL prepare request is processed. If a matching statement exists in the cache, use the results of that prepare. This option allows the application to potentially have better performing prepares.
	*NO	Specifies that the system-wide SQL Statement Cache is not examined when processing an SQL prepare request.
SYSTIME_PERIOD_ADJ For update and delete operations involving system-period temporal tables, this option resolves conflict for a historical row when its row end value could be less than its row begin value.	*DEFAULT	The default value is set to *ERROR.
	*ERROR	An SQ20528 error will be signaled.
	*ADJUST	These three things will happen: 1. The row end value of the history row will be set to the row begin value plus a small delta of one microsecond. 2. The row begin value of the temporal table current row will also be set to the adjusted value. 3. An SQL warning SQ20528 will be signaled.
TEXT_SEARCH_DEFAULT_TIMEZONE Specifies the time zone to apply to any date or dateTime value specified in an XML text search using the CONTAINS or SCORE function. The time zone is the offset from UTC (Greenwich mean time). It is only applicable when a specific time zone is not given for the value.	*DEFAULT	Use the default as defined by database. This option is equivalent to UTC.
	sHH:MM	A time zone formatted value where • s is the sign, + or – • HH is the hour • MM is the minute The valid range for HH is 00 - 23. The valid range for MM is 00 - 59. The format is specific. All values are required, including sign. If HH or MM is less than 10, it must have a leading zero specified.
UDF_TIME_OUT Note: Only modifies the environment for the Classic Query Engine. Specifies the amount of time, in seconds, that the database waits for a User Defined Function (UDF) to finish processing.	*DEFAULT	The amount of time to wait is determined by the database. The default is 30 seconds.
	*MAX	The maximum amount of time that the database waits for the UDF to finish.
	integer value	Specify the number of seconds that the database waits for a UDF to finish. If the value given exceeds the database maximum wait time, the maximum wait time is used by the database. Minimum value is 1 and maximum value is system defined.
VARIABLE_LENGTH_OPTIMIZATION Specifies whether aggressive optimization techniques are used on variable length columns.	*DEFAULT	The default value is set to *YES.
	*YES	Enables aggressive optimization of variable-length columns, including index-only access. It also allows constant value substitution when an equal predicate is present against the columns. As a consequence, the length of the data returned for the variable-length column might not include any trailing blanks that existed in the original data. As a result, the application can receive the substituted value back instead of the original data. Function calls could operate on the substituted value instead of the original string value.
	*NO	Do not allow aggressive optimization of variable length columns.

Note: The following QAQQINI options will be ignored for SQE native query access. These options were previously honored for CQE native query access.

- LIMIT_PREDICATE_OPTIMIZATION
- STAR_JOIN
- UDF_TIME_OUT

Note: The following QAQQINI options will be honored for SQE native query access. These options were previously ignored for CQE native query access.

- DETERMINISTIC_UDF_SCOPE
- FIELDPROC_ENCODED_COMPARISON
- MATERIALIZED_QUERY_TABLE_USAGE
- MATERIALIZED_QUERY_TABLE_REFRESH_AGE
- MEMORY_POOL_PREFERENCE
- VARIABLE_LENGTH_OPTIMIZATION

SQL_XML_DATA_CCSID QAQQINI option

The SQL_XML_DATA_CCSID QAQQINI option has several settings that affect SQL processing.

The SQL_XML_DATA_CCSID QAQQINI setting is applied within SQL in the following SQL processing:

SQL Processing item	Description
Valid values for the QAQQINI option are CCSIDs allowed on an XML column.	Valid values are all EBCDIC SBCS and mixed CCSIDs, and Unicode 1208, 1200, and 13488 CCSIDs.
Does not affect the promotion of SQL data types.	Other SQL data types cannot be directly promoted to the SQL XML data type.
XMLPARSE untyped parameter markers.	The QAQQINI setting applies to untyped parameter markers passed as string-expression. The type is CLOB(2G) for SBCS, mixed, and UTF-8 values. The type is DBCLOB(1G) for Unicode 1200 and 13488.
XMLCOMMENT, XMLTEXT, XMLPI untyped parameter markers.	The QAQQINI setting applies to untyped parameter markers passed as string-expression. The type is VARCHAR(32740) for SBCS, mixed, and UTF-8 values. The type is VARGRAPHIC(16370) for Unicode 1200 and 13488.
Applies to parameter marker casts to the XML type for XMLCONCAT, and XMLDOCUMENT.	Applies to an untyped parameter marker passed as an XML-expression. Unless an explicit CCSID clause is specified, the CCSID of the parameter marker is obtained from the QAQQINI setting.
The QAQQINI setting does not affect storage and retrieval assignment rules.	The CCSID of the host variables and table columns apply.
String to column assignment on SQL INSERT and UPDATE.	An implicit or explicit XMLPARSE is required on the column assignment.
String to host variable assignment.	An implicit or explicit XMLSERIALIZE is required on the host variable assignment.
Column to column assignment.	When the target column is XML, an implicit XMLPARSE is applied if the source column is not XML. The target XML column has a defined XML CCSID. When the source column is XML, an explicit XMLSERIALIZE is required if the target column is not XML.
Host variable to column assignment.	The target column has a defined CCSID.
UNION ALL (if XML publishing functions in query).	The XML result CCSID is obtained from the QAQQINI setting.
Does not apply to SQL constants.	UX constants are defined as UTF-16. FX constants are defined as UTF-8.

Table 52. SQL_XML_DATA_CCSID setting application within SQL (continued)

SQL Processing item	Description
Result type of XML data built-in functions.	If the first operand of XMLPARSE and XMLVALIDATE is an untyped parameter marker, the CCSID is set from the QAQQINI setting, which then affects the XML result CCSID. The QAQQINI setting is used for XMLSERIALIZE for CHAR, VARCHAR, and LOB AS data-type. UTF-16 is used for GRAPHIC, DBCLOB, and NCHAR.
Result type of XML publishing functions - XMLAGG, XMLGROUP, XMLATTRIBUTES, XMLCOMMENT, XMLCONCAT, XMLDOCUMENT, XMELEMENT, XMLFOREST, XMLNAMESPACES, XMLPI, XMLROW, and XMLTEXT.	The XML result CCSID for XML publishing functions is obtained from the QAQQINI setting.
Result type of XML publishing functions in a view.	The XML result CCSID is set when the view is created.
XML data type on external procedure XML AS parameters.	The XML parameter CCSID is set when the procedure is created.
XML data type on external user-defined functions.	The XML parameter and result CCSID are set when the function is created.
CREATE TABLE XML column.	The QAQQINI setting is used for dynamic SQL. The QAQQINI setting is set in *PGM, *SRVPGM, and *SQLPKG objects when created.
MQTs containing select-statement with XML publishing functions.	The CCSID is set when the MQT is created. The CCSID is maintained for an ALTER TABLE.
ALTER TABLE ADD MATERIALIZED QUERY definition.	The QAQQINI setting is used if the select-statement contains XML publishing functions.
XML AS CLOB CCSID	The QAQQINI setting is built into *PGM and *SRVPGM objects when the program is created. The CCSID defaults to UTF-8 for CLOB when QAQQINI setting is UTF-16 or UCS2.
XML AS DBCLOB CCSID	The default for DBCLOB is always UTF-16 for XML.
SQL GET and SET DESCRIPTOR XML data type.	QAQQINI setting applied to XML data type.
SQL Global variables.	QAQQINI setting applied to global variables with the XML data type.

Query Supervisor

The Db2 for i SQL Query Engine (SQE) provides a Query Supervisor which enables real-time monitoring of resource consumption by SQL and native queries, for example the Open Query File (OPNQRYF) command. Query Supervisor threshold levels can be established for general or specific scenarios. When a threshold is met or exceeded, the query execution is interrupted, and user-supplied exit program(s) are called.

Using Query Supervisor to monitor query resource usage

The Query Supervisor enables monitoring and management of queries that reach pre-determined thresholds of resource consumption. Unlike the Predictive Query Governor, which intervenes on the basis of *estimated* resource usage *before* a query runs, the Query Supervisor reacts to *actual* resource usage *while* the query runs.

The Query Supervisor monitors any SQL queries that are run to implement user SQL statements, including native database queries that are processed by SQE. SQL statements that do not require query processing such as a simple INSERT (for example, INSERT INTO <table> VALUES(123)) or COMMIT are not monitored by the Query Supervisor. Query supervision does not occur for queries initiated by the IBM i operating system or for SQL that has been classified as specific to operating system processing.

The Query Supervisor allows a Database Engineer (DBE) to:

- Deploy real-time notification solutions when a query exceeds a specific resource threshold
- Take actions to terminate queries based on real-time query consumption of system resources
- Capture and log performance details for long-running queries

By configuring the Query Supervisor, a DBE can proactively manage excessive resource usage, monitor for unexpected workload variation, and automatically end run-away queries. The Query Supervisor provides the infrastructure for establishing and detecting thresholds. The specific action(s) taken when a threshold is reached is determined by one or more exit programs that the DBE provides.

Query Supervisor configuration and operation

Multiple thresholds can be defined across the system for various resource types and can apply to all queries or be restricted to specific users, jobs, and subsystems.

Query Supervisor thresholds are configured using the add and remove procedures: “[ADD_QUERY_THRESHOLD procedure](#)” on page 342 and “[REMOVE_QUERY_THRESHOLD procedure](#)” on page 354. The “[QUERY_SUPERVISOR view](#)” on page 352 shows the defined thresholds.

The four threshold types which can be monitored by the Query Supervisor are:

1. **CPU Time** – The total processing unit time used by the query, in seconds
2. **Elapsed Time** – The total clock time, in seconds
3. **Temporary storage** – The amount of storage, in megabytes (MB), that the query allocates
4. **Total I/O count** – The total number of I/O operations

Before a query runs, a list of applicable thresholds is passed to SQE. As the query executes, SQE monitors the resource usage and determines if a threshold has been reached. When a threshold is met or exceeded, the query execution is interrupted and any exit programs registered with the Query Supervisor Exit Point (QIBM_QQQ_QRY_SUPER) are called in sequence of their exit program registration number, from lowest to highest. The exit program is called inline within the same thread of the query that reached the threshold. As a result, the query is interrupted and paused until the exit program processing has completed.

Information passed to the exit programs includes details such as the threshold reached, the job name, the SQL statement or native query request, the client special register values, and host variable or parameter marker values. The structure passed to the exit program includes enough detail to allow the DBE to take a wide variety of actions, such as logging the information, sending a message, or retrieving detailed information about the query from the plan cache.

The exit program also has the option to indicate that the query should be terminated. If query termination is requested, no further exit programs are called, and the Query Supervisor issues a CPF5209 escape message with reason code 3. SQL statements will fail with SQLCODE -666 and SQLSTATE 57005.

If query termination is not requested, execution of the query resumes after all the registered exit programs have completed. It is possible for multiple, distinct thresholds to be reached simultaneously, in which case multiple calls to the exit programs will be made before the query resumes.

Resource usage is measured only for processing that the query engine performs while producing the query result set. It does not apply to other database or operating system processing that happens in conjunction with the operation. Consider the following SQL DELETE statement: DELETE FROM <table> WHERE <column> <= 100. Query supervision only applies to the system resources used to determine the rows selected by the WHERE predicate. The resources consumed by the deletion of rows, journal processing, and any associated index maintenance for the DELETE are not supervised.

The Query Supervisor will also supervise queries executed as part of a user-defined function (UDF) or user-defined table function (UDTF) invocation when the reference to that function is not inlined. When a query uses a function, the Query Supervisor independently supervises the resources consumed by any queries run during execution of the function. Resources consumed by the invoking query prior to the function invocation are not counted as part of the resources used by the function's queries; the resource usage counters for each query within the function start at 0. However, resources consumed by the queries within the function are added to the resource usage totals for the invoking query.

Any threshold that is applied to the function's queries and that is met while the function is executing will cause the exit program(s) to be called at that point in time. However, when a threshold that is applied to the invoking query is met while a function is running, the exit program call will be delayed until the function completes and the invoking query continues executing.

Consider a TOTAL IO COUNT threshold of 500 I/Os and a query that invokes a function that executes another query. Assume the invoking query consumes 400 I/Os and then invokes the function, whose query consumes 200 I/Os. The exit program will be called for the invoking query but only after the function completes. However, if the function's query consumes 500 I/Os, it is possible (subject to the threshold's DETECTION_FREQUENCY) that the exit program could be called both within the function execution (with 500 I/Os) and for the invoking query (with 900 I/Os) once the function completes.

In general, resource usage is checked on sub-second intervals while SQE is processing the query. As a result, there may be a small delay between when the query reaches a threshold and when the query supervisor detects this and calls the exit program. The delay is most likely to affect TOTAL IO COUNT and TEMPORARY STORAGE thresholds and may result in threshold consumption values that exceed the defined threshold value. Certain operations within the query engine, such as queries containing UDF calls as described above, can produce a more measurable delay that affects all threshold types. In all cases, however, the exit program will eventually be called and will be provided with the accurate and current resource consumption detail.

A specific Query Supervisor threshold will apply at most one time for each query execution within a thread. For example, a threshold defined for ELAPSED TIME of 5 seconds is reached only at the first 5 seconds of a query's execution and not repeatedly at further intervals of 5 seconds while the query runs.

Managing Query Supervisor activity

To make it easier to identify any Query Supervisor exit program problems, the first occurrence of an exit program failure each day will be noted with a CPD43B0 message sent to QSYSOPR.

Any misconfiguration or exit program failures are tolerated and will not affect the supervised query. The CPD43B0 message allows the DBE to easily recognize that the exit program processing is failing.

In the following figure, the exit program was registered, but the *PGM did not exist with the specified library and program name. As shown below, the CPD43B0 second level text includes the threshold name, the exit program library and name, the job that encountered the exit program problem, and the message identifier related to the exit program failure.

```

Message ID . . . . . : CPD43B0          Severity . . . . . : 80
Message type . . . . . : Diagnostic
Date sent . . . . . : 03/22/21        Time sent . . . . . : 13:04:46

Message . . . . . : An exit point program registered to exit point
QIBM_QQQ_QRY_SUPER encountered an error.
Cause . . . . . : An error was encountered while resolving to or running one
or more exit programs registered to exit point QIBM_QQQ_QRY_SUPER. The first
exit program was SUPERTERM in library SCOTTf. The current user was TIMMR.
Refer to message ID MCH3401 in the job log for job 212791/TIMMR/QDFTJOBd for
more information about the error.

```

Figure 7. CPD43B0 message in QSYSOPR highlights an exit program setup problem

Summary information about the Query Supervisor’s behavior is available in the SQE Plan Cache Properties which are accessed with the IBM i Access Client Solutions (ACS) SQL Performance Center. The properties can also be retrieved using “[DUMP_PLAN_CACHE_PROPERTIES procedure](#)” on page 360. The properties show the number of times since the last IPL that a Query Supervisor threshold has been reached along with the most recent job and time that the threshold was reached. Similar information is provided for the most recent instance of a Query Supervisor exit program that directed SQE to terminate a query. Finally, if there is a problem with the configuration or execution of an exit program, the most recent job and time of the failure is noted.

These Query Supervisor metrics are provided to give the database engineer (DBE) a basic understanding of whether thresholds are being encountered, whether queries are being terminated, and whether any exit program failures exist. The following figure illustrates the query supervision summary metrics.

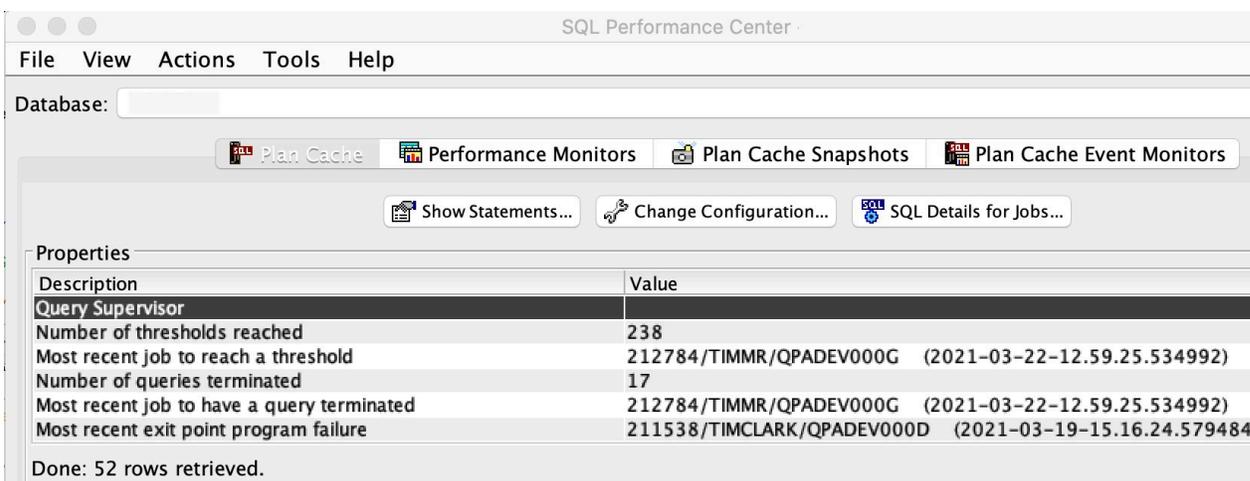

Figure 8. SQE Plan Cache properties include Query Supervisor detail

Using DETECTION_FREQUENCY to protect system resources

Because the Query Supervisor may be the first line of detection and defense against a critical performance problem, it is important to make the operation of the Query Supervisor as light-weight as possible. For this reason, each threshold has a DETECTION_FREQUENCY associated with it. This value, which defaults to 600 seconds (10 minutes), indicates how much time a given thread must wait after detecting the threshold before it may detect and signal the same threshold again. If the threshold is exceeded again in the thread before the defined interval is completed, the threshold will be ignored, and the exit program(s) will not be called.

Note that the DETECTION_FREQUENCY applies to multiple occurrences of a specific threshold within the same thread.

Consider a single threaded job, JOB1, which is executing queries. The following thresholds are defined:

- THRESHOLD_NAME => 'WARNING'
THRESHOLD_TYPE => 'ELAPSED TIME'

```
THRESHOLD_VALUE => 10
DETECTION_FREQUENCY => 600
• THRESHOLD_NAME => 'RUNAWAY'
  THRESHOLD_TYPE => 'ELAPSED TIME'
  THRESHOLD_VALUE => 120
  DETECTION_FREQUENCY => 600
```

The following example timeline shows the impact of DETECTION_FREQUENCY:

00:00:00 JOB1 begins a query that will take 20 seconds to complete.

00:00:10 Query Supervisor calls the exit program in JOB1. The exit program input structure includes the name of the threshold: WARNING.

The WARNING threshold will be silenced for any future queries in JOB1 for 600 seconds, until 00:10:10.

00:00:30 JOB1 begins another query that runs for 25 seconds.

No Query Supervisor action is taken after 10 seconds of execution since the WARNING threshold's DETECTION_FREQUENCY time interval has not been met.

00:01:05 JOB1 begins a query that runs for 215 seconds.

00:03:05 Query Supervisor calls the exit program in JOB1. The exit program input structure includes the name of the threshold: RUNAWAY.

The RUNAWAY threshold will be silenced for any future queries in JOB1 for 600 seconds, until 00:13:05.

00:09:59 JOB1 begins a query that will run for 50 seconds.

No Query Supervisor action is taken after 10 seconds of execution since the WARNING threshold's DETECTION_FREQUENCY time interval has not been met. Since the threshold value is detected while reporting is silenced, this query will not call the exit program for the WARNING threshold.

A DETECTION_FREQUENCY of 0 is permitted, in which case every instance of the threshold is processed by a call to the exit program(s).

Writing a Query Supervisor exit program

A well-written exit program is the key to making the Query Supervisor effective. Each time a threshold is reached, the exit program receives information about the threshold, the job, and the query. The exit program can take action based on this information, including the option to terminate the query.

Because exit programs run inline and interrupt the query execution, it is recommended that the exit program should be as simple as possible. When more complex operations are required of the exit program, it is suggested that they be done asynchronously by passing information to another job for processing. By doing this, the exit program can complete faster, allowing the query to resume execution.

Some possible operations an exit program can perform are:

- Send an inquiry message, suspending the thread (and query) until a reply is received
- Send the query text, host variables, and parameter markers to another job to be logged to a database table for future review and analysis
- Terminate the query

SQL and native database I/O must not be run within an exit program. However, it is possible to run SQL native database I/O in a separate job. Some useful SQL operations include:

- Send a message to QSYSOPR using the QSYS2.SEND_MESSAGE procedure. See [“SEND_MESSAGE procedure”](#) on page 865 for details.

1. The exit program can send the message using the SQL7064 message identifier which has been defined for Query Supervisor notifications. The message is in the QSYS/QSQLMSG message file and has a severity level of 80.
 2. Alternatively, the exit program can send the message with a user created message identifier.
- Dump information about the plan for the query that was running when the exit program was called. The plan identifier that is part of the exit program data can be passed on the call to this procedure. See [“DUMP_PLAN_CACHE procedure” on page 358](#) for details.
 - Use INSERT or MERGE statements to maintain a log of expensive queries.
 - Push details regarding the query supervision event to external systems management solutions.

Any messages generated by a failure to call the exit program or by an unhandled exception within the exit program will appear in the job log of the job that caused the threshold criteria to be met.

Query Supervisor example exit programs

The exit programs in this section demonstrate some of the ways an exit program can be used when a Query Supervisor threshold is reached. They are provided to enable quick and easy adoption of Query Supervisor.

The details of the exit program interface can be found here: [Query Supervisor Exit Program](#)

Exit program to send message to QSYSOPR

This Query Supervisor exit program sends an informational message to the QSYSOPR message queue.

This program sends an SQL7064 message to the QSYSOPR message queue when it is called for any threshold. Because SQL cannot be used directly in the exit program, the Run SQL (RUNSQL) CL command is submitted as a batch job.

The SQL7064 message ID is provided to be used with Query Supervisor. The caller provides a string containing the text for the message. In this example, the threshold name and the job name that reached the threshold are included in the message.

ILE RPG exit program to send message to QSYSOPR

This Query Supervisor exit program sends an informational message to the QSYSOPR message queue.

To compile this ILE RPG program, use the following command.

```
CRTBNDRPG PGM(SUPERVISOR/QS_SENDMSG) SRCFILE(SUPERVISOR/QRPGLESRC)
```

If CRTRPGMOD and CRTPGM are used to compile and build the program, be sure to include USRPRF(*OWNER) and ACTGRP(*CALLER) on the CRTPGM command.

The program can be registered as an exit program using this command:

```
ADDEXITPGM EXITPNT(QIBM_QQQ_QRY_SUPER) FORMAT(QRYS0100) PGMNBR(*LOW) PGM(SUPERVISOR/QS_SENDMSG) THDSAFE(*YES) TEXT('Query Supervisor send message to QSYSOPR')
```

By including the THREAD, USRPRF, DFACTGRP, and ACTGRP options in the source, they can be omitted on the compiler command. By using USRPRF(*OWNER), *PUBLIC does not need to be given access to the objects used by this program. The owning profile of the created program must have authority to the commands and objects used by the exit program. The program uses THREAD(*CONCURRENT) to ensure thread safety. The program will run in the activation group of the caller.

```
**free
ctl-opt main(QS_sendmsg);
ctl-opt ccsid(*char : *jobrun);
ctl-opt thread(*concurrent);
/if defined(*crtbndrpg)
  ctl-opt usrprf(*owner);
  ctl-opt dftactgrp(*no);
  ctl-opt actgrp(*caller);
/endif
```

```

C exit program to send message to QSYSOPR

This Query Supervisor exit program sends an informational message to the QSYSOPR message queue.

To compile this C program, use the following commands. By using USRPRF(*OWNER), *PUBLIC does not need to be given access to the objects used by this program. The owning profile of the created program must have authority to the commands and objects used by the exit program.

```
CRTCMOD MODULE(SUPERVISOR/SND_QS_MSG) SRCFILE(SUPERVISOR/QCSRC)
CRTPGM  PGM(SUPERVISOR/SND_QS_MSG) USRPRF(*OWNER) ACTGRP(*CALLER)
```

The program can be registered as an exit program using this command:

```
ADDEXITPGM EXITPNT(QIBM_QQQ_QRY_SUPER) FORMAT(QRYS0100) PGMNBR(*LOW) PGM(SUPERVISOR/SND_QS_MSG)
THDSAFE(*YES) TEXT('Query Supervisor send QSYSOPR message')
```

```
#include <stddef.h>
#include <string.h>

```

Exit program to end query

This Query Supervisor exit program shows how to request that the query that was running when the threshold was reached is to be stopped.

When this exit program is called, it instructs the Query Supervisor to end the query if it is called for either:

1. An ELAPSED TIME threshold when the threshold consumption has reached at least 60 minutes
2. A threshold with a name that starts with the letters TERMINATE

The threshold definitions used by the C and ILE RPG sample programs are:

```

CALL QSYS2.ADD_QUERY_THRESHOLD(THRESHOLD_NAME=>'One hour limit',
      THRESHOLD_TYPE=>'ELAPSED TIME',
      THRESHOLD_VALUE=>'3600');
CALL QSYS2.ADD_QUERY_THRESHOLD(THRESHOLD_NAME=>'TERMINATE FOR STORAGE',
      THRESHOLD_TYPE=>'TEMPORARY STORAGE',
      THRESHOLD_VALUE=>'500');

```

ILE RPG exit program to end query

This Query Supervisor exit program shows how to request that the query should be ended.

To compile this ILE RPG program, use the following command.

```

CRTBNDRPG PGM(SUPERVISOR/QS_ENDQRY) SRCFILE(SUPERVISOR/QRPGLESRC)

```

If CRTRPGMOD and CRTPGM are used to compile and build the program, be sure to include USRPRF(*OWNER) and ACTGRP(*CALLER) on the CRTPGM command.

The program can be registered as an exit program using this command:

```

ADDEXITPGM EXITPNT(QIBM_QQQ_QRY_SUPER) FORMAT(QRYS0100) PGMNBR(*LOW) PGM(SUPERVISOR/QS_ENDQRY)
THDSAFE(*YES) TEXT('End query after 60 minutes or TERMINATE threshold')

```

By including the THREAD, USRPRF, DFACTGRP, and ACTGRP options in the source, they can be omitted on the compiler command. By using USRPRF(*OWNER), *PUBLIC does not need to be given access to the objects used by this program. The owning profile of the created program must have authority to the commands and objects used by the exit program. The program uses THREAD(*CONCURRENT) to ensure thread safety. The program will run in the activation group of the caller.

```

Exit program to dump plan cache information for query

This Query Supervisor exit program dumps plan cache information about the query that reached a threshold.

The information is placed in a table named SUPERVISOR.PLAN_DUMPS. If the table does not exist, it will be created. If the table exists, the new plan cache snapshot will be appended to it. The SUPERVISOR schema must exist. See [“DUMP_PLAN_CACHE procedure”](#) on page 358 for details.

Because SQL cannot be used directly in the exit program, the Run SQL (RUNSQL) CL command is submitted as a batch job.

ILE RPG exit program to dump plan cache information for query

This Query Supervisor exit program dumps plan cache information about the query that reached a threshold.

To compile this ILE RPG program, use the following command. Before compiling, the sample source must be modified as indicated by the comment in the code. The USER parameter on the SBMJOB command must name a profile on the system that has the required authority to call QSYS2.DUMP_PLAN_CACHE(). This authority is *JOBCTL special authority or QIBM_DB_SQLADM function usage. In addition, the owner of the QS_DMPQRY program must have *USE authority to the profile specified on the USER parameter. One option is to make USER the same as the program owner.

```
CRTBNDRPG PGM(SUPERVISOR/QS_DMPQRY) SRCFILE(SUPERVISOR/QRPGLESRC)
```

If CRTRPGMOD and CRTPGM are used to compile and build the program, be sure to include USRPRF(*OWNER) and ACTGRP(*CALLER) on the CRTPGM command.

The program can be registered as an exit program using this command:

```
ADDEXITPGM EXITPNT(QIBM_QQQ_QRY_SUPER) FORMAT(QRYS0100) PGMNBR(*LOW) PGM(SUPERVISOR/QS_DMPQRY)
THDSAFE(*YES) TEXT('Query supervisor dump plan cache')
```

By including the THREAD, USRPRF, DFACTGRP, and ACTGRP options in the source, they can be omitted on the compiler command. By using USRPRF(*OWNER), *PUBLIC does not need to be given access to the objects used by this program. The owning profile of the created program must have authority to the commands and objects used by the exit program. The program uses THREAD(*CONCURRENT) to ensure thread safety. The program will run in the activation group of the caller.

```

Exit program to log information using a data queue

This Query Supervisor exit program shows how to use an asynchronous job to log information about the query that reported a threshold.

This example is more complicated. It illustrates how a lightweight exit program can offload processing to a background job for more complex consumption. By doing this, the exit program can complete quicker, causing less of a disruption to the query that caused the threshold to be reported. The example has three pieces.

1. Configuration details
2. An exit program (written in ILE RPG or C)
3. An SQL procedure that performs the actual logging

The exit program produces a JSON object encoded in UTF-16 that contains all of the threshold information sent to the exit program. It sends this JSON object to a data queue named SUPERVISOR/SUPER_DQ. An SQL procedure running in a separate job consumes JSON objects from the data queue. In this example, the procedure logs the entry to a log table.

Setup configuration

There are several objects that need to be defined for this data queue processing solution.

The following table is used to log the Query Supervisor data received from the SEND_JSON exit program. It is populated by the process_QS_data_queue() procedure defined later.

```

create schema SQE_QUERY_SUPERVISOR for schema SUPERVISOR ;

create table SQE_QUERY_SUPERVISOR.SUPERVISOR_LOG for system name SUPERLOG (
  THRESHOLD_TIMESTAMP for column WHENHIT          timestamp,
  JOB_NAME              varchar(10)              default null,
  JOB_USER              varchar(10)              default null,
  JOB_NUMBER            for column JOBNUM          varchar(6)        default null,
  SUBSYSTEM             varchar(10)              default null,
  USER_NAME             varchar(10)              default null,
  THRESHOLD_NAME        for column THRESHNAME      varchar(30)       ccsid 1208 default null,
  THRESHOLD_TYPE        for column THRESHTYPE      varchar(30)       ccsid 1208 default null,
  THRESHOLD_CONSUMPTION_VALUE for column THRESHVAL bigint         default null,
  OPERATION_TYPE        for column OP              smallint         default null,
  SQL_STATEMENT_TEXT    for column STMTTEXT        varchar(10000)    ccsid 1208 default null,
  HOST_VARIABLE_LIST    for column HVLIST         varchar(10000)    ccsid 1208 default null,
  CLIENT_ACCTNG          for column "ACCTNG"       varchar(255)      ccsid 1208 default null,
  CLIENT_APPLNAME        for column "APPLNAME"     varchar(255)      ccsid 1208 default null,
  CLIENT_PROGRAMID      for column "PROGRAMID"     varchar(255)      ccsid 1208 default null,

```

CLIENT_USERID	for column "USERID"	varchar(255)	ccsid 1208 default null,
CLIENT_WRKSTNNAME	for column "WRKSTNNAME"	varchar(255)	ccsid 1208 default null,
QUERY_IDENTIFIER	for column QRO_HASH	varchar(8)	ccsid 1208 default null,
QUERY_PLAN_IDENTIFIER	for column plan_id	decimal(20,0)	default null);

The following data queue is the communication mechanism used by the exit program that got control because of a Query Supervisor threshold having been met or exceeded. The detail passed in the data queue is a JSON document where each key name is a piece of data passed to the Query Supervisor exit program.

```
c1: CRTDTAQ DTAQ(SUPERVISOR/SUPER_DQ) MAXLEN(45000) FORCE(*YES) SIZE(*MAX2GB 1000)
  AUTORCL(*YES) TEXT('Query Supervisor Threshold Processor');
```

Once the programs are in place, a job must be started to run the asynchronous SQL procedure. It will sit and wait for data queue entries to process.

This command can be added to the QSTRUP processing to allow it to be automatically restarted upon system IPL

```
c1: SBMJOB CMD(RUNSQL SQL('call supervisor.process_QS_data_queue()') COMMIT(*NONE))
  JOB(SUPERMGR)
  INLASPGRP(*NONE) LOG(4 00 *SECLVL) JOBMMSGQFL(*PRTWRAP) CCSID(37);
```

ILE RPG exit program to log information using a data queue

This Query Supervisor exit program shows how to use an asynchronous job to log information about the query that reported a threshold.

To compile this ILE RPG program, use the following command.

```
CRTBNDRPG PGM(SUPERVISOR/QS_DTAQ) SRCFILE(SUPERVISOR/QRPGLESRC)
```

If CRTRPGMOD and CRTPGM are used to compile and build the program, be sure to include USRPRF(*OWNER) and ACTGRP(*CALLER) on the CRTPGM command.

The program can be registered as an exit program using this command:

```
ADDEXITPGM EXITPNT(QIBM_QQQ_QRY_SUPER) FORMAT(QRYS0100) PGMNBR(*LOW) PGM(SUPERVISOR/QS_DTAQ)
  THDSAFE(*YES) TEXT('Query Supervisor logging with data queue')
```

By including the THREAD, USRPRF, DFACTGRP, and ACTGRP options in the source, they can be omitted on the compiler command. By using USRPRF(*OWNER), *PUBLIC does not need to be given access to the objects used by this program. The owning profile of the created program must have authority to the commands and objects used by the exit program. The program uses THREAD(*CONCURRENT) to ensure thread safety. The program will run in the activation group of the caller.

```
**free
ctl-opt main(QS_dtaq);
ctl-opt ccsid(*char : *jobrun);
ctl-opt thread(*concurrent);
/ifdef(*crtbnrdpg)
  ctl-opt usrprf(*owner);
  ctl-opt dftactgrp(*no);
  ctl-opt actgrp(*caller);
/endif

C exit program to log information using a data queue

This Query Supervisor exit program shows how to use an asynchronous job to log information about the query that reported a threshold.

This is the registered exit program. It sends the exit program input data to a data queue named SUPERVISOR/SUPER_DQ for further processing by an SQL procedure. The data is sent as a JSON object, encoded as UTF-16 data.

To compile this C program, use the following commands. By using USRPRF(*OWNER), *PUBLIC does not need to be given access to the objects used by this program. The owning profile of the created program must have authority to the commands and objects used by the exit program.

```

CRTCMOD MODULE(SUPERVISOR/SEND_JSON) SRCFILE(SUPERVISOR/QCSRC) LOCALETYPE(*LOCALEUCS2)

SQL procedure used to log information using a data queue

This SQL procedure, running in an asynchronous job, logs information about the query that reported a threshold.

The procedure receives entries from the SUPERVISOR/SUPER_DQ data queue. Each entry represents an instance of a Query Supervisor threshold having been met or exceeded. The Query Supervisor exit program that got control put the entry on the data queue so it could be handled asynchronously by this SQL procedure.

Using MONITOR = *SYSTEM, ensures that the procedure's activity is not supervised by Query Supervisor. This prevents possible recursion if the procedure itself were to reach a Query Supervisor threshold.

```

create or replace procedure supervisor.process_QS_data_queue ()
modifies sql data

```

```

Setting resource limits with the Predictive Query Governor

The Db2 for i Predictive Query Governor can stop the initiation of a query if the estimated run time (elapsed execution time) or estimated temporary storage for the query is excessive. The governor acts *before* a query is run instead of while a query is run. The governor can be used in any interactive or batch job on the system. It can be used with all Db2 for i query interfaces and is not limited to use with SQL queries.

The ability of the governor to predict and stop queries before they are started is important because:

- Operating a long-running query and abnormally ending the query before obtaining any results wastes system resources.
- Some CQE operations within a query cannot be interrupted by the **End Request (ENDRQS)** CL command. The creation of a temporary index or a query using a column function without a GROUP BY clause are two examples of these types of queries. It is important to not start these operations if they take longer than the user wants to wait.

The governor in Db2 for i is based on two measurements:

- The estimated runtime for a query.
- The estimated temporary storage consumption for a query.

If the query estimated runtime or temporary storage usage exceed the user-defined limits, the initiation of the query can be stopped.

To define a time limit (in seconds) for the governor to use, do one of the following:

- Use the Query Time Limit (QRYTIMLMT) parameter on the **Change Query Attributes (CHGQRYA)** CL command. The command language used is the first place where the optimizer attempts to find the time limit.
- Set the Query Time Limit option in the query options file. The query options file is the second place where the query optimizer attempts to find the time limit.
- Set the QQRYTIMLMT system value. Allow each job to use the value *SYSVAL on the **Change Query Attributes (CHGQRYA)** CL command, and set the query options file to *DEFAULT. The system value is the third place where the query optimizer attempts to find the time limit.

To define a temporary storage limit (in megabytes) for the governor to use, do the following:

- Use the Query Storage Limit (QRYSTGLMT) parameter on the **Change Query Attributes (CHGQRYA)** CL command. The command language used is the first place where the query optimizer attempts to find the limit.

- Set the Query Storage Limit option STORAGE_LIMIT in the query options file. The query options file is the second place where the query optimizer attempts to find the time limit.

The time and temporary storage values generated by the optimizer are *only* estimates. The actual query runtime might be more or less than the estimate. In certain cases when the optimizer does not have full information about the data being queried, the estimate could vary considerably from the actual resource used. In those cases, you might need to artificially adjust your limits to correspond to an inaccurate estimate.

When setting the time limit for the entire system, set it to the maximum allowable time that any query must be allowed to run. By setting the limit too low you run the risk of preventing some queries from completing and thus preventing the application from successfully finishing. There are many functions that use the query component to internally perform query requests. These requests are also compared to the user-defined time limit.

You can check the inquiry message CPA4259 for the predicted runtime and storage. If the query is canceled, debug messages are still written to the job log.

You can also add the Query Governor Exit Program that is called when estimated runtime and temporary storage limits have exceeded the specified limits.

[Query Governor Exit Program](#)

[End Request \(ENDRQS\) command](#)

[Change Query Attributes \(CHGQRYA\) command](#)

Using the Query Governor

The resource governor works with the query optimizer.

When a user issues a request to the system to run a query, the following occurs:

1. The query access plan is created by the optimizer.

As part of the evaluation, the optimizer predicts or estimates the runtime for the query. This estimate helps determine the best way to access and retrieve the data for the query. In addition, as part of the estimating process, the optimizer also computes the estimated temporary storage usage for the query.

2. The estimated runtime and estimated temporary storage are compared against the user-defined query limit currently in effect for the job or user session.
3. If the estimates for the query are less than or equal to the specified limits, the query governor lets the query run without interruption. No message is sent to the user.
4. If the query limit is exceeded, inquiry message CPA4259 is sent to the user. The message states the estimates as well as the specified limits. Realize that only one limit needs to be exceeded; it is possible that you see that only one limit was exceeded. Also, if no limit was explicitly specified by the user, a large integer value is shown for that limit.

Note: A default reply can be established for this message so that the user does not have the option to reply. The query request is *always* ended.

5. If a default message reply is not used, the user chooses to do one of the following:

- End the query request before it is run.
- Continue and run the query even though the estimated value exceeds the associated governor limit.

Setting the resource limits for jobs other than the current job

You can set either or both resource limits for a job other than the current job. You set these limits by using the JOB parameter on the **Change Query Attributes (CHGQRYA)** command. Specify either a query options file library to search (QRYOPLIB) or a specific QRYTIMLMT, or QRYSTGLMT, or both for that job.

Using the resource limits to balance system resources

After the source job runs the **Change Query Attributes (CHGQRYA)** command, effects of the governor on the target job are not dependent upon the source job. The query resource limits remain in

effect for the duration of the job or user session, or until a resource limit is changed by a **Change Query Attributes (CHGQRYA)** command.

Under program control, a user might be given different limits depending on the application function performed, time of day, or system resources available. These limits provide a significant amount of flexibility when trying to balance system resources with temporary query requirements.

Cancel a query with the Query Governor

When a query is expected to take more resources than the set limit, the governor issues inquiry message CPA4259.

You can respond to the message in one of the following ways:

- Enter a C to cancel the query. Escape message CPF427F is issued to the SQL runtime code. SQL returns SQLCODE -666.
- Enter an I to ignore the exceeded limit and let the query run to completion.

Control the default reply to the query governor inquiry message

The system administrator can control whether the interactive user has the option of ignoring the database query inquiry message by using the **Change Job (CHGJOB)** CL command.

Changes made include the following:

- If a value of *DFT is specified for the INQMSGRPY parameter of the **Change Job (CHGJOB)** CL command, the interactive user does not see the inquiry messages. The query is canceled immediately.
- If a value of *RQD is specified for the INQMSGRPY parameter of the **Change Job (CHGJOB)** CL command, the interactive user sees the inquiry. The user must reply to the inquiry.
- If a value of *SYSRPLY is specified for the INQMSGRPY parameter of the **Change Job (CHGJOB)** CL command, a system reply list is used to determine whether the interactive user sees the inquiry and whether a reply is necessary. The system reply list entries can be used to customize different default replies based on user profile name, user id, or process names. The fully qualified job name is available in the message data for inquiry message CPA4259. This algorithm allows the keyword CMPDTA to be used to select the system reply list entry that applies to the process or user profile. The user profile name is 10 characters long and starts at position 51. The process name is 10 character long and starts at position 27.
- The following example adds a reply list element that causes the default reply of C to cancel requests for jobs whose user profile is 'QPGMR'.

```
ADDRPYLE SEQNBR(56) MSGID(CPA4259) CMPDTA(QPGMR 51) RPY(C)
```

The following example adds a reply list element that causes the default reply of C to cancel requests for jobs whose process name is 'QPADEV0011'.

```
ADDRPYLE SEQNBR(57) MSGID(CPA4259) CMPDTA(QPADEV0011 27) RPY(C)
```

[Change Job \(CHGJOB\) command](#)

Testing performance with the query governor

You can use the query governor to test the performance of your queries.

To test the performance of a query with the query governor, do the following:

1. Set the query time limit to zero (QRYTIMLMT(0)) using the **Change Query Attributes (CHGQRYA)** command or in the INI file. This forces an inquiry message from the governor stating that the estimated time to run the query exceeds the query time limit.
2. Prompt for message help on the inquiry message and find the same information that you can find by running the **Print SQL Information (PRTSQLINF)** command.

The query governor lets you optimize performance without having to run through several iterations of the query.

Additionally, if the query is canceled, the query optimizer evaluates the access plan and sends the optimizer debug messages to the job log. This process occurs even if the job is *not* in debug mode. You can then review the optimizer tuning messages in the job log to see if additional tuning is needed to obtain optimal query performance.

This method allows you to try several permutations of the query with different attributes, indexes, and syntax, or both. You can then determine what performs better through the optimizer without actually running the query to completion. This process saves on system resources because the actual query of the data is never done. If the tables to be queried contain many rows, this method represents a significant savings in system resources.

Be careful when you use this technique for performance testing, because all query requests are stopped before they are run. This caution is especially important for a CQE query that cannot be implemented in a single query step. For these types of queries, separate multiple query requests are issued, and then their results are accumulated before returning the final results. Stopping the query in one of these intermediate steps gives you only the performance information for that intermediate step, and not for the entire query.

[Print SQL Information \(PRTSQLINF\) command](#)

[Change Query Attributes \(CHGQRYA\) command](#)

Examples of setting query time limits

You can set the query time limit for the current job or user session using query options file QAQQINI. Specify the QRYOPLIB parameter on the **Change Query Attributes (CHGQRYA)** command. Use a user library where the QAQQINI file exists with the parameter set to QUERY_TIME_LIMIT, and the value set to a valid query time limit.

To set the query time limit for 45 seconds you can use the following **Change Query Attributes (CHGQRYA)** command:

```
CHGQRYA JOB(*) QRYTIMLMT(45)
```

This command sets the query time limit at 45 seconds. If the user runs a query with an estimated runtime equal to or less than 45 seconds, the query runs without interruption. The time limit remains in effect for the duration of the job or user session, or until the time limit is changed by the **Change Query Attributes (CHGQRYA)** command.

Assume that the query optimizer estimated the runtime for a query as 135 seconds. A message is sent to the user that stated that the estimated runtime of 135 seconds exceeds the query time limit of 45 seconds.

To set or change the query time limit for a job other than your current job, the **Change Query Attributes (CHGQRYA)** command is run using the JOB parameter. To set the query time limit to 45 seconds for job 123456/USERNAME/JOBNAME use the following **Change Query Attributes (CHGQRYA)** command:

```
CHGQRYA JOB(123456/USERNAME/JOBNAME) QRYTIMLMT(45)
```

This command sets the query time limit at 45 seconds for job 123456/USERNAME/JOBNAME. If job 123456/USERNAME/JOBNAME tries to run a query with an estimated runtime equal to or less than 45 seconds the query runs without interruption. If the estimated runtime for the query is greater than 45 seconds, for example, 50 seconds, a message is sent to the user. The message states that the estimated runtime of 50 seconds exceeds the query time limit of 45 seconds. The time limit remains in effect for the duration of job 123456/USERNAME/JOBNAME, or until the time limit for job 123456/USERNAME/JOBNAME is changed by the **Change Query Attributes (CHGQRYA)** command.

To set or change the query time limit to the QQRYTIMLMT system value, use the following **Change Query Attributes (CHGQRYA)** command:

```
CHGQRYA QRYTIMLMT(*SYSVAL)
```

The QQRYTIMLMT system value is used for duration of the job or user session, or until the time limit is changed by the **Change Query Attributes (CHGQRYA)** command. This use is the default behavior for the **Change Query Attributes (CHGQRYA)** command.

Note: The query time limit can also be set in the INI file, or by using the **Change System Value (CHGSYSVAL)** command.

Related information

[Change Query Attributes \(CHGQRYA\) command](#)

[Change System Value \(CHGSYSVAL\) command](#)

Test temporary storage usage with the query governor

The predictive storage governor specifies a temporary storage limit for database queries. You can use the query governor to test if a query uses any temporary object, such as a hash table, sort, or temporary index.

To test for usage of a temporary object, do the following:

- Set the query storage limit to zero (QRYSTGLMT(0)) using the **Change Query Attributes (CHGQRYA)** command or in the INI file. This forces an inquiry message from the governor anytime a temporary object is used for the query. The message is sent regardless of the estimated size of the temporary object.
- Prompt for message help on the inquiry message and find the same information that you can find by running the **Print SQL Information (PRTSQLINF)** command. This command allows you to see what temporary objects were involved.

Related information

[Print SQL Information \(PRTSQLINF\) command](#)

[Change Query Attributes \(CHGQRYA\) command](#)

Examples of setting query temporary storage limits

The temporary storage limit can be specified either in the QAQQINI file or on the **Change Query Attributes (CHGQRYA)** command.

You can set the query temporary storage limit for a job using query options file QAQQINI. Specify the QRYOPTLIB parameter on the **Change Query Attributes (CHGQRYA)** command. Use a user library where the QAQQINI file exists with a valid value set for parameter STORAGE_LIMIT.

To set the query temporary storage limit on the **Change Query Attributes (CHGQRYA)** command itself, specify a valid value for the QRYSTGLMT parameter.

If a value is specified both on the **Change Query Attributes (CHGQRYA)** command QRYSTGLMT parameter and in the QAQQINI file specified on the QRYOPTLIB parameter, the QRYSTGLMT value is used.

To set the temporary storage limit for 100 MB in the current job, you can use the following **Change Query Attributes (CHGQRYA)** command:

```
CHGQRYA JOB(*) QRYSTGLMT(100)
```

If the user runs any query with an estimated temporary storage consumption equal to or less than 100 MB, the query runs without interruption. If the estimate is more than 100 MB, the CPA4259 inquiry message is sent by the database. To set or change the query time limit for a job other than your current

job, the CHGQRYA command is run using the JOB parameter. To set the same limit for job 123456/USERNAME/JOBNAME use the following CHGQRYA command:

```
CHGQRYA JOB(123456/USERNAME/JOBNAME) QRYSTGLMT(100)
```

This sets the query temporary storage limit to 100 MB for job 123456/USERNAME/JOBNAME.

Note: Unlike the query time limit, there is no system value for temporary storage limit. The default behavior is to let any queries run regardless of their temporary storage usage. The query temporary storage limit can be specified either in the INI file or on the **Change Query Attributes (CHGQRYA)** command.

[Change Query Attributes \(CHGQRYA\) command](#)

Controlling parallel processing for queries

There are two types of parallel processing available. The first is a parallel I/O that is available at no charge. The second is Db2 Symmetric Multiprocessing, a feature that you can purchase. You can turn parallel processing on and off.

Even if parallelism is enabled for a system or job, the individual queries that run in a job might not actually use a parallel method. This decision might be because of functional restrictions, or the optimizer might choose a non-parallel method because it runs faster.

Queries processed with parallel access methods aggressively use main storage, CPU, and disk resources. The number of queries that use parallel processing must be limited and controlled. Activating parallel processing system wide with the QQRYDEGREE system value is not recommended.

The parallel processing level can be controlled at a system or job level. For a job, either the CURRENT DEGREE special register or the PARALLEL_DEGREE QAQQINI option can be used.

Controlling system-wide parallel processing for queries

You can use the QQRYDEGREE system value to control parallel processing for a system.

The current value of the system value can be displayed or modified using the following CL commands:

- **WRKSYSVAL - Work with System Value**
- **CHGSYSVAL - Change System Value**
- **DSPSYSVAL - Display System Value**
- **RTVSYSVAL - Retrieve System Value**

The special values for QQRYDEGREE control whether parallel processing is allowed by default for all jobs on the system. The possible values are:

- *NONE** No parallel processing is allowed for database query processing.
- *IO** I/O parallel processing is allowed for queries.
- *OPTIMIZE** The query optimizer can choose to use any number of tasks for either I/O or SMP parallel processing to process the queries. SMP parallel processing is used only if the Db2 Symmetric Multiprocessing feature is installed. The query optimizer chooses to use parallel processing to minimize elapsed time based on the job share of the memory in the pool.
- *MAX** The query optimizer can choose to use either I/O or SMP parallel processing to process the query. SMP parallel processing can be used only if the Db2 Symmetric Multiprocessing feature is installed. The choices made by the query optimizer are like the choices made for parameter value *OPTIMIZE. The exception is that the optimizer assumes that all active memory in the pool can be used to process the query.

The default QQRYDEGREE system value is *NONE. You must change the value if you want parallel query processing as the default for jobs run on the system.

Changing this system value affects all jobs that is run or are currently running on the system whose DEGREE query attribute is *SYSVAL. However, queries that have already been started or queries using reusable ODPs are not affected.

Controlling job level parallel processing for queries

You can also control query parallel processing at the job level using the DEGREE parameter of the **Change Query Attributes (CHGQRYA)** command or in the QAQQINI file. You can also use the SET_CURRENT_DEGREE SQL statement.

Using the Change Query Attributes (CHGQRYA) command

The parallel processing option allowed and, optionally, the number of tasks that can be used when running database queries in the job can be specified. You can prompt on the **Change Query Attributes (CHGQRYA)** command in an interactive job to display the current values of the DEGREE query attribute.

Changing the DEGREE query attribute does not affect queries that have already been started or queries using reusable ODPs.

The parameter values for the DEGREE keyword are:

- | | |
|--|--|
| *SAME | The parallel degree query attribute does not change. |
| *NONE | No parallel processing is allowed for database query processing. |
| *IO | The CQE optimizer can use any number of tasks when it chooses to use I/O parallel processing for queries. SMP parallel processing is not allowed. The SQE optimizer considers I/O parallelism with or without this setting. |
| *OPTIMIZE | <p>The query optimizer can choose to use any number of tasks for either I/O or SMP parallel processing to process the query. SMP parallel processing can be used only if the Db2 Symmetric Multiprocessing feature is installed. Use of parallel processing and the number of tasks used is determined by:</p> <ul style="list-style-type: none">• the number of system processors available• the job share of active memory available in the pool• whether the expected elapsed time is limited by CPU processing or I/O resources <p>The query optimizer chooses an implementation that minimizes elapsed time based on the job share of the memory in the pool.</p> |
| *MAX | The query optimizer can choose to use either I/O or SMP parallel processing to process the query. SMP parallel processing can be used only if the Db2 Symmetric Multiprocessing feature is installed. The choices made by the query optimizer are like the choices made for parameter value *OPTIMIZE. The exception is that the optimizer assumes that all active memory in the pool can be used to process the query. |
| *NBRTASKS
<i>number-of-tasks</i> | <p>Specifies the number of tasks to be used when the query optimizer chooses to use SMP parallel processing to process a query. I/O parallelism is also allowed. SMP parallel processing can be used only if the Db2 Symmetric Multiprocessing feature is installed.</p> <p>Using a number of tasks less than the number of system processors available restricts the number of processors used simultaneously for running a query. A larger number of tasks ensures that the query is allowed to use all the processors available on the system to run the query. Too many tasks can degrade performance because of the over commitment of active memory and the overhead cost of managing all the tasks.</p> |
| *SYSVAL | Specifies that the processing option used is set to the current value of the QQRYDEGREE system value. |

The initial value of the DEGREE attribute for a job is *SYSVAL.

Using the SET CURRENT DEGREE SQL statement

You can use the SET CURRENT DEGREE SQL statement to change the value of the CURRENT_DEGREE special register. The possible values for the CURRENT_DEGREE special register are:

- 1** No parallel processing is allowed.
- 2 through 32767** Specifies the degree of parallelism that is used.
- ANY** Specifies that the database manager can choose to use any number of tasks for either I/O or SMP parallel processing. Use of parallel processing and the number of tasks used is determined by:
- the number of system processors available
 - the job share of active memory available in the pool
 - whether the expected elapsed time is limited by CPU processing or I/O resources
- The database manager chooses an implementation that minimizes elapsed time based on the job share of the memory in the pool.
- NONE** No parallel processing is allowed.
- MAX** The database manager can choose to use any number of tasks for either I/O or SMP parallel processing. MAX is like ANY except the database manager assumes that all active memory in the pool can be used.
- IO** The CQE optimizer can use any number of tasks when it chooses to use I/O parallel processing for queries. SMP parallel processing is not allowed. The SQE optimizer considers I/O parallelism with or without this setting.

The value can be changed by invoking the SET CURRENT DEGREE statement.

The initial value of CURRENT DEGREE comes from the CHGQRYA CL command, PARALLEL_DEGREE parameter in the current query options file (QAQQINI), or the QQRYDEGREE system value.

[DB2 Symmetric Multiprocessing](#)

Collecting statistics with the statistics manager

The collection of statistics is handled by a separate component called the statistics manager. Statistical information can be used by the query optimizer to determine the best access plan for a query. Since the query optimizer bases its choice of access plan on the statistical information found in the table, it is important that this information is current.

On many platforms, statistics collection is a manual process that is the responsibility of the database administrator. With IBM i products, the database statistics collection process is handled automatically, and only rarely is it necessary to update statistics manually.

The statistics manager does not actually run or optimize the query. It controls the access to the metadata and other information that is required to optimize the query. It uses this information to answer questions posed by the query optimizer. The answers can either be derived from table header information, from existing indexes, or from single-column statistics.

The use of indexes for estimates includes Maintained Temporary Indexes (MTIs), which the statistics manager is able to use in the same way as standard permanent indexes. When deciding which index to use for an estimate, the statistics engine will prioritize permanent indexes over equivalent MTIs.

The statistics manager must always provide an answer to the questions from the Optimizer. It uses the best method available to provide the answers. For example, it could use a single-column statistic or perform a key range estimate over an index. Along with the answer, the statistics manager returns

a confidence level to the optimizer that the optimizer can use to provide greater latitude for sizing algorithms. If the statistics manager provides a low confidence in the number of groups estimated for a grouping request, the optimizer can increase the size of the temporary hash table allocated.

Related concepts

Statistics manager

In CQE, the retrieval of statistics is a function of the Optimizer. When the Optimizer needs to know information about a table, it looks at the table description to retrieve the row count and table size. If an index is available, the Optimizer might extract information about the data in the table. In SQE, the collection and management of statistics is handled by a separate component called the statistics manager. The statistics manager leverages all the same statistical sources as CQE, but adds more sources and capabilities.

Automatic statistics collection

When the statistics manager prepares its responses to the optimizer, it tracks the responses that were generated using default filter factors. Default filter factors are used when column statistics or indexes are not available. The statistics manager uses this information to automatically generate a statistic collection request for the columns. This request occurs while the access plan is written to the plan cache. If system resources allow, statistics collections occur in real time for direct use by the current query, avoiding a default answer to the optimizer.

Otherwise, as system resources become available, the requested column statistics are collected in the background. The next time the query is executed, the missing column statistics are available to the statistics manager. This process allows the statistics manager to provide more accurate information to the optimizer at that time. More statistics make it easier for the optimizer to generate a better performing access plan.

If a query is canceled before or during execution, the requests for column statistics are still processed. These requests occur if the execution reaches the point where the generated access plan is written to the Plan Cache.

To minimize the number of passes through a table during statistics collection, the statistics manager groups multiple requests for the same table. For example, two queries are executed against table T1. The first query has selection criteria on column C1 and the second over column C2. If no statistics are available for the table, the statistics manager identifies both of these columns as good candidates for column statistics. When the statistics manager reviews requests, it looks for multiple requests for the same table and groups them into one request. This grouping allows both column statistics to be created with only one pass through table T1.

One thing to note is that column statistics are usually automatically created when the statistics manager must answer questions from the optimizer using default filter factors. However, when an index is available that might be used to generate the answer, then column statistics are not automatically generated. In this scenario, there might be cases where optimization time benefits from column statistics. Using column statistics to answer questions from the optimizer is more efficient than using the index data. So if query performance seems extended, you might want to verify that there are indexes over the relevant columns in your query. If so, try manually generating column statistics for these columns.

As stated before, statistics collection occurs as system resources become available. If you have a low priority job permanently active on your system that is supposed to use all spare CPU cycles for processing, your statistics collection is never active.

Automatic statistics refresh

Column statistics are not maintained when the underlying table data changes. The statistics manager determines if columns statistics are still valid or if they no longer represent the column accurately (stale).

This validation is done each time one of the following occurs:

- A full open occurs for a query where column statistics were used to create the access plan
- A new plan is added to the plan cache, either because a new query was optimized or because an existing plan was reoptimized.

- A significant number of inserts / updates / deletes have been made to a table. The actual number of changes before checking the column statistics staleness depends on several factors, including the number of entries in the table.

To validate the statistics, the statistics manager checks to see if any of the following apply:

- Number of rows in the table has changed by more than 15% of the total table row count
- Number of rows changed in the table is more than 15% of the total table row count

If the statistics are stale, the statistics manager still uses them to answer the questions from the optimizer. However, the statistics manager marks the statistics as stale in the plan cache and generates a request to refresh them.

Viewing statistics requests

You can view the current statistics requests by using System i Navigator or by using Statistics APIs.

To view requests in System i Navigator, right-click **Database** and select **Statistic Requests**. This window shows all user requested statistics collections that are pending or active. The view also shows all system requested statistics collections that are being considered, are active, or have failed. You can change the status of the request, order the request to process immediately, or cancel the request.

[Statistics manager APIs](#)

You can use APIs to implement the statistics function of System i Navigator.

Indexes and column statistics

While performing similar functions, indexes and column statistics are different.

If you are trying to decide whether to use statistics or indexes to provide information to the statistics manager, keep in mind the following differences.

One major difference between indexes and column statistics is that indexes are permanent objects that are updated when changes to the underlying table occur. Column statistics are not updated. If your data is constantly changing, the statistics manager might need to rely on stale column statistics. However, maintaining an index after each table change might use more system resources than refreshing stale column statistics after a group of changes have occurred.

Another difference is the effect that the existence of new indexes or column statistics has on the optimizer. When new indexes become available, the optimizer considers them for implementation. If they are candidates, the optimizer reoptimizes the query and tries to find a better implementation. However, this reoptimization is not true for column statistics. When new or refreshed column statistics are available, the statistics manager interrogates immediately. Reoptimization occurs only if the answers are different from the ones that were given before these refreshed statistics. It is possible to use statistics that are refreshed without causing a reoptimization of an access plan.

Also, column statistics and EVIs can be used to recognize data skew in joins, which standard radix indexes are not able to do. So, when join columns contain certain values that occur far more frequently than other values, column statistics or EVIs may be used to help provide better estimates.

Requests for selectivity information from indexes are obtained in the form of key range estimate operations. In order to get accurate information for a given predicate, the statistics manager may need to evaluate a significant portion of an index's data. This evaluation can take a long time for large indexes as index pages are loaded into active memory and then analyzed. The optimizer must wait for each estimate operation to complete before continuing with query optimization. Each query that is optimized will generally require multiple key range estimates. As a result, the time spent obtaining these estimates can significantly impact the overall time required to optimize a query.

In order to shorten the time required to optimize a query, the statistics manager uses several different strategies when faced with the need to perform a key range estimate. One strategy is to avoid getting the estimate when other information (e.g. file size or selectivity information from column statistics) indicate that the information returned by the estimate would not be worth the time required to obtain it. A second

strategy is to cache prior estimates so that subsequent requests for the same key range can be returned quickly. Each index has a cache associated with it. Estimates are stored in this cache until the cache fills or becomes stale relative to the data in the index or until an IPL occurs. A third strategy, introduced in IBM i 7.3, is to quickly return a less accurate initial estimate while submitting a background request for a more accurate full estimate. With this strategy, the statistics manager adds a timeout value to each key range estimate operation. If the operation does not complete in the time indicated by the timeout value, the operation is interrupted. The statistics manager then looks at some other fast estimate sources (including similar ranges from the cache and a shallower evaluation of the index) and returns the best answer obtained thus far. This allows the query to resume optimizing with a reasonable estimate but without waiting for the full estimate to complete. In the meantime, the QDBFSTCCOL system job will take up the request to process the full key range estimate and will place an updated (and more accurate) final result in the estimate cache when it is ready. Once the full estimate is complete and in the cache, any query which used the initial estimate will have its plan invalidated and re-optimized on the next execution.

The amount of time that the statistics manager waits for a key range estimate to complete can be configured in the QAQQINI query options file with option KEY_RANGE_ESTIMATE_TIMEOUT. This control should be seen as a way to influence the optimization time and not as a hard limit. Although KEY_RANGE_ESTIMATE_TIMEOUT limits the amount of time that the optimizer may take for any individual estimate operation, it does not guarantee an upper bound on the overall optimization time. This is because the optimizer may request multiple key range estimates, each of which receives the full timeout duration.

When trying to determine the selectivity of predicates, the statistics manager considers column statistics and indexes as resources for its answers in the following order with some caveats and exceptions:

1. Try to recognize if an index-based estimate would be very long running, and if so circumvent the index estimate and use column statistics instead
2. Try to use a multi-column keyed index when ANDed or ORed predicates reference multiple columns
3. If there is no perfect index that contains all the columns in the predicates, it tries to find a combination of indexes that can be used.
4. For single column questions, it uses available column statistics
5. If the answer derived from the column statistics shows a selectivity of less than 2%, indexes are used to verify this answer

Accessing column statistics to answer questions is faster than trying to obtain these answers from indexes.

Column statistics can only be used by SQE. For CQE, all statistics are retrieved from indexes.

Finally, column statistics can be used only for query optimization. They cannot be used for the actual implementation of a query, whereas indexes can be used for both.

Monitoring background statistics collection

The system value QDBFSTCCOL controls who is allowed to create statistics in the background.

The following list provides the possible values:

- *ALL** Allows all statistics to be collected in the background. *ALL is the default setting.
- *NONE** Restricts everyone from creating statistics in the background. *NONE does not prevent immediate user-requested statistics from being collected, however.
- *USER** Allows only user-requested statistics to be collected in the background.
- *SYSTEM** Allows only system-requested statistics to be collected in the background.

When you switch the system value to something other than *ALL or *SYSTEM, the statistics manager continues to place statistics requests in the plan cache. When the system value is switched back to *ALL, for example, background processing analyzes the entire plan cache and looks for any existing column statistics requests. This background task also identifies column statistics that have been used by a plan in

the plan cache. The task determines if these column statistics have become stale. Requests for the new column statistics as well as requests for refresh of the stale columns statistics are then executed.

All background statistic collections initiated by the system or submitted by a user are performed by the system job QDBFSTCCOL. User-initiated immediate requests are run within the user job. This job uses multiple threads to create the statistics. The number of threads is determined by the number of processors that the system has. Each thread is then associated with a request queue.

There are four types of request queues based on who submitted the request and how long the collection is estimated to take. The default priority assigned to each thread can determine to which queue the thread belongs:

- Priority 90 — short user requests
- Priority 93 — long user requests
- Priority 96 — short system requests
- Priority 99 — long system requests

Background statistics collections attempt to use as much parallelism as possible. This parallelism is independent of the SMP feature installed on the system. However, parallel processing is allowed only for immediate statistics collection if SMP is installed on the system. The job that requests the column statistics also must allow parallelism.

Determining what column statistics exist

You can determine what column statistics exist in a couple of ways.

The first is to view statistics by using System i Navigator. Right-click a table or alias and select **Statistic Data**. Another way is to create a user-defined table function and call that function from an SQL statement or stored procedure.

Manually collecting and refreshing statistics

You can manually collect and refresh statistics through System i Navigator or by using statistics APIs.

To collect statistics using System i Navigator, right-click a table or alias and select **Statistic Data**. On the **Statistic Data** dialog, click **New**. Then select the columns that you want to collect statistics for. Once you have selected the columns, you can collect the statistics immediately or collect them in the background.

To refresh a statistic using System i Navigator, right-click a table or alias and select **Statistic Data**. Click **Update**. Select the statistic that you want to refresh. You can collect the statistics immediately or collect them in the background.

There are several scenarios in which the manual management (create, remove, refresh, and so on) of column statistics could be beneficial and recommended.

High Availability (HA) solutions High availability solutions replicate data to a secondary system by using journal entries. However, column statistics are not journaled. That means that, on your backup system, no column statistics are available when you first start using that system. To prevent the "warm up" effect, you might want to propagate the column statistics that were gathered on your production system. Recreate them on your backup system manually.

ISV (Independent Software Vendor) preparation An ISV might want to deliver a customer solution that already includes column statistics frequently used in the application, rather than waiting for the automatic statistics collection to create them. Run the application on the development system for some time and examine which column statistics were created automatically. You can then generate a script file to execute on the customer system after the initial data load takes place. The script file can be shipped as part of the application

Business Intelligence environments

In a large Business Intelligence environment, it is common for large data load and update operations to occur overnight. Column statistics are marked stale only when they are touched by the statistics manager, and then refreshed after first touch. You might want to consider refreshing the column statistics manually after loading the data.

You can do this refresh easily by toggling the system value QDBFSTCCOL to *NONE and then back to *ALL. This process causes all stale column statistics to be refreshed. It also starts collection of any column statistics previously requested by the system but not yet available. Since this process relies on the access plans stored in the plan cache, avoid performing a system initial program load (IPL) before toggling QDBFSTCCOL. An IPL clears the plan cache.

This procedure works only if you do not delete (drop) the tables and recreate them in the process of loading your data. When deleting a table, access plans in the plan cache that refer to this table are deleted. Information about column statistics on that table is also lost. The process in this environment is either to add data to your tables or to clear the tables instead of deleting them.

Massive data updates

Updating rows in a column statistics-enabled table can significantly change the cardinality, add new ranges of values, or change the distribution of data values. These updates can affect query performance on the first query run against the new data. On the first run of such a query, the optimizer uses stale column statistics to determine the access plan. At that point, it starts a request to refresh the column statistics.

Prior to this data update, you might want to toggle the system value QDBFSTCCOL to *NONE and back to *ALL or *SYSTEM. This toggle causes an analysis of the plan cache. The analysis includes searching for column statistics used in access plan generation, analyzing them for staleness, and requesting updates for the stale statistics.

If you massively update or load data, and run queries against these tables at the same time, the automatic column statistics collection tries to refresh every time 15% of the data is changed. This processing can be redundant since you are still updating or loading the data. In this case, you might want to block automatic statistics collection for the tables and unblock it again after the data update or load finishes. An alternative is to turn off automatic statistics collection for the whole system before updating or loading the data. Switch it back on after the updating or loading has finished.

Backup and recovery

When thinking about backup and recovery strategies, keep in mind that creation of column statistics is not journaled. Column statistics that exist at the time a save operation occurs are saved as part of the table and restored with the table. Any column statistics created after the save took place are lost and cannot be recreated by using techniques such as applying journal entries. If you have a long interval between save operations and rely on journaling to restore your environment, consider tracking column statistics that are generated after the latest save operation.

Viewing statistics requests

You can view the current statistics requests by using System i Navigator or by using Statistics APIs.

Displaying materialized query table columns

You can display materialized query tables associated with another table using System i Navigator.

To display materialized query tables, follow these steps:

1. In the System i Navigator window, expand the system that you want to use.
2. Expand **Databases** and the database that you want to work with.
3. Expand **Schemas** and the schema that you want to work with.
4. Right-click a table and select **Show Materialized Query Tables**.

Column name	Description
Name	The SQL name for the materialized query table
Schema	Schema or library containing the materialized query table
Partition	Partition detail for the index. Possible values: <ul style="list-style-type: none"> • <blank>, which means For all partitions • For Each Partition • specific name of the partition
Owner	The user ID of the owner of the materialized query table.
System Name	System table name for the materialized query table
Enabled	Whether the materialized query table is enabled. Possible values are: <ul style="list-style-type: none"> • Yes • No <p>If the materialized query table is not enabled, it cannot be used for query optimization. It can, however, be queried directly.</p>
Creation Date	The timestamp of when the materialized table was created.
Last Refresh Date	The timestamp of the last time the materialized query table was refreshed.

Table 53. Columns used in Show materialized query table window (continued)

Column name	Description
Last Query Use	The timestamp when the materialized query table was last used by the optimizer to replace user specified tables in a query.
Last Query Statistics Use	The timestamp when the materialized query table was last used by the statistics manager to determine an access method.
Query Use Count	The number of instances the materialized query table was used by the optimizer to replace user specified tables in a query.
Query Statistics Use Count	The number of instances the materialized query table was used by the statistics manager to determine an access method.
Last Used Date	The timestamp when the materialized query table was last used.
Days Used Count	The number of days the materialized query table has been used.
Date Reset Days Used Count	The year and date when the days-used count was last set to 0.
Current Number of Rows	The total number of rows included in this materialized query table at this time.
Current Size	The current size of the materialized query table.
Last Changed	The timestamp when the materialized query table was last changed.
Maintenance	The maintenance for the materialized query table. Possible values are: <ul style="list-style-type: none"> • User • System
Initial Data	Whether the initial data was inserted immediately or deferred. Possible values are <ul style="list-style-type: none"> • Deferred • Immediate
Refresh Mode	The refresh mode for the materialized query table. A materialized query table can be refreshed whenever a change is made to the table or deferred to a later time.
Isolation Level	The isolation level for the materialized query table.
Sort Sequence	The alternate character sorting sequence for National Language Support (NLS).
Language Identifier	The language code for the object.
SQL Statement	The SQL statement that is used to populate the table.
Text	The text description of the materialized query table.
Table	Schema and table name.

<i>Table 53. Columns used in Show materialized query table window (continued)</i>	
Column name	Description
Table Partition	Table partition.
Table System Name	System name of the table.

Managing check pending constraints columns

You can view and change constraints that have been placed in a check pending state by the system. Check pending constraints refers to a state in which a mismatch exists between a parent and foreign key in a referential constraint. A mismatch can also occur between the column value and the check constraint definition in a check constraint.

To view constraints that have been placed in a check pending state, follow these steps:

1. Expand the system name and **Databases**.
2. Expand the database that you want to work with.
3. Expand the **Database Maintenance** folder.
4. Select **Check Pending Constraints**.
5. From this interface, you can view the definition of the constraint and the rows that are in violation of the constraint rules. Select the constraint that you want to work with and then select **Edit Check Pending Constraint** from the **File** menu.
6. You can either alter or delete the rows that are in violation.

<i>Table 54. Columns used in Check pending constraints window</i>	
Column name	Description
Name of Constraint in Check Pending	Displays the name of the constraint that is in a check pending state.
Schema	Schema containing the constraint that is in a check pending state.
Type	Displays the type of constraint that is in check pending. Possible values are: Check constraint Foreign key constraint
Table name	The name of the table associated with the constraint in check pending state.
Enabled	Displays whether the constraint is enabled. The constraint must be disabled or the relationship taken out of the check pending state before any input/output (I/O) operations can be performed.

Limiting temporary storage and CPU used by queries

Follow these recommendations to limit temporary storage and CPU usage.

You can prevent the query optimizer from using excessive temporary storage when running a query by setting the maximum temporary storage parameter for jobs on your system. The maximum temporary storage parameter (**MAXTMPSTG**) can be assigned to a class of jobs or it can be set for an individual job. The parameter, defined in megabytes, limits the amount of temporary storage that a job may allocate while it is running. The default value is *NOMAX, meaning no limit is placed on the temporary storage. See the Change Job (**CHGJOB**) command for more information: https://www.ibm.com/support/knowledgecenter/ssw_ibm_i_74/cl/chgjob.htm#CHGJOB.MAXTMPSTG

Temporary storage can be allocated by application code, by the optimizer, or by other parts of the operating system. If the total temporary storage currently allocated by the job exceeds the maximum, the job is held and a CPI112E message, "Job & held by the system, MAXTMPSTG limit exceeded ." is sent to the job log and to the QSYSOPR message queue. The job remains held until the maximum is increased or removed and the job is released, or until the job is ended. Note that with respect to the maximum temporary storage limit, only temporary storage newly allocated by the optimizer for the currently running query is counted. If a query plan is reused from the plan cache, any associated temporary storage will not be counted against the limit. Likewise, once the query has completed, the optimizer's temporary storage is no longer counted against the limit, even if the cached plan and its associated runtime objects continue to remain allocated.

Consider the following example for a job with **MAXTMPSTG** set to 100 MB:

1. Query 1 is submitted, is optimized, and allocates 60 MB of temporary storage. When the query is done, the plan and its temporary storage are cached.
2. Query 2 is submitted, is optimized, and allocates 50 MB of temporary storage. When the query is done, the plan and its temporary storage are cached. Total temporary storage usage has increased by 110 MB, but no single query has exceeded 100 MB, so the job continues to run.
3. Query 3 is submitted, and a matching plan produced from a previous run is found. This plan uses temporary objects totaling 150 MB. However, because this job is not newly allocating the temporary storage, **MAXTMPSTG** is not exceeded.
4. Query 4 is submitted, is optimized, and allocates 200 MB of temporary storage. **MAXTMPSTG** is exceeded and the job is held.

In a similar manner, the Maximum CPU time (**CPUTIME**) parameter may be used to prevent jobs from utilizing excessive amounts of CPU. The limit is specified in the number of milliseconds of CPU time that a job may consume. As with **MAXTMPSTG**, exceeding the limit will cause the job to be held until the limit is changed or the job is ended.

Related limits on temporary storage and running time are also available on the Change Query Attributes (**CHGQRYA**) https://www.ibm.com/support/knowledgecenter/ssw_ibm_i_74/cl/chgqrya.htm command. Query processing time limit (**QRYTIMLMT**) can be used to prevent the optimizer from running queries that are expected to take a long time, whereas **QRYSTGLMT** can prevent the optimizer from running queries that are expected to use a large amount of temporary storage. Note that these differ from **MAXTMPSTG** and **CPUTIME** in that they apply to each query individually and are based on estimates calculated by the optimizer before the query runs. By contrast, the job-based limits apply to the actual resource usage measured as the job runs.

Creating an index strategy

Db2 for i provides two basic means for accessing tables: a table scan and an index-based retrieval. Index-based retrieval is typically more efficient than table scan when less than 20% of the table rows are selected.

There are two kinds of persistent indexes: binary radix tree indexes, which have been available since 1988, and encoded vector indexes (EVIs). Both types of indexes are useful in improving performance for certain kinds of queries.

Binary radix indexes

A radix index is a multilevel, hybrid tree structure that allows many key values to be stored efficiently while minimizing access times. A key compression algorithm assists in this process. The lowest level of the tree contains the leaf nodes, which contain the base table row addresses associated with the key value. The key value is used to quickly navigate to the leaf node with a few simple binary search tests.

The binary radix tree structure is good for finding a few rows because it finds a given row with a minimal amount of processing. For example, create a binary radix index over a customer number column. Then create a typical OLTP request like "find the outstanding orders for a single customer". The binary index results in fast performance. An index created over the customer number column is considered the perfect

index for this type of query. The index allows the database to find the rows it needs and perform a minimal number of I/Os.

In some situations, however, you do not always have the same level of predictability. Many users want on demand access to the detail data. For example, they might run a report every week to look at sales data. Then they want to "drill down" for more information related to a particular problem area they found in the report. In this scenario, you cannot write all the queries in advance on behalf of the end users. Without knowing what queries might run, it is impossible to build the perfect index.

Related information

[SQL Create Index statement](#)

Derived key index

You can use the SQL CREATE INDEX statement to create a derived key index using an SQL expression.

Traditionally an index could only specify column names in the key of the index over the table it was based on. With this support, an index can have an expression in place of a column name that can use built-in functions, or some other valid expression. Additionally, you can use the SQL CREATE INDEX statement to create a sparse index using a WHERE condition.

For restrictions and other information about derived indexes, see the Create Index statement and Using derived indexes.

Related reference

[Using derived indexes](#)

SQL indexes can be created where the key is specified as an expression. This type of key is also referred to as a derived key.

Related information

[SQL Create Index statement](#)

Sparse indexes

You can use the SQL CREATE INDEX statement to create a sparse index using SQL selection predicates.

The SQL CREATE INDEX statement can be used to create a sparse index using a WHERE condition. With this support, the query optimizer recognizes and considers sparse indexes during its optimization. If the query WHERE selection is a subset of the sparse index WHERE selection, then the sparse index is used to implement the query. Use of the sparse index usually results in improved performance.

Examples

In this example, the query selection is a subset of the sparse index selection and an index scan over the sparse index is used. The remaining query selection (COL3=30) is executed following the index scan.

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20 and COL3=30
```

In this example, the query selection is not a subset of the sparse index selection and the sparse index cannot be used.

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20 and COL3=30
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20
```

Related reference

Using sparse indexes

SQL indexes can be created using WHERE selection predicates. These indexes can also be referred to as sparse indexes. The advantage of a sparse index is that fewer entries are maintained in the index. Only those entries matching the WHERE selection criteria are maintained in the index.

Related information

SQL Create Index statement

Sparse index optimization

An SQL sparse index is like a select/omit access path. Both the sparse index and the select/omit logical file contain only keys that meet the selection specified. For a sparse index, the selection is specified with a WHERE clause. For a select/omit logical file, the selection is specified in the DDS using the COMP operation.

The reason for creating a sparse index is to provide performance enhancements for your queries. The performance enhancement is done by precomputing and storing results of the WHERE selection in the sparse index. The database engine can use these results instead of recomputing them for a user specified query. The query optimizer looks for any applicable sparse index and can choose to implement the query using a sparse index. The decision is based on whether using a sparse index is a faster implementation choice.

For a sparse index to be used, the WHERE selection in the query must be a subset of the WHERE selection in the sparse index. That is, the set of records in the sparse index must contain all the records to be selected by the query. It might contain extra records, but it must contain all the records to be selected by the query. This comparison of WHERE selection is performed by the query optimizer during optimization. It is like the comparison that is performed for Materialized Query Tables (MQT).

Besides the comparison of the WHERE selection, the optimization of a sparse index is identical to the optimization that is performed for any Binary Radix index.

Refer to section 'Indexes and the Optimizer' for more details on how Binary Radix indexes are optimized.

Related concepts

Indexes & the optimizer

Since the optimizer uses cost based optimization, more information about the database rows and columns makes for a more efficient access plan created for the query. With the information from the indexes, the optimizer can make better choices about how to process the request (local selection, joins, grouping, and ordering).

Related reference

Using sparse indexes

SQL indexes can be created using WHERE selection predicates. These indexes can also be referred to as sparse indexes. The advantage of a sparse index is that fewer entries are maintained in the index. Only those entries matching the WHERE selection criteria are maintained in the index.

Sparse index matching algorithm

This topic is a generalized discussion of how the sparse index matching algorithm works.

The selection in the query must be a subset of the selection in the sparse index in order for the sparse index to be used. This statement is true whether the selection is ANDed together, ORed together, or a combination of the two. For selection where all predicates are ANDed together, all WHERE selection predicates specified in the sparse index must also be specified in the query. The query can contain additional ANDed predicates. The selection for the additional predicates will be performed after the entries are retrieved from the sparse index. See examples A1, A2, and A3 following.

Example A1

In this example, the query selection exactly matches the sparse index selection and an index scan over the sparse index can be used.

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20 and COL3=30
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20 and COL3=30
```

Example A2

In this example, the query selection is a subset of the sparse index selection and an index scan over the sparse index can be used. The remaining query selection (COL3=30) is executed following the index scan.

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20 and COL3=30
```

Example A3

In this example, the query selection is not a subset of the sparse index selection and the sparse index cannot be used.

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20 and COL3=30
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20
```

For selection where all predicates are ORed together, all WHERE selection predicates specified in the query, must also be specified in the sparse index. The sparse index can contain additional ORed predicates. All the ORed selection in the query will be executed after the entries are retrieved from the sparse index. See examples O1, O2, and O3 following.

Example O1

In this example, the query selection exactly matches the sparse index selection and an index scan over the sparse index can be used. The query selection is executed following the index scan.

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 or COL2=20 or COL3=30
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 or COL2=20 or COL3=30
```

Example O2

In this example, the query selection is a subset of the sparse index selection and an index scan over the sparse index can be used. The query selection is executed following the index scan.

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 or COL2=20 or COL3=30
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 or COL2=20
```

Example O3

In this example, the query selection is not a subset of the sparse index selection and the sparse index cannot be used.

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 or COL2=20
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 or COL2=20 or COL3=30
```

The previous examples used simple selection, all ANDed, or all ORed together. These examples are not typical, but they demonstrate how the selection of the sparse index is compared to the selection of the query. Obviously, the more complex the selection the more difficult it becomes to determine compatibility.

In the next example T1, the constant 'MN' was replaced by a parameter marker for the query selection. The sparse index had the local selection of COL1='MN' applied to it when it was created. The sparse index matching algorithm matches the parameter marker to the constant 'MN' in the query predicate COL1=?. It verifies that the value of the parameter marker is the same as the constant in the sparse index; therefore the sparse index can be used.

The sparse index matching algorithm attempts to match where the predicates between the sparse index and the query are not the same. An example is a sparse index with a predicate SALARY > 50000, and a query with the predicate SALARY > 70000. The sparse index contains the rows necessary to run the query. The sparse index is used in the query, but the predicate SALARY > 70000 remains as selection in the query (it is not removed).

Example T1

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1='MN' or COL2='TWINS'
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=? or COL2='TWINS' or COL3='WIN'
```

In the next example T2, the keys of the sparse index match the ORDER BY fields in the query. For the sparse index to satisfy the specified ordering, the optimizer must verify that the query selection is a subset of the sparse index selection. In this example, the sparse index can be used.

Example T2

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL1, COL3)
WHERE COL1='MN' or COL2='TWINS'
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL2='TWINS'
ORDER BY COL1, COL3
```

Using sparse indexes

SQL indexes can be created using WHERE selection predicates. These indexes can also be referred to as sparse indexes. The advantage of a sparse index is that fewer entries are maintained in the index. Only those entries matching the WHERE selection criteria are maintained in the index.

Details on the MQT matching algorithm

What follows is a generalized discussion of how the MQT matching algorithm works.

Sparse index examples

This topic shows examples of how the sparse index matching algorithm works.

In example S1, the query selection is a subset of the sparse index selection and consequently an index scan over the sparse index is used. The remaining query selection (COL3=30) is executed following the index scan.

Example S1

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20 and COL3=30
```

In example S2, the query selection is not a subset of the sparse index selection and the sparse index cannot be used.

Example S2

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20 and COL3=30
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20
```

In example S3, the query selection exactly matches the sparse index selection and an index scan over the sparse index can be used.

Example S3

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20 and COL3=30
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20 and COL3=30
```

In example S4, the query selection is a subset of the sparse index selection and an index scan over the sparse index can be used. The remaining query selection (COL3=30) is executed following the index scan.

Example S4

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20 and COL3=30
```

In example S5, the query selection is not a subset of the sparse index selection and the sparse index cannot be used.

Example S5

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20 and COL3=30
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20
```

In example S6, the query selection exactly matches the sparse index selection and an index scan over the sparse index can be used. The query selection is executed following the index scan to eliminate excess records from the sparse index.

Example S6

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 or COL2=20 or COL3=30
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 or COL2=20 or COL3=30
```

In example S7, the query selection is a subset of the sparse index selection and an index scan over the sparse index can be used. The query selection is executed following the index scan to eliminate excess records from the sparse index.

Example S7

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 or COL2=20 or COL3=30
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 or COL2=20
```

In example S8, the query selection is not a subset of the sparse index selection and the sparse index cannot be used.

Example S8

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 or COL2=20
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 or COL2=20 or COL3=30
```

In the next example S9, the constant 'MN' was replaced by a parameter marker for the query selection. The sparse index had the local selection of COL1='MN' applied to it when it was created. The sparse index matching algorithm matches the parameter marker to the constant 'MN' in the query predicate COL1=?. It verifies that the value of the parameter marker is the same as the constant in the sparse index; therefore the sparse index can be used.

Example S9

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1='MN' or COL2='TWINS'
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
Where Col3='WIN' and (Col1=? or Col2='TWINS')
```

In the next example S10, the keys of the sparse index match the order by fields in the query. For the sparse index to satisfy the specified ordering, the optimizer must verify that the query selection is a subset of the sparse index selection. In this example, the sparse index can be used.

Example S10

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL1, COL3)
WHERE COL1='MN' or COL2='TWINS'
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
Where Col3='WIN' and (Col1='MN' or Col2='TWINS')
ORDER BY COL1, COL3
```

In the next example S11, the keys of the sparse index do not match the order by fields in the query. But the selection in sparse index T2 is a superset of the query selection. Depending on size, the optimizer might choose an index scan over sparse index T2 and then use a sort to satisfy the specified ordering.

Example S11

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL2, COL4)
WHERE COL1='MN' or COL2='TWINS'
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
Where Col3='WIN' and (Col1='MN' or Col2='TWINS')
ORDER BY COL1, COL3
```

The next example S12 represents the classic optimizer decision: is it better to do an index probe using index IX1 or is it better to do an index scan using sparse index SPR1? Both indexes retrieve the same number of index entries and have the same cost from that point forward. For example, both indexes have the same cost to retrieve the selected records from the dataspace, based on the retrieved entries/keys.

The cost to retrieve the index entries is the deciding criteria. In general, if index IX1 is large then an index scan over sparse index SPR1 has a lower cost to retrieve the index entries. If index IX1 is rather small then an index probe over index IX1 has a lower cost to retrieve the index entries. Another cost decision is reusability. The plan using sparse index SPR1 is not as reusable as the plan using index IX1 because of the static selection built into the sparse selection.

Example S12

```
CREATE INDEX MYLIB/IX1 on MYLIB/T1 (COL1, COL2, COL3)
```

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20 and COL3=30
```

```
CSELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20 and COL3=30
```

Specify PAGESIZE on index creates

You can use the PAGESIZE parameter to specify the access path logical page size used by the system when the access path is created. Use the PAGESIZE parameter when creating keyed files or indexes using the **Create Physical File (CRTPF)** or **Create Logical File (CRTLF)** commands, or the SQL CREATE INDEX statement.

The logical page size is the access path number of bytes that can be moved from auxiliary storage to the job storage pool for a page fault.

Consider using the default of *KEYLEN for this parameter, except in rare circumstances. Then the page size can be determined by the system based on the total length of the keys. When the access path is used by selective queries (for example, individual key lookup), a smaller page size is typically more efficient. When the query-selected keys are grouped in the access path with many records selected, or the access path is scanned, a larger page size is more efficient.

General index maintenance

Whenever indexes are created and used, there is a potential for a decrease in I/O velocity due to maintenance. Therefore, consider the maintenance cost of creating and using additional indexes. For radix indexes with MAINT(*IMMED), maintenance occurs when inserting, updating, or deleting rows.

To reduce the maintenance of your indexes consider:

- Minimizing the number of table indexes by creating composite (multiple column) key indexes. Composite indexes can be used for multiple different situations.
- Dropping indexes during batch inserts, updates, and deletes
- Creating in parallel. Either create indexes, one at a time, in parallel using SMP or create multiple indexes simultaneously with multiple batch jobs

- Maintaining indexes in parallel using SMP

The goal of creating indexes is to improve query performance by providing statistics and implementation choices. Maintain a reasonable balance on the number of indexes to limit maintenance overhead.

Encoded vector indexes

An encoded vector index (EVI) is used to provide fast data access in decision support and query reporting environments.

EVI is a complementary alternative to existing index objects (binary radix tree structure - logical file or SQL index) and are a variation on bitmap indexing. Because of their compact size and relative simplicity, EVIs provide for faster scans of a table that can also be processed in parallel.

An EVI is a data structure that is stored as two components:

- The symbol table contains statistical and descriptive information about each distinct key value represented in the table. Each distinct key is assigned a unique code, either 1 byte, 2 bytes or 4 bytes in size.

By specifying INCLUDE on the create, additional aggregate values can be maintained in real time as an extension of the key portion of the symbol table entry. These aggregated values are over non-key data in the table grouped by the specified EVI key.

- The vector is an array of codes listed in the same ordinal position as the rows in the table. The vector does not contain any pointers to the actual rows in the table.

Advantages of EVIs:

- Require less storage
- May have better build times than radix, especially if the number of unique values in the columns defined for the key is relatively small.
- Provide more accurate statistics to the query optimizer
- Considerably better performance for certain grouping types of queries
- Good performance characteristics for decision support environments.
- Can be further extended for certain types of grouping queries with the addition of INCLUDE values. Provides ready-made numeric aggregate values maintained in real time as part of index maintenance. INCLUDE values become an extension of the EVI symbol table. Multiple include values can be specified over different aggregating columns and maintained in the same EVI provided the group by values are the same. This technique can reduce overall maintenance.

Disadvantages of EVIs:

- Cannot be used in ordering.
- Use for grouping is specialized. Supports:
 - COUNT, DISTINCT requests over key columns
 - aggregate requests over key columns where all other selection can be applied to the EVI symbol table keys
 - INCLUDE aggregates
 - MIN or MAX, if aggregating value is part of the symbol table key.
- Use with joins always done in cooperation with hash table processing.
- Some additional maintenance idiosyncrasies.

How the EVI works

EVI works in different ways for costing and implementation.

For costing, the optimizer uses the symbol table to collect metadata information about the query.

For implementation, the optimizer can use the EVI in one of the following ways:

- **Selection (WHERE clause)**

The database engine uses the vector to build a dynamic bitmap or list of selected row ids. The bitmap or list contains 1 bit for each row in the table. The bit is turned on for each selected row. Like a bitmap index, these intermediate dynamic bitmaps (or lists) can be ANDed and ORed together to satisfy a query.

For example, a user wants to see sales data for a specific region and time period. You can define an EVI over the `region` and `quarter` columns of the table. When the query runs, the database engine builds dynamic bitmaps using the two EVIs. The bitmaps are ANDed together to produce a single bitmap containing only the relevant rows for both selection criteria.

This ANDing capability drastically reduces the number of rows that the system must read and test. The dynamic bitmaps exist only as long as the query is executing. Once the query is completed, the dynamic bitmaps are eliminated.

- **Grouping or Distinct**

The symbol table within the EVI contains distinct values for the specified columns in the key definition. The symbol table also contains a count of the number of records in the base table that have each distinct value. Queries involving grouping or distinct, based solely on columns in the key, are candidates for a technique that uses the symbol table directly to determine the query result.

The symbol table contains only the key values and their associated counts, unless `INCLUDE` is specified. Therefore, queries involving column function `COUNT` are eligible for this technique. But queries with column functions `MIN` or `MAX` on other non-key columns are not eligible. `MIN` and `MAX` values are not stored in the symbol table.

- **EVI INCLUDE aggregates**

Including additional aggregate values further extends the ability of the symbol table to provide ready-made results. Aggregate data is grouped by the specified columns in the key definition. Therefore, aggregate data must be over columns in the table other than those columns specified as EVI key values.

For performance, these included aggregates are limited to numeric results (`SUM`, `COUNT`, `AVG`, `VARIANCE`) as they can be maintained directly from the inserted or removed row.

`MIN` or `MAX` values would occasionally require other row comparisons during maintenance and therefore are not supported with the `INCLUDE` keyword.

EVI symbol table only access is used to satisfy distinct or grouping requests when the query is run with commitment control `*NONE` or `*CHG`.

`INCLUDE` for additional aggregate values can be used in join queries. When possible, the existence of EVIs with `INCLUDE` aggregates causes the group by process to be pushed down to each table as necessary. See the following EVI `INCLUDE` grouping push down example: [“EVI INCLUDE aggregate example” on page 83](#)

[Encoded vector index symbol table scan](#)

An encoded vector index symbol table scan operation is used to retrieve the entries from the symbol table portion of the index.

Encoded vector index symbol table probe

An encoded vector index symbol table probe operation is used to retrieve entries from the symbol table portion of the index. Scanning the entire symbol table is not necessary.

Index grouping implementation

There are two primary ways to implement grouping using an index: Ordered grouping and pre-summarized processing.

When to create EVIs

There are several instances to consider creating EVIs.

Consider creating encoded vector indexes when any one of the following is true:

- You want to gather 'live' statistics
- Full table scan is currently being selected for the query
- Selectivity of the query is 20%-70% and using skip sequential access with dynamic bitmaps speed up the scan
- When a star schema join is expected to be used for star schema join queries.
- When grouping or distinct queries are specified against a column, the columns have few distinct values and only the COUNT column function, if any, is used.
- When ready-made aggregate results grouped by the specified key columns would benefit query performance.

Create encoded vector indexes with:

- Single key columns with a low number of distinct values expected
- Keys columns with a low volatility (do not change often)
- Maximum number of distinct values expected using the WITH n DISTINCT VALUES clause
- Single key over foreign key columns for a star schema model

EVI with INCLUDE vs Materialized Query Tables

Although EVIs with INCLUDE are not a substitute for Materialized Query Tables (MQTs), INCLUDE EVIs have an advantage over single table aggregate MQTs (materialized query tables). The advantage is that the ready-made aggregate results are maintained in real time, not requiring explicit REFRESH TABLE requests. For performance and read access to aggregate results, consider turning your single table, aggregate MQTs into INCLUDE EVIs. Keep in mind that the other characteristics of a good EVI are applicable, such as a relatively low number of distinct key values.

As indexes, these EVIs are found during optimization just as any other indexes are found. Unlike MQTs, there is no INI setting to enable and no second pass through the optimizer to cost the application of this form of ready-made aggregate. In addition, EVIs with INCLUDE can be used to populate MQT summary tables if the EVI is a match for a portion of the MQT definition.

Index grouping implementation

There are two primary ways to implement grouping using an index: Ordered grouping and pre-summarized processing.

EVI maintenance

There are unique challenges to maintaining EVIs. The following table shows a progression of how EVIs are maintained, the conditions under which EVIs are most effective, and where EVIs are least effective, based on the EVI maintenance characteristics.

Table 55. EVI Maintenance Considerations

	Condition	Characteristics
Most Effective	When inserting an existing distinct key value	<ul style="list-style-type: none"> • Minimum overhead • Symbol table key value looked up and statistics updated • Vector element added for new row, with existing byte code • Minimal additional pathlength to maintain any INCLUDED aggregate values (the increment of a COUNT or adding to an accumulating SUM)
	When inserting a <i>new</i> distinct key value - in order, within byte code range	<ul style="list-style-type: none"> • Minimum overhead • Symbol table key value added, byte code assigned, statistics assigned • Vector element added for new row, with new byte code • Minimal additional pathlength to maintain any INCLUDED aggregate values (the increment of a COUNT or adding to an accumulating SUM)
	When inserting a new distinct key value - out of order, within byte code range	<ul style="list-style-type: none"> • Minimum overhead if contained within overflow area threshold • Symbol table key value added to overflow area, byte code assigned, statistics assigned • Vector element added for new row, with new byte code • Considerable overhead if overflow area threshold reached • Access path validated - not available • EVI refreshed, overflow area keys incorporated, new byte codes assigned (symbol table and vector elements updated) • Minimal additional path-length to maintain any INCLUDED aggregate values (the increment of a COUNT or adding to an accumulating SUM)
	When inserting a new distinct key value - out of byte code range	<ul style="list-style-type: none"> • Considerable overhead • Access plan invalidated - not available • EVI refreshed, next byte code size used, new byte codes assigned (symbol table and vector elements updated) • Not applicable to EVIs with INCLUDE, as by definition the max allowed byte code is used
Least Effective

[Encoded vector index](#)

An encoded vector index is a permanent object that provides access to a table. This access is done by assigning codes to distinct key values and then representing those values in a vector.

Recommendations for EVI use

Encoded vector indexes are a powerful tool for providing fast data access in decision support and query reporting environments. To ensure the effective use of EVIs, use the following guidelines.

Create EVIs on

- Read-only tables or tables with a minimum of INSERT, UPDATE, DELETE activity.
- Key columns that are used in the WHERE clause - local selection predicates of SQL requests.
- Single key columns that have a relatively small set of distinct values.
- Multiple key columns that result in a relatively small set of distinct values.
- Key columns that have a static or relatively static set of distinct values.
- Non-unique key columns, with many duplicates.

Create EVIs with the maximum byte code size expected

- Use the "WITH n DISTINCT VALUES" clause on the CREATE ENCODED VECTOR INDEX statement.
- If unsure, use a number greater than 65,535 to create a 4 byte code. This method avoids the EVI maintenance involved in switching byte code sizes.
- EVIs with INCLUDE always create with a 4 byte code.

When loading data

- Drop EVIs, load data, create EVIs.
- EVI byte code size is assigned automatically based on the number of actual distinct key values found in the table.
- Symbol table contains all key values, in order, no keys in overflow area.
- EVIs with INCLUDE always use 4 byte code

Consider adding INCLUDE values to existing EVIs

An EVI index with INCLUDE values can be used to supply ready-made aggregate results. The existing symbol table and vector are still used for table selection, when appropriate, for skip sequential plans over large tables, or for index ANDing and ORing plans. If you already have EVIs, consider creating new ones with additional INCLUDE values, and then drop the pre-existing index.

Consider specifying multiple INCLUDE values on the same EVI create

If you need different aggregates over different table values for the same GROUP BY columns specified as EVI keys, define those aggregates in the same EVI. This definition cuts down on maintenance costs and allows for a single symbol table and vector.

For example:

```
Select SUM(revenue) from sales group by Country
```

```
Select SUM(costOfGoods) from sales group by Country, Region
```

Both queries could benefit from the following EVI:

```
CREATE ENCODED VECTOR INDEX  eviCountryRegion on Sales(country,region)  
INCLUDE(SUM(revenue), SUM(costOfGoods))
```

The optimizer does additional grouping (regrouping) if the EVI key values are wider than the corresponding GROUP BY request of the query. This additional grouping would be the case in the first example query.

If an aggregate request is specified over null capable results, an implicit COUNT over that same result is included as part of the symbol table entry. The COUNT is used to facilitate index maintenance when a requested aggregate needs to reflect. It can also assist with pushing aggregation through a join if the optimizer determines this push is possible. The COUNT is then used to help compensate for fewer join activity due to the pushed down grouping.

Consider EVI INCLUDE and Grouping Sets

EVI INCLUDE support has been expanded to match GROUPING SETs, ROLLUP and CUBE queries.

When EVI INCLUDES are available over a table being aggregated over in a grouping sets query, the query is rewritten to facilitate and match any EVI INCLUDE indexes that might be available. This can result in exceeding good query performance because the table is never accessed. All the aggregate variations necessary to perform the rollup, cube or grouping set query result can be performed over the EVI symbol table with INCLUDE values.

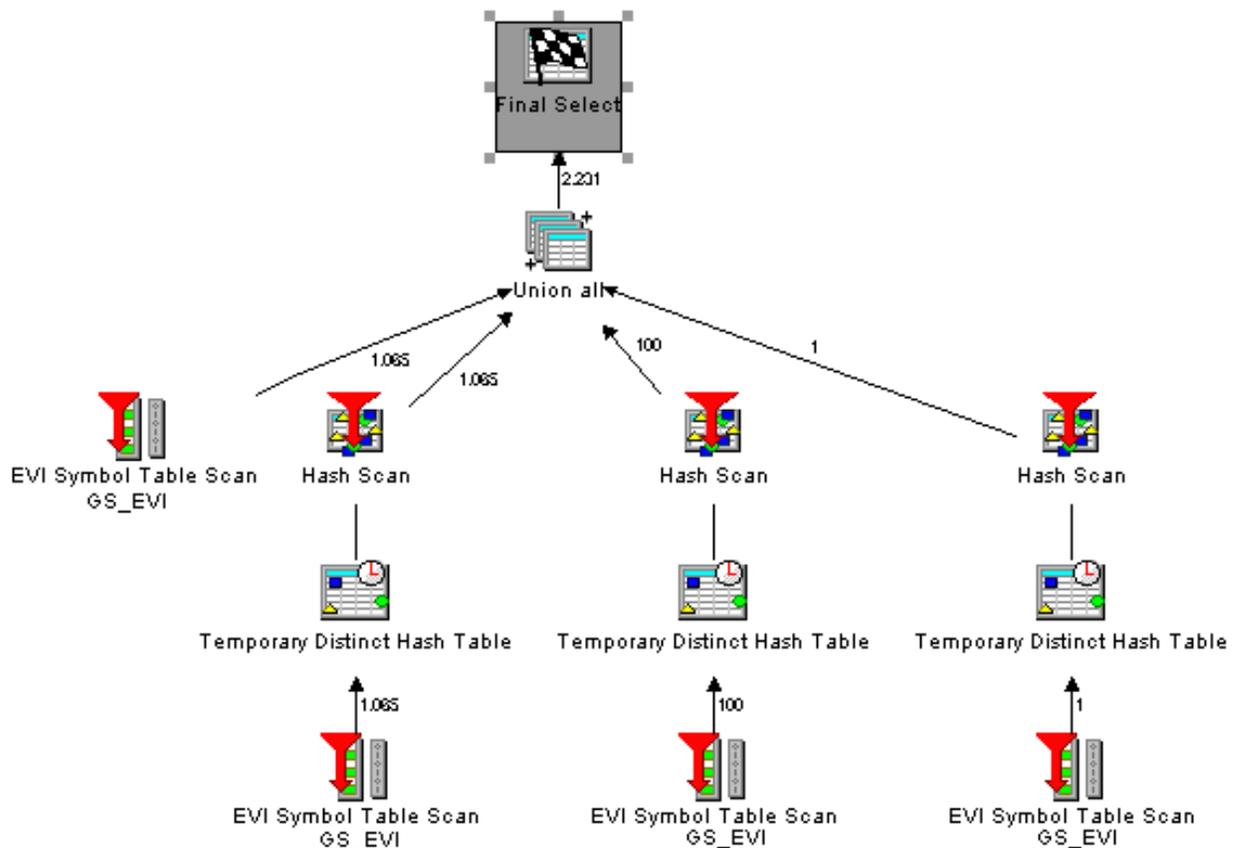

For example on the ROLLUP query below, the grouping is the sum of quantity rolled up at various levels (month, quarter, year) and ONLY the symbol table of the encoded vector index is accessed in the access plan.

```
SELECT year(shipdate) year_ship, quarter(shipdate) quarter, month(shipdate) month_ship,
       sum(quantity)
       as totquantity
FROM   item_fact
GROUP BY ROLLUP (Year(shipdate), Quarter(shipdate), month(shipdate));
```

Here is the EVI INCLUDE create that will facilitate the rollup query.

```
CREATE ENCODED VECTOR INDEX GS_EVI
ON   ITEM_FACT
    ( YEAR ( SHIPDATE ) ASC , QUARTER ( SHIPDATE ) ASC , MONTH ( SHIPDATE ) ASC )
INCLUDE ( SUM ( QUANTITY ) , COUNT ( * ) );
```

The following graphic shows a Visual Explain that illustrates the access and the performance. Instead of accessing potentially millions of rows, the access is over a rather modest size symbol table.

Consider SMP and parallel index creation and maintenance

Symmetrical Multiprocessing (SMP) is a valuable tool for building and maintaining indexes in parallel. The results of using the optional SMP feature of IBM i are faster index build times, and faster I/O velocities while maintaining indexes in parallel. Using an SMP degree value of either *OPTIMIZE or *MAX, additional multiple tasks and additional system resources are used to build or maintain the indexes. With a degree value of *MAX, expect linear scalability on index creation. For example, creating indexes on a 4-processor system can be four times as fast as a 1-processor system.

Checking values in the overflow area

You can also use the **Display File Description (DSPFD)** command (or System i Navigator - Database) to check how many values are in the overflow area. Once the **DSPFD** command is issued, check the overflow area parameter for details on the initial and actual number of distinct key values in the overflow area.

Using CHGLF to rebuild the access path of an index

Use the **Change Logical File (CHGLF)** command with the attribute Force Rebuild Access Path set to YES (FRCRBDAP(*YES)). This command accomplishes the same thing as dropping and recreating the index, but it does not require that you know about how the index was built. This command is especially effective for applications where the original index definitions are not available, or for refreshing the access path.

Comparing binary radix indexes and encoded vector indexes

Db2 for IBM i makes indexes a powerful tool.

The following table summarizes some of the differences between binary radix indexes and encoded vector indexes:

Comparison value	Binary Radix Indexes	Encoded Vector Indexes
Basic data structure	A wide, flat tree	A Symbol Table and a vector
Interface for creating	Command, SQL, System i Navigator	SQL, System i Navigator
Can be created in parallel	Yes	Yes
Can be maintained in parallel	Yes	Yes
Used for statistics	Yes	Yes
Used for selection	Yes	Yes, with dynamic bitmaps or RRN list
Used for joining	Yes	Yes (with a hash table)
Used for grouping	Yes	Yes
Used for ordering	Yes	No
Used to enforce unique Referential Integrity constraints	Yes	No
Source for predetermined or ready-made numeric aggregate results	No	Yes, with INCLUDE keyword option on create

Indexes & the optimizer

Since the optimizer uses cost based optimization, more information about the database rows and columns makes for a more efficient access plan created for the query. With the information from the indexes, the optimizer can make better choices about how to process the request (local selection, joins, grouping, and ordering).

The CQE optimizer attempts to examine most, if not all, indexes built over a table unless or until it times out. However, the SQE optimizer only considers those indexes that are returned by the Statistics Manager. These include only indexes that the Statistics Manager decides are useful in performing local selection based on the "where" clause predicates. Consequently, the SQE optimizer does not time out.

The primary goal of the optimizer is to choose an implementation that efficiently eliminates the rows that are not interesting or required to satisfy the request. Normally, query optimization is thought of as trying to find the rows of interest. A proper indexing strategy assists the optimizer and database engine with this task.

Instances where an index is not used

Db2 for i does not use indexes in the certain instances.

- For a column that is expected to be updated; for example, when using SQL, your program might include the following:

```
EXEC SQL
  DECLARE DEPTEMP CURSOR FOR
  SELECT EMPNO, LASTNAME, WORKDEPT
  FROM CORPDATA.EMPLOYEE
  WHERE (WORKDEPT = 'D11' OR
```

```

        WORKDEPT = 'D21') AND
        EMPNO = '000190'
FOR UPDATE OF EMPNO, WORKDEPT
END-EXEC.

```

When using the **OPNQRYF** command, for example:

```

OPNQRYF FILE((CORPDATA/EMPLOYEE)) OPTION(*ALL)
QRYSLT('(WORKDEPT *EQ 'D11'' *OR WORKDEPT *EQ 'D21'' )
*AND EMPNO *EQ '000190''')

```

Even if you do not intend to update the employee department, the system cannot use an index with a key of *WORKDEPT*.

An index can be used if all the index updatable columns are also used within the query as an isolatable selection predicate with an equal operator. In the previous example, the system uses an index with a key of *EMPNO*.

The system can operate more efficiently if the *FOR UPDATE OF* column list only names the column you intend to update: *WORKDEPT*. Therefore, do not specify a column in the *FOR UPDATE OF* column list unless you intend to update the column.

If you have an updatable cursor because of dynamic SQL, or *FOR UPDATE* was not specified and the program contains an *UPDATE* statement, then all columns can be updated.

- For a column being compared with another column from the same row. For example, when using SQL, your program might include the following:

```

EXEC SQL
  DECLARE DEPTDATA CURSOR FOR
  SELECT WORKDEPT, DEPTNAME
  FROM CORPDATA.EMPLOYEE
  WHERE WORKDEPT = ADMRDEPT
END-EXEC.

```

When using the **OPNQRYF** command, for example:

```

OPNQRYF FILE (EMPLOYEE) FORMAT(FORMAT1)
QRYSLT('WORKDEPT *EQ ADMRDEPT')

```

Even though there is an index for *WORKDEPT* and another index for *ADMRDEPT*, Db2 for i does not use either index. The index has no added benefit because every row of the table needs to be looked at.

Display indexes for a table

You can display indexes that are created on a table using System i Navigator.

To display indexes for a table, follow these steps:

1. In the System i Navigator window, expand the system that you want to use.
2. Expand **Databases** and the database that you want to work with.
3. Expand **Schemas** and the schema that you want to work with.
4. Right-click a table and select **Show Indexes**.

The Show index window includes the following columns:

<i>Table 57. Columns used in Show index window</i>	
Column name	Description
Name	The SQL name for the index

Table 57. Columns used in Show index window (continued)

Column name	Description
Type	The type of index displayed. Possible values are: <ul style="list-style-type: none"> • Keyed Physical File • Keyed Logical File • Primary Key Constraint • Unique Key Constraint • Foreign Key Constraint • Index
Schema	Schema or library containing the index or access path
Owner	User ID of the owner of this index or access path
System Name	System table name for the index or access path.
Text	The text description of the index or access path
Index partition	Partition detail for the index. Possible values: <ul style="list-style-type: none"> • <blank>, For all partitions • For Each Partition • specific name of the partition
Valid	Whether the access path or index is valid. The possible values are Yes or No.
Creation Date	The timestamp of when the index was created.
Last Build	The last time that the access path or index was rebuilt.
Last Query Use	Timestamp when the access path was last used by the optimizer.
Last Query Statistics Use	Timestamp when the access path was last used for statistics
Query Use Count	Number of times the access path has been used for a query
Query Statistics Use Count	Number of times the access path has been used for statistics
Last Used Date	Timestamp when the access path or index was last used.
Days Used Count	The number of days the index has been used.
Date Reset Days Used Count	The year and date when the days-used count was last set to 0.
Number of Key Columns	The number of key columns defined for the access path or index.
Key Columns	The key columns defined for the access path or index.
Current Key Values	The number of current key values.
Current Size	The size of the access path or index.
Current Allocated Pages	The current number of pages allocated for the access path or index.

Table 57. Columns used in Show index window (continued)

Column name	Description
Logical Page Size	The number of bytes used for the access path or the logical page size of the index. Indexes with larger logical page sizes are typically more efficient when scanned during query processing. Indexes with smaller logical page sizes are typically more efficient for simple index probes and individual key look ups. If the access path or index is an encoded vector, the value 0 is returned.
Duplicate Key Order	How the access path or index handles duplicate key values. Possible values are: <ul style="list-style-type: none"> • Unique - all values are unique. • Unique where not null - all values are unique unless null is specified.
Maximum Key Length	The maximum key length for the access path or index.
Unique Partial Key Values	The number of unique partial keys for the key fields 1 through 4. If the access path is an encoded vector, this number represents the number of full key distinct values.
Overflow Values	The number of overflow values for this encoded vector index.
Key Code Size	The length of the code assigned to each distinct key value of the encoded vector index.
Sparse	Is the index considered sparse. Sparse indexes only contain keys for rows that satisfy the query. Possible values are: <ul style="list-style-type: none"> • Yes • No
Derived Key	Is the index considered derived. A derived key is a key that is the result of an operation on the base column. Possible values are: <ul style="list-style-type: none"> • Yes • No
Partitioned	Is the index partition created for each data partition defined for the table using the specified columns. Possible values are: <ul style="list-style-type: none"> • Yes • No
Maximum Size	The maximum size of the access path or index.
Sort Sequence	The alternate character sorting sequence for National Language Support (NLS).
Language Identifier	The language code for the object.
Estimated Rebuild Time	The estimated time in seconds required to rebuild the access path or index.

Table 57. Columns used in Show index window (continued)

Column name	Description
Held	Is a rebuild of an access path or index held. Possible values are: <ul style="list-style-type: none"> • Yes • No
Maintenance	For objects with key fields or join logical files, the type of access path maintenance used. The possible values are: <ul style="list-style-type: none"> • Do not wait • Delayed • Rebuild
Delayed Maintenance Keys	The number of delayed maintenance keys for the access path or index.
Recovery	When the access path is rebuilt after damage to the access path is recognized. The possible values are: <ul style="list-style-type: none"> • After IPL • During IPL • Next Open
Index Logical Reads	The number of access path or index logical read operations since the last IPL.
WHERE Clause	Specifies the condition to apply for a row to be included in the index.
WHERE Clause Has UDF	Does the WHERE clause have a UDF. Possible values are: <ul style="list-style-type: none"> • Yes • No
Table	Table name of the table that the index is based on.
Table Partition	Partition name of the table that the index is based on.
Table System Name	System name of the table that the index is based on.
Last Rebuild Number Keys	Number of keys in the index when the index was last rebuilt.
Last Rebuild Parallel Degree	Parallel degree used when the index was last rebuilt.
Last Rebuild Time	Amount of time in seconds it took to rebuild the index the last time the index was rebuilt.
Keep in Memory	Is the index kept in memory. Possible values are: <ul style="list-style-type: none"> • Yes • No
Sort Sequence Schema	Schema of the sort sequence table if one is used.
Sort Sequence Name	Name of the sort sequence table if one is used.
Random Reads	The number of reads that have occurred in a random fashion. Random means that the location of the row or key could not be predicted ahead of time.

Table 57. Columns used in Show index window (continued)

Column name	Description
Media Preference	Indicates preference whether the storage for the table, partition, or index is allocated on Solid State Disk (SSD), if available.

Determine unnecessary indexes

You can easily determine which indexes are being used for query optimization.

Before V5R3, it was difficult to determine unnecessary indexes. Using the Last Used Date was not dependable, as it was only updated when the logical file was opened using a native database application (for example, an RPG application). Furthermore, it was difficult to find all the indexes over a physical file. Indexes are created as part of a keyed physical file, keyed logical file, join logical file, SQL index, primary key or unique constraint, or referential constraint. However, you can now easily find all indexes and retrieve statistics on index usage as a result of System i Navigator and IBM i functionality. To assist you in tuning your performance, this function now produces statistics on index usage as well as index usage in a query.

To access index information through the System i Navigator, navigate to: **Database > Schemas > Tables**. Right-click your table and select **Show Indexes**.

You can show all indexes for a schema by right-clicking on **Tables** or **Indexes** and selecting Show indexes.

Note: You can also view the statistics through the Retrieve Member Description (QUSRMBRD) API.

Certain fields available in the **Show Indexes** window can help you to determine any unnecessary indexes. Those fields are:

Last Query Use	States the timestamp when the index was last used to retrieve data for a query.
Last Query Statistic Use	States the timestamp when the index was last used to provide statistical information.
Query Use Count	Lists the number of instances the index was used in a query.
Query Statistics Use	Lists the number of instances the index was used for statistical information.
Last Used Date	The century and date this index was last used.
Days Used Count	The number of days the index was used. If the index does not have a last used date, the count is 0.
Date Reset Days Used Count	The date that the days used count was last reset.

The fields start and stop counting based on your situation, or the actions you are currently performing on your system. The following list describes what might affect one or both of your counters:

- The SQE and CQE query engines increment both counters. As a result, the statistics field is updated regardless of which query interface is used.
- A save and restore procedure does not reset the statistics counter if the index is restored over an existing index. If an index is restored that does not exist on the system, the statistics are reset.

You can use the QSYS2.RESET_TABLE_INDEX_STATISTICS procedure to update Last Query Use, Last Query Statistic Use, Query Use Count, and Query Statistics Use.

You can use the Change Object Description (CHGOBJD) CL command to update Last Query Use, Last Query Statistic Use, Query Use Count, Query Statistics Use, Days Used Count, and Date Reset Days Used Count.

Related information

[Retrieve Member Description \(QUSRMBRD\) API](#)

[Change Object Description \(CHGOBJD\) command](#)

Reset usage counts

Resetting the usage counts for a table allows you to determine how the changes you made to your indexing strategy affected the indexes and constraints on that table. For example, if your new strategy causes an index to never be used, you could then delete that index. Resetting usage counts on a table affect all indexes and constraints that are created on that object.

Note: Resetting usage counts for a keyed physical file or a constraint in the Show Indexes window resets the counts of all constraints and keyed access for that file or table.

You can reset index usage counts by right-clicking a specific index in the Indexes folder or in the Show Indexes dialog and selecting **Reset Usage Counts**.

View index build status

You can view a list of indexes that are being built by the database. This view might be helpful in determining when the index becomes usable to your applications.

To display indexes that are being built, follow these steps:

1. In the System i Navigator window, expand the system that you want to use.
2. Expand **Databases**.
3. Expand the database that you want to work with and then expand the Database Maintenance folder. Select **Index Builds**.

Manage index rebuilds

You can manage the rebuild of your indexes using System i Navigator. You can view a list of access paths that are rebuilding and either hold the access path rebuild or change the priority of a rebuild.

To display access paths to rebuild, follow these steps:

1. In the System i Navigator window, expand the system that you want to use.
2. Expand **Databases**.
3. Expand the database that you want to work with and then expand the **Database Maintenance** folder. Select **Index Rebuilds**.

The access paths to rebuild dialog includes the following columns:

<i>Table 58. Columns used in Index rebuilds window</i>	
Column name	Description
Name	Name of access path being rebuilt.
Schema	Schema name where the index is located.
System Name	The system name of the file that owns the index to be rebuilt.
System Schema	System schema name of access path being rebuilt.

Table 58. Columns used in Index rebuilds window (continued)

Column name	Description
Type	The type of index displayed. Possible values are: Keyed Physical File Keyed Logical File Primary Key Unique Key Foreign Key Index
Status	Displays the status of the rebuild. Possible values are: 1-99 – <i>Rebuild Priority</i> Running – <i>Rebuilding</i> Held – <i>Held from be rebuilt</i>
Rebuild Priority	Displays the priority in which the rebuild for this access path is run. Also referred to as sequence number. Possible values are: 1-99: Order to rebuild Held Open

Table 58. Columns used in Index rebuilds window (continued)

Column name	Description
Rebuild Reason	<p>Displays the reason why this access path needs to be rebuilt. Possible values are:</p> <ul style="list-style-type: none"> Create or build index IPL Runtime error Change file or index sharing Other Not needed Change End of Data Restore Alter table Change table Change file Reorganize Enable a constraint Alter table recovery Change file recovery Index shared Runtime error Verify constraint Convert member Restore recovery

Indexing strategy

There are two approaches to index creation: proactive and reactive. Proactive index creation involves anticipating which columns are most often used for selection, joining, grouping, and ordering. Then building indexes over those columns. In the reactive approach, indexes are created based on optimizer feedback, query implementation plan, and system performance measurements.

It is useful to initially build indexes based on the database model and applications and not any particular query. As a starting point, consider designing basic indexes based on the following criteria:

- Primary and foreign key columns based on the database model
- Commonly used local selection columns, including columns that are dependent, such as an automobile's make and model
- Commonly used join columns not considered primary or foreign key columns
- Commonly used grouping columns

Related information

[Indexing and statistics strategies for DB2 for i5/OS](#)

Reactive approach to tuning

To perform reactive tuning, build a prototype of the proposed application without any indexes and start running some queries. Or you could build an initial set of indexes and start running the application to see which ones get used and which do not. Even with a smaller database, the slow running queries become obvious quickly.

The reactive tuning method is also used when trying to understand and tune an existing application that is not performing up to expectations. Use the appropriate debugging and monitoring tools, described in the next section, to view the database feedback messages:

- the indexes the optimizer recommends for local selection
- the temporary indexes used for a query
- the query implementation methods the optimizer chose

If the database engine is building temporary indexes to process joins or perform grouping and selection over permanent tables, build permanent indexes over the same columns. This technique is used to eliminate the temporary index creation. In some cases, a temporary index is built over a temporary table, so a permanent index is not able to be built for those tables. You can use the optimization tools listed in the previous section to note the temporary index creation, the reason it was created, and the key columns.

Proactive approach to tuning

Typically you will create an index for the most selective columns and create statistics for the least selective columns in a query. By creating an index, the optimizer knows that the column is selective and it also gives the optimizer the ability to use that index to implement the query.

In a perfect radix index, the order of the columns is important. In fact, it can make a difference as to whether the optimizer uses it for data retrieval at all. As a general rule, order the columns in an index in the following way:

- Equal predicates first. That is, any predicate that uses the "=" operator may narrow down the range of rows the fastest and should therefore be first in the index.
- If all predicates have an equal operator, then order the columns as follows:
 - Selection predicates + join predicates
 - Join predicates + selection predicates
 - Selection predicates + group by columns
 - Selection predicates + order by columns

In addition to the guidelines above, in general, the most selective key columns should be placed first in the index.

Consider the following SQL statement:

```
SELECT b.col1, b.col2, a.col1
FROM table1 a, table2 b
WHERE b.col1='some_value' AND
      b.col2=some_number AND
      a.join_col=b.join_col
GROUP BY b.col1, b.col2, a.col1
ORDER BY b.col1
```

With a query like this, the proactive index creation process can begin. The basic rules are:

- Custom-build a radix index for the largest or most commonly used queries. Example using the query above:

```
radix index over join column(s) - a.join_col and b.join_col
radix index over most commonly used local selection column(s) - b.col2
```

- For ad hoc online analytical processing (OLAP) environments or less frequently used queries, build single-key EVIs over the local selection column(s) used in the queries. Example using the query above:

```
EVI over non-unique local selection columns - b.col1 and b.col2
```

Coding for effective indexes

The following topics provide suggestions to help you design code which allows Db2 for i to take advantage of available indexes:

Avoid numeric conversions

When a column value and a host variable (or constant value) are being compared, try to specify the same data types and attributes. Db2 for i might not use an index for the named column if the host variable or constant value has a greater precision than the precision of the column. If the two items being compared have different data types, Db2 for i needs to convert one or the other of the values, which can result in inaccuracies (because of limited machine precision).

To avoid problems for columns and constants being compared, use the following:

- same data type
- same scale, if applicable
- same precision, if applicable

For example, EDUCLVL is a halfword integer value (SMALLINT). When using SQL, specify:

```
... WHERE EDUCLVL < 11 AND
      EDUCLVL >= 2
```

instead of

```
... WHERE EDUCLVL < 1.1E1 AND
      EDUCLVL > 1.3
```

When using the OPNQRYF command, specify:

```
... QRYSLT('EDUCLVL *LT 11 *AND EDUCLVL *GE 2')
```

instead of

```
... QRYSLT('EDUCLVL *LT 1.1E1 *AND EDUCLVL *GT 1.3')
```

If an index was created over the EDUCLVL column, then the optimizer might not use the index in the second example. The constant precision is greater than the column precision. It attempts to convert the constant to the precision of the column. In the first example, the optimizer considers using the index, because the precisions are equal.

Avoid arithmetic expressions

Do not use an arithmetic expression as an operand to compare to a column in a row selection predicate. The optimizer does not use an index on a column compared to an arithmetic expression. While this technique might not cause the column index to become unusable, it prevents any estimates and possibly the use of index scan-key positioning. The primary thing that is lost is the ability to use and extract any statistics that might be useful in the optimization of the query.

For example, when using SQL, specify the following:

```
... WHERE SALARY > 16500
```

instead of

```
... WHERE SALARY > 15000*1.1
```

Avoid character string padding

Try to use the same data length when comparing a fixed-length character string column value to a host variable or constant value. Db2 for i might not use an index if the constant value or host variable is longer than the column length.

For example, EMPNO is CHAR(6) and DEPTNO is CHAR(3). For example, when using SQL, specify the following:

```
... WHERE EMPNO > '000300' AND  
      DEPTNO < 'E20'
```

instead of

```
... WHERE EMPNO > '000300 ' AND  
      DEPTNO < 'E20 '
```

When using the OPNQRYF command, specify:

```
... QRYSLT('EMPNO *GT "000300" *AND DEPTNO *LT "E20"')
```

instead of

```
... QRYSLT('EMPNO *GT "000300" *AND DEPTNO *LT "E20"')
```

Avoid the use of LIKE patterns beginning with % or _

The percent (%), and underline (_), used in the pattern of a LIKE (OPNQRYF %WLDCRD) predicate, specify a character string like the row column values to select. They can take advantage of indexes when used to denote characters in the middle or at the end of a character string.

For example, when using SQL, specify the following:

```
... WHERE LASTNAME LIKE 'J%SON%'
```

When using the OPNQRYF command, specify the following:

```
... QRYSLT('LASTNAME *EQ %WLDCRD(''J*SON*'')')
```

However, when used at the beginning of a character string, they can prevent Db2 for i from using any indexes that might be defined on the LASTNAME column to limit the number of rows scanned using index scan-key positioning. Index scan-key selection, however, is allowed. For example, in the following queries index scan-key selection can be used, but index scan-key positioning cannot.

In SQL:

```
... WHERE LASTNAME LIKE '%SON'
```

In OPNQRYF:

```
... QRYSLT('LASTNAME *EQ %WLDCRD(''*SON'')')
```

Avoid patterns with a % so that you can get the best performance with key processing on the predicate. If possible, try to get a partial string to search so that index scan-key positioning can be used.

For example, if you were looking for the name "Smithers", but you only type "S%," this query returns all names starting with "S." Adjust the query to return all names with "Smi%". By forcing the use of partial strings, you might get better performance in the long term.

Using derived indexes

SQL indexes can be created where the key is specified as an expression. This type of key is also referred to as a derived key.

Suppose the following index is defined:

```
CREATE INDEX TOTALIX ON EMPLOYEE(SALARY+BONUS+COMM AS TOTAL)
```

Now, return all the employees whose total compensation is greater than 50000.

```
SELECT * FROM EMPLOYEE
WHERE SALARY+BONUS+COMM > 50000
ORDER BY SALARY+BONUS+COMM
```

The optimizer uses the index TOTALIX with index probe to satisfy both the WHERE selection and the ordering criteria.

There are some special considerations for matching the derived key with an expression used in the query.

- No expression matching is done to match index key constants with host variables used in a query. This includes implicit parameter marker conversion performed by the database manager.

```
CREATE INDEX D_IDX1 ON EMPLOYEE (SALARY/12 AS MONTHLY)
```

In this example, return all employees whose monthly salary is greater than 3000. Use a host variable to provide the value used by the query.

```
long months = 12;
EXEC SQL SELECT * FROM EMPLOYEE WHERE SALARY/:months > 3000
```

The optimizer does not use the index since there is no support for matching the host variable value *months* in the query to the constant 12 in the index.

- For a dynamic SQL statement, using the QAQQINI option PARAMETER_MARKER_CONVERSION with value *NO can be used to prevent conversion of constants to parameter markers. This technique allows for improved derived index key matching. However, because of the performance implications of using this QAQQINI setting, take care with its usage.
- In general, expressions in the index must match the expression in the query.

```
SELECT * FROM EMPLOYEE
WHERE SALARY+COMM+BONUS > 50000
```

In this example, the SALARY+COMM+BONUS expression is in a different order than the index key SALARY+BONUS+COMM and would not match.

- It is recommended that derived index keys be kept as simple as possible. The index is less likely to be selected when a complex query expression and a complex index key expression need to be matched.
- The CQE optimizer has limited support for matching derived key indexes.

[Derived key index](#)

You can use the SQL CREATE INDEX statement to create a derived key index using an SQL expression.

Related information

[SQL Create Index statement](#)

Using sparse indexes

SQL indexes can be created using WHERE selection predicates. These indexes can also be referred to as sparse indexes. The advantage of a sparse index is that fewer entries are maintained in the index. Only those entries matching the WHERE selection criteria are maintained in the index.

In general, the query WHERE selection must be a subset of the sparse index WHERE selection in order for the sparse index to be used.

Here is a simple example of when a sparse index can be used:

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20 and COL3=30
```

It is recommended that the WHERE selection in the sparse index is kept as simple as possible. The more complex the WHERE selection, the more difficult it becomes to match the sparse index WHERE selection to the query WHERE selection. Then it is less likely that the sparse index is used. The CQE optimizer does not support sparse indexes. It does support select/omit logical files however. The SQE optimizer matches the CQE optimizer in its support for select/omit logical files and has nearly full support for sparse indexes.

[SQL Create Index statement](#)

Using indexes with sort sequence

The following sections provide useful information about how indexes work with sort sequence tables.

Using indexes and sort sequence with selection, joins, or grouping

Before using an existing index, Db2 for i ensures the attributes of the columns (selection, join, or grouping columns) match the attributes of the key columns in the existing index. The sort sequence table is an additional attribute that must be compared.

The query sort sequence table (specified by the SRTSEQ and LANGID) must match the index sort sequence table. Db2 for i compares the sort sequence tables. If they do not match, the existing index cannot be used.

There is an exception to this rule, however. If the sort sequence table associated with the query is a unique-weight sequence table (including *HEX), Db2 for i acts as though no sort sequence table is specified for selection, join, or grouping columns that use the following operators and predicates:

- equal (=) operator
- not equal (^= or <>) operator
- LIKE predicate (OPNQRYF %WLDCRD and *CT)
- IN predicate (OPNQRYF %VALUES)

When these conditions are true, Db2 for i is free to use any existing index where the key columns match the columns and either:

- The index does not contain a sort sequence table or
- The index contains a unique-weight sort sequence table

Note:

1. The table does not need to match the unique-weight sort sequence table associated with the query.

2. Bitmap processing has a special consideration when multiple indexes are used for a table. If two or more indexes have a common key column referenced in the query selection, then those indexes must either use the same sort sequence table or no sort sequence table.

Using indexes and sort sequence with ordering

Unless the optimizer chooses a sort to satisfy the ordering request, the index sort sequence table must match the query sort sequence table.

When a sort is used, the translation is done during the sort. Since the sort is handling the sort sequence requirement, this technique allows Db2 for i to use any existing index that meets the selection criteria.

Index examples

The following index examples are provided to help you create effective indexes.

For the purposes of the examples, assume that three indexes are created.

Assume that an index HEXIX was created with *HEX as the sort sequence.

```
CREATE INDEX HEXIX ON STAFF (JOB)
```

Assume that an index UNQIX was created with a unique-weight sort sequence.

```
CREATE INDEX UNQIX ON STAFF (JOB)
```

Assume that an index SHRIX was created with a shared-weight sort sequence.

```
CREATE INDEX SHRIX ON STAFF (JOB)
```

Index example: Equal selection with no sort sequence table

Equal selection with no sort sequence table (SRTSEQ(*HEX)).

```
SELECT * FROM STAFF  
WHERE JOB = 'MGR'
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF))  
QRYSLT('JOB *EQ ''MGR''')  
SRTSEQ(*HEX)
```

The system can use either index HEXIX or index UNQIX.

Index example: Equal selection with a unique-weight sort sequence table

Equal selection with a unique-weight sort sequence table (SRTSEQ(*LANGIDUNQ) LANGID(ENU)).

```
SELECT * FROM STAFF  
WHERE JOB = 'MGR'
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF))  
QRYSLT('JOB *EQ ''MGR''')  
SRTSEQ(*LANGIDUNQ) LANGID(ENU)
```

The system can use either index HEXIX or index UNQIX.

Index example: Equal selection with a shared-weight sort sequence table

Equal selection with a shared-weight sort sequence table (SRTSEQ(*LANGIDSHR) LANGID(ENU)).

```
SELECT * FROM STAFF
WHERE JOB = 'MGR'
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF))
QRYSLT('JOB *EQ ''MGR''')
SRTSEQ(*LANGIDSHR) LANGID(ENU)
```

The system can only use index SHRIX.

Index example: Greater than selection with a unique-weight sort sequence table

Greater than selection with a unique-weight sort sequence table (SRTSEQ(*LANGIDUNQ) LANGID(ENU)).

```
SELECT * FROM STAFF
WHERE JOB > 'MGR'
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF))
QRYSLT('JOB *GT ''MGR''')
SRTSEQ(*LANGIDUNQ) LANGID(ENU)
```

The system can only use index UNQIX.

Index example: Join selection with a unique-weight sort sequence table

Join selection with a unique-weight sort sequence table (SRTSEQ(*LANGIDUNQ) LANGID(ENU)).

```
SELECT * FROM STAFF S1, STAFF S2
WHERE S1.JOB = S2.JOB
```

or the same query using the JOIN syntax.

```
SELECT *
FROM STAFF S1 INNER JOIN STAFF S2
ON S1.JOB = S2.JOB
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE(STAFF STAFF)
FORMAT(FORMAT1)
JFLD((1/JOB 2/JOB *EQ))
SRTSEQ(*LANGIDUNQ) LANGID(ENU)
```

The system can use either index HEXIX or index UNQIX for either query.

Index example: Join selection with a shared-weight sort sequence table

Join selection with a shared-weight sort sequence table (SRTSEQ(*LANGIDSHR) LANGID(ENU)).

```
SELECT * FROM STAFF S1, STAFF S2
WHERE S1.JOB = S2.JOB
```

or the same query using the JOIN syntax.

```
SELECT *
FROM STAFF S1 INNER JOIN STAFF S2
ON S1.JOB = S2.JOB
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE(STAFF STAFF) FORMAT(FORMAT1)
JFLD((1/JOB 2/JOB *EQ))
SRTSEQ(*LANGIDSHR) LANGID(ENU)
```

The system can only use index SHRIX for either query.

Index example: Ordering with no sort sequence table

Ordering with no sort sequence table (SRTSEQ(*HEX)).

```
SELECT * FROM STAFF
WHERE JOB = 'MGR'
ORDER BY JOB
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF))
QRYSLT('JOB *EQ ''MGR''')
KEYFLD(JOB)
SRTSEQ(*HEX)
```

The system can only use index HEXIX.

Index example: Ordering with a unique-weight sort sequence table

Ordering with a unique-weight sort sequence table (SRTSEQ(*LANGIDUNQ) LANGID(ENU)).

```
SELECT * FROM STAFF
WHERE JOB = 'MGR'
ORDER BY JOB
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF))
QRYSLT('JOB *EQ ''MGR''')
KEYFLD(JOB) SRTSEQ(*LANGIDUNQ) LANGID(ENU)
```

The system can only use index UNQIX.

Index example: Ordering with a shared-weight sort sequence table

Ordering with a shared-weight sort sequence table (SRTSEQ(*LANGIDSHR) LANGID(ENU)).

```
SELECT * FROM STAFF
WHERE JOB = 'MGR'
ORDER BY JOB
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF))
QRYSLT('JOB *EQ ''MGR''')
KEYFLD(JOB) SRTSEQ(*LANGIDSHR) LANGID(ENU)
```

The system can only use index SHRIX.

Index example: Ordering with ALWCPYDTA(*OPTIMIZE) and a unique-weight sort sequence table

Ordering with ALWCPYDTA(*OPTIMIZE) and a unique-weight sort sequence table (SRTSEQ(*LANGIDUNQ) LANGID(ENU)).

```
SELECT * FROM STAFF
WHERE JOB = 'MGR'
ORDER BY JOB
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF))
QRYSLT('JOB *EQ ''MGR''')
KEYFLD(JOB)
SRTSEQ(*LANGIDUNQ) LANGID(ENU)
ALWCPYDTA(*OPTIMIZE)
```

The system can use either index HEXIX or index UNQIX for selection. Ordering is done during the sort using the *LANGIDUNQ sort sequence table.

Index example: Grouping with no sort sequence table

Grouping with no sort sequence table (SRTSEQ(*HEX)).

```
SELECT JOB FROM STAFF
GROUP BY JOB
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF)) FORMAT(FORMAT2)
GRPFLD((JOB))
SRTSEQ(*HEX)
```

The system can use either index HEXIX or index UNQIX.

Index example: Grouping with a unique-weight sort sequence table

Grouping with a unique-weight sort sequence table (SRTSEQ(*LANGIDUNQ) LANGID(ENU)).

```
SELECT JOB FROM STAFF
GROUP BY JOB
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF)) FORMAT(FORMAT2)
GRPFLD((JOB))
SRTSEQ(*LANGIDUNQ) LANGID(ENU)
```

The system can use either index HEXIX or index UNQIX.

Index example: Grouping with a shared-weight sort sequence table

Grouping with a shared-weight sort sequence table (SRTSEQ(*LANGIDSHR) LANGID(ENU)).

```
SELECT JOB FROM STAFF
GROUP BY JOB
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF)) FORMAT(FORMAT2)
GRPFLD((JOB))
SRTSEQ(*LANGIDSHR) LANGID(ENU)
```

The system can only use index SHRIX.

The following examples assume that three more indexes are created over columns JOB and SALARY. The CREATE INDEX statements precede the examples.

Assume an index HEXIX2 was created with *HEX as the sort sequence.

```
CREATE INDEX HEXIX2 ON STAFF (JOB, SALARY)
```

Assume that an index UNQIX2 was created and the sort sequence is a unique-weight sort sequence.

```
CREATE INDEX UNQIX2 ON STAFF (JOB, SALARY)
```

Assume an index SHRIX2 was created with a shared-weight sort sequence.

```
CREATE INDEX SHRIX2 ON STAFF (JOB, SALARY)
```

Index example: Ordering and grouping on the same columns with a unique-weight sort sequence table

Ordering and grouping on the same columns with a unique-weight sort sequence table (SRTSEQ(*LANGIDUNQ) LANGID(ENU)).

```
SELECT JOB, SALARY FROM STAFF
GROUP BY JOB, SALARY
ORDER BY JOB, SALARY
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF)) FORMAT(FORMAT3)
GRPFLD(JOB SALARY)
KEYFLD(JOB SALARY)
SRTSEQ(*LANGIDUNQ) LANGID(ENU)
```

The system can use UNQIX2 to satisfy both the grouping and ordering requirements. If index UNQIX2 did not exist, the system creates an index using a sort sequence table of *LANGIDUNQ.

Index example: Ordering and grouping on the same columns with ALWCPYDTA(*OPTIMIZE) and a unique-weight sort sequence table

Ordering and grouping on the same columns with ALWCPYDTA(*OPTIMIZE) and a unique-weight sort sequence table (SRTSEQ(*LANGIDUNQ) LANGID(ENU)).

```
SELECT JOB, SALARY FROM STAFF
GROUP BY JOB, SALARY
ORDER BY JOB, SALARY
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF)) FORMAT(FORMAT3)
GRPFLD(JOB SALARY)
KEYFLD(JOB SALARY)
SRTSEQ(*LANGIDUNQ) LANGID(ENU)
ALWCPYDTA(*OPTIMIZE)
```

The system can use UNQIX2 to satisfy both the grouping and ordering requirements. If index UNQIX2 did not exist, the system does one of the following actions:

- Create an index using a sort sequence table of *LANGIDUNQ or
- Use index HEXIX2 to satisfy the grouping and to perform a sort to satisfy the ordering

Index example: Ordering and grouping on the same columns with a shared-weight sort sequence table

Ordering and grouping on the same columns with a shared-weight sort sequence table (SRTSEQ(*LANGIDSHR) LANGID(ENU)).

```
SELECT JOB, SALARY FROM STAFF
GROUP BY JOB, SALARY
ORDER BY JOB, SALARY
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF)) FORMAT(FORMAT3)
GRPFLD(JOB SALARY)
KEYFLD(JOB SALARY)
SRTSEQ(*LANGIDSHR) LANGID(ENU)
```

The system can use SHRIX2 to satisfy both the grouping and ordering requirements. If index SHRIX2 did not exist, the system creates an index using a sort sequence table of *LANGIDSHR.

Index example: Ordering and grouping on the same columns with ALWCPYDTA(*OPTIMIZE) and a shared-weight sort sequence table

Ordering and grouping on the same columns with ALWCPYDTA(*OPTIMIZE) and a shared-weight sort sequence table (SRTSEQ(*LANGIDSHR) LANGID(ENU)).

```
SELECT JOB, SALARY FROM STAFF
GROUP BY JOB, SALARY
ORDER BY JOB, SALARY
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF)) FORMAT(FORMAT3)
GRPFLD(JOB SALARY)
KEYFLD(JOB SALARY)
SRTSEQ(*LANGIDSHR) LANGID(ENU)
ALWCPYDTA(*OPTIMIZE)
```

The system can use SHRIX2 to satisfy both the grouping and ordering requirements. If index SHRIX2 did not exist, the system creates an index using a sort sequence table of *LANGIDSHR.

Index example: Ordering and grouping on different columns with a unique-weight sort sequence table

Ordering and grouping on different columns with a unique-weight sort sequence table (SRTSEQ(*LANGIDUNQ) LANGID(ENU)).

```
SELECT JOB, SALARY FROM STAFF
GROUP BY JOB, SALARY
ORDER BY SALARY, JOB
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF)) FORMAT(FORMAT3)
GRPFLD(JOB SALARY)
KEYFLD(SALARY JOB)
SRTSEQ(*LANGIDSHR) LANGID(ENU)
```

The system can use index HEXIX2 or index UNQIX2 to satisfy the grouping requirements. A temporary result is created containing the grouping results. A temporary index is then built over the temporary result using a *LANGIDUNQ sort sequence table to satisfy the ordering requirements.

Index example: Ordering and grouping on different columns with ALWCPYDTA(*OPTIMIZE) and a unique-weight sort sequence table

Ordering and grouping on different columns with ALWCPYDTA(*OPTIMIZE) and a unique-weight sort sequence table (SRTSEQ(*LANGIDUNQ) LANGID(ENU)).

```
SELECT JOB, SALARY FROM STAFF
GROUP BY JOB, SALARY
ORDER BY SALARY, JOB
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF)) FORMAT(FORMAT3)
GRPFLD(JOB SALARY)
KEYFLD(SALARY JOB)
SRTSEQ(*LANGIDUNQ) LANGID(ENU)
ALWCPYDTA(*OPTIMIZE)
```

The system can use index HEXIX2 or index UNQIX2 to satisfy the grouping requirements. A sort is performed to satisfy the ordering requirements.

Index example: Ordering and grouping on different columns with ALWCPYDTA(*OPTIMIZE) and a shared-weight sort sequence table

Ordering and grouping on different columns with ALWCPYDTA(*OPTIMIZE) and a shared-weight sort sequence table (SRTSEQ(*LANGIDSHR) LANGID(ENU)).

```
SELECT JOB, SALARY FROM STAFF
GROUP BY JOB, SALARY
ORDER BY SALARY, JOB
```

When using the **OPNQRYF** command, specify:

```
OPNQRYF FILE((STAFF)) FORMAT(FORMAT3)
GRPFLD(JOB SALARY)
KEYFLD(SALARY JOB)
SRTSEQ(*LANGIDSHR) LANGID(ENU)
ALWCPYDTA(*OPTIMIZE)
```

The system can use index SHRIX2 to satisfy the grouping requirements. A sort is performed to satisfy the ordering requirements.

Sparse index examples

This topic shows examples of how the sparse index matching algorithm works.

In example S1, the query selection is a subset of the sparse index selection and consequently an index scan over the sparse index is used. The remaining query selection (COL3=30) is executed following the index scan.

Example S1

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20 and COL3=30
```

In example S2, the query selection is not a subset of the sparse index selection and the sparse index cannot be used.

Example S2

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20 and COL3=30
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20
```

In example S3, the query selection exactly matches the sparse index selection and an index scan over the sparse index can be used.

Example S3

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20 and COL3=30
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20 and COL3=30
```

In example S4, the query selection is a subset of the sparse index selection and an index scan over the sparse index can be used. The remaining query selection (COL3=30) is executed following the index scan.

Example S4

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20 and COL3=30
```

In example S5, the query selection is not a subset of the sparse index selection and the sparse index cannot be used.

Example S5

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20 and COL3=30
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20
```

In example S6, the query selection exactly matches the sparse index selection and an index scan over the sparse index can be used. The query selection is executed following the index scan to eliminate excess records from the sparse index.

Example S6

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 or COL2=20 or COL3=30
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 or COL2=20 or COL3=30
```

In example S7, the query selection is a subset of the sparse index selection and an index scan over the sparse index can be used. The query selection is executed following the index scan to eliminate excess records from the sparse index.

Example S7

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 or COL2=20 or COL3=30
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 or COL2=20
```

In example S8, the query selection is not a subset of the sparse index selection and the sparse index cannot be used.

Example S8

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 or COL2=20
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 or COL2=20 or COL3=30
```

In the next example S9, the constant 'MN' was replaced by a parameter marker for the query selection. The sparse index had the local selection of COL1='MN' applied to it when it was created. The sparse index matching algorithm matches the parameter marker to the constant 'MN' in the query predicate COL1=?. It verifies that the value of the parameter marker is the same as the constant in the sparse index; therefore the sparse index can be used.

Example S9

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1='MN' or COL2='TWINS'
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
Where Col3='WIN' and (Col1=? or Col2='TWINS')
```

In the next example S10, the keys of the sparse index match the order by fields in the query. For the sparse index to satisfy the specified ordering, the optimizer must verify that the query selection is a subset of the sparse index selection. In this example, the sparse index can be used.

Example S10

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL1, COL3)
WHERE COL1='MN' or COL2='TWINS'
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
Where Col3='WIN' and (Col1='MN' or Col2='TWINS')
ORDER BY COL1, COL3
```

In the next example S11, the keys of the sparse index do not match the order by fields in the query. But the selection in sparse index T2 is a superset of the query selection. Depending on size, the optimizer might choose an index scan over sparse index T2 and then use a sort to satisfy the specified ordering.

Example S11

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL2, COL4)
WHERE COL1='MN' or COL2='TWINS'
```

```
SELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
Where Col3='WIN' and (Col1='MN' or Col2='TWINS')
ORDER BY COL1, COL3
```

The next example S12 represents the classic optimizer decision: is it better to do an index probe using index IX1 or is it better to do an index scan using sparse index SPR1? Both indexes retrieve the same number of index entries and have the same cost from that point forward. For example, both indexes have the same cost to retrieve the selected records from the dataspace, based on the retrieved entries/keys.

The cost to retrieve the index entries is the deciding criteria. In general, if index IX1 is large then an index scan over sparse index SPR1 has a lower cost to retrieve the index entries. If index IX1 is rather small

then an index probe over index IX1 has a lower cost to retrieve the index entries. Another cost decision is reusability. The plan using sparse index SPR1 is not as reusable as the plan using index IX1 because of the static selection built into the sparse selection.

Example S12

```
CREATE INDEX MYLIB/IX1 on MYLIB/T1 (COL1, COL2, COL3)
```

```
CREATE INDEX MYLIB/SPR1 on MYLIB/T1 (COL3)
WHERE COL1=10 and COL2=20 and COL3=30
```

```
CSELECT COL1, COL2, COL3, COL4
FROM MYLIB/T1
WHERE COL1=10 and COL2=20 and COL3=30
```

Application design tips for database performance

There are some design tips that you can apply when designing SQL applications to maximize your database performance.

Using live data

The term *live data* refers to the type of access that the database manager uses when it retrieves data without making a copy of the data. Using this type of access, the data, which is returned to the program, always reflects the current values of the data in the database. The programmer can control whether the database manager uses a copy of the data or retrieves the data directly. This control is done by specifying the allow copy data (ALWCOPYDTA) parameter on the precompiler commands or the **Start SQL (STRSQL)** command.

Specifying ALWCOPYDTA(*NO) instructs the database manager to always use live data. In most cases, forcing live data access is a detriment to performance. It severely limits the possible plan choices that the optimizer could use to implement the query. Avoid it in most cases. However, in specialized cases involving a simple query, live data access can be used as a performance advantage. The cursor does not need to be closed and opened again to refresh the data being retrieved.

An example application demonstrating this advantage is one that produces a list on a display. If the display can show only 20 list elements at a time, then, after the initial 20 elements are displayed, the programmer can request that the next 20 rows be displayed. A typical SQL application designed for an operating system other than the IBM i operating system, might be structured as follows:

```
EXEC SQL
  DECLARE C1 CURSOR FOR
  SELECT EMPNO, LASTNAME, WORKDEPT
  FROM CORPDATA.EMPLOYEE
  ORDER BY EMPNO
END-EXEC.

EXEC SQL
  OPEN C1
END-EXEC.

*   PERFORM FETCH-C1-PARA 20 TIMES.

    MOVE EMPNO to LAST-EMPNO.

EXEC SQL
  CLOSE C1
END-EXEC.

*   Show the display and wait for the user to indicate that
*   the next 20 rows should be displayed.

EXEC SQL
  DECLARE C2 CURSOR FOR
  SELECT EMPNO, LASTNAME, WORKDEPT
  FROM CORPDATA.EMPLOYEE
  WHERE EMPNO > :LAST-EMPNO
  ORDER BY EMPNO
```

```

END-EXEC.

EXEC SQL
  OPEN C2
END-EXEC.

*   PERFORM FETCH-C21-PARA  20 TIMES.

*   Show the display with these 20 rows of data.

EXEC SQL
  CLOSE C2
END-EXEC.

```

In the preceding example, notice that an additional cursor had to be opened to continue the list and to get current data. This technique can result in creating an additional ODP that increases the processing time on the system. In place of the preceding example, the programmer can design the application specifying ALWCPYDTA(*NO) with the following SQL statements:

```

EXEC SQL
  DECLARE C1 CURSOR FOR
  SELECT EMPNO, LASTNAME, WORKDEPT
  FROM   CORPDATA.EMPLOYEE
  ORDER BY EMPNO
END-EXEC.

EXEC SQL
  OPEN C1
END-EXEC.

*   Display the screen with these 20 rows of data.

*   PERFORM FETCH-C1-PARA  20 TIMES.

*   Show the display and wait for the user to indicate that
*   the next 20 rows should be displayed.

*   PERFORM FETCH-C1-PARA  20 TIMES.

EXEC SQL
  CLOSE C1
END-EXEC.

```

In the preceding example, the query might perform better if the FOR 20 ROWS clause was used on the multiple-row FETCH statement. Then, the 20 rows are retrieved in one operation.

Reducing the number of open operations

The SQL data manipulation language statements must do database open operations in order to create an open data path (ODP) to the data. An open data path is the path through which all input/output operations for the table are performed. In a sense, it connects the SQL application to a table. The number of open operations in a program can significantly affect performance.

A database open operation occurs on:

- An OPEN statement
- SELECT INTO statement
- An INSERT statement with a VALUES clause
- An UPDATE statement with a WHERE condition
- An UPDATE statement with a WHERE CURRENT OF cursor and SET clauses that refer to operators or functions
- SET statement that contains an expression
- VALUES INTO statement that contains an expression
- A DELETE statement with a WHERE condition

An INSERT statement with a select-statement requires two open operations. Certain forms of subqueries could also require one open per subselect.

To minimize the number of opens, Db2 for i leaves the open data path (ODP) open and reuses the ODP if the statement is run again, unless:

- The ODP used a host variable to build a subset temporary index. The optimizer could choose to build a temporary index with entries for only the rows that match the row selection specified in the SQL statement. If a host variable was used in the row selection, the temporary index does not have the entries required for a different host variable value.
- Ordering was specified on a host variable value.
- An **Override Database File (OVRDBF)** or **Delete Override (DLTOVR)** CL command has been issued since the ODP was opened, which affects the SQL statement execution.

Note: Only overrides that affect the name of the table being referred to causes the ODP to be closed within a given program invocation.

- The join is a complex join that requires temporary objects to contain the intermediate steps of the join.
- Some cases involve a complex sort, where a temporary file is required, might not be reusable.
- A change to the library list since the last open has occurred, which changes the table selected by an unqualified referral in system naming mode.
- The join was implemented by the CQE optimizer using hash join.

For embedded static SQL, Db2 for i only reuses ODPs opened by the same statement. An identical statement coded later in the program does not reuse an ODP from any other statement. If the identical statement must be run in the program many times, code it once in a subroutine and call the subroutine to run the statement.

The ODPs opened by Db2 for i are closed when any of the following occurs:

- a CLOSE, INSERT, UPDATE, DELETE, or SELECT INTO statement completes and the ODP required a temporary result that was not reusable or a subset temporary index.
- the **Reclaim Resources (RCLRSC)** command is issued. A **Reclaim Resources (RCLRSC)** is issued when the first COBOL program on the call stack ends or when a COBOL program issues the STOP RUN COBOL statement. **Reclaim Resources (RCLRSC)** does not close the ODPs created for programs precompiled using CLOSQCSR(*ENDJOB). For interaction of **Reclaim Resources (RCLRSC)** with non-default activation groups, see the following books:
 - WebSphere® Development Studio: ILE C/C++ Programmer's Guide
 - WebSphere Development Studio: ILE COBOL Programmer's Guide
 - WebSphere Development Studio: ILE RPG Programmer's Guide
- the last program containing SQL statements on the call stack exits. Exception is for ODPs created for programs precompiled using CLOSQCSR(*ENDJOB) or modules precompiled using CLOSQCSR(*ENDACTGRP).
- a CONNECT (Type 1) statement changes the application server for an activation group, all ODPs created for the activation group are closed.
- a DISCONNECT statement ends a connection to the application server, all ODPs for that application server are closed.
- a released connection is ended by a successful COMMIT, all ODPs for that application server are closed.
- the threshold for open cursors specified by the query options file (QAQQINI) parameter OPEN_CURSOR_THRESHOLD is reached.
- the SQL LOCK TABLE or CL ALCOBJ OBJ((filename *FILE *EXCL)) CONFLICT(*RQSRLS) command closes any pseudo-closed cursors associated with the specified table.
- an application has requested a close, but the data path was left open. The ODP can be forced closed for a specific file by using the ALCOBJ CL command. This close does not force the ODP to close if the application has not requested that the cursor be closed. The syntax for the command is: ALCOBJ OBJ((library/file *FILE *EXCL)) CONFLICT(*RQSRLS).

- an MQT plan expired based on the timestamp.
- an incompatible commitment control change occurred.
- the table size changed beyond tolerance. The optimizer needs to reoptimize based on the new table size.
- a new index or indexes were created. The optimizer can cost a plan created with the new indexes and compare its cost to the previous plan.
- new statistics were created. The optimizer can take advantage of these new statistics to create a more efficient plan.
- host variables are incompatible with a non-reusable MTI, an MQT, or a sparse index used to implement the query.
- data is warm (in memory).
- the OPTIMIZATION_GOAL *All IO or *First IO specified in query options file QAQQINI was changed.
- a hard close was forced.

The optimizer does not recognize that query selectivity has changed due to host variable changes. It continues to use the existing open and access plan. Change of selectivity due to host variables is only evaluated at full open time unless the PSEUDO_OPEN_CHECK_HOST_VARS qaqqini option is altered.

You can control whether the system keeps the ODPs open in the following ways:

- Design the application so a program that issues an SQL statement is always on the call stack
- Use the CLOSQLCSR(*ENDJOB) or CLOSQLCSR(*ENDACTGRP) parameter
- By specifying the OPEN_CURSOR_THRESHOLD and OPEN_CURSOR_CLOSE_COUNT parameters of the query options file (QAQQINI)

You can control whether the optimizer factors in host variable selectivity once in pseudo mode for queries with host variable that have considerable selectivity variability.

- By specifying the PSEUDO_OPEN_CHECK_HOST_VARS parameter of the query options file (QAQQINI)

An open operation occurs for the first execution of each UPDATE WHERE CURRENT OF, when any SET clause expression contains an operator or function. The open can be avoided by coding the function or operation in the host language code.

For example, the following UPDATE causes the system to do an open operation:

```
EXEC SQL
  FETCH EMPT INTO :SALARY
END-EXEC.

EXEC SQL
  UPDATE CORPDATA.EMPLOYEE
  SET SALARY = :SALARY + 1000
  WHERE CURRENT OF EMPT
END-EXEC.
```

Instead, use the following coding technique to avoid opens:

```
EXEC SQL
  FETCH EMPT INTO :SALARY
END EXEC.

ADD 1000 TO SALARY.

EXEC SQL
  UPDATE CORPDATA.EMPLOYEE
  SET SALARY = :SALARY
  WHERE CURRENT OF EMPT
END-EXEC.
```

You can determine whether SQL statements result in full opens in several ways. The preferred methods are to use the Database Monitor or by looking at the messages issued while debug is active. You can also use the CL commands **Trace Job (TRCJOB)** or **Display Journal (DSPJRN)**.

Retaining cursor positions

You can improve performance by retaining cursor positions.

Retaining cursor positions for non-ILE program calls

For non-ILE program calls, the close SQL cursor (CLOSQLCSR) parameter allows you to specify the scope of the following:

- The cursors
- The prepared statements
- The locks

When used properly, the CLOSQLCSR parameter can reduce the number of SQL OPEN, PREPARE, and LOCK statements needed. It can also simplify applications by allowing you to retain cursor positions across program calls.

***ENDPGM** The default for all non-ILE precompilers. With this option, a cursor remains open and accessible only while the program that opened it is on the call stack. When the program ends, the SQL cursor can no longer be used. Prepared statements are also lost when the program ends. Locks, however, remain until the last SQL program on the call stack has completed.

***ENDSQL** SQL cursors and prepared statements that are created by a program remain open until the last SQL program on the call stack has completed. They cannot be used by other programs, only by a different call to the same program. Locks remain until the last SQL program in the call stack completes.

***ENDJOB** This option allows you to keep SQL cursors, prepared statements, and locks active for the duration of the job. When the last SQL program on the stack has completed, any SQL resources created by *ENDJOB programs are still active. The locks remain in effect. The SQL cursors that were not explicitly closed by the CLOSE, COMMIT, or ROLLBACK statements remain open. The prepared statements are still usable on subsequent calls to the same program.

Related reference

[Effects of precompile options on database performance](#)

Several precompile options are available for creating SQL programs with improved performance. They are only options because using them could impact the function of the application. For this reason, the default value for these parameters is the value that ensures successful migration of applications from prior releases. However, you can improve performance by specifying other options.

Retaining cursor positions across ILE program calls

For ILE program calls, the close SQL cursor (CLOSQLCSR) parameter allows you to specify the scope of the following:

- The cursors
- The prepared statements
- The locks

When used properly, the CLOSQLCSR parameter can reduce the number of SQL OPEN, PREPARE, and LOCK statements needed. It can also simplify applications by allowing you to retain cursor positions across program calls.

***ENDACTGRP** The default for the ILE precompilers. With this option, SQL cursors and prepared statements remain open until the activation group that the program is running under ends. They cannot be used by other programs, only by a different call to the same program. Locks remain until the activation group ends.

***ENDMOD** With this option, a cursor remains open and accessible only while the module that opened it is active. When the module ends, the SQL cursor can no longer be used. Prepared statements are also lost when the module ends. Locks, however, remain until the last SQL program in the call stack completes.

General rules for retaining cursor positions for all program calls

Programs compiled with either CLOSQLCSR(*ENDPGM) or CLOSQLCSR(*ENDMOD) must open a cursor every time the program or module is called, in order to access the data. If the SQL program or module is called several times, and you want to take advantage of a reusable ODP, then the cursor must be explicitly closed before the program or module exits.

Using the CLOSQLCSR parameter and specifying *ENDSQL, *ENDJOB, or *ENDACTGRP, you might not need to run an OPEN and a CLOSE statement on every call. In addition to having fewer statements to run, you can maintain the cursor position between calls to the program or module.

The following examples of SQL statements help demonstrate the advantage of using the CLOSQLCSR parameter:

```
EXEC SQL
  DECLARE DEPTDATA CURSOR FOR
  SELECT EMPNO, LASTNAME
  FROM CORPDATA.EMPLOYEE
  WHERE WORKDEPT = :DEPTNUM
END-EXEC.

EXEC SQL
  OPEN DEPTDATA
END-EXEC.

EXEC SQL
  FETCH DEPTDATA INTO :EMPNUM, :LNAME
END-EXEC.

EXEC SQL
  CLOSE DEPTDATA
END-EXEC.
```

If this program is called several times from another SQL program, it is able to use a reusable ODP. This technique means that, as long as SQL remains active between the calls to this program, the OPEN statement does not require a database open operation. However, the cursor is still positioned to the first result row after each OPEN statement, and the FETCH statement will always return the first row.

In the following example, the CLOSE statement has been removed:

```
EXEC SQL
  DECLARE DEPTDATA CURSOR FOR
  SELECT EMPNO, LASTNAME
  FROM CORPDATA.EMPLOYEE
  WHERE WORKDEPT = :DEPTNUM
END-EXEC.

  IF CURSOR-CLOSED IS = TRUE THEN
EXEC SQL
  OPEN DEPTDATA
END-EXEC.

EXEC SQL
  FETCH DEPTDATA INTO :EMPNUM, :LNAME
END-EXEC.
```

If this program is precompiled with the *ENDJOB or *ENDACTGRP option and the activation group remains active, the cursor position is maintained. The cursor position is also maintained when the following occurs:

- The program is precompiled with the *ENDSQL option.
- SQL remains active between program calls.

The result of this strategy is that each call to the program retrieves the next row in the cursor. On subsequent data requests, the OPEN statement is unnecessary and, in fact, fails with a -502 SQLCODE. You can ignore the error, or add code to skip the OPEN. Use a FETCH statement first, and then run the OPEN statement only if the FETCH operation failed.

This technique also applies to prepared statements. A program can first try the EXECUTE, and if it fails, perform the PREPARE. The result is that the PREPARE is only needed on the first call to the program, assuming that the correct CLOSQLCSR option was chosen. If the statement can change between calls to the program, perform the PREPARE in all cases.

The main program might also control cursors by sending a special parameter on the first call only. This special parameter value indicates that because it is the first call, the subprogram performs the OPENS, PREPAREs, and LOCKs.

Note: If you are using COBOL programs, do not use the STOP RUN statement. When the first COBOL program on the call stack ends or a STOP RUN statement runs, a reclaim resource (RCLRSC) operation is done. This operation closes the SQL cursor. The *ENDSQL option does not work as you wanted.

Programming techniques for database performance

By changing the coding of your queries, you can improve their performance.

Use the OPTIMIZE clause

If an application is not going to retrieve the entire result table for a cursor, using the OPTIMIZE clause can improve performance. The query optimizer modifies the cost estimates to retrieve the subset of rows using the value specified on the OPTIMIZE clause.

Assume that the following query returns 1000 rows:

```
EXEC SQL
  DECLARE C1 CURSOR FOR
  SELECT EMPNO, LASTNAME, WORKDEPT
  FROM CORPDATA.EMPLOYEE
  WHERE WORKDEPT = 'A00'
  ORDER BY LASTNAME
  OPTIMIZE FOR 100 ROWS
END EXEC.
```

Note: The values that can be used for the preceding OPTIMIZE clause are 1–9999999 or ALL.

The optimizer calculates the following costs.

The optimize ratio = optimize for n rows value / estimated number of rows in answer set.

Cost using a temporarily created index:

```
      Cost to retrieve answer set rows
+ Cost to create the index
+ Cost to retrieve the rows again
      with a temporary index          * optimize ratio
```

Cost using a SORT:

```
      Cost to retrieve answer set rows
+ Cost for SORT input processing
+ Cost for SORT output processing    * optimize ratio
```

Cost using an existing index:

Cost to retrieve answer set rows
using an existing index * optimize ratio

In the previous examples, the estimated cost to sort or to create an index is not adjusted by the optimize ratio. This method allows the optimizer to balance the optimization and preprocessing requirements.

If the optimize number is larger than the number of rows in the result table, no adjustments are made to the cost estimates.

If the OPTIMIZE clause is not specified for a query, a default value is used based on the statement type, value of ALWCPYDTA, or output device.

Table 59. OPTIMIZE FOR n ROWS default value

Statement Type	ALWCPYDTA(*OPTIMIZE)	ALWCPYDTA(*YES or *NO)
DECLARE CURSOR	The number or rows in the result table.	30 rows or the number of rows in the result table.
Embedded Select	2	2
INTERACTIVE Select output to display	30 rows or the number of rows in the result table.	30 rows or the number of rows in the result table.
INTERACTIVE Select output to printer or database table	The number of rows in the result table.	The number of rows in the result table.

The OPTIMIZE clause influences the optimization of a query:

- To use an existing index (by specifying a small number).
- To enable the creation of an index, or run a sort or hash by specifying many possible rows in the answer set.

Related information

[select-statement](#)

Use FETCH FOR n ROWS

Applications that perform many FETCH statements in succession could be improved by using FETCH FOR n ROWS. With this clause, you can retrieve multiple rows of table data with a single FETCH, putting them into a host structure array or row storage area.

An SQL application that uses a FETCH statement without the FOR n ROWS clause can be improved by using the multiple-row FETCH statement to retrieve multiple rows. After the host structure array or row storage area is filled by the FETCH, the application loops through the data, processing each of the individual rows. The statement runs faster because the SQL run-time was called only once and all the data was simultaneously returned to the application program.

You can change the application program to allow the database manager to block the rows that the SQL run-time retrieves from the tables.

In the following table, the program attempted to FETCH 100 rows into the application. Note the differences in the table for the number of calls to SQL runtime and the database manager when blocking can be performed.

Table 60. Number of Calls Using a FETCH Statement

	Database Manager Not Using Blocking	Database Manager Using Blocking
Single-Row FETCH Statement	100 SQL calls 100 database calls	100 SQL calls one database call
Multiple-Row FETCH Statement	one SQL runtime call 100 database calls	one SQL runtime call one database call

Related information

[FETCH statement](#)

Improve SQL blocking performance when using FETCH FOR n ROWS

Use these performance techniques to improve SQL blocking performance when using FETCH FOR n ROWS.

You can improve SQL blocking performance with the following:

- Match the attribute information in the host structure array or the descriptor associated with the row storage area with the attributes of the columns retrieved.
- Retrieve as many rows as possible with a single multiple-row FETCH call. The blocking factor for a multiple-row FETCH request is not controlled by the system page sizes or the SEQONLY parameter on the OVRDBF command. It is controlled by the number of rows that are requested on the multiple-row FETCH request.
- Do not mix single- and multiple-row FETCH requests against the same cursor within a program. If one FETCH against a cursor is treated as a multiple-row FETCH, all fetches against that cursor are treated as multiple-row fetches. In that case, each of the single-row FETCH requests is treated as a multiple-row FETCH of one row.
- Do not use the PRIOR, CURRENT, and RELATIVE scroll options with multiple-row FETCH statements. To allow random movement of the cursor by the application, the database manager must maintain the same cursor position as the application. Therefore, the SQL run-time treats all FETCH requests against a scrollable cursor with these options specified as multiple-row FETCH requests.

Use INSERT n ROWS

Applications that perform many INSERT statements in succession could be improved by using INSERT n ROWS. With this clause, you can insert one or more rows of data from a host structure array into a target table. This array must be an array of structures where the elements of the structure correspond to columns in the target table.

An SQL application that loops over an INSERT...VALUES statement (without the n ROWS clause) can be improved by using the INSERT n ROWS statement to insert multiple rows into the table. After the application has looped to fill the host array with rows, a single INSERT n ROWS statement inserts the entire array into the table. The statement runs faster because the SQL runtime was only called once and all the data was simultaneously inserted into the target table.

In the following table, the program attempted to INSERT 100 rows into a table. Note the differences in the number of calls to SQL runtime and to the database manager when blocking can be performed.

Table 61. Number of Calls Using an INSERT Statement

	Database Manager Not Using Blocking	Database Manager Using Blocking
Single-Row INSERT Statement	100 SQL runtime calls 100 database calls	100 SQL runtime calls one database call
Multiple-Row INSERT Statement	1 SQL runtime call 100 database calls	1 SQL runtime call 1 database call

Related information

[INSERT statement](#)

Control database manager blocking

To improve performance, the SQL runtime attempts to retrieve and insert rows from the database manager a block at a time whenever possible.

You can control blocking, if you want. Use the SEQONLY parameter on the CL command **Override Database File (OVRDBF)** before calling the application program that contains the SQL statements. You can also specify the ALWBLK parameter on the CRTSQLxxx commands or use the QSY2.OVERRIDE_TABLE application service.

The database manager does not allow blocking in the following situations:

- The cursor is update or delete capable.
- The length of the row plus the feedback information is greater than 32767. The minimum size for the feedback information is 11 bytes. The feedback size is increased by the number of bytes in the index key columns used by the cursor, and the number of key columns, if any, that are null capable.
- COMMIT(*CS) is specified, and ALWBLK(*ALLREAD) is not specified.
- COMMIT(*ALL) is specified, and the following are true:
 - A SELECT INTO statement or a blocked FETCH statement is not used
 - The query does not use column functions or specify group by columns.
 - A temporary result table does not need to be created.
- COMMIT(*CHG) is specified, and ALWBLK(*ALLREAD) is not specified.
- The cursor contains at least one subquery and the outermost subselect provided a correlated reference for a subquery, or the outermost subselect processed a subquery with an IN, = ANY, or < > ALL subquery predicate operator, which is treated as a correlated reference, and that subquery is not isolatable.

The SQL runtime automatically blocks rows with the database manager in the following cases:

- INSERT

If an INSERT statement contains a select-statement, inserted rows are blocked and not inserted into the target table until the block is full. The SQL runtime automatically does blocking for blocked inserts.

Note: If an INSERT with VALUES is specified, the SQL runtime might not close the internal cursor used to perform the inserts until the program ends. If the same INSERT statement is run again, a full open is not necessary and the application runs much faster.

- OPEN

Blocking is done under the OPEN statement when the rows are retrieved if all the following conditions are true:

- The cursor is only used for FETCH statements.
- No EXECUTE or EXECUTE IMMEDIATE statements are in the program, or ALWBLK(*ALLREAD) was specified, or the cursor is declared with the FOR FETCH ONLY clause.
- COMMIT(*CHG) and ALWBLK(*ALLREAD) are specified, COMMIT(*CS) and ALWBLK(*ALLREAD) are specified, or COMMIT(*NONE) is specified.

OVERVERRIDE_TABLE procedure

The OVERVERRIDE_TABLE procedure sets the blocking size for a table. This procedure uses the Override with Database File (OVRDBF) and Delete Override (DLTOVR) CL commands to control the blocking factor when the file is accessed within the current job.

Effects of precompile options on database performance

Several precompile options are available for creating SQL programs with improved performance. They are only options because using them could impact the function of the application. For this reason, the default value for these parameters is the value that ensures successful migration of applications from prior releases. However, you can improve performance by specifying other options.

Related information

[Override Database File \(OVRDBF\) command](#)

Optimize the number of columns that are selected with SELECT statements

For each column in the SELECT statement, the database manager retrieves the data from the underlying table and maps it to a host variable in the application program. By minimizing the number of columns that are specified, processing unit resource usage can be conserved.

Even though it is convenient to code SELECT *, it is far better to explicitly code the columns that are required for the application. This technique is especially important for index-only access, or if all the columns participate in a sort operation (as in SELECT DISTINCT and SELECT UNION).

This technique is also important when considering index only access. You minimize the number of columns in a query and increase the odds that an index can be used to completely satisfy the data request.

[select-statement](#)

Eliminate redundant validation with SQL PREPARE statements

The processing which occurs when an SQL PREPARE statement is run is like the processing which occurs during precompile processing.

The following processing occurs for the statement that is being prepared:

- The syntax is checked.
- The statement is validated to ensure that the usage of objects is valid.
- An access plan is built.

When the statement is executed or opened, the database manager revalidates that the access plan is still valid. Much of this open processing validation is redundant with the validation which occurred during the PREPARE processing. The DLYPRP(*YES) parameter specifies whether PREPARE processing in this program completely validates the dynamic statement. The validation is completed when the dynamic statement is opened or executed. This parameter can provide a performance benefit for programs which use the PREPARE SQL statement because it eliminates redundant validation. Programs that specify this precompile option must check the SQLCODE and SQLSTATE after running the OPEN or EXECUTE statement to ensure that the statement is valid. DLYPRP(*YES) does not provide any performance improvement if the INTO clause is used on the PREPARE statement, or if a DESCRIBE statement uses the dynamic statement before an OPEN is issued for the statement.

Page interactively displayed data with REFRESH(*FORWARD)

In large tables, paging performance is typically degraded because of the REFRESH(*ALWAYS) parameter on the **Start SQL (STRSQL)** command. STRSQL dynamically retrieves the latest data directly from the table. Paging performance can be improved by specifying REFRESH(*FORWARD).

When interactively displaying data using REFRESH(*FORWARD), the results of a select-statement are copied to a temporary table as you page forward through the display. Other users sharing the table can change the rows while you are displaying the select-statement results. If you page backward or forward

to rows that have already been displayed, the rows shown are in the temporary table instead of the updated table.

The refresh option can be changed on the Session Services display.

[Start SQL \(STRSQL\) command](#)

Improve concurrency by avoiding lock waits

The concurrent access resolution option directs the database manager on how to handle cases of record lock conflicts under certain isolation levels.

The concurrent access resolution, when applicable, can have one of the following values:

- **Wait for outcome** (default). This value directs the database manager to wait for the commit or rollback when encountering locked data in the process of being updated or deleted. Locked rows that are in the process of being inserted are not skipped. This option does not apply for read-only queries running under isolation level None or Uncommitted Read.
- **Use currently committed**. This value allows the database manager to use the currently committed version of the data for read-only queries when encountering locked data in the process of being updated or deleted. Locked rows in the process of being inserted can be skipped. This option applies if possible when the isolation level in effect is Cursor Stability and is ignored otherwise.
- **Skip locked data**. This value directs the database manager to skip rows in the case of record lock conflicts. This option is applicable only when the query is running under an isolation level of Cursor Stability or Read Stability and additionally for UPDATE and DELETE queries when the isolation level is None or Uncommitted Read.

The concurrent access resolution values of USE CURRENTLY COMMITTED and SKIP LOCKED DATA can be used to improve concurrency by avoiding lock waits. However, care must be used when using these options because they might affect application functionality. For more information on the USE CURRENTLY COMMITTED option, see [Concurrency](#).

WAIT FOR OUTCOME, USE CURRENTLY COMMITTED, and SKIP LOCKED DATA can be specified as the concurrent-access-resolution-clause in the attribute-string of a PREPARE statement.

Additionally, they can be specified as the concurrent-access-resolution-clause at the statement level on a select-statement, SELECT INTO, searched UPDATE, or searched DELETE statement.

Concurrent access resolution is also specifiable as a precompiler option by using the CONACC parameter on the CRTSQLxxx. The CONACC parameter accepts one of the following values:

- *DFT - specifies that the concurrent access option is not explicitly set for this program. The value that is in effect when the program is invoked is used. The value can be set using the SQL_CONCURRENT_ACCESS_RESOLUTION option in the query options file QAQQINI.
- *CURCMT - use currently committed.
- *WAIT - wait for outcome.

These same options can be set on the RUNSQLSTM and RUNSQL CL commands and by using the SET OPTION SQL statement. Concurrent access resolution can be specified for SQL triggers, functions, and procedures by using the SET OPTION statement.

When the concurrent access resolution option is not directly set by the application, it is set to the value of the SQL_CONCURRENT_ACCESS_RESOLUTION option in the query options file QAQQINI. This option accepts one of the following values:

- *DEFAULT - the default value is set to *WAIT.
- *CURCMT - use currently committed.
- *WAIT - wait for outcome.

Use SELECTIVITY to supply missing information

Some query predicates are inherently difficult for the optimizer to analyze, yet effective optimization depends on accurate information about the data being selected. When other statistics are unavailable, careful use of the SELECTIVITY clause can give the optimizer the information it needs to produce the best access plan for a query.

The optimizer uses a variety of techniques to evaluate and estimate the number of rows a query predicate will select. This information may come from key range estimates, from column statistics, or from inferences based on the cardinality of the data. Sometimes, however, the optimizer has no way to determine how a predicate will apply to the underlying data. In these cases, the SELECTIVITY clause can be added to difficult predicates to provide the extra information that the optimizer needs.

Using SELECTIVITY to correct inaccurate estimates

One common type of incomplete information involves data that is transformed before it is used in a predicate. The transformation could be performed by a user defined function or it could be performed by a built in function. In either case, something about the function prevents the optimizer from making inferences about how the transformation will affect the data.

Consider the following query:

```
SELECT EXCHANGE, S.SYMBOL, NAME, CURRENT_POSITION
FROM SECURITIES S INNER JOIN POSITIONS P ON S.SYMBOL = P.SYMBOL
WHERE RISK_SCORE(EXCHANGE, S.SYMBOL) > .8
      AND EXCHANGE = 'NYSE'
      AND CURRENT_POSITION > 1000
ORDER BY EXCHANGE, S.SYMBOL
```

Because the optimizer does not know the internal logic of the RISK_SCORE function, it uses a default selectivity value. The optimizer will generally assume 33% of the rows satisfy the predicate `RISK_SCORE(EXCHANGE, S.SYMBOL) > .8`. If this assumption is not accurate, it could cause the optimizer to select an inappropriate query plan. To mitigate this, a user who understands the behavior of the RISK_SCORE function and knows that only 1% of the rows in the table will satisfy the predicate can rewrite the WHERE clause as:

```
WHERE RISK_SCORE(EXCHANGE, S.SYMBOL) > .8 SELECTIVITY .01
      AND EXCHANGE = 'NYSE'
      AND CURRENT_POSITION > 10000
```

Another common cause of missing information is when the query selects a small number of rows that have been added to the table very recently. These rows may not yet be reflected in the statistical information automatically maintained by the statistics manager, leading the optimizer to believe that the query selects no rows. As in the above example, the solution is to add a SELECTIVITY clause that accurately represents the percentage of rows selected by the predicate.

To determine when the use of SELECTIVITY could be helpful for a query, use Visual Explain to identify operations with significantly inaccurate *Percent Selectivity* attributes under the *Estimated rows selected and query join info* heading. In many cases, you may have a reasonable intuition for the correct selectivity for the operation. In cases where you need additional information, either **Run and Explain** or use Visual Explain on a plan that is cached in the plan cache, since these options provide you with information about the actual number of rows processed by each operation. These values are given as *Actual Rows Selected Per Plan Step Iteration* and can be compared to the estimated *Rows Selected Per Plan Step Iteration*. Keep in mind that a given operation could process multiple predicates that have been logically combined. Since SELECTIVITY applies to an individual predicate, the effect of SELECTIVITY on the overall *Percent Selectivity* of the operation can be difficult to predict. In general, the effect of adding SELECTIVITY is

easiest to predict and understand when the operation has only a single simple predicate (for example, a UDF.)

Using SELECTIVITY to reduce plan volatility

The optimizer uses a variety of factors when re-validating whether a cached access plan should be re-used. One key factor is the selectivity of the query's predicates. The same predicate with different host variable values may select a very different number of rows and thus run best with a different access plan. For this reason, the optimizer will not re-use a cached plan that it estimates will select a significantly different number of rows. Instead, it will re-optimize the query with the new values.

Under some circumstances, you may prefer to use a single plan for all host variable values rather than relying on the dynamic behavior of the optimizer. If the plan is changing due to the selectivity of a host variable value changing, the SELECTIVITY clause can help to lock in a preferred plan.

For example, consider the following query where the plan changes depending on the given value (for example, 1000 rows vs 1,000,000 rows are returned.)

```
SELECT ... FROM EMPLOYEE WHERE SALARY > ?
```

If the preferred plan is known to occur when SALARY > 40000 and it is known that 20% of the rows are selected by this predicate, then this query can be rewritten as:

```
SELECT ... FROM EMPLOYEE WHERE SALARY > ? SELECTIVITY .2
```

When running this query, changes to the host variable value will no longer influence the optimized plan.

Considerations for using SELECTIVITY

While SELECTIVITY can be useful when applied carefully, it can also produce some surprising results. Used without care, SELECTIVITY can cause more harm than benefit.

The optimizer integrates multiple pieces of information - including I/O costs, predicate selectivity, and correlation between columns - to form a coherent model of the data and the environment. By overriding the internal model, a user-provided SELECTIVITY value may introduce inconsistencies into and reduce some of the benefits of the model. As a result, SELECTIVITY can lead to less accurate estimates of I/O costs. It may also prevent the optimizer from detecting correlation between related columns and thereby reduce the accuracy of the estimates for the overall set of predicates.

Furthermore, by locking in a single value, SELECTIVITY prevents the optimizer from automatically responding to changes in the underlying data. As the data grows and changes, the SELECTIVITY value may become inaccurate, requiring you to occasionally re-evaluate and adjust it.

For these reasons, SELECTIVITY is best reserved for use in the limited situations described in this section. Before using SELECTIVITY to solve a query performance problem, follow the other recommendations in this document. For example, creating a new index or column statistic might help the optimizer not simply with one but with many queries. Keep in mind that a hard-to-optimize query may be a sign that re-writing the query or improving the data model is a better long-term strategy. SELECTIVITY should be a last resort when no other options exist for providing the optimizer with the needed information.

General Db2 for i performance considerations

As you code your applications, there are some general tips that can help you optimize performance.

Effects on database performance when using long object names

Long object names are converted internally to system object names when used in SQL statements. This conversion can have some performance impacts. Names of tables, views, indexes, and aliases that are 30 characters or less will generally perform much better than names longer than 30 characters.

Qualify the long object name with a library name and the conversion to the short name happens at precompile time. In this case, there is minimal performance impact when the statement is executed. Otherwise, the conversion is done at execution time and has a small performance impact.

Effects of precompile options on database performance

Several precompile options are available for creating SQL programs with improved performance. They are only options because using them could impact the function of the application. For this reason, the default value for these parameters is the value that ensures successful migration of applications from prior releases. However, you can improve performance by specifying other options.

The following table shows these precompile options and their performance impacts.

Some of these options might be suitable for most of your applications. Use the command **CRTDUPOBJ** to create a copy of the SQL **CRTSQLxxx** command, and the **CHGCMDFFT** command to customize the optimal values for the precompile parameters. The **DSPPGM**, **DSPSRVPGM**, **DSPMOD**, or **PRTSQLINF** commands can be used to show the precompile options that are used for an existing program object.

Table 62. Precompile options and their performance impacts

Precompile Option	Optimal Value	Improvements	Considerations
ALWCPYDTA	*OPTIMIZE (the default)	Queries where the ordering or grouping criteria conflicts with the selection criteria.	A copy of the data could be made when the query is opened.
ALWBLK	*ALLREAD (the default)	Additional read-only cursors use blocking.	ROLLBACK HOLD might not change the position of a read-only cursor. Dynamic processing of positioned updates or deletes might fail.
CLOSQLCSR	*ENDJOB, *ENDSQL, or *ENDACTGRP	Cursor position can be retained across program invocations.	Implicit closing of SQL cursor is not done when the program invocation ends.
DLYPRP	*YES	Programs using SQL PREPARE statements could run faster.	Complete validation of the prepared statement is delayed until the statement is run or opened.
TGTRLS	*CURRENT (the default)	The precompiler can generate code that takes advantage of performance enhancements available in the current release.	The program object cannot be used on a system from a previous release.

[Eliminate redundant validation with SQL PREPARE statements](#)

The processing which occurs when an SQL PREPARE statement is run is like the processing which occurs during precompile processing.

Effects of the ALWCPYDTA parameter on database performance

Some complex queries can perform better by using a sort or hashing method to evaluate the query instead of using or creating an index.

By using the sort or hash, the database manager is able to separate the row selection from the ordering and grouping process. Bitmap processing can also be partially controlled through this parameter. This separation allows the use of the most efficient index for the selection. For example, consider the following SQL statement:

```
EXEC SQL
  DECLARE C1 CURSOR FOR
  SELECT EMPNO, LASTNAME, WORKDEPT
  FROM CORPDATA.EMPLOYEE
  WHERE WORKDEPT = 'A00'
  ORDER BY LASTNAME
END-EXEC.
```

The above SQL statement can be written in the following way by using the OPNQRYF command:

```
OPNQRYF FILE(CORPDATA/EMPLOYEE)
  FORMAT(FORMAT1)
  QRYSLT(WORKDEPT *EQ 'A00')
  KEYFLD(LASTNAME)
```

In the preceding example, when ALWCPYDTA(*NO) or ALWCPYDTA(*YES) is specified, the database manager could try to create an index from the first index with a column named LASTNAME, if such an index exists. The rows in the table are scanned, using the index, to select only the rows matching the WHERE condition.

If ALWCPYDTA(*OPTIMIZE) is specified, the database manager uses an index with the first index column of WORKDEPT. It then makes a copy of all the rows that match the WHERE condition. Finally, it could sort the copied rows by the values in LASTNAME. This row selection processing is more efficient, because the index used immediately locates the rows to be selected.

ALWCPYDTA(*OPTIMIZE) optimizes the total time that is required to process the query. However, the time required to receive the first row could be increased because a copy of the data must be made before returning the first row of the result table. This initial change in response time could be important for applications that are presenting interactive displays or that retrieve only the first few rows of the query. The Db2 for i query optimizer can be influenced to avoid sorting in memory by using the OPTIMIZE clause.

Queries that involve a join operation might also benefit from ALWCPYDTA(*OPTIMIZE) because the join order can be optimized regardless of the ORDER BY specification.

Effects of precompile options on database performance

Several precompile options are available for creating SQL programs with improved performance. They are only options because using them could impact the function of the application. For this reason, the default value for these parameters is the value that ensures successful migration of applications from prior releases. However, you can improve performance by specifying other options.

Radix index scan

A radix index scan operation is used to retrieve the rows from a table in a keyed sequence. Like a table scan, all the rows in the index are sequentially processed, but the resulting row numbers are sequenced based upon the key columns.

Radix index probe

A radix index probe operation is used to retrieve the rows from a table in a keyed sequence. The main difference between the radix index probe and the scan is that the rows returned are first identified by a probe operation to subset them.

Tips for using VARCHAR and VARGRAPHIC data types in databases

Variable-length column (VARCHAR or VARGRAPHIC) support allows you to define any number of columns in a table as variable length. If you use VARCHAR or VARGRAPHIC support, the size of a table can typically be reduced.

Data in a variable-length column is stored internally in two areas: a fixed-length or ALLOCATE area and an overflow area. If a default value is specified, the allocated length is at least as large as the value. The following points help you determine the best way to use your storage area.

When you define a table with variable-length data, you must decide the width of the ALLOCATE area. If the primary goal is:

- **Space saving:** use ALLOCATE(0).
- **Performance:** the ALLOCATE area must be wide enough to incorporate at least 90% to 95% of the values for the column.

It is possible to balance space savings and performance. In the following example of an electronic telephone book, the following data is used:

- 8600 names that are identified by: last, first, and middle name
- The Last, First, and Middle columns are variable length.
- The shortest last name is two characters; the longest is 22 characters.

This example shows how space can be saved by using variable-length columns. The fixed-length column table uses the most space. The table with the carefully calculated allocate sizes uses less disk space. The table that was defined with no allocate size (with all the data stored in the overflow area) uses the least disk space.

<i>Table 63. Disk space used with variable-length columns</i>					
Variety of Support	Last Name Max/Alloc	First Name Max/Alloc	Middle Name Max/Alloc	Total Physical File Size	Number of Rows in Overflow Space
Fixed Length	22	22	22	567 K	0
Variable Length	40/10	40/10	40/7	408 K	73
Variable-Length Default	40/0	40/0	40/0	373 K	8600

In many applications, performance must be considered. If you use the default ALLOCATE(0), it doubles the disk unit traffic. ALLOCATE(0) requires two reads; one to read the fixed-length portion of the row and one to read the overflow space. The variable-length implementation, with the carefully chosen ALLOCATE, minimizes overflow and space and maximizes performance. The size of the table is 28% smaller than the fixed-length implementation. Because 1% of rows are in the overflow area, the access requiring two reads is minimized. The variable-length implementation performs about the same as the fixed-length implementation.

Varying length columns with a length less than 30 may be implemented by the database using a non-zero allocate value. As a result, changing the allocated length for these columns may not impact the disk I/O performance efficiency.

To create the table using the ALLOCATE keyword:

```
CREATE TABLE PHONEDIR
  (LAST   VARCHAR(40) ALLOCATE(10),
   FIRST  VARCHAR(40) ALLOCATE(10),
   MIDDLE VARCHAR(40) ALLOCATE(7))
```

If you are using host variables to insert or update variable-length columns, use variable length host variables. Because blanks are not truncated from fixed-length host variables, using fixed-length host variables can cause more rows to spill into the overflow space. This increases the size of the table.

In this example, fixed-length host variables are used to insert a row into a table:

```
01 LAST-NAME PIC X(40).
...
MOVE "SMITH" TO LAST-NAME.
EXEC SQL
  INSERT INTO PHONEDIR
    VALUES (:LAST-NAME, :FIRST-NAME, :MIDDLE-NAME, :PHONE)
END-EXEC.
```

The host-variable LAST-NAME is not variable length. The string "SMITH", followed by 35 blanks, is inserted into the VARCHAR column LAST. The value is longer than the allocate size of 10. 30 of 35 trailing blanks are in the overflow area.

In this example, variable-length host variables are used to insert a row into a table:

```
01 VLAST-NAME.
49 LAST-NAME-LEN PIC S9(4) BINARY.
49 LAST-NAME-DATA PIC X(40).
...
MOVE "SMITH" TO LAST-NAME-DATA.
MOVE 5 TO LAST-NAME-LEN.
EXEC SQL
  INSERT INTO PHONEDIR
    VALUES (:VLAST-NAME, :VFIRST-NAME, :VMIDDLE-NAME, :PHONE)
END-EXEC.
```

The host variable VLAST-NAME is variable length. The actual length of the data is set to 5. The value is shorter than the allocated length. It can be placed in the fixed portion of the column.

Running the **Reorganize Physical File Member (RGZPFM)** command against tables that contain variable-length columns can improve performance. The fragments in the overflow area that are not in use are compacted by the **Reorganize Physical File Member (RGZPFM)** command. This technique reduces the read time for rows that overflow, increases the locality of reference, and produces optimal order for serial batch processing.

Choose the appropriate maximum length for variable-length columns. Selecting lengths that are too long increases the process access group (PAG). A large PAG slows performance. A large maximum length makes SEQONLY(*YES) less effective. Variable-length columns longer than 2000 bytes are not eligible as key columns.

Using LOBs and VARCHAR in the same table

Storage for LOB columns allocated in the same manner as VARCHAR columns. When a column stored in the overflow storage area is referenced, currently all the columns in that area are paged into memory. A reference to a "smaller" VARCHAR column that is in the overflow area can potentially force extra paging of LOB columns. For example, A VARCHAR(256) column retrieved by application has side-effect of paging in two 5 MB BLOB columns that are in the same row. In order to prevent this side-effect, you might want to use ALLOCATE keyword to ensure that only LOB columns are stored in the overflow area.

Using field procedures to provide column level encryption

Field procedures can provide column level encryption in Db2 for i.

A field procedure is a user-written exit routine to transform values in a single column. When values in the column are changed, or new values inserted, the field procedure is invoked for each value. The field procedure can transform that value (encode it) in any way. The encoded value is then stored. When values are retrieved from the column, the field procedure is invoked for each encoded value. The field procedure decodes each value back to the original value. Any indexes defined on a column that uses a field procedure are built with encoded values.

Field procedures are assigned to a table by the FIELDPROC clause of CREATE TABLE and ALTER TABLE.

A field procedure that is specified for a column is invoked in three general situations:

- For field-definition, when the CREATE TABLE or ALTER TABLE statement that names the procedure is executed. During this invocation, the procedure is expected to:
 - Determine whether the data type and attributes of the column are valid.
 - Verify the literal list, and change it if wanted.
 - Provide the field description of the column.
- For field-encoding, when a column value is field-encoded. That occurs for any value that:
 - is inserted in the column by an SQL INSERT statement, SQL MERGE statement, or native write.
 - is changed by an SQL UPDATE statement, SQL MERGE statement, or native update.
 - is the target column for a copy from a column with an associated field procedure. The field procedure might be invoked to encode the copied data. Examples include SQL Statements ALTER TABLE or CREATE TABLE LIKE/AS and CL commands CPYF and RGZPFM.
 - is compared to a column with a field procedure. The QAQQINI option FIELDPROC_ENCODED_COMPARISON is used to determine if the column value is decoded, or the host variable, constant, or join column is encoded.
 - is the DEFAULT value for a column with an associated field procedure in a CREATE or ALTER TABLE statement.

If there are any **after** or **read** triggers, the field procedure is invoked *before* any of these triggers. If there are any **before** triggers, the field procedure is invoked *after* the before trigger.

- For field-decoding, when a stored value is field-decoded back into its original value. Field-decoding occurs for any value that:
 - is retrieved by an SQL SELECT or FETCH statement, or by a native read.
 - is a column with an associated field procedure that is copied. The field procedure might be invoked to decode the data before making the copy. Examples include SQL Statements ALTER TABLE, CREATE TABLE LIKE/AS, and CL commands CPYF and RGZPFM.

- is compared to a column with a field procedure. The QAQQINI option FIELDPROC_ENCODED_COMPARISON is used by the optimizer to decide if the column value is decoded, or if the host variable or constant is encoded.

A field procedure is never invoked to process a null value. It is also not invoked for a DELETE operation without a WHERE clause when the table has no DELETE triggers. The field procedure is invoked for empty strings.

Improving performance

For queries that use field procedures, the path length is longer due to the additional processing of calling the field procedure. In order to improve performance of queries, the SQE optimizer:

- attempts to remove decoding operations, based on the QAQQINI FIELDPROC_ENCODED_COMPARISON setting.
- matches existing indexes over columns that have an associated field procedure.
- creates and uses MTIs over columns with field procedures. The MTI will be created as non-resuable which means it will not be shared between queries.
- creates statistics over the encoded values through statistics collection.

The SQE optimizer attempts to do the following optimizations:

- optimization of predicates that compare a field procedure column to a constant or host variable. For example, predicate FP1(4, C1) = 'abc' is optimized as C1 = FP1(0,'abc'). With this specific example, the optimization is done as long as the QAQQINI option is not *NONE.
- remove field procedure decoding operations from join predicates when the same field procedure is applied to both sides of the join predicate, and no compatibility conversion is required. For example, join predicate FP1(4,T1.C1) > FP1(4,T2.C1) is rewritten as T1.C1 > T2.C1. With this specific example, the optimization is done as long as the QAQQINI option is either *ALLOW_RANGE or *ALL. This technique is also applied to = predicates when the QAQQINI option is *ALLOW_EQUAL.
- remove field procedures from GROUP BY and ORDER BY clauses. For example, ORDER BY FP1(4,C1) is rewritten as ORDER BY C1 if the QAQQINI setting is either *ALLOW_RANGE or *ALL

The CQE optimizer does not look at the QAQQINI option, which means it always runs in *NONE mode. *NONE mode requires that all references to the column are decoded before any other operation is performed. A CQE query does not match any existing indexes when the column has an associated field procedure. If an index is required, a temporary index is built with the index keys decoded.

[Defining field procedures](#)

[CREATE TABLE](#)

Field procedure examples

The following examples show various field procedure-related optimizations done by the SQE optimizer.

The examples show the FieldProc name along with the encoding (field procedure function code 0) or decoding (field procedure function code 4) in the pseudo-SQL. These codes indicate how the optimizer is optimizing the field procedure calls.

Given the following table and index:

```
CREATE TABLE T1 (col1 CHAR(10), col2 CHAR(10) FIELDPROC 'FP1')
CREATE INDEX IX1 on T1(col2)
```

Example 1

A user query written as:

```
SELECT col1, col2 FROM T1 WHERE col2 = 'abc'
```

Is represented by the optimizer as:

```
SELECT col1, FP1(4, col2) FROM T1 WHERE FP1(4,col2) = 'abc'
```

Note the FP1 with the decode operation around the COL2 references in the SELECT list and the WHERE clause.

Assuming the QAQQINI FIELDPROC_ENCODED COMPARISON is set to *ALLOW_EQUAL, *ALLOW_RANGE or *ALL:

The query optimizer rewrites the query as:

```
SELECT col1, 'abc' FROM T1 WHERE col2 = FP1(0, 'abc')
```

This rewrite allows the query optimizer to use the encoded index IX1 to implement the WHERE clause and only cause one invocation of the field procedure for the query.

Example 2

```
SELECT col2 FROM T1 ORDER BY col2
```

Is represented by the query optimizer as:

```
SELECT FP1(4, col2) FROM T1 ORDER BY FP1(4, col2)
```

The optimized version removes the FieldProc from the ORDER BY clause assuming that the field procedure QAQQINI option is set to *ALLOW_RANGE or *ALL:

```
SELECT FP1(4, col2) FROM T1 ORDER BY col2
```

Example 3

```
Select col2, COUNT(*) FROM T1 GROUP BY col2
```

Is represented by the query optimizer as:

```
Select FP1(4, col2), COUNT(*) FROM T1 GROUP BY FP1(4, col2)
```

The optimized version removes the field procedure invocation from the GROUP BY clause column col2, allowing it to group the encoded data and only run the field procedure once per group. The decoded grouped data is returned to the user. This optimization is done if the field procedure QAQQINI option is set to *ALLOW_RANGE or *ALL:

```
SELECT FP1(4, col2), COUNT(*) FROM T1 GROUP BY col2
```

IS NULL/IS NOT NULL predicate does not require calling the field procedure field-decode option 4. The field procedure cannot change the nullability of the field.

Db2 for i Services

There are many system-provided views, procedures, and functions.

These are grouped in the following categories.

Application Services

These procedures provide interfaces that are useful for application development.

DELIMIT_NAME scalar function

The DELIMIT_NAME function returns a name with delimiters if the delimiters are needed for use in an SQL statement.

Authorization: None required.

►► DELIMIT_NAME ((— *name* —)) ◄◄

The schema is QSYS2.

name A character or graphic string expression that identifies a name. The string must contain only characters allowed in an SQL identifier. If the string is longer than 128 characters, it will be truncated to 128 characters.

The result of the function is a varying length character string that contains *name* correctly delimited. This includes delimiting reserved words. If *name* is the null value or an empty string, null is returned.

Example

- Delimit these names:

```
VALUES DELIMIT_NAME('ABC'),
        DELIMIT_NAME('abc'),
        DELIMIT_NAME('test"name'),
        DELIMIT_NAME('test' 'name2'),
        DELIMIT_NAME('NEW')
```

Returns the values:

```
ABC
"abc"
"test" "name"
"test" 'name2'
"NEW"
```

OVERRIDE_QAQQINI procedure

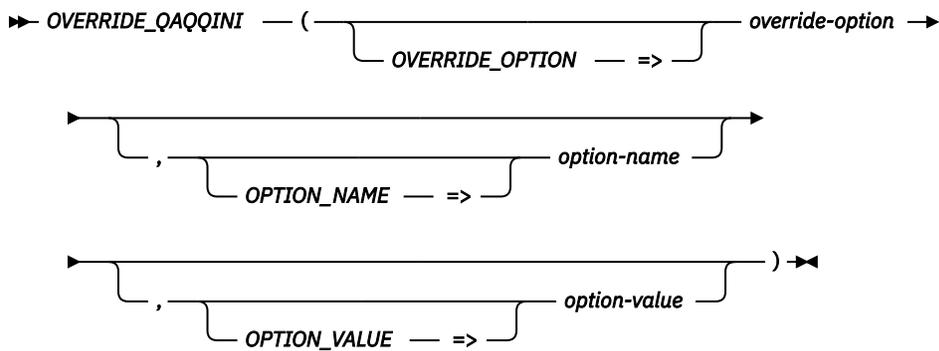

The OVERRIDE_QAQQINI procedure creates and modifies a temporary version of the QAQQINI file.

The temporary QAQQINI file will be created in QTEMP. It inherits all query options that are already in place for the job. The OVERRIDE_QAQQINI procedure can be called multiple times to establish job specific QAQQINI settings.

The procedure can also be called to discard the temporary customization settings.

Authorization: For most QAQQINI options, none is required. For the following three options, the caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM function usage ID. These options are more restrictive because they can affect the performance of other jobs.

- QUERY_TIME_LIMIT when the *option-value* is not 0.
- STORAGE_LIMIT
- PARALLEL_DEGREE

The schema is QSYS2.

override-option

An integer value that indicates the function to perform.

- 1 Create the QAQQINI override file. A procedure call with this *override-option* value must be run before option 2 can be used to change QAQQINI options.
- 2 Set a QAQQINI option to the specified value. See [“QAQQINI query options” on page 197](#) for the list of options and values.
- 3 Discard the temporary QAQQINI file.

option-name

A character or graphic string expression that identifies the name of the QAQQINI option to be changed.

This parameter is required when *override-option* is 2. For options 1 and 3, it can be omitted or passed as the empty string.

option-value

A character or graphic string expression that identifies the value to assign to the QAQQINI option identified by *option-name*.

This parameter is required when *override-option* is 2. For options 1 and 3, it can be omitted or passed as the empty string.

Example

- Establish the temporary override for QAQQINI. The job's current QAQQINI values will be used as the initial values.

```
CALL QSYS2.OVERRIDE_QAQQINI(1);
```

- Improve the chances that you can acquire an exclusive lock for a database file. Multiple calls to the procedure can be used to change more than one QAQQINI value.

```
CALL QSYS2.OVERRIDE_QAQQINI(2, 'PREVENT_ADDITIONAL_CONFLICTING_LOCKS', '*YES');
```

- Discard the temporary QAQQINI file and revert to using the job's version of the QAQQINI file.

```
CALL QSYS2.OVERRIDE_QAQQINI(3);
```

OVERRIDE_TABLE procedure

The `OVERRIDE_TABLE` procedure sets the blocking size for a table. This procedure uses the `Override with Database File (OVRDBF)` and `Delete Override (DLTOVR)` CL commands to control the blocking factor when the file is accessed within the current job.

Authorization: The caller must have `*USE` authority to the `OVRDBF` and `DLTOVR` CL commands.

The schema is QSYS2.

schema-name A character string expression containing the name of the schema.

table-name A character string expression containing the name of the table.

blocking-size A character string expression containing the blocking size. It can be a specific byte count or a special value of *BUF32KB, *BUF64KB, *BUF128KB, or *BUF256KB.

Example

- Override the EMPLOYEE table to use 256K blocking for sequential processing.

```
CALL QSYS2.OVERRIDE_TABLE('CORPDATA', 'EMP', '*BUF256KB');
```

- Remove the override.

```
CALL QSYS2.OVERRIDE_TABLE('CORPDATA', 'EMP', 0);
```

Related reference

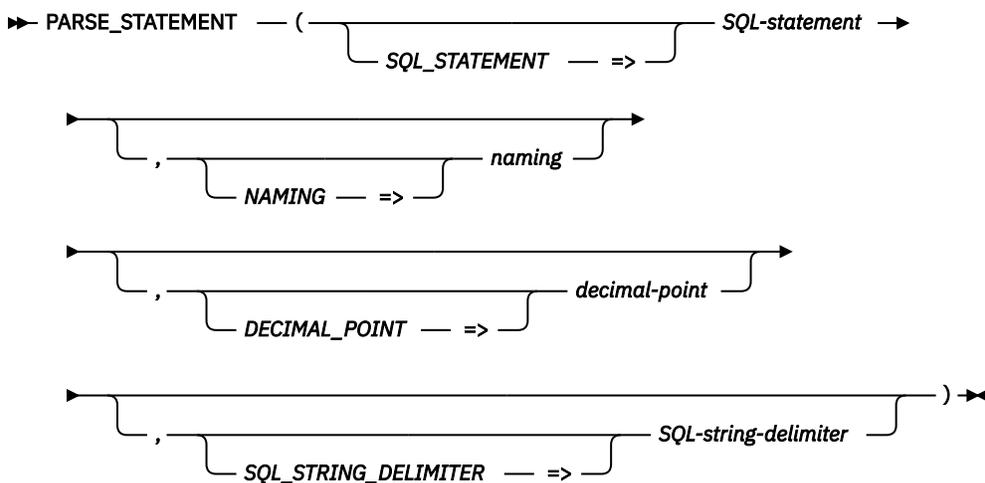

[Control database manager blocking](#)

To improve performance, the SQL runtime attempts to retrieve and insert rows from the database manager a block at a time whenever possible.

PARSE_STATEMENT table function

The PARSE_STATEMENT table function returns a list of object and column names that are used in an SQL query, data change statement, or other statement where a query or expression is specified.

Authorization: None required.

The schema is QSYS2.

SQL-statement A character or graphic string expression that contains a valid SQL statement. The maximum string length is 2 megabytes.

naming A character or graphic string expression that defines the naming rule for the statement.

***SYS** System naming rules apply. This is the default.

***SQL** SQL naming rules apply.

decimal-point A character or graphic string expression that defines the decimal point for numeric constants in *SQL-statement*.

***PERIOD or .** The decimal point is the period. This is the default.

***COMMA or ,** The decimal point is the comma.

SQL-string-delimiter

A character or graphic string expression that defines the string delimiter for strings in *SQL-statement*. Delimited identifiers in the SQL statement will use the opposite character.

***APOSTSQL or '** The apostrophe character (') is used to delimit strings. This is the default.

***QUOTESQL or "** The quote character (") is used to delimit strings.

When the SQL statement is parsed, object names are identified and a result row is returned for every name. This is done at the SQL parser level where names are identified strictly by where they appear in the syntax. The following rules apply:

- Names used in data change statements and in any query construct are returned.
- For CALL, the procedure being called is returned.
- For DDL statements, most items are returned. Notable exceptions are:
 - RCD_FMT name for CREATE TABLE, CREATE VIEW, and CREATE INDEX.
 - FIELDPROC program name for CREATE TABLE and ALTER TABLE.
 - Columns used as partitioning keys for CREATE TABLE and ALTER TABLE.
 - Parameter names for CREATE FUNCTION and CREATE PROCEDURE.
 - Return column names for CREATE FUNCTION (Table).
 - External program name for functions and procedures.

Any statement that does not contain these constructs, a query, or an expression returns no rows.

- Names in a *routine-body*, *triggered-action*, and *trigger-body* are not returned. To see these references, use QSYS2.SYSPROGRAMSTMTSTAT to find all the statements for the generated program or service program and pass each of them as an argument to this table function.
- If the SQL statement is the null value, an empty string, a string of all blanks, or contains a syntax error, no row is returned.

The result of the function is a table containing a row for each name reference with the format shown in the following table. All the columns are null capable.

Table 64. PARSE_STATEMENT table function

Column Name	Data Type	Description
NAME_TYPE	VARCHAR(30)	Type of object name.
		ALIAS This is an alias name.
		COLUMN This is a column name, or a global variable name not returned as a DDL TARGET OBJECT.
		CONSTRAINT This is a constraint name.
		FUNCTION This is a function name.
		INDEX This is an index name.
		MASK This is a mask name.
		PACKAGE This is a package name.
		PARAMETER This is a parameter name for a COMMENT statement.
		PERM This is a permission name.
		PROC This is a procedure name.
		PROGRAM This is the program name for a CREATE FUNCTION, CREATE PROCEDURE, or CREATE TRIGGER statement.
		RETURN COLUMN This is a return column for a COMMENT statement.
		ROUTINE This is a routine name for a DDL operation.
		SCHEMA This is a schema name.
		SEQUENCE This is a sequence name.
		SPECIFIC This is a routine specific name for a DDL operation.
		TABLE This is a table, view, or alias name.
		TRIGGER This is a trigger name.
		TYPE This is a user-defined type name.
VARIABLE This is a variable name for a DDL operation.		
VIEW This is a view name for a DDL operation.		
XSROBJ This is an XSROBJECT name.		
NAME	VARCHAR(128)	The object name. Contains null if NAME_TYPE is COLUMN without a table qualifier.
SCHEMA	VARCHAR(128)	The schema name. Contains null if NAME is not qualified with a schema name.
RDB	VARCHAR(128)	The relational database name. Contains null if NAME is not qualified with a relational database name.
COLUMN_NAME	VARCHAR(128)	The column name. Contains null if NAME_TYPE is not COLUMN.
ADDITIONAL_NAME	VARCHAR(128)	Contains an additional name for some name types. <ul style="list-style-type: none"> Name of a member for an alias Name of a parameter Name of a table function return column System object name when FOR SYSTEM NAME provided in DDL System column name when two column names provided in DDL Contains null if there is no additional name.

Table 64. PARSE_STATEMENT table function (continued)

Column Name	Data Type	Description	
USAGE_TYPE	VARCHAR(17)	How this name is used in the statement.	
		CHECK CONSTRAINT	Column is used in a check constraint.
		DDL SOURCE OBJECT	Name identifies the table an index or trigger is being created on, the table referenced by CREATE TABLE LIKE, the table referenced by an alias, or the object being renamed.
		DDL TARGET OBJECT	Name is the primary object of a DDL statement or the new name for a renamed object.
		EXPRESSION	Name is referenced in an index key expression.
		FOREIGN KEY	Column is used in a foreign key constraint.
		HISTORY TABLE	Table is the history table for an ALTER TABLE statement with ADD VERSIONING.
		PARAMETER DEFAULT	Name is referenced in a parameter default expression.
		PRIMARY KEY	Column is used in a primary key constraint.
		QUERY	Name is referenced as part of a query construct.
		REFERENCES	Name is part of a foreign key constraint referencing another table.
		TARGET PROCEDURE	This is the procedure that is the target of a CALL statement.
TARGET TABLE	This is the table that will be affected for an insert, update, delete, merge, truncate, lock table, or refresh table statement. The value is also returned for any explicitly specified columns from the target table for insert, update, and merge.		
UNIQUE KEY	Column is used in a unique key constraint.		
NAME_START_POSITION	INTEGER	Position within the <i>SQL-statement</i> string that this name begins. For qualified TABLE names, this is the position where the RDB or schema name begins. For all other name types, this is the position of the name.	

Table 64. PARSE_STATEMENT table function (continued)

Column Name	Data Type	Description
SQL_STATEMENT_TYPE	VARCHAR(32)	Type of SQL statement. <ul style="list-style-type: none"> • ALTER FUNCTION • ALTER MASK • ALTER PERMISSION • ALTER PROCEDURE • ALTER SEQUENCE • ALTER TABLE • ALTER TRIGGER • ASSOCIATE LOCATOR • CALL • COMMENT ALIAS • COMMENT COLUMN • COMMENT CONSTRAINT • COMMENT FUNCTION • COMMENT INDEX • COMMENT MASK • COMMENT PACKAGE • COMMENT PARAMETER • COMMENT PERMISSION • COMMENT PROCEDURE • COMMENT RETURN COLUMN • COMMENT ROUTINE • COMMENT SEQUENCE • COMMENT TABLE • COMMENT TRIGGER • COMMENT TYPE • COMMENT VARIABLE • COMMENT XSROBJECT

Table 64. PARSE_STATEMENT table function (continued)

Example

For every program and service program in library APPLIB, find all the references to table names in static SQL statements.

```

WITH program_statements(naming_mode, dec_point, string_delim, stmt_text,
  system_program_name, program_type)
AS (SELECT a.naming, a.decimal_point, a.sql_string_delimiter, b.statement_text,
  a.system_program_name, a.program_type
  FROM qsys2.sysprogramstat a INNER JOIN
  qsys2.sysprogramstmtstat b ON a.program_schema = b.program_schema AND
  a.program_name = b.program_name AND
  a.module_name = b.module_name

  WHERE a.number_statements > 0 AND
  a.program_schema = 'APPLIB' AND b.program_schema = 'APPLIB')
SELECT system_program_name, program_type, c.schema, c.name, stmt_text

```

```
FROM program_statements,
TABLE(qsys2.parse_statement(stmt_text, naming_mode, dec_point, string_delim)) c
WHERE c.name_type = 'TABLE'
ORDER BY c.schema, c.name;
```

SELFCODES global variable

This global variable determines the list of SQLCODEs that are handled by the SQL Error Logging Facility (SELF).

This global variable has the following characteristics:

- It is updateable.
- The type is VARCHAR(256).
- The schema is SYSIBMADM.
- The scope of this global variable is session.
- The default value is null, which corresponds to OFF.

The global variable can be set to a string containing up to 32 SQLCODEs with one or more blanks between values.

By default, the READ and WRITE privileges on this global variable are granted to PUBLIC.

To change the value of this global variable within a specific job, the user must have the WRITE privilege.

To replace the default value of the global variable, the user must have the authorizations listed for the CREATE VARIABLE statement, including the OR REPLACE authority. See [CREATE VARIABLE](#).

To confirm that the string value being used with SELFCODES is syntactically correct, use the [“VALIDATE_SELF scalar function”](#) on page 335.

Example

Configure SELF to capture detail for all jobs started in the future, for any SQL statements that fail with SQLCODE = -913 or SQLCODE = -204.

```
CREATE OR REPLACE VARIABLE SYSIBMADM.SELFCODES
  VARCHAR(256) DEFAULT '-913, -204';
```

SQL_ERROR_LOG view

The SQL_ERROR_LOG view returns information captured by the SQL Error Logging Facility (SELF).

Authorization: The caller must have *ALLOBJ special authority or be authorized to the QIBM_DB_SQLADM function usage identifier.

The following table describes the columns in the view. The system name is SQL_ERROR. The schema is QSYS2.

Table 65. SQL_ERROR_LOG view

Column Name	System Column Name	Data Type	Description
LOGGED_SQLCODE	LOG_CODE	INTEGER	The SQLCODE for this instance of SELF detail.
LOGGED_SQLSTATE	LOG_STATE	CHAR(5)	The SQLSTATE that corresponds to LOGGED_SQLCODE.
NUMBER_OCCURRENCES	MATCHES	BIGINT	Number of times this LOGGED_SQLCODE has occurred for this STATEMENT_TEXT from the program or service program identified by PROGRAM_LIBRARY, PROGRAM_NAME, and MODULE_NAME.
STATEMENT_TEXT	STMTTEXT	DBCLOB(2M) CCSID 1200	The SQL statement that encountered the SQLSTATE that corresponds to LOGGED_SQLCODE. Can contain the special value of UNKNOWN if the statement text is not available.

Table 65. SQL_ERROR_LOG view (continued)

Column Name	System Column Name	Data Type	Description
STATEMENT_OPERATION	OP_CODE	CHAR(2)	The SQL statement operation. For a list of values, see the QQC21 field in "Database monitor view 1000 - SQL Information" on page 1177.
STATEMENT_OPERATION_DETAIL	OP_DETAIL	VARCHAR(50)	Descriptive text that corresponds to STATEMENT_OPERATION.
REASON_CODE	SQLCODE_RC	INTEGER Nullable	The reason code returned for LOGGED_SQLCODE. Contains the null value if LOGGED_SQLCODE has no reason code.
PROGRAM_LIBRARY	PGM_LIB	VARCHAR(10)	Library containing PROGRAM_NAME. Can contain the special value of UNKNOWN if the program library is not available.
PROGRAM_NAME	PGM_NAME	VARCHAR(10)	Program or service program name that encountered LOGGED_SQLCODE. Can contain the special value of UNKNOWN if the program name is not available.
PROGRAM_TYPE	PGM_TYPE	VARCHAR(7)	Object type of PROGRAM_NAME. *PGM This is a program *SRVPGM This is a service program *SQLPKG This is an SQL package Can contain the special value of UNKNOWN if the program type is not available.
MODULE_NAME	MOD_NAME	VARCHAR(10) Nullable	Module name if PROGRAM_NAME is an ILE program or service program. Contains the null value if PROGRAM_NAME is not an ILE program or service program.
LOGGED_TIME	LOG_TIME	TIMESTAMP	Timestamp of the most recent occurrence of LOGGED_SQLCODE.
JOB_NAME	JOB_NAME	VARCHAR(28)	The qualified job name of the most recent occurrence of LOGGED_SQLCODE.
THREAD_ID	THREAD_ID	BIGINT	The thread identifier of the most recent occurrence of LOGGED_SQLCODE. A thread ID of 0 indicates that the thread ID is not available.
ADOPTED_USER_NAME	ADOPT_USER	VARCHAR(10)	Value of the CURRENT_USER special register for the most recent occurrence of LOGGED_SQLCODE.
USER_NAME	USER_NAME	VARCHAR(10)	Value of the USER special register for the most recent occurrence of LOGGED_SQLCODE.
SYSTEM_USER_NAME	SYS_USER	VARCHAR(10)	Value of the SYSTEM_USER special register for the most recent occurrence of LOGGED_SQLCODE.
CLIENT_ACCTNG	ACCTNG	VARCHAR(255) Nullable	Value of the CURRENT CLIENT_ACCTNG special register for the most recent occurrence of LOGGED_SQLCODE. Contains the null value if the special register has no value.
CLIENT_APPLNAME	APPLNAME	VARCHAR(255) Nullable	Value of the CURRENT CLIENT_APPLNAME special register for the most recent occurrence of LOGGED_SQLCODE. Contains the null value if the special register has no value.
CLIENT_PROGRAMID	PROGRAMID	VARCHAR(255) Nullable	Value of the CURRENT CLIENT_PROGRAMID special register for the most recent occurrence of LOGGED_SQLCODE. Contains the null value if the special register has no value.

Table 65. SQL_ERROR_LOG view (continued)

Column Name	System Column Name	Data Type	Description
CLIENT_USERID	USERID	VARCHAR(255) Nullable	Value of the CURRENT_CLIENT_USERID special register for the most recent occurrence of LOGGED_SQLCODE. Contains the null value if the special register has no value.
CLIENT_WRKSTNNAME	WRKSTNNAME	VARCHAR(255) Nullable	Value of the CURRENT_CLIENT_WRKSTNNAME special register for the most recent occurrence of LOGGED_SQLCODE. Contains the null value if the special register has no value.
RDB_NAME	RDB_NAME	VARCHAR(18)	Value of the CURRENT_SERVER special register for the most recent occurrence of LOGGED_SQLCODE.
INITIAL_LOGGED_TIME	INIT_TIME	TIMESTAMP	Timestamp of the initial occurrence of LOGGED_SQLCODE.
INITIAL_JOB_NAME	INIT_JOB	VARCHAR(28)	Qualified job name of the initial occurrence of LOGGED_SQLCODE.
INITIAL_THREAD_ID	INIT_THD	BIGINT	The thread identifier of the initial occurrence of LOGGED_SQLCODE. A thread ID of 0 indicates that the thread ID is not available.
INITIAL_ADOPTED_USER_NAME	INIT_ADOPT E	VARCHAR(10)	Value of the CURRENT_USER special register for the most recent occurrence of LOGGED_SQLCODE.
INITIAL_STACK	INIT_STACK	CLOB(1M) CCSID 1208	The call stack of the current thread for the initial occurrence of LOGGED_SQLCODE.

SQLCODE_INFO table function

The SQLCODE_INFO table function returns the SQL message associated with the specified SQLCODE value.

Every non-zero SQLCODE returned by a Db2 for i operation corresponds to a message in the QSQLMSG message file. This table function returns the message identifier and message text that is associated with a specific SQLCODE.

Authorization: See Note below.

➤ SQLCODE_INFO ((*P_SQLCODE* =>) *sqlcode*) ➤

The schema is SYSTOOLS.

sqlcode An integer value that represents a positive (warning) or negative (error) SQLCODE.

The result of the function is a table containing one row for a recognized SQLCODE value. If an unsupported SQLCODE value is provided, no row is returned. The columns of the result table are described in the following table. The result columns are nullable.

Table 66. SQLCODE_INFO table function

Column Name	Data Type	Description
MESSAGE_ID	CHAR(7)	The message identifier that corresponds to the SQLCODE.
MESSAGE_TEXT	VARGRAPHIC(132) CCSID 1200	The text of the message.
MESSAGE_SECOND_LEVEL_TEXT	VARGRAPHIC(3000) CCSID 1200	The second-level message text of the message.

Note

This function is provided in the SYSTOOLS schema as an example of finding a specific message in a message file. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

Return the message information for SQLCODE -204.

```
SELECT * FROM TABLE(SYSTOOLS.SQLCODE_INFO(-204));
```

VALIDATE_SELF scalar function

The VALIDATE_SELF scalar function is intended to be used with the SQL Error Logging Facility (SELF). The function can be used to confirm the syntactic validity of a string to be assigned to the SYSIBMADM.SELFCODES global variable.

The input to VALIDATE_SELF is a comma or space delimited list of positive or negative integers. Positive integers are denoted with a single leading plus sign (+), or no preceding sign. Negative integers are denoted with a single leading negative sign (-).

The function validates the syntax of the string. It reorders the list of values in ascending sequence within a comma separated list.

A successful completion returns a string value that is syntactically valid to be used with SELF for setting the SYSIBMADM.VALIDATE_SELF global variable.

While the list of values is intended to be comprised of valid SQLCODE values, the function does not verify that the integer values correspond to defined SQLCODEs. For a list of SQLCODE values supported by Db2 for i, see [SQL messages and codes](#).

To specify all SQLCODEs that are error conditions (negative values), use the special value of *ERROR.

To specify all SQLCODEs that are warning conditions (positive values), use the special value of *WARN.

To specify all SQLCODEs that are error or warning conditions, use the special value of *ALL.

To turn off SELF processing, specify 0 anywhere in the list of values.

*NONE is a special value:

- When set as the value for the current job, it turns off SELF processing for the job.
- When set as the default value for SYSIBMADM.SELFCODES global variable, it turns off SELF processing for all jobs.

Authorization: None required.

► VALIDATE_SELF (*self-sqlcodes*) ►
 └── SELF_SQLCODES ── => ─┘

The schema is SYSIBMADM.

self-sqlcodes A character or graphic string expression that contains one or more SQLCODE values, separated by commas or blanks.

The string must conform to the following rules:

- An error SQLCODE must be preceded by a single minus sign ('-').

- A warning SQLCODE can be preceded by an optional plus sign ('+').
- Multiple SQLCODE values in the string can be separated by any number of blanks and can have one comma between values.
- Up to 32 SQLCODE values can be provided in the string.
- A value of 100 or +100 is not allowed.
- A special value or *ERROR, *WARN, *ALL, or *NONE must be the only value in the string.
- If the string contains the value *NONE or zero (0), the character zero (0) is returned, which can be used to turn off SELF.

The result of the function is VARCHAR(32700).

The function returns the input string as an ordered list of SQLCODE values, separated by a comma and a space. The positive SQLCODEs are listed first followed by the negative SQLCODEs.

Examples

- Validate a string of SQLCODE values before assigning it to the SELFCODES global variable.

```
VALUES SYSIBMADM.VALIDATE_SELF(' -913,      -104, ,+406,802');
```

Returns: '406, 802, -104, -913'

- Turn on SELF for the current session, capturing any instances of SQL statements which complete with an SQLCODE = 406, 802, -104, or -913.

```
SET SYSIBMADM.SELFCODES =
  SYSIBMADM.VALIDATE_SELF(' -913,      -104, ,+406,802');
```

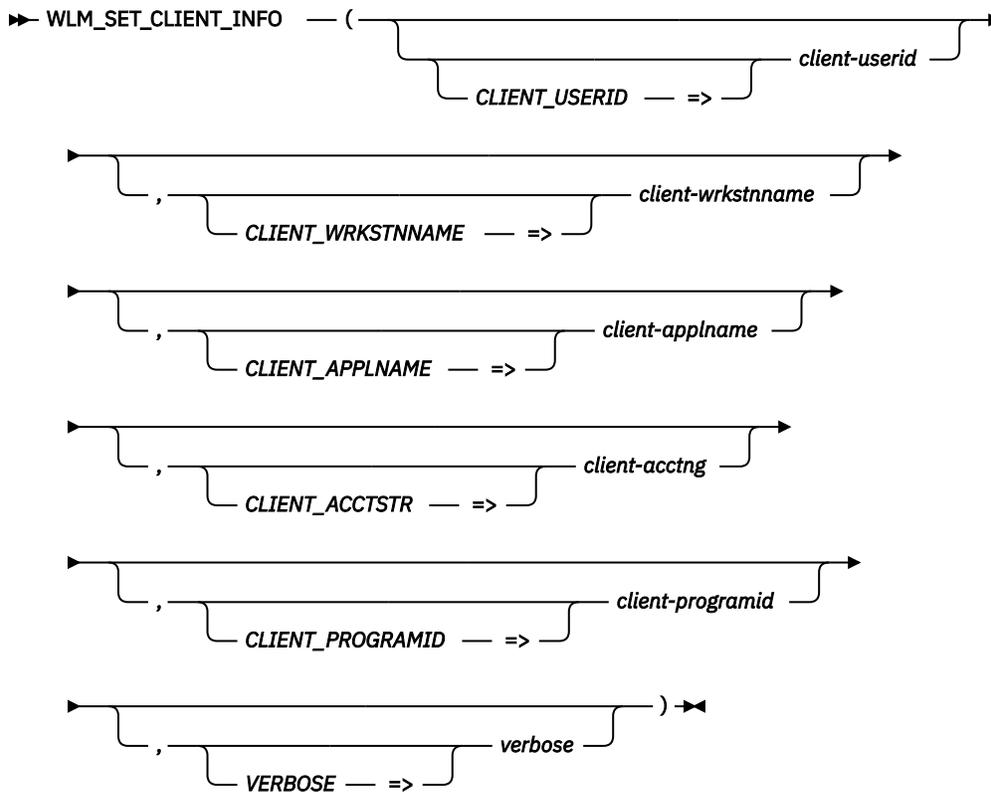

- Configure SELF to capture detail for all jobs started in the future, for any SQL statements that fail with SQLCODE = -913.

```
CREATE OR REPLACE VARIABLE SYSIBMADM.SELFCODES
  VARCHAR(256) DEFAULT (SYSIBMADM.VALIDATE_SELF(' -913'));
```

WLM_SET_CLIENT_INFO procedure

The WLM_SET_CLIENT_INFO procedure sets values for the SQL client special registers.

Authorization: None required.

The schema is SYSPROC.

- client-userid** A character or graphic string expression containing the value to set for the CURRENT CLIENT_USERID special register for the current connection.
 If this parameter is omitted, the value of the CURRENT CLIENT_USERID special register is not changed.
- client-wrkstnname** A character or graphic string expression containing the value to set for the CURRENT CLIENT_WRKSTNNAME special register for the current connection.
 If this parameter is omitted, the value of the CURRENT CLIENT_WRKSTNNAME special register is not changed.
- client-applname** A character or graphic string expression containing the value to set for the CURRENT CLIENT_APPLNAME special register for the current connection.
 If this parameter is omitted, the value of the CURRENT CLIENT_APPLNAME special register is not changed.
- client-acctng** A character or graphic string expression containing the value to set for the CURRENT CLIENT_ACCTNG special register for the current connection.
 If this parameter is omitted, the value of the CURRENT CLIENT_ACCTNG special register is not changed.
- client-programid** A character or graphic string expression containing the value to set for the CURRENT CLIENT_PROGRAMID special register for the current connection.
 If this parameter is omitted, the value of the CURRENT CLIENT_PROGRAMID special register is not changed.
- verbose** A character or graphic string expression that indicates whether the informational, severity 10 message SQL799C should be sent to the joblog when this procedure is called. The message lists the changed client special registers and their new values.

NO SQL799C will not be sent to the joblog when this procedure is called.

YES SQL799C will be sent to the joblog when this procedure is called. This is the default.

Example

- Change the values of the CURRENT CLIENT_USERID and CURRENT CLIENT_PROGRAMID special registers for the current connection.

```
CALL SYSPROC.WLM_SET_CLIENT_INFO(CLIENT_USERID => 'PGM1USER',  
                                CLIENT_PROGRAMID => 'PGM1');
```

Performance Services

These services include procedures that provide interfaces to work with indexes and a view to see information about database monitors.

Related reference

QAQQINI file override support

If you find working with the QAQQINI query options file cumbersome, consider using the QSYS2.OVERRIDE_QAQQINI procedure. Instead of creating, managing, and using a QAQQINI *FILE object directly, this procedure can be called to work with a temporary version of the INI file. It uses user-specified options and values. The support relies upon the QTEMP library, so any changes affect only the job which calls the procedure.

ACT_ON_INDEX_ADVICE procedure

The ACT_ON_INDEX_ADVICE procedure creates new indexes for a table based on indexes that have been advised for the table.

Authorization: See Note below.

```
►► ACT_ON_INDEX_ADVICE ( ( — schema-name — , — table-name — , ►  
  
    ► — times_advised — , — mti_used — , — average_estimate — ) ►◄
```

The schema is SYSTOOLS.

schema-name A character string containing the system name of the schema containing the table.

table-name A character string containing the system name of the table. If NULL is passed, this parameter is not used to select the target index advice.

times-advised The number of times an index should have been advised before creating a permanent index. If NULL is passed, this parameter is not used to select the target index advice.

mti-used The number of times a maintained temporary index (MTI) has been used because a matching permanent index did not exist. If NULL is passed, this parameter is not used to select the target index advice.

average-estimate The average estimated number of seconds needed to execute the query that drove the index advice. If NULL is passed, this parameter is not used to select the target index advice.

For each potential index meeting the specified criteria, a CREATE INDEX statement will be run to generate the permanent index. A radix index will be named name_RADIX_INDEX_n. An EVI index will be named name_EVI_INDEX_n. The *name* represents the table name and *n* is a unique number. The row containing this advised index is removed from the QSYS2.SYSIXADV table.

Note

This procedure is provided in the SYSTOOLS schema as an example of how to process index advice using an SQL procedure. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar procedures, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Examples

For schema PRODLIB, find all instances of index advice where a maintained temporary index was used more than 1000 times and create permanent SQL indexes.

```
CALL SYSTOOLS.ACT_ON_INDEX_ADVICE('PRODLIB',NULL,NULL,1000,NULL)
```

SYSTOOLS

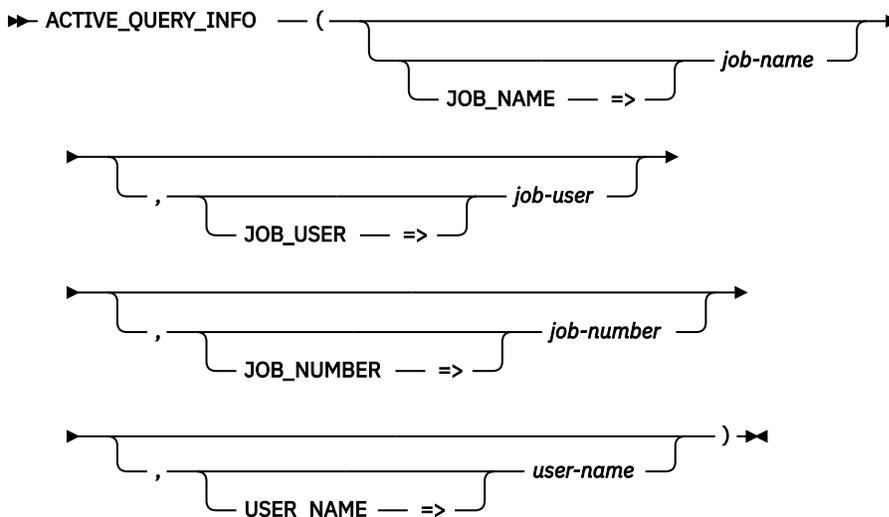

SYSTOOLS is a set of Db2 for IBM i supplied examples and tools.

ACTIVE_QUERY_INFO table function

The ACTIVE_QUERY_INFO table function returns information about active SQL Query Engine (SQE) queries. An active query is either open or pseudo-closed.

Authorization: None required to see information for the current job.

Otherwise, the caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM function usage ID.

The schema is QSYS2.

The values specified on the input parameters are ANDed together.

job-name A character or graphic string expression that contains an unqualified job name that determines the job information to be returned.

The job name can end with a wildcard character. For example, 'QPADEV*' indicates that any job name starting with the characters 'QPADEV' is a match.

The string can be the following special values:

* Information for the current job is returned. The *job-user* and *job-number* parameters cannot be specified.

***ALL** Information for all job names is returned.

If this parameter is not specified, is an empty string, or is the null value, information for all jobs is returned.

job-user A character or graphic string expression that contains a user name that determines the job information to be returned.

The job user name can end with a wildcard character. For example, 'Q*' indicates that any job user name starting with the character 'Q' is a match.

The string can be the following special value:

***ALL** Information for all job user names is returned.

If this parameter is not specified, is an empty string, or is the null value, information for all users is returned.

job-number A character or graphic string expression that contains a job number that determines the job information to be returned.

The string can be the following special value:

***ALL** Information for all job numbers is returned.

If this parameter is not specified, is an empty string, or is the null value, information for all job numbers is returned.

user-name A character or graphic string expression that contains a user name. This is the user profile under which the initial thread is running at this time.

The user name can end with a wildcard character. For example, 'BA*' indicates that any user name starting with the characters 'BA' is a match.

The string can be the following special value:

***ALL** Information for all users is returned.

If this parameter is not specified, is an empty string, or is the null value, the results are not filtered by the user name used by the initial thread .

The result of the function is a table containing multiple rows with the format shown in the following table. All the columns are nullable.

Table 67. ACTIVE_QUERY_INFO table function

Column Name	Data Type	Description
QUALIFIED_JOB_NAME	VARCHAR(28)	The qualified job name.
JOB_NAME	VARCHAR(10)	The name of the job.
JOB_USER	VARCHAR(10)	The user profile that started the job.
JOB_NUMBER	VARCHAR(6)	The job number of the job.
USER_NAME	VARCHAR(10)	The user profile under which the initial thread is running at this time. For jobs that swap user profiles, this user profile name and the user profile that started the job can be different.

Table 67. ACTIVE_QUERY_INFO table function (continued)

Column Name	Data Type	Description
QUERY_TYPE	VARCHAR(6)	The type of query. HLL High Level Language (HLL) open done using SQE. HLL opens include opens done via RPG, C, and COBOL NATIVE Native query SQL SQL query
PSEUDO_CLOSED	VARCHAR(3)	The current state of the SQL cursor associated with the query. NO Query is open YES Query is pseudo-closed Contains the null value if the query is not an SQL query.
QRO_HASH	VARCHAR(8)	The QRO_HASH which uniquely identifies an SQE query.
PLAN_IDENTIFIER	DECIMAL(20,0)	The Plan Identifier of the SQE plan.
FULL_OPEN_TIMESTAMP	TIMESTAMP	The full open timestamp.
LAST_PSEUDO_OPEN_TIMESTAMP	TIMESTAMP	The timestamp of the last pseudo-open. Contains the null value if the query has not been pseudo opened.
LIBRARY_NAME	VARCHAR(10)	The name of the library that contains FILE_NAME.
FILE_NAME	VARCHAR(10)	The database file name of the first table referenced by the query.
NUMBER_OF_PSEUDO_CLOSSES	BIGINT	The number of complete runs for this full open of the query. Returns 0 if this query has not been pseudo-closed.
CURRENT_ROW_COUNT	BIGINT	If this cursor is not pseudo-closed, the current number of rows fetched for this run of the query. Contains the null value if this cursor is currently pseudo-closed.
CURRENT_RUNTIME	BIGINT	If this cursor is not pseudo-closed, the current runtime in microseconds for this run of the query. Contains the null value if this cursor is currently pseudo-closed.
CURRENT_TEMPORARY_STORAGE	BIGINT	The current amount of temporary storage, in MB, used by the query. This size does not include storage used by MTIs.
CURRENT_DATABASE_READS	BIGINT	If this cursor is not pseudo-closed, the current number of asynchronous and synchronous database reads for this run of the query. Contains the null value if this cursor is currently pseudo-closed.
CURRENT_PAGE_FAULTS	BIGINT	If this cursor is not pseudo-closed, the current number of page faults for this run of the query. Contains the null value if this cursor is currently pseudo-closed.
MTI_COUNT	BIGINT	The number of Maintained Temporary Indexes (MTIs). Returns 0 if no MTIs are used by the query.
MTI_SIZE	BIGINT	The current size of MTIs, in MB. This size includes shared MTIs. Contains the null value if no MTIs are used by the query.
AVERAGE_ROW_COUNT	BIGINT	The average number of rows fetched for pseudo-closed runs of this query. Contains the null value if there are no prior runs.
AVERAGE_RUNTIME	BIGINT	The average runtime in microseconds for pseudo-closed runs of this query. Contains the null value if there are no prior runs.
AVERAGE_TEMPORARY_STORAGE	BIGINT	The average amount of temporary storage in MB for pseudo-closed runs of this query. This size does not include storage used by MTIs. Contains the null value if there are no prior runs.

Table 67. ACTIVE_QUERY_INFO table function (continued)

Column Name	Data Type	Description
AVERAGE_DATABASE_READS	BIGINT	The average number of asynchronous and synchronous database reads for pseudo-closed runs of this query. Contains the null value if there are no prior runs.
AVERAGE_PAGE_FAULTS	BIGINT	The average number of page faults for pseudo-closed runs of this query. Contains the null value if there are no prior runs.

Examples

- Retrieve information about all active SQE queries on the system.

```
SELECT *
FROM TABLE(QSYS2.ACTIVE_QUERY_INFO( ));
```

- Find which QZDASOINIT jobs are using MTIs.

```
SELECT JOB_NAME, MTI_COUNT, MTI_SIZE
FROM TABLE(QSYS2.ACTIVE_QUERY_INFO(
  JOB_NAME => 'QZDASOINIT'))
WHERE MTI_COUNT > 0;
```

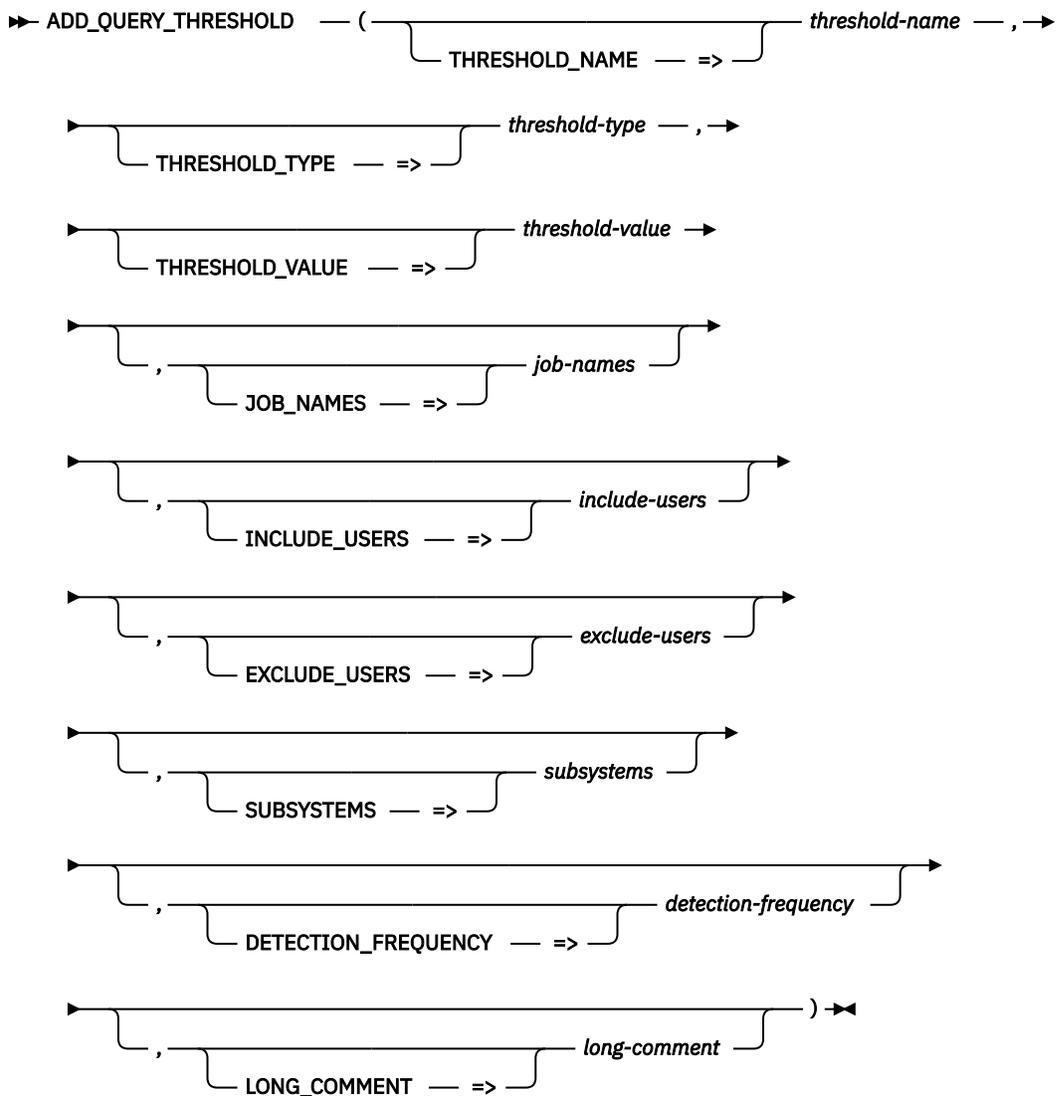

ADD_QUERY_THRESHOLD procedure

The ADD_QUERY_THRESHOLD procedure defines a new threshold to be used by the Query Supervisor. Adding a threshold only affects subsequently executed queries. Queries that are currently running continue to use the thresholds that were in effect when the query execution was initiated. The Query Supervisor only supervises user jobs. It does not affect system jobs or queries run by the operating system. The thresholds only apply to resources used by the SQL Query Engine (SQE).

Query Supervisor thresholds can include using job name, user name, and subsystem filters. The filters are combined to restrict the set of jobs for the rule. For jobs that meet the filtering criteria, when the threshold is met or exceeded, any exit programs registered with the QIBM_QQQ_QRY_SUPER exit point are called. An exit program can be used to implement actions such as query logging or real-time notification. It can also direct SQE to terminate the query. The exit program interface is described here: [Query Supervisor Exit Program](#). If the QIBM_QQQ_QRY_SUPER exit point does not exist, the ADD_QUERY_THRESHOLD procedure will create it.

When the first threshold is defined for a system, any active jobs, including the job that runs the initial ADD_QUERY_THRESHOLD, will not be affected by Query Supervisor thresholds.

Authorization: The caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM function usage ID.

The schema is QSYS2.

threshold-name A character or graphic string that provides a name for the threshold. The name can be up to 30 characters long and can contain any characters including blanks. The name cannot be the same as an existing threshold name.

threshold-type A character or graphic string that specifies the type of the threshold to be enforced.

CPU TIME The total processing unit time used by the query, in seconds.

ELAPSED TIME The total clock time, in seconds.

TEMPORARY STORAGE The amount of storage, in megabytes (MB), that the query allocates.

TOTAL IO COUNT The total number of I/O operations.

threshold-value A big integer value that contains the threshold value, in units defined by the specified *threshold-type*. The value must be greater than 0.

job-names A character or graphic string that specifies up to 100 job names separated by either a blank or a comma. Each job name can end with a wildcard character. For example, 'QPADEV*' indicates that any job name starting with the characters 'QPADEV' is a match.

Only jobs running with a matching job name are eligible to be supervised. Can contain the following special value:

***ALL** All jobs are supervised. This is the default.

include-users A character or graphic string that specifies up to 100 user names separated by either a blank or a comma. A group profile does not expand to include all profiles that are members of the group. Each name can end with a wildcard character. For example, 'ADM*' indicates that any user name starting with the characters 'ADM' is a match. Queries where the effective user of the thread matches one of these names are eligible to be supervised. If one or more names are specified for *include-users*, the *exclude-users* parameter must have a value of *NONE. Can contain the following special value:

***ALL** Jobs for all users are supervised. This is the default.

exclude-users A character or graphic string that specifies up to 100 user names separated by either a blank or a comma. A group profile does not expand to include all profiles that are members of the group. Each name can end with a wildcard character. For example, 'ADM*' indicates that any user name starting with the characters 'ADM' is a match. Queries where the effective user of the thread matches one of these names are not supervised. If one or more names are specified for *exclude-users*, the *include-users* parameter must have a value of *ALL. Can contain the following special value:

***NONE** No jobs are explicitly eliminated from being supervised based on the user name. This is the default.

subsystems A character or graphic string that specifies up to 100 subsystem names separated by either a blank or a comma. Each name can end with a wildcard character. For example, 'RSBS*' indicates that any subsystem name starting with the characters 'RSBS' is a match.

Only jobs running in a subsystem that match one of these names are eligible to be supervised. Can contain the following special value:

***ALL** All jobs are supervised. This is the default.

detection-frequency An integer value that specifies the minimum time, in seconds, between calls to exit programs registered with the QIBM_QQQ_QRY_SUPER exit point for this threshold for a specific thread. During the *detection-frequency* time interval following a threshold detection, the Query Supervisor does not process additional instances for this threshold in the same thread. Each time a query is run in a thread, a specific threshold can be processed at most once during the execution of that query.

The *detection-frequency* provides a protection from having a specific threshold recognized and processed more frequently than desired. If the same threshold is encountered within the same thread and the *detection-frequency* time period has not yet completed, the associated exit programs are not called and there is no external evidence that the Query Supervisor did not perform threshold detection.

The default is 600 (10 minutes).

long-comment A character or graphic string that describes this Query Supervisor threshold. It can be up to 2000 characters long.

Examples

- Set a threshold value for total CPU time to 30 seconds for all jobs. When this value is reached, any registered exit programs will be called.

```
CALL QSYS2.ADD_QUERY_THRESHOLD(THRESHOLD_NAME => 'MAXTIME',  
                               THRESHOLD_TYPE => 'CPU TIME',
```

```

THRESHOLD_VALUE => 30,
LONG_COMMENT    => 'Maximum runtime for all jobs');

```

- Set a threshold value for temporary storage to 10 megabytes for all jobs except for those running with the BATCHRUN user profile. Set a detection frequency of 2 minutes. When the storage threshold value is reached, any registered exit programs will be called. If the same thread reaches this threshold for a different query within 2 minutes, the registered exit programs will not be called.

```

CALL QSYS2.ADD_QUERY_THRESHOLD(THRESHOLD_NAME    => 'Temp storage',
                               THRESHOLD_TYPE    => 'TEMPORARY STORAGE',
                               THRESHOLD_VALUE    => 10,
                               EXCLUDE_USERS     => 'BATCHRUN',
                               DETECTION_FREQUENCY => 120);

```

DATABASE_MONITOR_INFO view

The DATABASE_MONITOR_INFO view returns information about database monitors and plan cache event monitors on the server. Database monitors are started using the Start Database Monitor (STRDBMON) command. The QSYS2.START_PLAN_CACHE_EVENT_MONITOR procedure is used to start a plan cache event monitor. SQL Performance Monitors within IBM i Navigator are synonymous with database monitors and are included in this view.

Authorization: None required.

The following table describes the columns in the view. The system name is DBMON_INFO. The schema is QSYS2.

Table 68. DATABASE_MONITOR_INFO view

Column Name	System Column Name	Data Type	Description
MONITOR_ID	MONITOR_ID	CHAR(10)	The system-assigned monitor ID for this monitor.
MONITOR_TYPE	MONTYPE	VARCHAR(7)	Type of monitor. PUBLIC A monitor is considered public when the STRDBMON JOB parameter indicates that jobs other than the current job should be monitored. Public monitors remain active until they are explicitly ended using the End Database Monitor (ENDDDBMON) command. PRIVATE A private monitor occurs when the STRDBMON JOB parameter indicates to monitor only the current job. The monitor is ended as part of job termination processing, if needed. Only a private monitor that is active in the current connection will be returned. EVENT An SQL plan cache event monitor intercepts plans as they are moved from the plan cache into a database monitor file.
MONITOR_STATUS	STATUS	VARCHAR(8)	Status of this monitor. ACTIVE Monitor is active. INACTIVE For a PUBLIC or PRIVATE monitor, it is inactive and can become ACTIVE. For an EVENT monitor, entries are no longer being collected. CLOSING The PUBLIC or PRIVATE monitor is not active or is in the processing of ending. It is not known if the entry can be reused for monitoring.
MONITOR_RECORD_TYPE	RCDTYPE	VARCHAR(6)	Type of database records in this monitor. DETAIL Both basic and detail database monitor records. An EVENT monitor always has a value of DETAIL. BASIC Only basic database monitor records
MONITOR_LIBRARY	MONLIB	VARCHAR(10)	Library for this monitor.
MONITOR_FILE	MONFILE	VARCHAR(10)	The file to which the database activity detail is written for this monitor.

Table 68. DATABASE_MONITOR_INFO view (continued)

Column Name	System Column Name	Data Type	Description
MONITOR_MEMBER	MONMBR	VARCHAR(10)	Member for this monitor.
IASP_NUMBER	IASPNUMBER	SMALLINT	The independent auxiliary storage pool (IASP) number for the monitor file. 0 indicates the system ASP.
MONITOR_MEMBER_OPTION	MBROPT	VARCHAR(7) Nullable	Value used for the member replace option the last time this monitor was started. <ul style="list-style-type: none"> REPLACE ADD Contains the null value for an EVENT monitor.
NUMBER_ROWS	CARD	BIGINT Nullable	The number of rows in the database monitor file. Contains the null value if information is not available.
DATA_SIZE	SIZE	BIGINT Nullable	The total size, in bytes, of the database monitor file. Contains the null value if information is not available.
MONITOR_JOB_FILTER	JOB	VARCHAR(32)	Qualified job name for this monitor. For an EVENT monitor, this is the job that started the monitor. Following the qualified job name is the filter operator that applies to the job name. This is either *EQ or *NE. The special value of *ALL indicates all jobs on the system are monitored. A generic name is allowed for both the job name and the user name.
HOST_VARIABLE	HOSTVAR	VARCHAR(9) Nullable	How host variables are handled in this database monitor. <p>BASIC Host variables are written in the QQQ3010 database monitor record.</p> <p>SECURE No host variables are captured and no QQQ3010 record is written.</p> <p>CONDENSED Host variable values are captured in the QQQ1000 database monitor record in column QQDBCLOB1. No QQQ3010 record is written.</p> Contains the null value for an EVENT monitor.
FORCE_RECORDS	FRCRCD	SMALLINT Nullable	The number of records to be held in the buffer before forcing the records to be written to the file when running with a private monitor. Contains the null value if the system calculates the value or for an EVENT monitor.
RUN_THRESHOLD_FILTER	RUNTHLD	INTEGER Nullable	The filtering threshold, in seconds, based on the estimated run time of SQL statements in this monitor. Contains the null value if a run time threshold is not used for filtering or for an EVENT monitor.
STORAGE_THRESHOLD_FILTER	STGTHLD	INTEGER Nullable	The filtering threshold, in megabytes, based on the estimated temporary storage usage of SQL statements in this monitor. Contains the null value if a temporary threshold is not used for filtering or for an EVENT monitor.
INCLUDE_SYSTEM_SQL	INCSYSSQL	VARCHAR(3)	Monitor includes records for system-generated SQL statements. <p>YES Monitor records are generated for both user-specified and system-generated SQL statements.</p> <p>NO Monitor records are generated for only user-specified SQL statements.</p> <p>INI For a PUBLIC or PRIVATE monitor, records are generated based on the value of the SQL_DBMON_OUTPUT option in the QAQINI query options.</p>

Table 68. DATABASE_MONITOR_INFO view (continued)

Column Name	System Column Name	Data Type	Description
FILE_FILTER	FTRFILE	VARCHAR(2728) Nullable	<p>A list of up to 10 qualified file references that are used for filtering. Following each file name is the filter operator that applies to the file name. This is either *EQ or *NE. When more than one file is listed, a comma and a single blank separate the entries. Either the file name or the library name can be a generic name.</p> <p>A special value of *ALL for the file name indicates all files in the library.</p> <p>Contains the null value if no database files are used for filtering.</p>
USER_FILTER	FTRUSER	VARCHAR(158) Nullable	<p>A list of up to 10 user profiles that are used for filtering. Following each user profile name is the filter operator that applies to the user profile. This is either *EQ or *NE. When more than one profile is listed, a comma and a single blank separate the entries. A profile name can be a generic name.</p> <p>Contains the null value if the user profile is not used for filtering.</p>
TCPIP_FILTER	FTRINTNETA	VARCHAR(254) Nullable	<p>The TCP/IP address or host name is used for filtering.</p> <p>This is an IPv4, IPv6, or IP host domain name, or the special value of *LOCAL.</p> <p>Contains the null value if the TCP/IP address or host name is not used for filtering or for an EVENT monitor.</p>
LOCAL_PORT_FILTER	FTRLCLPORT	INTEGER Nullable	<p>Filtering is based on the local TCP/IP port number. Monitor records will be created for TCP/IP database server jobs running on behalf of the specified local TCP/IP port. Jobs named QRWTSRVR and QZDASOINIT are examples of these server jobs.</p> <p>The IBM i well defined port numbers are documented here: Port numbers for host servers and server mapper.</p> <p>Contains the null value if the port number is not used for filtering or for an EVENT monitor.</p>
QUERY_GOVERNOR_FILTER	FTRQRYGOVR	VARCHAR(11) Nullable	<p>The query governor is used for filtering.</p> <p>ALL Monitor records will be collected when a query governor limit is exceeded.</p> <p>CONDITIONAL Monitor records will be conditionally collected when a query governor limit is exceeded.</p> <p>Contains the null value if the query governor is not used for filtering or for an EVENT monitor.</p>
CLIENT_ACCTNG_FILTER	FTRCLTACG	VARCHAR(128) Nullable	<p>The CURRENT CLIENT_ACCTNG special register is used for filtering.</p> <p>Contains the null value if the CURRENT CLIENT_ACCTNG special register is not used for filtering or for an EVENT monitor.</p>
CLIENT_APPLNAME_FILTER	FTRCLTAPP	VARCHAR(128) Nullable	<p>The CURRENT CLIENT_APPLNAME special register is used for filtering.</p> <p>Contains the null value if the CURRENT CLIENT_APPLNAME special register is not used for filtering or for an EVENT monitor.</p>
CLIENT_PROGRAMID_FILTER	FTRCLTPGM	VARCHAR(128) Nullable	<p>The CURRENT CLIENT_PROGRAMID special register is used for filtering.</p> <p>Contains the null value if the CURRENT CLIENT_PROGRAMID special register is not used for filtering or for an EVENT monitor.</p>
CLIENT_USERID_FILTER	FTRCLTUSR	VARCHAR(128) Nullable	<p>The CURRENT CLIENT_USERID special register is used for filtering.</p> <p>Contains the null value if the CURRENT CLIENT_USERID special register is not used for filtering or for an EVENT monitor.</p>
CLIENT_WRKSTNNAME_FILTER	FTRCLTWS	VARCHAR(128) Nullable	<p>The CURRENT CLIENT_WRKSTNNAME special register is used for filtering.</p> <p>Contains the null value if the CURRENT CLIENT_WRKSTNNAME special register is not used for filtering or for an EVENT monitor.</p>

Table 68. DATABASE_MONITOR_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SQL_CODE_FILTER	FTRSQCODE	VARCHAR(7) Nullable	How the SQLCODE result from a statement execution is used for filtering. NONZERO Any SQL statement with an SQLCODE value that is non-zero is included in the monitor. ERROR Any SQL statement with an SQLCODE that is less than zero is collected in the monitor. WARNING Any SQL statement with an SQLCODE that is greater than zero is collected in the monitor. SQLCODE Any SQL statement with an SQLCODE that exactly matches the value in the SQLCODE_VALUE column is collected in the monitor. Contains the null value if the SQLCODE for a statement is not used for filtering or for an EVENT monitor.
SQLCODE_VALUE	SQLCODEVAL	INTEGER Nullable	The positive or negative SQLCODE value to use for filtering. Contains the null value if the SQL_CODE_FILTER column contains a value other than SQLCODE.

Examples

Example 1: Get the MONITOR_ID for all the active PUBLIC monitors and the file names associated with the MONITOR_IDs.

```
SELECT MONITOR_ID, MONITOR_LIBRARY, MONITOR_FILE
FROM QSYS2.DATABASE_MONITOR_INFO
WHERE MONITOR_STATUS = 'ACTIVE' AND
MONITOR_TYPE = 'PUBLIC'
```

Example 2: Find the active monitors that have outfiles larger than 1Gig.

```
SELECT MONITOR_LIBRARY, MONITOR_FILE, NUMBER_ROWS, DATA_SIZE
FROM QSYS2.DATABASE_MONITOR_INFO
WHERE MONITOR_STATUS = 'ACTIVE' AND
DATA_SIZE > 1073741824
```

Example 3: Find any active monitors that are filtering based upon a specific SQLCODE (FTRSQCODE).

```
SELECT MONITOR_ID, MONITOR_LIBRARY, MONITOR_FILE, SQLCODE_VALUE
FROM QSYS2.DATABASE_MONITOR_INFO
WHERE MONITOR_STATUS = 'ACTIVE' AND
SQL_CODE_FILTER = 'SQLCODE'
```

Example 4: Get the MONITOR_ID for a user's SQL plan cache event monitor and use it to end the active event monitor.

```
CALL QSYS2.END_PLAN_CACHE_EVENT_MONITOR (SELECT MONITOR_ID
FROM QSYS2.DATABASE_MONITOR_INFO
WHERE MONITOR_TYPE = 'EVENT' AND
MONITOR_LIBRARY = 'USERLIB')
```

HARVEST_INDEX_ADVICE procedure

The HARVEST_INDEX_ADVICE procedure generates one or more CREATE INDEX statements in source file members for a specified table based on indexes that have been advised for the table.

Authorization: See Note below.

```

▶▶ HARVEST_INDEX_ADVICE — ( — schema-name — , — table-name — , →
    ▶ — times_advised — , — mti_used — , — average_estimate — , — output-library — , — output-file →
    ▶ — ) ▶▶

```

The schema is SYSTOOLS.

<i>schema-name</i>	A character string containing the system name of the schema containing the table.
<i>table-name</i>	A character string containing the system name of the table.
<i>times-advised</i>	The number of times an index should have been advised before creating a permanent index. Pass a value of 1 to not limit index creation by the number of times advised.
<i>mti-used</i>	The number of times a maintained temporary index (MTI) has been used because a matching permanent index did not exist. Pass a value of 0 to not limit index creation by MTI use.
<i>average-estimate</i>	The average estimated number of seconds needed to execute the query that drove the index advice. Pass a value of 0 to not limit index creation by the average query estimate.
<i>output-library</i>	A character string value containing the name of the library for the output source file.
<i>output-file</i>	A character string value containing the name of the output source file. The file must exist and must be a source physical file.

For each potential index meeting the specified criteria, a CREATE INDEX statement to create the permanent index will be generated in a member in the source file provided to this procedure. A radix index will be named name_RADIX_INDEX_n. An EVI index will be named name_EVI_INDEX_n. The *name* represents the table name and *n* is a unique number. The row containing this advised index is removed from the QSYS2.SYSIXADV table.

Note

This procedure is provided in the SYSTOOLS schema as an example of how to process index advice using an SQL procedure. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar procedures, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

Harvest create index statements for file TOYSTORE/SALES into source physical file QGPL/INDEXSRC. Then use RUNSQLSTM to create the indexes.

```

BEGIN
  DECLARE NOT_FOUND CONDITION FOR '02000';
  DECLARE ERROR_COUNT INTEGER DEFAULT 0;
  DECLARE AT_END INT DEFAULT 0;
  DECLARE V_INDEX_COUNT INTEGER DEFAULT 0;
  DECLARE V_PARTITION_NAME VARCHAR(10);
  DECLARE INDEX_SOURCE_CURSOR CURSOR FOR
    SELECT TABLE_PARTITION FROM QSYS2.SYSPARTITIONSTAT
      WHERE TABLE_SCHEMA = 'QGPL' AND TABLE_NAME = 'INDEXSRC';
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION SET ERROR_COUNT = ERROR_COUNT + 1;

  CALL QSYS2.QCMDXEC('DLTF FILE(QGPL/INDEXSRC)');
  CALL QSYS2.QCMDXEC('CRTSRCPF FILE(QGPL/INDEXSRC) RCDLEN(10000)');
  -- Create the source file with a big record length,
  -- to allow the create index statement to fit on one line
  CALL SYSTOOLS.HARVEST_INDEX_ADVICE('TOYSTORE', 'SALES', 100, 50, 5, 'QGPL', 'INDEXSRC');

```

```

BEGIN
  DECLARE V_RUNSQLSTM_TEXT VARCHAR(500);
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION SET AT_END = 1;
  DECLARE CONTINUE HANDLER FOR NOT_FOUND SET AT_END = 1;
  OPEN INDEX_SOURCE_CURSOR;
  FETCH FROM INDEX_SOURCE_CURSOR INTO V_PARTITION_NAME;
  WHILE ( AT_END = 0 ) DO
    -- Now that QGPL/INDEXSRC has been populated with members named HARVnnnn,
    -- the RUNSQLSTM command can be used to execute the CREATE INDEX statement.
    -- By using ERRlvl = 30, we'll ignore any failures.
    SET V_RUNSQLSTM_TEXT = 'RUNSQLSTM SRCFILE(QGPL/INDEXSRC) SRCMBR('
      CONCAT RTRIM(V_PARTITION_NAME)
      CONCAT ') COMMIT(*NONE) NAMING(*SQL) ERRlvl(30) MARGINS(10000)';
    CALL QSYS2.QCMDXEC(V_RUNSQLSTM_TEXT);
    FETCH FROM INDEX_SOURCE_CURSOR INTO V_PARTITION_NAME;
  END WHILE;
  CLOSE INDEX_SOURCE_CURSOR;
END;
END;

```

Related reference

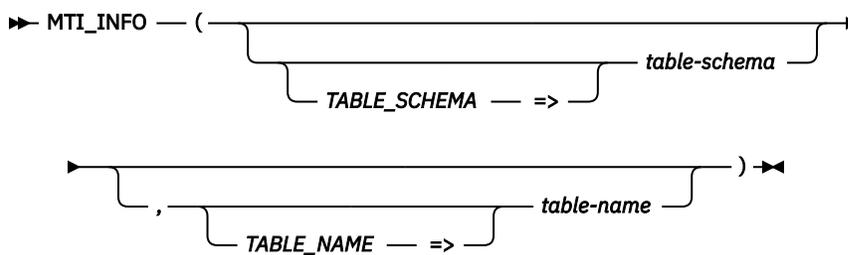

SYSTOOLS

SYSTOOLS is a set of Db2 for IBM i supplied examples and tools.

MTI_INFO table function

The MTI_INFO table function returns information about Maintained Temporary Indexes (MTIs).

Authorization: The caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM function usage ID.

The schema is QSYS2.

table-schema A character or graphic string expression that contains the schema name of the base table for the MTIs to be returned. The schema name may be either the SQL or the system schema name.

Can contain the following special value:

***ALL** Information for MTIs in all schemas with a base table specified by *table-schema* is returned. This is the default.

If this parameter contains an empty string or the null value, *ALL is used.

table-name A character or graphic string expression that contains the table name of the base table for the MTIs to be returned. The table name may be either the SQL or the system table name.

Can contain the following special value:

***ALL** Information for all MTIs with a base table in *table-schema* is returned. This is the default.

If this parameter contains an empty string or the null value, *ALL is used.

The result of the function is a table containing multiple rows with the format shown in the following table. Each row contains information for one MTI on the system. All columns are nullable.

Table 69. MTI_INFO table function

Column Name	Data Type	Description
TABLE_SCHEMA	VARCHAR(128)	Schema name of the base table that the MTI is created over.
TABLE_NAME	VARCHAR(128)	Name of the base table that the MTI is created over.
TABLE_PARTITION	VARCHAR(128)	Name of the table partition or member that the MTI is created over.
REFERENCE_COUNT	BIGINT	The current number of references to this MTI. This includes plans in the plan cache and open queries that are using this MTI. When this count goes to 0, the MTI will be deleted.
KEYS	INTEGER	Number of keys.
KEY_DEFINITION	DBCLOB(10000) CCSID 1200	Key definition.
STATE	VARCHAR(20)	The current state of the MTI. CREATED MTI is in a valid state but has not been populated. This can occur if the query subtree that uses the MTI has not been run. CREATING MTI is currently being created. DELETING MTI is currently being deleted. MAPPING ERROR A selection or mapping error occurred during index build. A mapping or selection error can occur if the key definition or the sparse definition contains an expression and that expression resulted in an error when being run. An example of that is a divide by zero. POPULATING The MTI is currently populating. REBUILD REQUIRED The index portion of the MTI will need to be re-populated on the next use of the MTI. VALID MTI is in a valid state and populated. nnnn A 4 digit number indicating an error status to be used by IBM support.
MTI_SIZE	BIGINT	The current size of the MTI in bytes.
CREATE_TIME	TIMESTAMP	The timestamp of when the MTI was created.
LAST_BUILD_START_TIME	TIMESTAMP	Start of the last index build. Contains the null value if the index portion of the MTI has not been populated.
LAST_BUILD_END_TIME	TIMESTAMP	End of the last index build. Contains the null value if the index portion of the MTI has not been populated or is currently being populated.
REUSABLE	VARCHAR(3)	MTI is reusable across queries. NO MTI can only be used for this query. YES MTI is reusable.
SPARSE	VARCHAR(3)	MTI is sparse. NO MTI is not sparse. YES MTI is sparse.
SPARSE_DEFINITION	DBCLOB(10000) CCSID 1200	The predicate used to create the sparse MTI. Contains the null value if SPARSE is NO.
QRO_HASH	VARCHAR(8)	An internally generated identifier which identifies the SQE query which originally created the MTI.
PLAN_IDENTIFIER	DECIMAL(20,0)	Identifies the plan within the plan cache which originally created the MTI.
USER_NAME	VARCHAR(10)	The effective user of the thread that created the MTI.
QUALIFIED_JOB_NAME	VARCHAR(28)	The fully qualified job name of the job that created the MTI.
JOB_NAME	VARCHAR(10)	The name of the job.

Table 69. MTI_INFO table function (continued)

Column Name	Data Type	Description
JOB_USER	VARCHAR(10)	The user profile that started the job.
JOB_NUMBER	VARCHAR(6)	The job number of the job.
MTI_NAME	VARCHAR(128)	A generated name that identifies the MTI.
LIBRARY_NAME	VARCHAR(10)	The name of the library that contains FILE_NAME.
FILE_NAME	VARCHAR(10)	The database file name of the base table that the MTI is created over.

Example

- Return information about all MTIs that exist over the APPLIB/EMPLOYEE table.

```
SELECT * FROM TABLE(QSYS2.MTI_INFO('APPLIB', 'EMPLOYEE'));
```

QUERY_SUPERVISOR view

The QUERY_SUPERVISOR view contains the threshold rules defined for the Query Supervisor.

Authorization: The caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM function usage ID.

The following table describes the columns in the view. The system name is QRY_SUPER. The schema is QSYS2.

Table 70. QUERY_SUPERVISOR view

Column Name	System Column Name	Data Type	Description
THRESHOLD_NAME	NAME	VARGRAPHIC(30) CCSID 1200	The name of the threshold.
THRESHOLD_TYPE	TYPE	VARCHAR(30)	The type of threshold CPU TIME The total processing unit time used by the query, in seconds. ELAPSED TIME The total clock time, in seconds. TEMPORARY STORAGE The amount of storage, in megabytes (MB), that the query allocates. TOTAL IO COUNT The total number of I/O operations.
THRESHOLD_VALUE	VALUE	BIGINT	The value associated with THRESHOLD_TYPE, in the appropriate units.
JOB_NAMES	JOB_NAMES	VARCHAR(1099) Nullable	A list of job names supervised by this threshold. Each name in the list is padded with blanks to fill ten characters, with a single comma separating the name entries. Contains the null value if all job names are supervised.
INCLUDE_USERS	INCL_USERS	VARCHAR(1099) Nullable	A list of user names supervised by this threshold. Each name in the list is padded with blanks to fill ten characters, with a single comma separating the name entries. Contains the null value if all user names are supervised.
EXCLUDE_USERS	EXCL_USERS	VARCHAR(1099) Nullable	A list of user names that are not supervised by this threshold. Each name in the list is padded with blanks to fill ten characters, with a single comma separating the name entries. Contains the null value if no user names are excluded.

Table 70. QUERY_SUPERVISOR view (continued)

Column Name	System Column Name	Data Type	Description
SUBSYSTEMS	SUBSYSTEMS	VARCHAR(1099) Nullable	A list of subsystems supervised by this threshold. Each name in the list is padded with blanks to fill ten characters, with a single comma separating the name entries. Contains the null value if all subsystems are supervised.
DETECTION_FREQUENCY	FREQUENCY	INTEGER	The minimum frequency, in seconds, that a notification is sent for this threshold within a specific thread. During the time interval following a threshold detection, the Query Supervisor does not process additional instances for this threshold, in the same thread. Each time a query is run in a thread, a specific threshold can be processed at most once during the execution of that query. The <i>detection-frequency</i> value provides a protection from having a specific threshold recognized and processed more frequently than desired. If the same threshold is encountered within the same thread and the <i>detection-frequency</i> time period has not yet completed, the associated exit programs are not called and there is no external evidence that the Query Supervisor did not perform threshold detection.
LONG_COMMENT	REMARKS	VARGRAPHIC(2000) CCSID 1200 Nullable	Description of this threshold rule. Contains the null value if the rule has no descriptive text.

Example

- List all the thresholds defined for the Query Supervisor.

```
SELECT *
FROM QSYS2.QUERY_SUPERVISOR ORDER BY THRESHOLD_TYPE, THRESHOLD_VALUE DESC;
```

REMOVE_INDEXES procedure

The REMOVE_INDEXES procedure drops any indexes meeting the specified criteria.

Authorization: See Note below.

►► REMOVE_INDEXES (— *schema-name* — , — *times_used* — , — *index-age* —) ►►

The schema is SYSTOOLS.

schema-name A character string containing the system name of the schema containing the indexes to be evaluated. If the NULL value is passed, the entire database is processed.

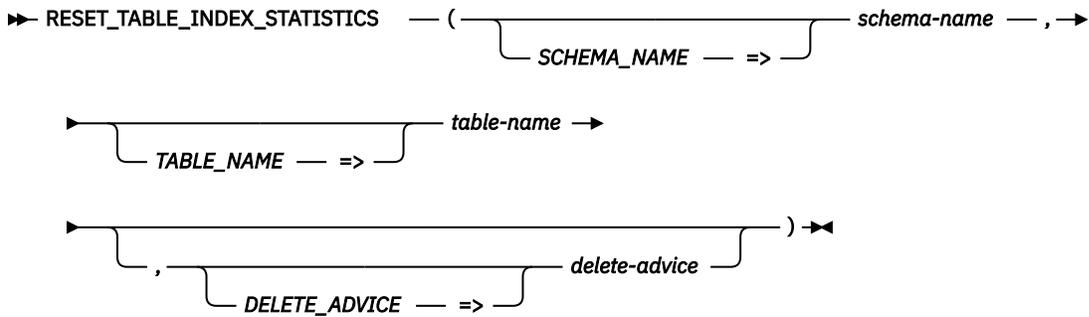

times_used A big integer value indicating the number of times an index has been used.

index-age A character string containing an SQL labeled duration, such as '2 MONTHS'.

The procedure will evaluate all indexes for the specified *schema-name* value and drop any index that does not meet the *times-used* and *index-age* threshold. If the number of times the index has been used by a query and used for statistics is less than the *times-used* value, the index is considered under utilized and is a candidate to be dropped. An index that has existed at least the length of time indicated by *index-age* is also a candidate to be dropped. Any index that meets both criteria is dropped.

Only index names that have names like name_RADIX_INDEX_x or name_EVI_INDEX_x will be considered by this procedure.

To delete index advice, the DELETE privilege is required on QSYS2/SYSIXADV. Index advice is only deleted when the caller has the required authority to the table and index.

The schema is QSYS2.

This procedure will reset the LAST_QUERY_USE, LAST_STATISTICS_USE, QUERY_USE_COUNT, and QUERY_STATISTICS_COUNT usage statistics for all indexes over the specified tables. These counts can also be reset using the Change Object Description (CHGOBJD) CL command, but the command requires an exclusive lock.

- schema-name** A character string expression for the name of the schema or schemas to use. The name is case-sensitive and must not be delimited. Wildcard characters (_ and %) are allowed in the string following the rules for the SQL LIKE predicate.
- table-name** A character string expression for the name of the table or tables to use. The name is case-sensitive and must not be delimited. Wildcard characters (_ and %) are allowed in the string following the rules for the SQL LIKE predicate.
- delete-advice** A character string expression that indicates whether this procedure should remove rows from the index advice tracking table.
 - NO** Index advice for the table is not affected. This is the default.
 - YES** This procedure will delete rows from the index advice tracking table (QSYS2/SYSIXADV) that correspond to *schema-name* and *table-name*. To be removed, an index must exist and the user must be authorized to the index.

The procedure writes information related to every index processed into an SQL global temporary table. The LAST_USE_DATE and NUMBER_DAYS_USED fields are not affected. The following query will display the results of the last call to the procedure:

```
SELECT * FROM SESSION.SQL_INDEXES_RESET
```

The table that is created contains the following columns:

Table 71. SQL_INDEXES_RESET result table

Column Name	System Column Name	Data Type	Description
TABLE_SCHEMA	DBNAME	VARCHAR(128)	Schema name of table.
TABLE_NAME	NAME	VARCHAR(128)	Name of table.
TABLE_PARTITION	TABLE00001	VARCHAR(128)	Name of the table partition or member.
PARTITION_TYPE	PARTI00001	CHAR(1)	The type of table partitioning.
PARITION_NUMBER	PARTI00002	INTEGER	The partition number of this partition.
NUMBER_DISTRIBUTED_PARTITIONS	NUMBE00001	INTEGER	If the table is a distributed table, contains the total number of partitions.
INDEX_SCHEMA	INDEX00001	VARCHAR(128)	Schema name of index.
INDEX_NAME	INDEX_NAME	VARCHAR(128)	Name of index.
INDEX_MEMBER	INDEX00002	VARCHAR(128)	Partition or member name of index.

Table 71. SQL_INDEXES_RESET result table (continued)

Column Name	System Column Name	Data Type	Description
INDEX_TYPE	INDEX_TYPE	CHAR(11)	Type of index.
LAST_QUERY_USE	LAST_00002	TIMESTAMP	The timestamp of the last time the SQL index was used in a query since the last time the usage statistics were reset. Contains the null value if the SQL index has never been used in a query since the last time the usage statistics were reset.
LAST_STATISTICS_USE	LAST_00003	TIMESTAMP	The timestamp of the last time the SQL index was used by the optimizer for statistics since the last time the usage statistics were reset. Contains the null value if the SQL index has never been used in a query since the last time the usage statistics were reset.
QUERY_USE_COUNT	QUERY00001	BIGINT	The number of times the SQL index was used in a query since the last time the usage statistics were reset. Contains 0 if the SQL index has never been used in a query since the last time the usage statistics were reset.
QUERY_STATISTICS_COUNT	QUERY00002	BIGINT	The number of times the SQL index was used by the optimizer for statistics since the last time the usage statistics were reset. Contains 0 if the SQL index has never been used in a query since the last time the usage statistics were reset.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System table schema name.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System table name.
SYSTEM_TABLE_MEMBER	SYSTE00001	CHAR(10)	System member name.

Examples

- Zero the statistics for all indexes over table TOYSTORE.SALES

```
CALL QSYS2.RESET_TABLE_INDEX_STATISTICS ('TOYSTORE', 'SALES')
```

- Zero the statistics for all indexes over any table in schema TOYSTORE whose name starts with the letter S.

```
CALL QSYS2.RESET_TABLE_INDEX_STATISTICS ('TOYSTORE', 'S%')
```

Plan Cache Services

These services include procedures to assist you in performing database administration (DBA) and database engineering (DBE) tasks.

These procedures allow for programmatic access to the SQL plan cache and can be used for tasks such as scheduling plan cache captures or pre-starting an event monitor.

CHANGE_PLAN_CACHE_SIZE procedure

The CHANGE_PLAN_CACHE_SIZE procedure provides a way to change the maximum amount of storage used by the plan cache.

Authorization: The caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM function usage ID.

►► CHANGE_PLAN_CACHE_SIZE — (— *integer-expression* —) ►►

The schema is QSYS2.

integer-expression A numeric expression that specifies the size, in megabytes, that the plan cache cannot exceed. Once set, the maximum size of the plan cache will be retained across IPLs and IBM i operating system upgrades. If the value is zero, the plan cache is reset to its default value which allows the plan cache to be auto-sized by the database.

Example

- Change the plan cache maximum size to 3072 megabytes:

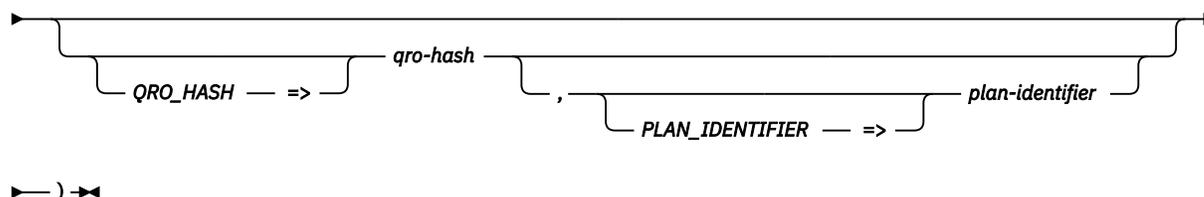

```
CALL QSYS2.CHANGE_PLAN_CACHE_SIZE(3072);
```

CLEAR_PLAN_CACHE procedure

The CLEAR_PLAN_CACHE procedure either clears all plans or removes the specified plans from the SQL plan cache without requiring a system IPL.

Authorization: The caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM function usage ID.

►► CLEAR_PLAN_CACHE — (→

The schema is QSYS2.

qro-hash A character or graphic string expression that identifies a set of plans for a specific SQE query. If *qro-hash* is not specified, the null value is used.

plan-identifier A numeric value which uniquely identifies a plan within the plan cache. If *plan-identifier* is not specified, the null value is used.

If *qro-hash* is specified and *plan-identifier* is not specified, the procedure will clear all the plans from the SQL plan cache with that *qro-hash*. If a *qro-hash* and a *plan-identifier* are specified, that specific plan will be removed. If no matching plan is found, the procedure returns without error.

If no parameters are specified, or a null value is specified for both *qro-hash* and *plan-identifier*, the procedure will clear all plans in the SQL plan cache that exist at the time the procedure is run.

Besides clearing the plan information, any Maintained Temporary Indexes (MTIs) not currently in use by a query will be deleted as part of the clear operation. Queries run while the CLEAR_PLAN_CACHE procedure is running may have their plans removed, but the queries themselves will not incur a failure related to plan removal. After the clear is complete, as queries are re-optimized, they will be inserted into the plan cache.

Removal of all plans is intended for use primarily in performance test and quality assurance environments. It provides database performance analysts with a way to create a consistent environment from which to evaluate potential database performance changes.

Removal of a specific plan is intended for limited use, such as when directed by IBM service or when needing to force the optimizer to re-optimize a specific query.

The time the CLEAR_PLAN_CACHE procedure takes to run will vary depending on the plan cache size. To avoid tying up an interactive job, it is recommended that the procedure should be submitted in a batch job using a combination of the Submit Job (SBMJOB) and Run SQL (RUNSQL) CL commands.

Notes

The QRO hash is an internally generated identifier for an SQE query. In general, this identifier will be unique for each SQE query and uses implicit schema qualification among other data to generate the QRO hash. If the SQE optimizer generates multiple plans for the same query, then multiple plans will have the same QRO hash. However, every plan will have a unique plan identifier. The QRO hash for a statement may change on release boundaries or after loading PTFs. The QRO hash is externalized:

- In a Visual Explain
- From Show Statements exploration of the SQL Plan Cache and SQL Plan Cache Snapshots
- In the QQC83 column of the 3014 record of a database monitor or plan cache snapshot file
- As information passed to a Query Supervisor exit program.
- As returned from the QSYS2.ACTIVE_JOB_INFO table function

The plan identifier is a unique number that is generated when the plan is optimized. The plan identifier is externalized:

- The statement number of a Visual Explain of a plan cache snapshot or a Visual Explain from the Show Statements exploration of the SQL Plan Cache
- From Show Statements exploration of the SQL Plan Cache and SQL Plan Cache Snapshots
- In the QQCNT column of the 1000 record of a plan cache snapshot file.
- As information passed to a Query Supervisor exit program.

Example

- Submit a job to clear the plan cache.

```
SBMJOB CMD(RUNSQL SQL('CALL QSYS2.CLEAR_PLAN_CACHE()') COMMIT(*NONE) NAMING(*SQL))
```

- Clear all plans that have a QRO hash of 'D0C257FD'.

```
CALL QSYS2.CLEAR_PLAN_CACHE(QRO_HASH => 'D0C257FD');
```

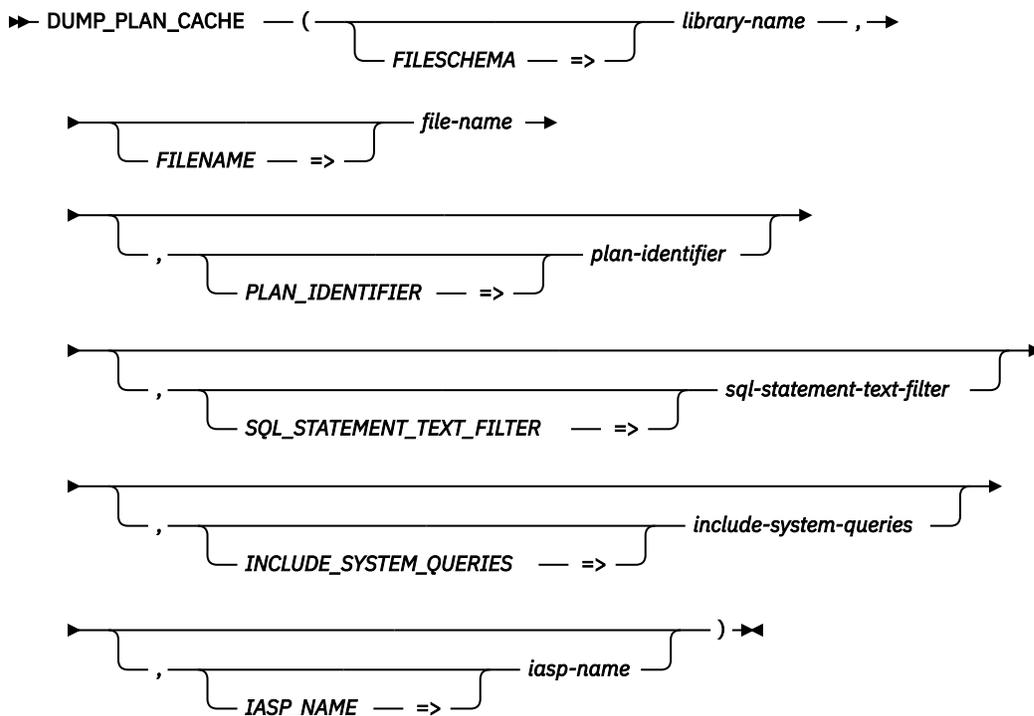

- Clear one specific plan.

```
CALL QSYS2.CLEAR_PLAN_CACHE(QRO_HASH => '1239A9F0',
                             PLAN_IDENTIFIER => 1305582);
```

DUMP_PLAN_CACHE procedure

The DUMP_PLAN_CACHE procedure creates a database monitor file (snapshot) from the plan cache.

Authorization: The caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM function usage ID.

The schema is QSYS2.

library-name A character or graphic string expression that identifies the name of the library containing *file-name*. The special value of *CURLIB can be used.

file-name A character or graphic string expression that identifies the name of the resulting database monitor file. If the file does not exist, it is created. If the file exists, the new plan cache snapshot will be appended to it.

plan-identifier A numeric value which uniquely identifies a plan within the plan cache. When a *plan-identifier* is specified, *sql-statement-text-filter*, *include-system-queries*, and *iasp-name* are ignored. *SYSBAS and all available IASPs are searched for the *plan-identifier*.

sql-statement-text-filter A character or graphic string expression that identifies a substring of text that must match for a plan to be selected. The comparison is case insensitive. Blanks, control characters, and comments embedded in the statement text are significant. If this parameter is not provided, plans are not filtered by statement text.

include-system-queries A character or graphic string expression that indicates whether system queries are dumped in addition to user queries.

NO Only user queries are dumped. This is the default.

YES System queries and user queries are dumped.

iasp-name A character or graphic string expression that identifies the independent ASP (IASP) group to be used for finding plans to dump. An IASP must be available to access its plans.

name The name of the IASP containing plans to dump.

***ALL** Plans from SYSBASE and all available IASPs are dumped.

***CURRENT** Only plans in the current IASP are dumped. This is the default.

***SYSBAS** Only plans in SYSBASE are dumped.

If *plan-identifier* is specified, only that specific plan is dumped. If *plan-identifier* is not specified, all plans in the plan cache matching *sql-statement-text-filter* and *include-system-queries* that are found in the IASP identified by *iasp-name* are dumped.

The file has the same definition as the QSYS/QAQQDBMN file. See [Database monitor SQL table format](#) for more information.

If the file already exists, the authorities are not changed. If the file does not exist, it is created, and ownership of the file is assigned to the effective user of the thread that calls DUMP_PLAN_CACHE. The public authority is set to *EXCLUDE. All other authorities are copied from the QSYS/QAQQDBMN file.

The time the DUMP_PLAN_CACHE procedure takes to run will vary depending on the plan cache size. To avoid tying up an interactive job, it is recommended that the procedure should be submitted in a batch job using a combination of the Submit Job (SBMJOB) and Run SQL (RUNSQL) CL commands.

Notes

The plan identifier is a unique number that is generated when the plan is optimized. The plan identifier is externalized in several ways:

- The statement number of a Visual Explain of a plan cache snapshot or a Visual Explain from the Show Statements exploration of the SQL Plan Cache
- From Show Statements exploration of the SQL Plan Cache and SQL Plan Cache Snapshots
- In the QUCNT column of the 1000 record of a plan cache snapshot file.
- As information passed to a Query Supervisor exit program.

Example

- Dump the plan cache to a database performance monitor file called SNAPSHOT1 in library SNAPSHOTS.

```
CALL QSYS2.DUMP_PLAN_CACHE('SNAPSHOTS', 'SNAPSHOT1');
```

- Dump a specific plan to a database performance monitor file called QUERY1 in library SNAPSHOTS.

```
CALL QSYS2.DUMP_PLAN_CACHE('SNAPSHOTS', 'QUERY1', 126783);
```

- Dump all plans in the current IASP that reference table TOYSTORE_SALES.

```
CALL QSYS2.DUMP_PLAN_CACHE(FILESCHEMA => 'SNAPSHOTS',  
                           FILENAME    => 'SALES',  
                           SQL_STATEMENT_TEXT_FILTER => 'TOYSTORE_SALES');
```

- Dump all plans in *SYSBAS that reference table TOYSTORE_SALES.

```
CALL QSYS2.DUMP_PLAN_CACHE(FILESCHEMA => 'SNAPSHOTS',  
                           FILENAME    => 'SALES',  
                           SQL_STATEMENT_TEXT_FILTER => 'TOYSTORE_SALES',  
                           IASP_NAME   => '*SYSBAS');
```

DUMP_PLAN_CACHE_PROPERTIES procedure

The DUMP_PLAN_CACHE_PROPERTIES creates a file containing the properties of the plan cache.

Authorization: The caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM function usage ID.

➔ DUMP_PLAN_CACHE_PROPERTIES (— *library-name* — , — *file-name* —) ➔

The schema is QSYS2.

library-name A character or graphic string expression that identifies the name of the library containing *file-name*.

file-name A character or graphic string expression that identifies the name of the resulting properties file. It must be a valid system file name. If the file does not exist, it is created with public authority for the file the same as the create authority specified for the library in which the file is created. Use the QSYS2.LIBRARY_INFO table function or the Display Library Description (DSPLIBD) command to show the library's create authority. If the file exists, the new plan cache properties will be appended to it.

The file definition matches the definition of QSYS2/QDBOPPCGEN, which has the following definition.

Table 72. QDBOPPCGEN table

Column Name	System Column Name	Data Type	Description
HEADING	HEADING	VARCHAR(128)	Description of the value for this row.
VALUE	VALUE	VARCHAR(128)	The current value of the item.
VALUE_UNITS	VALUEUNITS	VARCHAR(128)	The type of unit that applies to the VALUE columns. MB The number is in megabytes. % The number represents a percentage. If there is no unit, the value is a single blank.
ENTRY_NUMBER	ENTRYNBR	INTEGER	A unique identifying number for this row. The number assigned to a value will be the same in every generated plan cache properties file.
ENTRY_TYPE	ENTRY_TYPE	CHAR(2)	The type of entry. DA Detail entry HE Heading entry AD Modifiable detail entry
GRAPHABLE	GRAPHABLE	CHAR(1)	The data value is meaningful to be graphed.
MINVALUE	MINVALUE	VARCHAR(128)	The minimum value allowed for this item
MAXVALUE	MAXVALUE	VARCHAR(128)	The maximum value allowed for this item.
DFTVALUE	DFTVALUE	VARCHAR(128)	The initial value provided by the system for this value.
CHANGE_WARNING	CHGWARN	VARCHAR(512)	Not used.

Example

- Dump the plan cache properties to a file called PCPROP1 in library SNAPSHOTS.

```
CALL QSYS2.DUMP_PLAN_CACHE_PROPERTIES('SNAPSHOTS','PCPROP1');
```

DUMP_PLAN_CACHE_TOPN procedure

The DUMP_PLAN_CACHE_TOPN procedure creates a database monitor file (snapshot) from the plan cache containing the user-initiated queries based on the specified *category* option.

Authorization: The caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM function usage ID.

```

➔ DUMP_PLAN_CACHE_TOPN ( ( FILESCHEMA => library-name , ➔
                           FILENAME => file-name ,
                           TOPN => topn_number ➔
                           ) ➔
  , CATEGORY => category ) ➔

```

The schema is QSYS2.

library-name	A character or graphic string expression that identifies the name of the library containing <i>file-name</i> .
file-name	A character or graphic string expression that identifies the name of the resulting database monitor file. If the file does not exist, it is created. If the file exists, the new plan cache properties will be appended to it.
topn-number	An integer expression representing the number of queries to dump
category	A character or graphic string expression that identifies the type of top N queries to be dumped.
CPU	Dump the TOPN queries with the most accumulated CPU time.
DATABASE READS	Dump the TOPN queries with the most accumulated database read I/Os. This includes both synchronous and asynchronous reads.
RUNTIME	Dump the TOPN queries with the longest accumulated runtime. This is the default.
STORAGE	Dump the TOPN queries with the largest temporary storage usage.

The file has the same definition as the QSYS/QAQQDBMN file. If the file does not exist, it is created with the public authority set to *EXCLUDE. See [Database monitor SQL table format](#) for more information.

Example

- Capture the 20 queries with the largest elapsed time and dump the details into a snapshot file named SNAPSHOTS/TOPN121413

```
CALL QSYS2.DUMP_PLAN_CACHE_TOPN('SNAPSHOTS', 'TOPN121413', 20);
```

DUMP_SNAP_SHOT_PROPERTIES procedure

The DUMP_SNAP_SHOT_PROPERTIES returns a result set containing the properties for an existing plan cache snapshot.

Authorization: None required.

►► DUMP_SNAP_SHOT_PROPERTIES ((— *library-name* — , — *file-name* —)) ►►

The schema is QSYS2.

library-name	A character or graphic string expression that identifies the name of the library containing <i>file-name</i> .
file-name	A character or graphic string expression that identifies the name of an existing database monitor file.

The result set has the following definition.

Column Name	Data Type	Description
HEADING	VARCHAR(128)	Description of the value for this row.
VALUE	VARCHAR(128)	The current value of the item.
VALUE_UNITS	VARCHAR(128)	The type of unit that applies to the VALUE column. MB The number is in megabytes. Returns null if no unit applies.

Column Name	Data Type	Description
ENTRY_NUMBER	INTEGER	A unique identifying number for this row. The number assigned to a value will be the same in every generated plan cache properties file.
ENTRY_TYPE	CHAR(2)	The type of entry. DA Detail entry HE Heading entry AD Modifiable detail entry

Example

- Return the plan cache properties of an existing snapshot.

```
CALL QSYS2.DUMP_SNAP_SHOT_PROPERTIES('SNAPSHOTS', 'TOPN121413');
```

END_ALL_PLAN_CACHE_EVENT_MONITORS procedure

The END_ALL_PLAN_CACHE_EVENT_MONITORS procedure ends all active plan cache event monitors.

Authorization: The caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM function usage ID.

►► END_ALL_PLAN_CACHE_EVENT_MONITORS — (—) ◄◄

The schema is QSYS2.

Example

- End all active plan cache event monitors:

```
CALL QSYS2.END_ALL_PLAN_CACHE_MONITORS();
```

END_PLAN_CACHE_EVENT_MONITOR procedure

The END_PLAN_CACHE_EVENT_MONITOR procedure ends the event monitor identified by the given *monitor-ID*.

Authorization: The caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM function usage ID.

►► END_PLAN_CACHE_EVENT_MONITOR — (— *monitor-ID* —) ◄◄

The schema is QSYS2.

monitor-ID A character or graphic string expression that identifies the monitor to be ended.

Example

- End the plan cache monitor identified by PLANCACHE1.

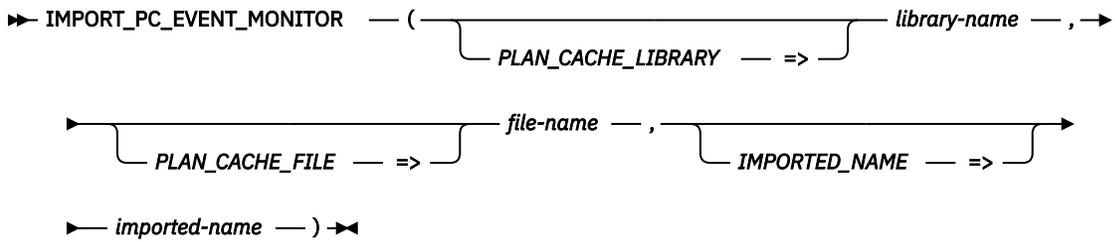

```
CALL QSYS2.END_PLAN_CACHE_EVENT_MONITOR('PLANC00001');
```

IMPORT_PC_EVENT_MONITOR procedure

The IMPORT_PC_EVENT_MONITOR procedure imports an event monitor file for usage in the SQL Performance Center that is part of IBM i Access Client Solutions (ACS).

Authorization: The caller must have:

- *EXECUTE authority to the library, and
- *OBJOPR and *READ authorities to the event monitor file.

The schema is QSYS2.

library-name A character or graphic string expression that identifies the name of the library containing *file-name*.

file-name A character or graphic string expression that identifies the name of an existing event monitor file.

imported-name The name of the plan cache event monitor to import. This name is used to identify the plan cache event monitor in the SQL Performance Center.

Example

- Import a plan cache event monitor SNAPSHOTS/MON1 and name it NEWMON.

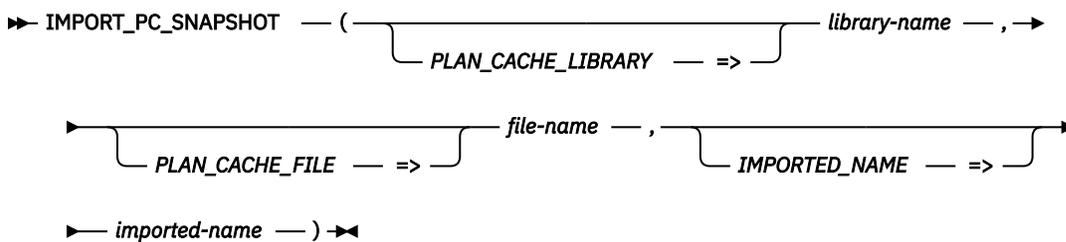

```
CALL QSYS2.IMPORT_PC_EVENT_MONITOR('SNAPSHOTS', 'MON1', 'NEWMON');
```

IMPORT_PC_SNAPSHOT procedure

The IMPORT_PC_SNAPSHOT procedure imports a plan cache snapshot file for usage in the SQL Performance Center that is part of IBM i Access Client Solutions (ACS).

Authorization: The caller must have:

- *EXECUTE authority to the library, and
- *OBJOPR and *READ authorities to the event monitor file.

The schema is QSYS2.

library-name A character or graphic string expression that identifies the name of the library containing *file-name*.

file-name A character or graphic string expression that identifies the name of an existing plan cache snapshot file.

imported-name The name of the plan cache snapshot to import. This name is used to identify the plan cache snapshot in the SQL Performance Center.

Example

- Import a plan cache snapshot file SNAPSHOTS/SNAP121413.

```
CALL QSYS2.IMPORT_PC_SNAPSHOT('SNAPSHOTS','SNAP121413','Snapshot captured on 12/14/2013');
```

REMOVE_PC_EVENT_MONITOR procedure

The REMOVE_PC_EVENT_MONITOR procedure deletes a file containing an event monitor.

Authorization: The caller must have:

- *USE authority to the library, and
- *OBJOPR and *OBJEXIST authorities to the event monitor file.

```
➤ REMOVE_PC_EVENT_MONITOR ( ( library-name )
                             PLAN_CACHE_LIBRARY => )
    , ( file-name ) ) ➤
```

PLAN_CACHE_FILE =>

The schema is QSYS2.

library-name A character or graphic string expression that identifies the name of the library containing *file-name*.

file-name A character or graphic string expression that identifies the name of an existing event monitor file.

Example

- Remove the plan cache event monitor PRUNEDP1 in SNAPSHOTS.

```
CALL QSYS2.REMOVE_PC_EVENT_MONITOR('SNAPSHOTS','PRUNEDP1');
```

REMOVE_PC_SNAPSHOT procedure

The REMOVE_PC_SNAPSHOT procedure deletes a file containing a plan cache snapshot.

Authorization: The caller must have:

- *USE authority to the library, and
- *OBJOPR and *OBJEXIST authorities to the performance monitor file and any dependent indexes.

```
➤ REMOVE_PC_SNAPSHOT ( ( library-name ) , ( file-name ) ) ➤
```

The schema is QSYS2.

library-name A character or graphic string expression that identifies the name of the library containing *file-name*.

file-name A character or graphic string expression that identifies the name of an existing plan cache snapshot file.

Example

- Remove the plan cache snapshot file called PC1 in library SNAPSHOTS.

```
CALL QSYS2.REMOVE_PC_SNAPSHOT('SNAPSHOTS','PC1');
```

REMOVE_PERFORMANCE_MONITOR procedure

The REMOVE_PERFORMANCE_MONITOR procedure deletes a file containing a performance monitor.

Authorization: The caller must have:

- *USE authority to the library, and
- *OBJOPR and *OBJEXIST authorities to the performance monitor file and any dependent indexes.

➤ REMOVE_PERFORMANCE_MONITOR — (— *library-name* — , — *file-name* —) ➤

The schema is QSYS2.

library-name A character or graphic string expression that identifies the name of the library containing *file-name*.

file-name A character or graphic string expression that identifies the name of an existing performance monitor file.

Example

- Remove the performance monitor MON1 in SNAPSHOTS.

```
CALL QSYS2.REMOVE_PERFORMANCE_MONITOR('SNAPSHOTS', 'MON1');
```

START_PLAN_CACHE_EVENT_MONITOR procedure

The START_PLAN_CACHE_EVENT_MONITOR procedure starts an event monitor to capture plans as they are removed from the cache and generates performance information into a database monitor file.

Authorization: The caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM function usage ID.

➤ START_PLAN_CACHE_EVENT_MONITOR — (— *library-name* — , — *file-name* →

→
— *monitor-ID* —) ➤

The schema is QSYS2.

library-name A character or graphic string expression that identifies the name of the library to contain *file-name*. *library-name* cannot be QTEMP.

file-name A character or graphic string expression that identifies the name of the database monitor file. It must be a valid system file name. If the file does not exist, it is created. Initially the file is created and populated with the starting record id 3018 (column QQRID = 3018).

monitor-ID An optional character string output variable that will contain the 10 character identifier of the event monitor that was started.

The event monitor stays active until one of the following occurs:

- It is ended by one of the end event monitor procedure calls.
- It is ended using the IBM i Navigator interface.
- An IPL of the system occurs.
- The specified database monitor file is deleted or otherwise becomes unavailable.

Example

- Start an event monitor and place plan information into a database monitor file called PRUNEDP1 in library SNAPSHOTS:

```
CALL QSYS2.START_PLAN_CACHE_EVENT_MONITOR('SNAPSHOTS', 'PRUNEDP1');
```

- Start an event monitor and place plan information into a database monitor file called PRUNEDPLANS1 in library SNAPSHOTS. Capture the monitor id into host variable HVmonid for use later:

```
CALL QSYS2.START_PLAN_CACHE_EVENT_MONITOR('SNAPSHOTS', 'PRUNEDPLANS1', :HVmonid);
```

Utility Services

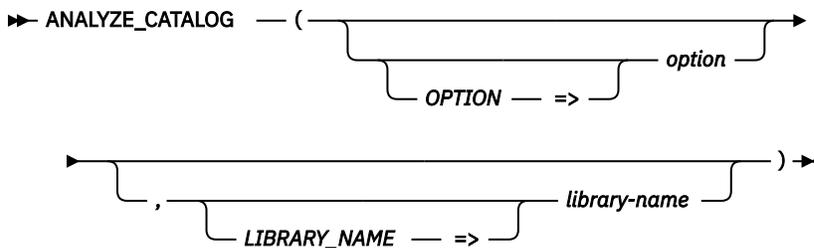

These procedures provide interfaces to monitor and work with SQL in jobs on the current system or to compare constraint and routine information across systems.

ANALYZE_CATALOG table function

The ANALYZE_CATALOG table function returns one row for each inconsistency it finds in the database catalog.

If no rows are returned, no inconsistencies were identified. Multiple rows can be returned for the same object.

Authorization: The caller must have *ALLOBJ special authority.

The schema is QSYS2.

option A character or graphic string expression that identifies the type of catalog analysis to perform.

DBXREF Analysis will be done for objects in the database cross reference files. This is the default.

Verification is done for constraints defined for *FILE objects.

The analysis done by this function goes beyond what RCLDBXREF OPTION(*CHECK) provides. It verifies that the constraint definitions in every database file object are correctly recorded in the database catalog.

DBXREF SERVER Analysis will be done of the database cross reference servers. The database cross reference servers will be verified to ensure they are functioning properly. One or more result rows with DBXREF SERVER in the CATEGORY column indicate the current database cross reference server status.

library-name A character or graphic string expression that identifies the library to be analyzed. This parameter only applies when *option* is DBXREF.

***ALL** All *FILE objects within all libraries will be analyzed, including any in independent auxiliary storage pools that are accessible. This is the default.

name All *FILE objects within this library will be analyzed.

The result of the function is a table containing one row for each reported item with the format shown in the following table. All the columns are nullable.

Table 73. ANALYZE_CATALOG table function

Column Name	Data Type	Description
LIBRARY_NAME	VARCHAR(10)	Name of the library containing the database object. Can contain the null value when CATEGORY is DBXREF SERVER.
OBJECT_NAME	VARCHAR(128)	Name of the database object. Can contain the null value when CATEGORY is DBXREF SERVER.
OBJECT_TYPE	VARCHAR(30)	Type of database object. Can contain the null value when CATEGORY is DBXREF SERVER.
SEVERITY	VARCHAR(7)	The severity of the reported item. ERROR This row indicates an error that should be corrected. INFO This row provides information about processing that was performed. WARNING This row indicates a problem that should be investigated, but it does not indicate a serious problem.
CATEGORY	VARCHAR(20)	The category of this catalog row. CONSTRAINT An inconsistency was found with a *FILE object constraint. DBXREF SERVER An inconsistency was found with the database cross reference server jobs. RECLAIM The CATALOG_NAME for this row is known to be inconsistent. Either RCLDBXREF *FIX or RCLSTG SELECT(*DBXREF) is required. Use RCLDBXREF *CHECK to determine the action that needs to be taken.
DESCRIPTION	VARCHAR(250)	A text description of the inconsistency in the database catalog.
DETAIL	VARCHAR(128)	Additional detail about the inconsistency. <ul style="list-style-type: none"> When CATEGORY is CONSTRAINT, this is the name of the constraint. When CATEGORY is DBXREF SERVER, this can contain the number of entries in the cross reference queue Contains the null value if this row does not have additional detail information.
CATALOG_LIBRARY	VARCHAR(10)	The name of the library containing the catalog. Contains the null value if this row is not related to a specific catalog.
CATALOG_NAME	VARCHAR(10)	The catalog table that contains inconsistent information. Contains the null value if this row is not related to a specific catalog.

Example

- Determine if there are any constraint inconsistencies for any database files on the system.

```
SELECT * FROM TABLE(QSYS2.ANALYZE_CATALOG(OPTION => 'DBXREF'));
```

- Determine if there are any constraint inconsistencies for database files in library APPLIB.

```
SELECT * FROM TABLE(QSYS2.ANALYZE_CATALOG(OPTION => 'DBXREF',  
LIBRARY_NAME => 'APPLIB'));
```

- Examine how the database cross reference servers are running. If they are behind on processing, the DESCRIPTION and DETAIL columns will indicate the number of entries in the queue that are waiting to be processed.

```
SELECT * FROM TABLE(QSYS2.ANALYZE_CATALOG(OPTION => 'DBXREF SERVER'));
```

CANCEL_SQL procedure

The CANCEL_SQL procedure requests cancellation of an SQL statement for the specified job.

Authorization: None required if the caller's user profile is the same as the job user identity of the qualified job which is being canceled. Otherwise, the caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM function usage ID.

►► CANCEL_SQL — (— *job-name* —) ◄◄

The schema is QSYS2.

job-name A character string containing the qualified job name to be canceled. It must be in upper case.

The CANCEL_SQL() procedure provides an alternative to end job immediate. It supports all application and interactive SQL environments.

When an SQL cancel is requested, an asynchronous request is sent to the job identified by *job-name*. If the job is processing an interruptible, long-running machine operation, analysis is done within the job to determine whether it is safe to cancel the statement. When it is determined to be safe to cancel the statement, an SQL0952 escape message is sent, causing the statement to terminate.

If it isn't safe to end the SQL statement, or if there is no active SQL statement, the request to cancel is ignored. The caller of the cancel procedure will observe a successful return which only indicates that the caller had the necessary authority to request a cancel and that the target job exists. The caller of the CANCEL_SQL() procedure has no programmatic means of determining that the cancel request resulted in a cancelled SQL statement.

If the cancel request occurs during the act of committing or rolling back a commitment-control transaction, the request is ignored.

Errors: The procedure will fail with a SQL0443 if the target job is not found. The procedure will fail with SQL0443 and SQL0552 if the caller does not have authority.

Commitment control: When the target application is running without commitment control (COMMIT = *NONE), the canceled SQL statement will terminate without rolling back the partial results of the statement. If the canceled statement is a query, the query ends. However, if the canceled statement was a long-running INSERT, UPDATE, or DELETE SQL statement, the changes made prior to cancellation remain intact.

If the target application is using transaction management, the SQL statement is running under a transaction savepoint level. When a long running INSERT, UPDATE, or DELETE SQL statement is canceled, the changes made prior to cancellation are rolled back.

In both cases, the application receives control back with an indication that the SQL statement failed. It is up to the application to determine the next action.

Example

Safely cancel a job running an SQL statement.

```
CALL QSYS2.CANCEL_SQL('483456/QUSER/QZDAS0INIT')
```

CHECK_SYSCST procedure

The CHECK_SYSCST procedure compares entries in the QSYS2.SYSCST table between two systems.

Authorization: See Note below.

➤ CHECK_SYSCST ((— *remote-rdb-name* — , — *schema-name* —) —) —) ➤
 , — *avoid-result-set* —)

The schema is SYSTOOLS.

remote-rdb-name A character string containing the name of the remote database.

schema-name A character string containing the name of the schema to compare.

avoid-result-set An integer value that indicates whether a result set should be returned. The default is 0.

1 No result set is returned.

0 Result set is returned.

This procedure will return a result set to the caller. If no result set is requested, the differences are logged to the SESSION.SYSCSTDIFF table.

The result set that is returned or the table that is created contains the following columns:

Table 74. SYSCSTDIFF result set

Column Name	System Column Name	Data Type	Description
SERVER_NAME	SRVRNAME	VARCHAR(18)	Name of server where the request was run.
CONSTRAINT_SCHEMA	CDNAME	VARCHAR(128)	Name of the schema containing the constraint.
CONSTRAINT_NAME	RELNAME	VARCHAR(128)	Name of the constraint.
CONSTRAINT_TYPE	TYPE	VARCHAR(11)	Type of constraint.
TABLE_SCHEMA	TDBNAME	VARCHAR(128)	Name of schema containing the table.
TABLE_NAME	TBNAME	VARCHAR(128)	Name of the table which the constraint is created over.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	CHAR(10)	System name of schema containing the table.
SYSTEM_TABLE_NAME	SYS_TNAME	CHAR(10)	System name of the table which the constraint is created over.
CONSTRAINT_KEYS	COLCOUNT	SMALLINT	Specifies the number of key columns if this is a UNIQUE, PRIMARY KEY, or FOREIGN KEY constraint.
CONSTRAINT_STATE	CST_STATE	VARCHAR(11)	Indicates whether the constraint is established or defined.
ENABLED	ENABLED	VARCHAR(3)	Indicates whether the constraint is enabled or disabled.
CHECK_PENDING	CHECK00001	VARCHAR(3)	Indicates whether the constraint is in check pending state.

Note

This procedure is provided in the SYSTOOLS schema as an example of how to compare catalog tables between systems using an SQL procedure. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar procedures, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

Find all the differences in constraint settings between the current system and LP01UT18 for the CORPDB_EX schema:

```
CALL SYSTOOLS.CHECK_SYSCST('LP01UT18', 'CORPDB_EX')
```

Note

This procedure is provided in the SYSTOOLS schema as an example of how to compare catalog tables between systems using an SQL procedure. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar procedures, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

Compare the current system to a remote system to find which routines differ, when they were created, and who created them.

```
CALL SYSTOOLS.CHECK_SYSRoutine('LP01UT18', 'CORPDB_EX')
```

Related reference

SYSTOOLS

SYSTOOLS is a set of Db2 for IBM i supplied examples and tools.

COMPARE_FILE table function

The COMPARE_FILE table function returns differences between the specified files, including SQL tables, physical files, and source physical files.

A value of YES or QUICK must be specified for at least one of the *compare-attributes* or *compare-data* parameters.

When comparing attributes, one row is returned for each attribute that is different between the files.

When comparing data, one row is returned for each row of data that is different between the files. The relative record number (RRN) is returned to identify the row. Files with multiple members, including partitioned tables and source physical files, where significant differences are found in the definition are not eligible for data comparison. All the member names must match. A result row will be returned to indicate that data comparison was not performed.

If a quick compare is requested, one row is returned if any difference is found. This compare option is faster because a complete list of differences is not returned.

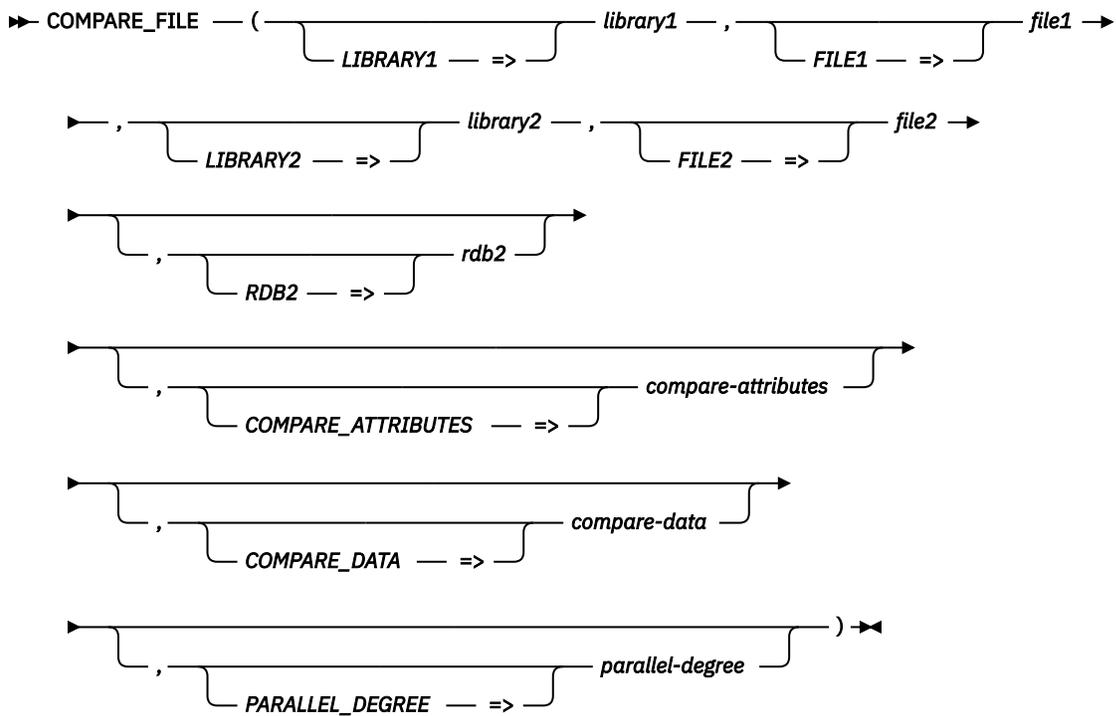

If no differences are found, no rows are returned.

Authorization: The caller must have:

- *EXECUTE authority on the library containing the file, and
- *OBJOPR and *READ authority to the file.

The caller must have *ALLOBJ or *AUDIT special authority to compare the object auditing attribute for the files. If the caller does not have this authority, a difference in this value will not be reported.

To specify a parallel degree value other than NONE, the privileges held by the authorization ID of the statement must include *JOBCTL special authority or have QIBM_DB_SQLADM function usage.

The schema is QSYS2.

- library1** A character or graphic string expression that identifies the library that contains *file1*. It must exist on the current server and cannot be QTEMP.
- file1** A character or graphic string expression that identifies the first file for the compare. This must be the system name of the file.
- library2** A character or graphic string expression that identifies the library that contains *file2*. It must exist on the server implicitly or explicitly identified by *rdb2* and cannot be QTEMP. If *library2* is omitted, *library1* is used.
- file2** A character or graphic string expression that identifies the second file for the compare. This must be the system name of the file. The two files cannot be the same file object. If *file2* is omitted, *file1* is used.
- rdb2** A character or graphic string expression that identifies the relational database where *library2* exists. If this parameter is omitted, *library2* must exist on the current server.
- compare-attributes** A character or graphic string expression that indicates whether attributes are compared for the file.
- NO** The attributes are not compared for the file.
- QUICK** The attributes are compared for the file until the first difference is found. Only a single row is returned if any differences are detected. This option is faster because a complete list of differences is not returned.
- YES** All the attributes are compared for the file. A row is returned for each difference found. This is the default.
- compare-data** A character or graphic string expression that indicates whether the data is compared for the file, including the relative record number (RRN) of each row.
- NO** The data is not compared for the file.

QUICK The data is compared for the file until the first difference is found. Only a single row is returned if any differences are detected. This option is faster because a complete list of differences is not returned.

YES All the data is compared for the file. A row is returned for each difference found. This is the default.

parallel-degree

A character or graphic string that specifies the maximum degree of parallelism to use when comparing the file.

If the Db2 Symmetric Multiprocessing (SMP) feature is not installed, a warning is issued if the value is not NONE and the compare will not use parallelism.

2-256 The maximum degree of parallelism to be used. Using parallelism can cause the compare to complete sooner, but it will have an impact on system resources.

NONE No parallelism will be used. This is the default.

The result of the function is a table containing rows with the format shown in the following table. All columns are nullable.

Table 76. COMPARE_FILE table function

Column Name	Data Type	Description
ATTRIBUTE_NAME	VARGRAPHIC(512) CCSID 1200	The name of file attribute or the relative record number (RRN) that is not identical.
FILE1	VARGRAPHIC(2048) CCSID 1200	The value for <i>file1</i> .
FILE2	VARGRAPHIC(2048) CCSID 1200	The value for <i>file2</i> .

Examples

- Compare the attributes and data for file T1 between the TEST library and the PROD library.

```
SELECT * FROM TABLE(QSYS2.COMPARE_FILE(  
    LIBRARY1=>'TEST', FILE1=>'T1',  
    LIBRARY2=>'PROD', FILE2=>'T1'));
```

- Compare the data for file T1 between the TEST library and the PROD library. As soon as any difference is detected, stop the compare.

```
SELECT * FROM TABLE(QSYS2.COMPARE_FILE(  
    LIBRARY1=>'TEST', FILE1=>'T1',  
    LIBRARY2=>'PROD', FILE2=>'T1',  
    COMPARE_ATTRIBUTES=>'NO',  
    COMPARE_DATA=>'QUICK'));
```

DUMP_SQL_CURSORS procedure

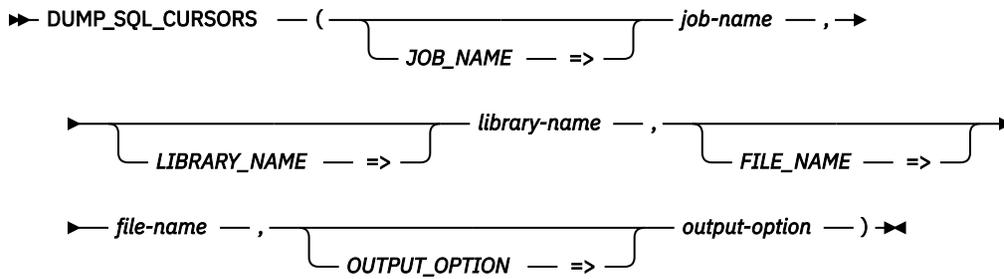

The DUMP_SQL_CURSORS procedure lists the open cursors for a job.

Authorization: None required if the caller's user profile is same as the job user identity of the qualified job for which the open cursors are being listed. Otherwise, the caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM or QIBM_DB_SYSMON function usage ID.

To place the results in *library-name.file-name*, the caller must have:

- *EXECUTE authority to the library, and
- *OBJOPR and *ADD authorities to the file.

If the file does not exist, the caller must have *ADD authority to the library.

The schema is QSYS2.

- job-name** A character string containing a qualified job name or a value of '*' to indicate the current job
- library-name** A character string containing a system library name for the procedure output. An empty string is allowed.
- file-name** A character string containing a system file name for the procedure output. An empty string is allowed.
- output-option** An integer value that indicates how to return the output.
 - 1 Ignore *library-name* and *file-name* parameters and return a result set.
 - 2 Ignore *library-name* and *file-name* parameters and place the results in table QTEMP/SQL_CURSORS.
 - 3 Place the results in file *file-name* in library *library-name*. If the file doesn't exist, it will be created. If the file already exists, the results will be appended to the existing file.
 - 4 Place the results in file *file-name* in library *library-name*. If the file doesn't exist, it will not be created.

The result set that is returned or the file that is created contains the following columns:

Table 77. DUMP_SQL_CURSORS result table

Column Name	System Column Name	Data Type	Description
SQL_IDENTITY	SQL_I00001	INTEGER	Unique identifier for the row.
DUMPTIME	DUMPTIME	TIMESTAMP	Timestamp when row was inserted.
DUMP_BY_USER	DUMPUSER	VARCHAR(18)	User ID used to insert row.
CURSOR_NAME	CSRNAME	VARCHAR(128)	Name of the cursor.
PSEUDO_CLOSED	PSEUDO	VARCHAR(3)	Pseudo close state of the cursor. YES Cursor is currently pseudo closed. NO Cursor is currently opened.
STATEMENT_NAME	STMTNAME	VARCHAR(128)	Name of the statement corresponding to the cursor
OBJECT_NAME	OBJNAME	CHAR(10)	Object containing the current SQL statement. Blank if current SQL statement is not in a program, service program, or package.
OBJECT_LIBRARY	OBJLIB	CHAR(10)	Library for object containing the current SQL statement. Blank if current SQL statement is not in a program, service program, or package.
OBJECT_TYPE	OBJTYPE	CHAR(10)	Type of object containing the current SQL statement. Blank if current SQL statement is not in a program, service program, or package.
JOBNAME	JOBNAME	CHAR(28)	System job name for the cursor. Contains * if current job was specified for <i>job-name</i> argument.

Example

Populate QGPL/SQLCSR1 file with open SQL cursors for the current job.

```
CALL QSYS2.DUMP_SQL_CURSORS('*','QGPL','SQLCSR1',3);
```

END_IDLE_SQE_THREADS procedure

The END_IDLE_SQE_THREADS procedure will end any idle SQE threads for the current job.

Authorization: None required.

➤ END_IDLE_SQE_THREADS — (—) ➤

The schema is QSYS2.

When the SQE database engine runs a query using Symmetric Multiprocessing (SMP) or a query that contains a fenced UDF or UDTF, system threads are started. These threads may be left active for a period of time so that they are eligible to be re-used. This can cause problems with an application when a non-threadsafe command is executed after the query is run. When this happens the application receives an error message, CPF180B "Function XXXX is not allowed in a job which has multiple threads." Running the END_IDLE_SQE_THREADS procedure will end all SQE threads for the job that are not actively being used, so this error can be avoided.

Example

- End the idle SQE threads.

```
CALL QSYS2.END_IDLE_SQE_THREADS();
```

EXTRACT_STATEMENTS procedure

The EXTRACT_STATEMENTS procedure returns details from an SQL plan cache snapshot, an SQL performance monitor, or an SQL plan cache event monitor in the form of an SQL table or a result set.

Authorization: The caller must have:

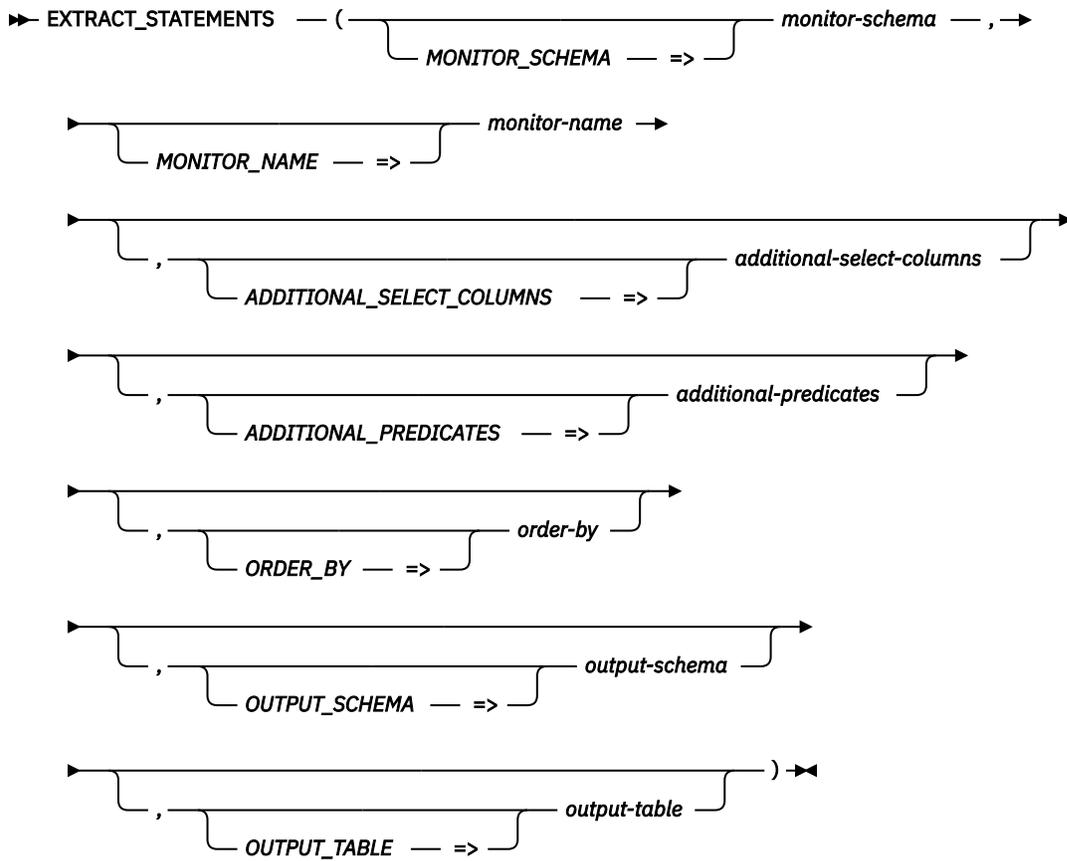

- *EXECUTE authority to the library containing the database monitor file, and
- *OBJOPR, *READ, and *UPDATE authorities to the database monitor file.

If *output-schema* and *output-table* are used to create a table, the caller must have:

- *OBJOPR, *READ, *EXECUTE, and *ADD authorities to *output-schema*, and
- *USE to the Create Physical File (CRTPF) command

If *output-schema* and *output-table* are used to append to a table, the caller must have:

- *USE authority to *output-schema*, and
- *OBJOPR and *ADD authorities to *output-table*

The schema is QSYS2.

- monitor-schema** A character or graphic string expression that identifies the name of the library containing *monitor-name*.
- monitor-name** A character or graphic string expression that identifies the name of an existing database monitor file.
- additional-select-columns** A character or graphic string of up to 5000 characters containing additional columns or expressions to be appended to the generated SELECT clause. A value of *AUDIT will cause the procedure to return the merged statement and columns that are normally interesting for auditing.
- If *additional-select-columns* is not specified or is the null value, no additions are made to the generated SELECT clause.
- additional-predicates** A character or graphic string of up to 5000 characters containing additional predicates to be appended to the generated WHERE clause.
- If *additional-predicates* is not specified or is the null value, no additions are made to the generated WHERE clause.
- order-by** A character or graphic string of up to 5000 characters containing additional options to be appended to the end of the generated query. This can include the ORDER BY clause or other clauses such as FETCH FIRST n ROWS.
- If *order-by* is not specified or is the null value, no additions are made to the end of the query.
- output-schema** The schema name for the output table.
- If *output-schema* is not specified, the null value is used.

output-table The table name to contain the output. If the table identified by *output-schema* and *output-table* does not exist, it will be created. If the table exists, the result of this calling this procedure will be appended to the table. For an existing table, the number of selected columns must match the selected columns when the table was generated.

If *output-name* is not specified, the null value is used.

If *output-schema* or *output-table* is the null value, a result set containing the extracted statement information is returned.

Examples

- Extract the 100 most recent statements from monitor APRIL1014:

```
CALL QSYS2.DUMP_PLAN_CACHE('SNAPSHOTS', 'APRIL2014');  
  
CALL QSYS2.EXTRACT_STATEMENTS('SNAPSHOTS', 'APRIL2014', '*AUDIT',  
'AND QQC21 NOT IN  
( 'CH', 'CL', 'CN', 'DE', 'DI', 'DM', 'HC', 'HH', 'JR', 'FE',  
'PD', 'PR', 'PD' )',  
' ORDER BY QQSTIM DESC FETCH FIRST 100 ROWS ONLY');
```

- Extract all the queries where the query took longer than one second:

```
CALL QSYS2.DUMP_PLAN_CACHE('SNAPSHOTS', 'APRIL2014');  
  
CALL QSYS2.EXTRACT_STATEMENTS('SNAPSHOTS', 'APRIL2014',  
  ADDITIONAL_SELECT_COLUMNS => 'DECIMAL(QQI6)/1000000.0 as Total_time,  
                                QVC102 as Current_User_Profile ',  
  ADDITIONAL_PREDICATES => ' AND QQI6 > 1000000 ',  
  ORDER_BY => ' ORDER BY QQI6 DESC');
```

FIND_AND_CANCEL_QSQSRVR_SQL procedure

The `FIND_AND_CANCEL_QSQSRVR_SQL` procedure finds a set of jobs with SQL activity and safely cancels them.

The `FIND_AND_CANCEL_QSQSRVR_SQL` procedure uses the `FIND_QSQSRVR_JOBS` and `CANCEL_SQL` procedures to determine the set of jobs that have SQL activity for the provided *job-name*. Each of these jobs is made a target of an SQL cancel request.

Authorization: The caller must have:

- QSYS2/FIND_QSQSRVR_JOBS() authorizations, and
- QSYS2/CANCEL_SQL() authorizations

► `FIND_AND_CANCEL_QSQSRVR_SQL` — (— *job-name* —) ◄

The schema is QSYS2.

job-name A character string containing a qualified job name.

Example

Cancel all the QSQSRVR jobs used by a specific job.

```
CALL QSYS2.FIND_AND_CANCEL_QSQSRVR_SQL('564321/APPUSER/APPJOBNAME')
```

FIND_QSQSRVR_JOBS procedure

The `FIND_QSQSRVR_JOBS` procedure returns information about a QSQSRVR job.

Authorization: The caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM or QIBM_DB_SYSMON function usage ID.

➤➤ FIND_QSQSRVR_JOBS — (— *job-name* —) ➤➤

The schema is QSYS2.

job-name A character string containing a qualified job name.

If the specified job is active and is set up to use SQL server mode, the procedure determines which QSQSRVR jobs are being used by the application in the form of active SQL server mode connections. The procedure collects and returns work management, performance, and SQL information. It returns two SQL result sets, one containing summary information and one containing detailed SQL server mode job information.

The results of the procedure call are saved in two temporary tables, QTEMP.QSQSRVR_SUMMARY and QTEMP.QSQSRVR_DETAIL. When called from within IBM i Navigator Run SQL Scripts, two results sets are displayed. When called from other interfaces, you need to query the temporary tables to see the data.

The result sets that are returned or the tables that are created contain the following columns:

Table 78. FIND_QSQSRVR_JOBS result set 1

Column Name	System Column Name	Data Type	Description
SQL_IDENTITY	SQL_I00001	INTEGER	Unique identifier for this row.
NUMBER_OF_ACTIVE_JOBS	NUMJOBS	INTEGER	Number of QSQSRVR jobs active for this job.
SERVER_MODE_JOB	SRVRJOB	CHAR(28)	The fully qualified QSQSRVR job name for an active SQL Server Mode connection established by <i>job-name</i> .
SERVER_MODE_CONNECTING_JOB	CONNJOB	CHAR(28)	The fully qualified job name of the application job. This value matches what was input for <i>job-name</i> .
TOTAL_PROCESSING_TIME	TOTALCPU	BIGINT	The total amount of CPU time (in milliseconds) that has been used by all server jobs.
TEMP_MEG_STORAGE	TEMPMSTG	INTEGER	The total amount of auxiliary storage (in megabytes) that is currently allocated to all server jobs.
PAGE_FAULTS	FAULTS	BIGINT	The total number of times an active program referenced an address that was not in main storage for all server jobs.
IO_REQUESTS	IOREQS	BIGINT	The total number of auxiliary I/O requests performed by the job across all routing steps for all server jobs. This includes both database and non-database paging.

Table 79. FIND_QSQSRVR_JOBS result set 2

Column Name	System Column Name	Data Type	Description
SQL_IDENTITY	SQL_I00001	INTEGER	Unique identifier for this row.
JOB_NAME	JOBNAME	CHAR(10)	Job name.
USER_NAME	USERNAME	CHAR(10)	User ID for the job.
JOB_NUMBER	JOBNUM	CHAR(6)	Job number.
JOB_INTERNAL_IDENTIFIER	JOBID	CHAR(16)	Internal identifier assigned to job.
CURRENT_USERNAME	CURRUSER	CHAR(10)	The user profile that the thread is currently running under.
SUBSYSTEM_DESCRIPTION_NAME	SBSNAME	CHAR(10)	Name of subsystem where job is running.
RUN_PRIORITY	PRIORITY	INTEGER	The highest run priority allowed for any thread within this job.
SYSTEM_POOL_IDENTIFIER	POOLID	INTEGER	The identifier of the system-related pool from which the job's main storage is allocated.
TOTAL_PROCESSING_TIME	TOTALCPU	BIGINT	The amount of CPU time (in milliseconds) that has been currently used by this job.
PAGE_FAULTS	FAULTS	BIGINT	The number of times an active program referenced an address that was not in main storage during the current routing step of the specified job.
IO_REQUESTS	IOREQS	BIGINT	The number of auxiliary I/O requests performed by the job across all routing steps. This includes both database and non-database paging.

Table 79. FIND_QSQRVR_JOBS result set 2 (continued)

Column Name	System Column Name	Data Type	Description
MEMORY_POOL_NAME	POOLNAME	CHAR(10)	The name of the memory pool in which the job started running.
TEMP_MEG_STORAGE	TEMPMSTG	INTEGER	The amount of auxiliary storage (in megabytes) that is currently allocated to this job.
TIME_SLICE	TSLICE	INTEGER	The maximum amount of processor time (in milliseconds) given to each thread in this job before other threads in this job and in other jobs are given the opportunity to run.
DEFAULT_WAIT	DFTWAIT	INTEGER	The default maximum time (in seconds) that a thread in the job waits for a system instruction to acquire a resource.
SQL_APPLICATION_LIBRARY	SQLLIB	CHAR(10)	The library name for the SQL statement object.
SQL_APPLICATION_PROGRAM	SQLPGM	CHAR(10)	The program, service program, or package name of the object which contains the last SQL statement executed in the job.
SQL_APPLICATION_TYPE	APPTYPE	CHAR(10)	The object type.
SERVER_MODE_CONNECTING_JOB	CONNJOB	CHAR(28)	The qualified job name of the job which established the SQL Server Mode connection.
SERVER_MODE_CONNECTED_THREAD	CONNTHD	CHAR(10)	The thread identifier of the last thread to use this connection.
STATUS_OF_CURRENT_SQL_STMT	STMTSTAT	CHAR(10)	Status of the SQL statement. Values are ACTIVE or COMPLETED.
SQL_STATEMENT	SQLSTMT	VARCHAR(1000)	First 1000 characters of the SQL statement.

GENERATE_SQL procedure

The GENERATE_SQL procedure generates the SQL data definition language statements required to recreate a database object. The results are returned in the specified database source file member, source stream file, or as a result set.

The database source file member or integrated file system (IFS) stream file will contain the generated SQL statements. If the output source file is QTEMP/Q_GENSQL with a member name of Q_GENSQL, the source file is returned as a result set as well.

Authorization:

When writing to a database source physical file the caller must have:

- *EXECUTE to the library containing the source physical file
- To add a member:
 - *OBJOPR and *ADD to the source physical file
- To replace a member:
 - *OBJOPR, *DELETE, *ADD, and either *OBJMGT or *OBJALTER to the source physical file

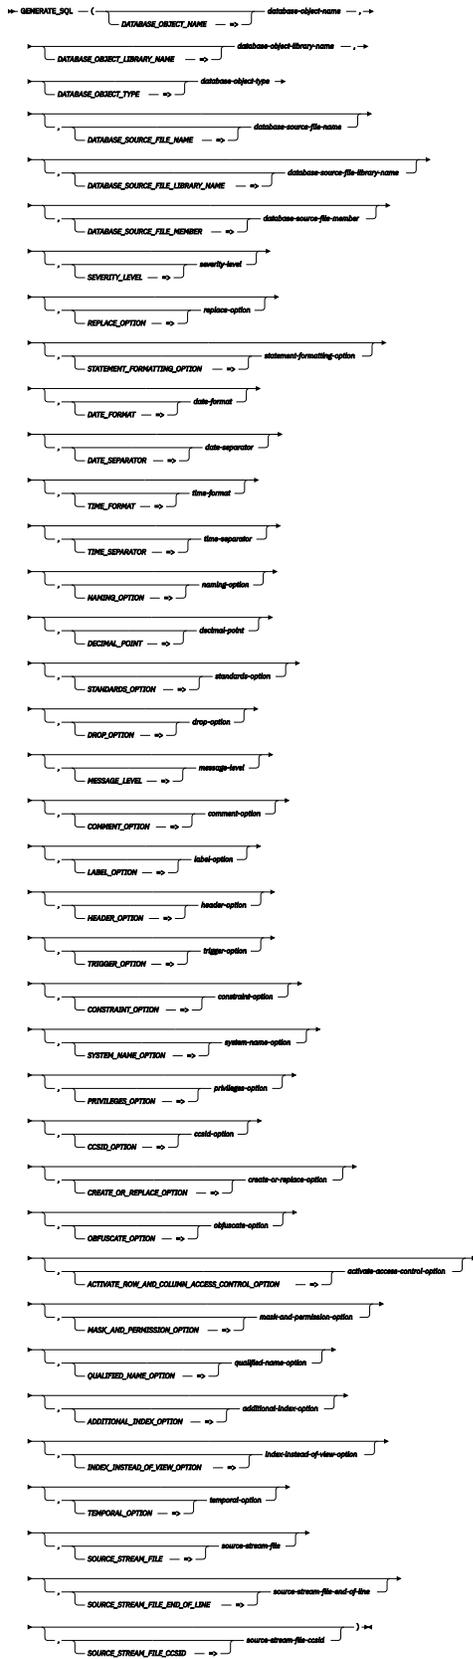

When writing to an IFS stream file:

- Execute (*X) data authority to each directory preceding the stream file being written and
- When the stream file exists:
 - Write (*W) data authority to the stream file
- When the stream file does not exist:
 - Write and Execute (*WX) authority to the parent directory of the stream file

To generate source for an object type, the following authorities are needed:

- TABLE, VIEW, CONSTRAINT, or TRIGGER
 - *EXECUTE and *OBJOPR to the library, and
 - *OBJOPR to the *FILE object
- INDEX

- *EXECUTE and *OBJOPR to the library, and
- *OBJOPR to the *FILE object, and
- *OBJOPR to the base *FILE object
- MASK or PERMISSION
 - *EXECUTE and *OBJOPR to the library, and at least one of the following:
 - *OBJOPR to the *FILE object
 - QIBM_DB_SECADM function usage
- ALIAS
 - *EXECUTE and *OBJOPR to the library, and
 - *OBJOPR to the *FILE object
- FUNCTION or PROCEDURE
 - *OBJOPR to the library
- TYPE
 - *EXECUTE and *OBJOPR to the library, and
 - *OBJOPR to the *SQLUDT object
- SCHEMA
 - *OBJOPR and either *READ or *EXECUTE to the *LIB object
- SEQUENCE
 - *EXECUTE and *OBJOPR to the library, and
 - *USE to the *DTAARA object
- VARIABLE
 - *EXECUTE and *OBJOPR to the library, and
 - *OBJOPR to the *SRVPGM object
- XSR
 - *EXECUTE and *OBJOPR to the library, and
 - *OBJOPR to the *SQLXSR object

The schema is QSYS2.

database-object-name

A character or graphic string expression that identifies the name of the database object for which DDL will be generated. Either the SQL name or the system name may be

specified. The name is case sensitive. Delimiters must not be specified. For example, a file with a name of "abc" must be specified as abc. A file with a name of ABC must be specified in upper case. If the object type is a FUNCTION or PROCEDURE, this name must be the specific name of the function or procedure. If TABLE or VIEW is specified for the object type, the object name may identify an alias. In this case, the object that the alias points to will be generated. A CREATE ALIAS statement will be generated only if ALIAS is specified for the object type.

A '%' wildcard character can be used to select multiple objects of the same type. For example, a name of 'TSTV%' will process all objects of *database-object-type* that start with the characters 'TSTV'

database-object-library-name A character or graphic string expression that identifies the name of the library containing the object for which DDL will be generated. Either the SQL name or the system name may be specified. The name is case sensitive. Delimiters must not be specified. This name is ignored if the specified object type is SCHEMA. A '%' wildcard character can be used to select multiple libraries.

database-object-type A character or graphic string expression that identifies the type of the database object or object attribute for which DDL is generated. You can use these special values for the object type:

ALIAS	The object is an SQL alias.
CONSTRAINT	The object attribute is a constraint.
FUNCTION	The object is an SQL function.
INDEX	The object is an SQL index.
MASK	The object is an SQL column mask.
PERMISSION	The object is an SQL row permission.
PROCEDURE	The object is an SQL procedure.
SCHEMA	The object is an SQL schema.
SEQUENCE	The object is an SQL sequence.
TABLE	The object is an SQL table or physical file.
TRIGGER	The object attribute is a trigger.
TYPE	The object is an SQL type.
VARIABLE	The object is an SQL global variable.
VIEW	The object is an SQL view or logical file.
XSR	The object is an XML schema repository object.

database-source-file-name A character or graphic string expression that identifies the name of the source file that contains the SQL statements generated by the procedure. The name must be a valid system name. The name is case sensitive. If delimiters are required for the name to be valid, they must be specified. For example, a file with a name of "abc" must be specified with the surrounding quotes. A file with a name of ABC must be specified in upper case. The record length of the specified source file must be greater than or equal to 92. Can contain the following special value:

***STMF** The output is to be written to *source-stream-file*.

If *database-source-file-name* is not specified, Q_GENSQL will be used.

database-source-file-library-name A character or graphic string expression that identifies the name of the library containing the source file that contains the SQL statements generated by the procedure. The name must be a valid system name. The name is case sensitive. If delimiters are required for

the name to be valid, they must be specified. You can use these special values for the library name:

***CURLIB** The job's current library
***LIBL** The library list

If *database-source-file-library-name* is not specified, QTEMP will be used.

database-source-file-member

A character or graphic string expression that identifies the name of the source file member that contains the SQL statements generated by the procedure. The name must be a valid system name. The name is case sensitive. If delimiters are required for the name to be valid, they must be specified. You can use these special values for the member name:

***FIRST** The first database physical file member found.
***LAST** The last database physical file member found.

If values are provided for *database-source-file-library-name*, *database-source-file-name*, and *database-source-file-member* the object must exist.

If *database-source-file-member* is not specified, Q_GENSQL will be used.

severity-level

The severity level at which the operation fails. If errors occur that have a severity level greater than this value, the operation ends. The valid values are in the range 0 through 39 inclusive. Any severity 40 error will cause the procedure to fail.

If *severity-level* is not specified, 39 will be used.

replace-option

The replace option for the database source file member or source stream file. The valid values are:

- 0** The resulting SQL statements are appended to the end of the database source file member or source stream file.
- 1** The database source file member or source stream file is cleared prior to adding the resulting SQL statements. If this option is chosen, the clear might happen even if an error is returned from the procedure.

If *replace-option* is not specified, 1 will be used.

statement-formatting-option

The formatting option used in the generated SQL statements. The valid values are:

- 0** No additional formatting characters are added to the generated SQL statements.
- 1** Additional end-of-line characters and tab characters are added to the generated SQL statements.

If *statement-formatting-option* is not specified, 1 will be used.

date-format

The date format used for date constants in a generated SQL CREATE TABLE statement. The date format may not apply to date constants that are in ISO, EUR, USA, or JIS format in a CREATE VIEW, CREATE TRIGGER, CREATE FUNCTION, CREATE PROCEDURE, CREATE MASK, or CREATE PERMISSION.

If *date-format* is not specified, ISO will be used.

date-separator

The date separator used for date constants in a generated SQL CREATE TABLE statement. The date separator may not apply to date constants that are in ISO, EUR, USA, or JIS format in a CREATE VIEW, CREATE TRIGGER, CREATE FUNCTION, CREATE PROCEDURE, CREATE MASK, or CREATE PERMISSION statement.

If *date-separator* is not specified, - will be used.

time-format

The format used for time constants in a generated SQL CREATE TABLE statement. The time format may not apply to time constants that are in ISO, EUR, USA, or JIS format in

a CREATE VIEW, CREATE TRIGGER, CREATE FUNCTION, CREATE PROCEDURE, CREATE MASK, or CREATE PERMISSION statement.

If *time-format* is not specified, ISO will be used.

time-separator

The time separator used for time constants in a generated SQL CREATE TABLE statement. The time separator may not apply to time constants that are in ISO, EUR, USA, or JIS format in a CREATE VIEW, CREATE TRIGGER, CREATE FUNCTION, CREATE PROCEDURE, CREATE MASK, or CREATE PERMISSION statement.

If *time-separator* is not specified, . will be used.

naming-option

The naming convention used for qualified names in the generated SQL statements. The valid values are:

SQL schema.table syntax

SYS library/file syntax

If *naming-option* is not specified, SQL will be used.

decimal-point The decimal point used for numeric constants. The valid values are:

. Period separator

, Comma separator

If *decimal-point* is not specified, . will be used.

standards-option

The standards option specifies whether the generated SQL statements should contain Db2 for i extensions or whether the statements should conform to the Db2 family SQL or to the ANS and ISO SQL standards. The valid values are:

0 Db2 for i extensions may be generated in SQL statements.

1 The generated SQL statements must conform to SQL statements common to the Db2 family.

2 The generated SQL statements must conform to the ANSI and ISO SQL standards.

If *standards-option* is not specified, 0 will be used.

drop-option

The drop option specifies whether DROP (or ALTER) SQL statements should be generated prior to the CREATE statement to drop the specified object. The valid values are:

0 DROP statements should not be generated.

1 DROP statements should be generated.

If *drop-option* is not specified, 0 will be used.

message-level

The severity level at which the messages are generated. If errors occur that have a severity level greater than this value, a message is generated in the output. The valid values are in the range 0 through 39 inclusive. The message level must be less than or equal to the severity level.

If *message-level* is not specified, 0 will be used.

comment-option

The comment option specifies whether COMMENT SQL statements should be generated if a comment exists on the specified database object. If comments are not supported by the specified database object, the comment option is ignored. The valid values are:

0 COMMENT SQL statements should not be generated.

1 COMMENT SQL statements should be generated. If the specified database object type is a table or view, COMMENT SQL statements will also be generated for columns of the table or view.

- 2** COMMENT SQL statements should be generated. If the specified database object has no comment and its type is INDEX, SEQUENCE, TABLE, TYPE, VARIABLE, VIEW, or XSR, the system object text will be used for the comment.
- If the specified database object type is a table or view, COMMENT SQL statements will also be generated for columns of the table or view.

If *comment-option* is not specified, **1** will be used.

label-option The label option specifies whether LABEL SQL statements should be generated if a label exists on the specified database object. If labels are not supported by the specified database object, the label option is ignored. The valid values are:

- 0** LABEL SQL statements should not be generated.
- 1** LABEL SQL statements should be generated. If the specified database object type is a table or view, LABEL SQL statements will also be generated for columns of the table or view.

If *label-option* is not specified, **1** will be used.

header-option The header option specifies whether a header should be generated prior to the CREATE statement. The header consists of comments that describe the version, date and time, the relational database, and some of the options used to generate the SQL statements. The valid values are:

- 0** A header should not be generated.
- 1** A header should be generated.

If *header-option* is not specified, **1** will be used.

trigger-option The trigger option specifies whether triggers should be generated when the object type is a TABLE or VIEW. The valid values are:

- 0** Triggers should not be generated.
- 1** Triggers should be generated.

If *trigger-option* is not specified, **1** will be used.

constraint-option The constraint option specifies whether constraints should be generated when the object type is a TABLE. The valid values are:

- 0** Constraints should not be generated.
- 1** Constraints should be generated.
- 2** Constraints should be generated as part of the CREATE TABLE statement.

If *constraint-option* is not specified, **1** will be used.

system-name-option The system name option specifies whether a FOR SYSTEM NAME clause should be generated for the system name when it is different from the SQL name and the object type is an INDEX, TABLE, VIEW, SEQUENCE, or VARIABLE. The valid values are:

- 0** A FOR SYSTEM NAME clause should not be generated.
- 1** A FOR SYSTEM NAME clause should be generated.

If *system-name-option* is not specified, **1** will be used.

privileges-option The privileges option specifies whether GRANT SQL statements should be generated on the specified database object. If privileges are not supported by the specified database object, the privileges option is ignored. The valid values are:

- 0 GRANT SQL statements should not be generated.
- 1 GRANT SQL statements should be generated.

If *privileges-option* is not specified, 1 will be used.

ccsid-option The CCSID option specifies whether the CCSID attribute should be generated for column definitions when the object type is a TABLE. The valid values are:

- 0 CCSID attribute should not be generated.
- 1 CCSID attribute should be generated.

If *ccsid-option* is not specified, 1 will be used.

create-or-replace-option The create or replace option specifies whether CREATE OR REPLACE should be generated for the specified database object on the CREATE statement. This option is ignored if the specified database object does not support CREATE OR REPLACE. The valid values are:

- 0 CREATE OR REPLACE should not be generated.
- 1 CREATE OR REPLACE should be generated.

If *create-or-replace-option* is not specified, 0 will be used.

obfuscate-option The obfuscate option specifies whether an obfuscated SQL statement should be returned for SQL functions, SQL procedures, or SQL triggers that were not created using obfuscated statements. This option is ignored if the standards option is not '0'. This option is also ignored if the object is not an SQL function, procedure, or trigger. This option is ignored if the object is already obfuscated. Setting Obfuscate option = 0 cannot be used as a means of obtaining the unobfuscated SQL statement for an obfuscated object. The valid values are:

- 0 An obfuscated statement should not be generated.
- 1 An obfuscated statement should be generated for SQL functions, SQL procedures, or SQL triggers.

If *obfuscate-option* is not specified, 0 will be used.

activate-access-control-option The activate row and column access control option specifies whether an ALTER TABLE to activate row and column access control should be generated when the object type is a TABLE. This option is ignored if the standards option is not '0' or '1'. The valid values are:

- 0 Activate row and column access control should not be generated.
- 1 Activate row and column access control should be generated.

If *activate-access-control-option* is not specified, 1 will be used.

mask-and-permission-option The mask and permission option specifies whether row permissions and column masks should be generated when the object type is a TABLE. This option is ignored if the standards option is not '0' or '1'. The valid values are:

- 0 Permissions and masks should not be generated.
- 1 Permissions and masks should be generated.

If *mask-and-permission-option* is not specified, 1 will be used.

qualified-name-option The qualified name option specifies whether qualified or unqualified names should be generated for the specified database object. The valid values are:

- 0 Qualified object names should be generated. Unqualified names within the body of SQL routines will remain unqualified.
- 1 Unqualified object names should be generated when a library is found which matches the database object library name. Any SQL object or column reference that is RDB qualified will be generated in its fully qualified form. For example, rdb-name.schema-name.table-name and rdb-name.schema-name.table-name.column-name references will retain their full qualification.

If *qualified-name-option* is not specified, 0 will be used.

additional-index-option

The additional index option specifies whether additional CREATE INDEX statements will be generated for DDS-created keyed physical or logical files. The valid values are:

- 0 Additional CREATE INDEX statements will not be generated.
- 1 An additional CREATE INDEX statement will be generated that matches the index for a DDS-created keyed physical file. If the physical file has a PRIMARY KEY constraint, a CREATE INDEX statement is not generated.

An additional CREATE INDEX statement will be generated that matches the index for a DDS-created keyed logical file. If a value of '1' is specified for the index instead of view option, an additional CREATE INDEX statement is not generated. Additional CREATE INDEX statements will also be generated that match the join indexes of a DDS-created join logical file.

If *additional-index-option* is not specified, 0 will be used.

index-instead-of-view-option

The index instead of view option specifies whether a CREATE INDEX or CREATE VIEW statement will be generated for a DDS-created keyed logical file. The valid values are:

- 0 A CREATE VIEW statement will be generated.
- 1 A CREATE INDEX statement will be generated that matches the index for a DDS-created keyed logical file.

If *index-instead-of-view-option* is not specified, 0 will be used.

temporal-option

The temporal option specifies whether a CREATE TABLE and an ALTER TABLE statement will be generated when the object type is a TABLE and the table is defined as a temporal table. This option is ignored if the object is not a temporal table or if the standards option is not '0' or '1'. The valid values are:

- 0 A CREATE TABLE statement will be generated.
- 1 A CREATE TABLE statement will be generated and an ALTER TABLE statement will be generated to add versioning.
- 2 Only an ALTER TABLE statement will be generated to add versioning.

If *temporal-option* is not specified, 0 will be used.

source-stream-file

A character or graphic string expression that identifies the source stream file that contains the SQL statements generated by the procedure. This parameter is ignored unless *database-source-file-name* has a value of *STMF.

If the file does not exist, it will be created using the CCSID specified by *source-stream-file-ccsid*. As lines are written to the file, *source-stream-file-end-of-line* determines the end of line sequence, if any, to be appended to each line.

When *source-stream-file* is used, values provided for *database-source-file-library-name* and *database-source-file-member* are ignored.

Writing to the QSYS.LIB file system is not supported.

source-stream-file-end-of-line

A character or graphic string expression that defines the end of line character(s) which will be appended to the end of each line when writing to *source-stream-file*. The carriage return character is always X'0D'. Based on the CCSID of the source stream file, the line feed character is X'25' for an EBCDIC CCSID and X'0A' for ASCII and UTF-8 CCSIDs. The valid values are:

- CR** A carriage return is appended.
- CRLF** A carriage return and line feed are appended.
- LF** A line feed is appended.
- LFCR** A line feed and carriage return are appended.

If *source-stream-file-end-of-line* is not specified, CRLF will be used.

This parameter is ignored when writing to a source file.

source-stream-file-ccsid

An integer value that defines the CCSID to use if a new source stream file is created. If *source-stream-file* is specified and the source stream file does not exist, it will be created with this CCSID value. A value of 0 indicates that the default job CCSID is to be used. A CCSID of 65535 cannot be specified.

If *source-stream-file-ccsid* is not specified, 0 will be used.

This parameter is ignored when writing to a source file.

Examples

- Generate DDL for all tables in a schema and return the source as a result set.

```
CALL QSYS2.GENERATE_SQL('%', 'SAMPLE_CORPDB', 'TABLE', REPLACE_OPTION => '0');
```

- Generate DDL for all indexes starting with 'X' within the SAMPLE_CORPDB schema, place the output in a file named DDLSOURCE/GENFILE member INDEXSRC.

```
CALL QSYS2.GENERATE_SQL('X%', 'SAMPLE_CORPDB', 'INDEX',  
    'GENFILE', 'DDLSOURCE', 'INDEXSRC',  
    REPLACE_OPTION => '0');
```

- Generate DDL for a single table and include the constraints within a CREATE OR REPLACE TABLE statement.

```
CALL QSYS2.GENERATE_SQL('EMPLOYEE', 'SAMPLE_CORPDB', 'TABLE',  
    'GENFILE', 'DDLSOURCE', 'MASTERSRC',  
    CREATE_OR_REPLACE_OPTION => '1',  
    CONSTRAINT_OPTION => '2');
```

- Generate DDL for MYLIB.MYTABLE, placing the output in source stream file /usr/mytable_ddl.

```
CALL QSYS2.GENERATE_SQL(DATABASE_OBJECT_NAME => 'MYTABLE',  
    DATABASE_OBJECT_LIBRARY_NAME => 'MYLIB',  
    DATABASE_OBJECT_TYPE => 'TABLE',  
    DATABASE_SOURCE_FILE_NAME => '*STMF',  
    SOURCE_STREAM_FILE => '/usr/mytable_ddl');
```

GENERATE_SQL_OBJECTS procedure

The GENERATE_SQL_OBJECTS procedure generates the SQL data definition language (DDL) statements required to recreate a set of database objects. The results are returned in the specified database source file member, source stream file, or as a result set. The procedure will generate the objects so that dependent objects are generated after depended on objects.

The database source file member or integrated file system (IFS) stream file will contain the generated SQL statements. If the output source file is QTEMP/Q_GENSQOBJ, the source file is returned as a result set as well.

Authorization:

When writing to a database source physical file the caller must have:

- *EXECUTE to the library containing the source physical file
- To add a member:
 - *OBJOPR and *ADD to the source physical file
- To replace a member:
 - *OBJOPR, *DELETE, *ADD, and either *OBJMGT or *OBJALTER to the source physical file

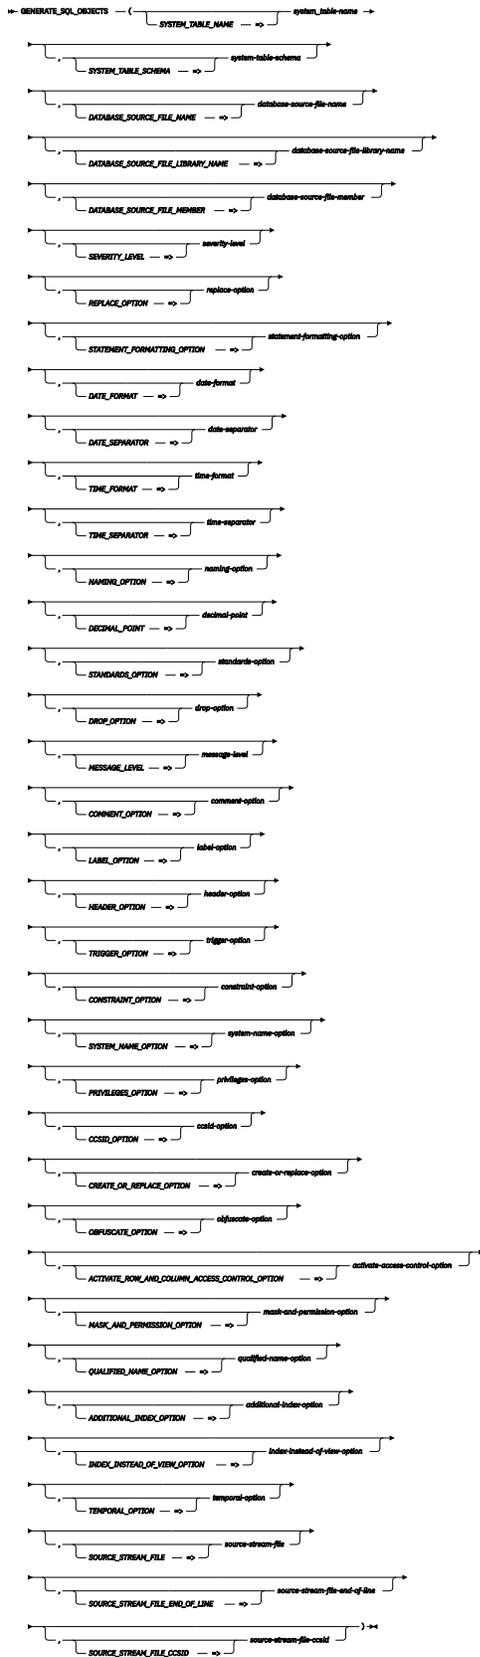

When writing to an IFS stream file:

- Execute (*X) data authority to each directory preceding the stream file being written and
- When the stream file exists:
 - Write (*W) data authority to the stream file
- When the stream file does not exist:
 - Write and Execute (*WX) authority to the parent directory of the stream file

To generate source for an object type, the following authorities are needed:

- TABLE, VIEW, CONSTRAINT, or TRIGGER
 - *EXECUTE and *OBJOPR to the library, and
 - *OBJOPR to the *FILE object
- INDEX
 - *EXECUTE and *OBJOPR to the library, and
 - *OBJOPR to the *FILE object, and
 - *OBJOPR to the base *FILE object
- MASK or PERMISSION
 - *EXECUTE and *OBJOPR to the library, and at least one of the following:
 - *OBJOPR to the *FILE object
 - QIBM_DB_SECADM function usage
- ALIAS
 - *EXECUTE and *OBJOPR to the library, and
 - *OBJOPR to the *FILE object
- FUNCTION or PROCEDURE
 - *OBJOPR to the library
- TYPE
 - *EXECUTE and *OBJOPR to the library, and
 - *OBJOPR to the *SQLUDT object
- SCHEMA
 - *OBJOPR and either *READ or *EXECUTE to the *LIB object
- SEQUENCE
 - *EXECUTE and *OBJOPR to the library, and
 - *USE to the *DTAARA object

- VARIABLE
 - *EXECUTE and *OBJOPR to the library, and
 - *OBJOPR to the *SRVPGM object
- XSR
 - *EXECUTE and *OBJOPR to the library, and
 - *OBJOPR to the *SQLXSR object

The schema is QSYS2.

system-table-name A character or graphic string expression that identifies the name of a table that contains the names and types of the database objects for which DDL will be generated. The

system name of the table must be specified. The name is case sensitive. Delimiters must be specified if they are required. For example, a file with a name of "abc" must be specified as "abc". A file with a name of ABC must be specified in upper case. Wildcard characters are not supported.

The specified table must contain three columns that contain the names and types of the objects for which DDL will be generated. The column names of the table must be OBJECT_SCHEMA, OBJECT_NAME, and SQL_OBJECT_TYPE, in that order.

For example, create the table like this:

```
CREATE TABLE QTEMP.INORDER (OBJECT_SCHEMA VARCHAR(258),
                             OBJECT_NAME VARCHAR(258),
                             SQL_OBJECT_TYPE CHAR(10));
```

The contents of the columns must be specified according to the following rules for the corresponding parameters in the QSQGNDDL API. Each row in the table must identify an object that is distinct from every other object in the table.

OBJECT_SCHEMA Identifies the schema name of an object for which DDL will be generated. The name must be delimited if delimiters are required in an SQL statement. This name is ignored if the specified object type is SCHEMA. *LIBL and *CURLIB are not allowed.

OBJECT_NAME Identifies the name of an object for which DDL will be generated. The name must be delimited if delimiters are required in an SQL statement. If the object type is a FUNCTION or PROCEDURE, this name must be the specific name of the function or procedure. If TABLE or VIEW is specified for the object type, the object name must not identify an alias.

SQL_OBJECT_TYPE Identifies the SQL object type of an object for which DDL will be generated.

ALIAS	The object is an SQL alias.
CONSTRAINT	The object attribute is a constraint.
FUNCTION	The object is an SQL function.
INDEX	The object is an SQL index.
MASK	The object is an SQL column mask.
PERMISSION	The object is an SQL row permission.
PROCEDURE	The object is an SQL procedure.
SCHEMA	The object is an SQL schema.
SEQUENCE	The object is an SQL sequence.
TABLE	The object is an SQL table or physical file.
TRIGGER	The object attribute is a trigger.
TYPE	The object is an SQL type.
VARIABLE	The object is an SQL global variable.
VIEW	The object is an SQL view or logical file.
XSR	The object is an XML schema repository object.

system-table-schema

A character or graphic string expression that identifies the name of the library of the table that contains the names and types of the database objects for which DDL will be generated. The system name of the schema must be specified. The name is case sensitive. Delimiters must be specified if they are required. For example, a schema with

a name of "lib1" must be specified as "lib1". A schema with a name of LIB1 must be specified in upper case. Wildcard characters are not supported. *LIBL and *CURLIB are not allowed.

The default is QTEMP.

database-source-file-name

A character or graphic string expression that identifies the name of the source file that contains the SQL statements generated by the procedure. The name must be a valid system name. The name is case sensitive. If delimiters are required for the name to be valid, they must be specified. For example, a file with a name of "abc" must be specified with the surrounding quotes. A file with a name of ABC must be specified in upper case. The record length of the specified source file must be greater than or equal to 92.

Can contain the following special value:

***STMF** The output is to be written to *source-stream-file*.

If *database-source-file-name* is not specified, Q_GENSQOBJ will be used.

database-source-file-library-name

A character or graphic string expression that identifies the name of the library containing the source file that contains the SQL statements generated by the procedure. The name must be a valid system name. The name is case sensitive. If delimiters are required for the name to be valid, they must be specified.

If *database-source-file-library-name* is not specified, QTEMP will be used.

database-source-file-member

A character or graphic string expression that identifies the name of the source file member that contains the SQL statements generated by the procedure. The name must be a valid system name. The name is case sensitive. If delimiters are required for the name to be valid, they must be specified.

If values are provided for *database-source-file-library-name*, *database-source-file-name*, and *database-source-file-member* the object must exist.

If *database-source-file-member* is not specified, Q_GENSQOBJ will be used.

severity-level

The severity level at which the operation fails. If errors occur that have a severity level greater than this value, the operation ends. The valid values are in the range 0 through 39 inclusive. Any severity 40 error will cause the procedure to fail.

If *severity-level* is not specified, 39 will be used.

replace-option

The replace option for the database source file member or source stream file. The valid values are:

0 The resulting SQL statements are appended to the end of the database source file member or source stream file.

1 The database source file member or source stream file is cleared prior to adding the resulting SQL statements. If this option is chosen, the clear might happen even if an error is returned from the procedure.

If *replace-option* is not specified, 1 will be used.

statement-formatting-option

The formatting option used in the generated SQL statements. The valid values are:

0 No additional formatting characters are added to the generated SQL statements.

1 Additional end-of-line characters and tab characters are added to the generated SQL statements.

If *statement-formatting-option* is not specified, 1 will be used.

date-format

The date format used for date constants in a generated SQL CREATE TABLE statement. The date format may not apply to date constants that are in ISO, EUR, USA,

or JIS format in a CREATE VIEW, CREATE TRIGGER, CREATE FUNCTION, CREATE PROCEDURE, CREATE MASK, or CREATE PERMISSION.

If *date-format* is not specified, ISO will be used.

date-separator

The date separator used for date constants in a generated SQL CREATE TABLE statement. The date separator may not apply to date constants that are in ISO, EUR, USA, or JIS format in a CREATE VIEW, CREATE TRIGGER, CREATE FUNCTION, CREATE PROCEDURE, CREATE MASK, or CREATE PERMISSION statement.

If *date-separator* is not specified, - will be used.

time-format

The format used for time constants in a generated SQL CREATE TABLE statement. The time format may not apply to time constants that are in ISO, EUR, USA, or JIS format in a CREATE VIEW, CREATE TRIGGER, CREATE FUNCTION, CREATE PROCEDURE, CREATE MASK, or CREATE PERMISSION statement.

If *time-format* is not specified, ISO will be used.

time-separator

The time separator used for time constants in a generated SQL CREATE TABLE statement. The time separator may not apply to time constants that are in ISO, EUR, USA, or JIS format in a CREATE VIEW, CREATE TRIGGER, CREATE FUNCTION, CREATE PROCEDURE, CREATE MASK, or CREATE PERMISSION statement.

If *time-separator* is not specified, . will be used.

naming-option

The naming convention used for qualified names in the generated SQL statements. The valid values are:

- SQL** schema.table syntax
- SYS** library/file syntax

If *naming-option* is not specified, SQL will be used.

decimal-point

The decimal point used for numeric constants. The valid values are:

- .** Period separator
- ,** Comma separator

If *decimal-point* is not specified, . will be used.

standards-option

The standards option specifies whether the generated SQL statements should contain Db2 for i extensions or whether the statements should conform to the Db2 family SQL or to the ANS and ISO SQL standards. The valid values are:

- 0** Db2 for i extensions may be generated in SQL statements.
- 1** The generated SQL statements must conform to SQL statements common to the Db2 family.
- 2** The generated SQL statements must conform to the ANSI and ISO SQL standards.

If *standards-option* is not specified, 0 will be used.

drop-option

The drop option specifies whether DROP (or ALTER) SQL statements should be generated prior to the CREATE statement to drop the specified object. The valid values are:

- 0** DROP statements should not be generated.
- 1** DROP statements should be generated.

If *drop-option* is not specified, 0 will be used.

message-level

The severity level at which the messages are generated. If errors occur that have a severity level greater than this value, a message is generated in the output. The valid

values are in the range 0 through 39 inclusive. The message level must be less than or equal to the severity level.

If *message-level* is not specified, 0 will be used.

comment-option

The comment option specifies whether COMMENT SQL statements should be generated if a comment exists on the specified database object. If comments are not supported by the specified database object, the comment option is ignored. The valid values are:

- 0** COMMENT SQL statements should not be generated.
- 1** COMMENT SQL statements should be generated. If the specified database object type is a table or view, COMMENT SQL statements will also be generated for columns of the table or view.
- 2** COMMENT SQL statements should be generated. If the specified database object has no comment and its type is INDEX, SEQUENCE, TABLE, TYPE, VARIABLE, VIEW, or XSR, the system object text will be used for the comment.
If the specified database object type is a table or view, COMMENT SQL statements will also be generated for columns of the table or view.

If *comment-option* is not specified, 1 will be used.

label-option

The label option specifies whether LABEL SQL statements should be generated if a label exists on the specified database object. If labels are not supported by the specified database object, the label option is ignored. The valid values are:

- 0** LABEL SQL statements should not be generated.
- 1** LABEL SQL statements should be generated. If the specified database object type is a table or view, LABEL SQL statements will also be generated for columns of the table or view.

If *label-option* is not specified, 1 will be used.

header-option

The header option specifies whether a header should be generated prior to the first generated statement. The header consists of comments that describe the version, date and time, the relational database, and some of the options used to generate the SQL statements. The valid values are:

- 0** A header should not be generated.
- 1** A header should be generated.

If *header-option* is not specified, 1 will be used.

trigger-option

The trigger option specifies whether triggers should be generated when the object type is a TABLE or VIEW. The valid values are:

- 0** Triggers should not be generated.
- 1** Triggers should be generated.

If *trigger-option* is not specified, 1 will be used.

constraint-option

The constraint option specifies whether constraints should be generated when the object type is a TABLE. The valid values are:

- 0** Constraints should not be generated.
- 1** Constraints should be generated.
- 2** Constraints should be generated as part of the CREATE TABLE statement.

If *constraint-option* is not specified, 1 will be used.

system-name-option The system name option specifies whether a FOR SYSTEM NAME clause should be generated for the system name when it is different from the SQL name and the object type is an INDEX, TABLE, VIEW, SEQUENCE, or VARIABLE. The valid values are:

- 0** A FOR SYSTEM NAME clause should not be generated.
- 1** A FOR SYSTEM NAME clause should be generated.

If *system-name-option* is not specified, **1** will be used.

privileges-option The privileges option specifies whether GRANT SQL statements should be generated on the specified database object. If privileges are not supported by the specified database object, the privileges option is ignored. The valid values are:

- 0** GRANT SQL statements should not be generated.
- 1** GRANT SQL statements should be generated.

If *privileges-option* is not specified, **1** will be used.

ccsid-option The CCSID option specifies whether the CCSID attribute should be generated for column definitions when the object type is a TABLE. The valid values are:

- 0** CCSID attribute should not be generated.
- 1** CCSID attribute should be generated.

If *ccsid-option* is not specified, **1** will be used.

create-or-replace-option The create or replace option specifies whether CREATE OR REPLACE should be generated for the specified database object on the CREATE statement. This option is ignored if the specified database object does not support CREATE OR REPLACE. The valid values are:

- 0** CREATE OR REPLACE should not be generated.
- 1** CREATE OR REPLACE should be generated.

If *create-or-replace-option* is not specified, **0** will be used.

obfuscate-option The obfuscate option specifies whether an obfuscated SQL statement should be returned for SQL functions, SQL procedures, or SQL triggers that were not created using obfuscated statements. This option is ignored if the standards option is not '0'. This option is also ignored if the object is not an SQL function, procedure, or trigger. This option is ignored if the object is already obfuscated. Setting Obfuscate option = 0 cannot be used as a means of obtaining the unobfuscated SQL statement for an obfuscated object. The valid values are:

- 0** An obfuscated statement should not be generated.
- 1** An obfuscated statement should be generated for SQL functions, SQL procedures, or SQL triggers.

If *obfuscate-option* is not specified, **0** will be used.

activate-access-control-option The activate row and column access control option specifies whether an ALTER TABLE to activate row and column access control should be generated when the object type is a TABLE. This option is ignored if the standards option is not '0' or '1'. The valid values are:

- 0** Activate row and column access control should not be generated.
- 1** Activate row and column access control should be generated.

If *activate-access-control-option* is not specified, **1** will be used.

mask-and-permission-option

The mask and permission option specifies whether row permissions and column masks should be generated when the object type is a TABLE. This option is ignored if the standards option is not '0' or '1'. The valid values are:

- 0** Permissions and masks should not be generated.
- 1** Permissions and masks should be generated.

If *mask-and-permission-option* is not specified, 1 will be used.

qualified-name-option

The qualified name option specifies whether qualified or unqualified names should be generated for the specified database object. The valid values are:

- 0** Qualified object names should be generated. Unqualified names within the body of SQL routines will remain unqualified.
- 1** Unqualified object names should be generated when a library is found which matches the database object library name. Any SQL object or column reference that is RDB qualified will be generated in its fully qualified form. For example, rdb-name.schema-name.table-name and rdb-name.schema-name.table-name.column-name references will retain their full qualification.

If *qualified-name-option* is not specified, 0 will be used.

additional-index-option

The additional index option specifies whether additional CREATE INDEX statements will be generated for DDS-created keyed physical or logical files. The valid values are:

- 0** Additional CREATE INDEX statements will not be generated.
- 1** An additional CREATE INDEX statement will be generated that matches the index for a DDS-created keyed physical file. If the physical file has a PRIMARY KEY constraint, a CREATE INDEX statement is not generated.
An additional CREATE INDEX statement will be generated that matches the index for a DDS-created keyed logical file. If a value of '1' is specified for the index instead of view option, an additional CREATE INDEX statement is not generated. Additional CREATE INDEX statements will also be generated that match the join indexes of a DDS-created join logical file.

If *additional-index-option* is not specified, 0 will be used.

index-instead-of-view-option

The index instead of view option specifies whether a CREATE INDEX or CREATE VIEW statement will be generated for a DDS-created keyed logical file. The valid values are:

- 0** A CREATE VIEW statement will be generated.
- 1** A CREATE INDEX statement will be generated that matches the index for a DDS-created keyed logical file.

If *index-instead-of-view-option* is not specified, 0 will be used.

temporal-option

The temporal option specifies whether a CREATE TABLE and an ALTER TABLE statement will be generated when the object type is a TABLE and the table is defined as a temporal table. This option is ignored if the object is not a temporal table or if the standards option is not '0' or '1'. The valid values are:

- 0** A CREATE TABLE statement will be generated.
- 1** A CREATE TABLE statement will be generated and an ALTER TABLE statement will be generated to add versioning.
- 2** Only an ALTER TABLE statement will be generated to add versioning.

If *temporal-option* is not specified, 0 will be used.

source-stream-file

A character or graphic string expression that identifies the source stream file that contains the SQL statements generated by the procedure. This parameter is ignored unless *database-source-file-name* has a value of *STMF.

If the file does not exist, it will be created using the CCSID specified by *source-stream-file-ccsid*. As lines are written to the file, *source-stream-file-end-of-line* determines the end of line sequence, if any, to be appended to each line.

When *source-stream-file* is used, values provided for *database-source-file-library-name* and *database-source-file-member* are ignored.

Writing to the QSYS.LIB file system is not supported.

source-stream-file-end-of-line

A character or graphic string expression that defines the end of line character(s) which will be appended to the end of each line when writing to *source-stream-file*. The carriage return character is always X'0D'. Based on the CCSID of the source stream file, the line feed character is X'25' for an EBCDIC CCSID and X'0A' for ASCII and UTF-8 CCSIDs. The valid values are:

- | | |
|-------------|---|
| CR | A carriage return is appended. |
| CRLF | A carriage return and line feed are appended. |
| LF | A line feed is appended. |
| LFCR | A line feed and carriage return are appended. |

If *source-stream-file-end-of-line* is not specified, CRLF will be used.

This parameter is ignored when writing to a source file.

source-stream-file-ccsid

An integer value that defines the CCSID to use if a new source stream file is created. If *source-stream-file* is specified and the source stream file does not exist, it will be created with this CCSID value. A value of 0 indicates that the default job CCSID is to be used. A CCSID of 65535 cannot be specified.

If *source-stream-file-ccsid* is not specified, 0 will be used.

This parameter is ignored when writing to a source file.

Notes

- If an error occurs while generating the DDL for an object, the source file or source stream file will contain the error and processing will continue to the next object. After processing the last object, a warning SQLSTATE '01H52' will be returned.
- Objects are generated in the following order:
 1. Schemas
 2. Types
 3. Sequences
 4. Aliases
 5. Non-MQT tables and any constraints and indexes on those tables
 6. Functions
 7. Procedures
 8. Variables
 9. Views, DDS-created logical files and MQTs and any constraints and indexes on those tables
 10. Triggers
 11. Masks
 12. Permissions

13. XSR objects

Restrictions

- One use of this procedure is to create a clone of a set of objects in another library by using `QUALIFIED_NAME_OPTION=>1`, setting the current schema and path, and then running the generated script.
 - If a depended on object is not included in the list of objects for which DDL will be generated, errors may occur when attempting to run the generated script. For example, if view V1 is based on table T1, but only V1 is specified, the attempt to run the generated script will fail because T1 was not included.
 - The QSQGNDDL API, on which this procedure is based, generates a qualified name in some cases. Thus, it may be necessary to make minor modifications to the script prior to running it. For more information see the Qualified name option parameter in [Generate Data Definition Language \(QSQGNDDL\) API](#).
- A function or procedure that has a parameter with a DEFAULT clause that references a variable, view, or MQT will not create when running the generated script. This is because variables, views, and MQTs are generated after functions and procedures. Note that references to variables, views, and MQTs within the body of function or procedure are soft dependencies and will not prevent the create.
- A variable that contains a DEFAULT clause that references a view or MQT will not create when running the generated script. This is because views and MQTs are generated after variables.

Examples

- Generate ordered DDL for the objects listed in the QTEMP.INORDER file.

```
CALL QSYS2.GENERATE_SQL_OBJECTS('INORDER', 'QTEMP');
```

RELATED_OBJECTS table function

The RELATED_OBJECTS table function returns a list of all objects that depend on the specified database file, either directly or indirectly.

The list contains all objects that are directly dependent on the input database file. Each identified view and global variable is processed recursively to obtain its dependents until no more dependents are found.

If the input file is an SQL alias, a program described file, or the file is not found, no rows are returned.

The dependency information is collected from the database cross reference tables and the SQL catalog. Some dependencies might not be returned based on how the dependent object was specified in the original statement. For example, if a CREATE FUNCTION statement references an unqualified table, the dependency will not be complete in the SQL catalog view (SYSROUTINEDEP) and subsequently will not be returned by this function.

Authorization: See Note below.

► RELATED_OBJECTS ((LIBRARY_NAME => library-name , →
FILE_NAME => file-name)) ◄

The schema is SYSTOOLS.

library-name A character or graphic string expression that identifies the library that contains *file-name*. It must exist on the current server.

file-name A character or graphic string expression that identifies the database file to list related objects for. This must be the system name of the file.

The result of the function is a table containing rows with the format shown in the following table. All columns are nullable.

Table 80. RELATED_OBJECTS table function

Column Name	Data Type	Description
SOURCE_SCHEMA_NAME	VARCHAR(128)	The name of the schema that contains SOURCE_SQL_NAME.
SOURCE_SQL_NAME	VARCHAR(128)	The name of the object that this row is dependent on.
SQL_OBJECT_TYPE	VARCHAR(24)	The SQL type of the dependent object. <ul style="list-style-type: none"> ALIAS An SQL alias defined for SOURCE_SQL_NAME FOREIGN KEY The child table in a referential constraint with SOURCE_SQL_NAME FUNCTION A function that references SOURCE_SQL_NAME HISTORY TABLE A history table associated with the temporal table defined by SOURCE_SQL_NAME INDEX An SQL index defined on SOURCE_SQL_NAME KEYED LOGICAL FILE A native keyed logical file defined on SOURCE_SQL_NAME LOGICAL FILE A native logical file defined on SOURCE_SQL_NAME MASK A column mask on a column in SOURCE_SQL_NAME or that references SOURCE_SQL_NAME in its definition MATERIALIZED QUERY TABLE A materialized query table that references SOURCE_SQL_NAME PERMISSION A row permission that is defined on SOURCE_SQL_NAME or that references SOURCE_SQL_NAME in its definition PROCEDURE A procedure that references SOURCE_SQL_NAME TEXT INDEX An OmniFind text index built over SOURCE_SQL_NAME TRIGGER An SQL trigger that is defined on SOURCE_SQL_NAME or that references SOURCE_SQL_NAME in its definition VARIABLE A global variable that references SOURCE_SQL_NAME in its default expression VIEW A view that references SOURCE_SQL_NAME in its definition XML SCHEMA An XML schema that uses SOURCE_SQL_NAME
SCHEMA_NAME	VARCHAR(128)	The SQL schema containing SQL_NAME.
SQL_NAME	VARCHAR(128)	The SQL name of the dependent object. <ul style="list-style-type: none"> • When SQL_OBJECT_TYPE is FOREIGN KEY, this is the name of the child table
LIBRARY_NAME	VARCHAR(10)	The system library name of the dependent object. <ul style="list-style-type: none"> • When SQL_OBJECT_TYPE is TRIGGER, the library containing the trigger program <p>Contains the null value when SQL_OBJECT_TYPE is FOREIGN KEY, FUNCTION, PROCEDURE, and TEXT INDEX.</p>

Table 80. RELATED_OBJECTS table function (continued)

Column Name	Data Type	Description
SYSTEM_NAME	VARCHAR(279)	The related system name of the dependent object. <ul style="list-style-type: none"> When SQL_OBJECT_TYPE is FOREIGN KEY, the constraint name When SQL_OBJECT_TYPE is FUNCTION or PROCEDURE, the external name When SQL_OBJECT_TYPE is MASK or PERMISSION, the mask or permission name When SQL_OBJECT_TYPE is TRIGGER, the name of the trigger program Contains the null value when SQL_OBJECT_TYPE is TEXT INDEX.
OBJECT_OWNER	VARCHAR(10)	The owner of the object. When SQL_OBJECT_TYPE is FUNCTION, MASK, PERMISSION, PROCEDURE, TRIGGER, or VARIABLE this is the object's definer. Contains the null value when SQL_OBJECT_TYPE is FOREIGN KEY or TEXT INDEX.
LONG_COMMENT	VARGRAPHIC(2000) CCSID 1200	The SQL long comment for the object. Contains the null value when the comment is not available.
OBJECT_TEXT	VARGRAPHIC(50) CCSID 1200	The system text description for the object. Contains the null value when the text is not available.
LAST_ALTERED	TIMESTAMP	The timestamp when the object was last altered. For objects that cannot be altered, this is the create timestamp. Contains the null value when SQL_OBJECT_TYPE is FOREIGN KEY.

Note

This procedure is provided in the SYSTOOLS schema as an example of how to use the SQL catalog to find dependency information using an SQL function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Examples

- List all the objects that are dependent on the ORDERS file in APPLIB.

```
SELECT * FROM TABLE(SYSTOOLS.RELATED_OBJECTS(
    LIBRARY_NAME=>'APPLIB',
    FILE_NAME =>'ORDERS'));
```

- List all the objects that are dependent on the ORDERS file in APPLIB. For each object, return how many recursive steps were required to find the object.

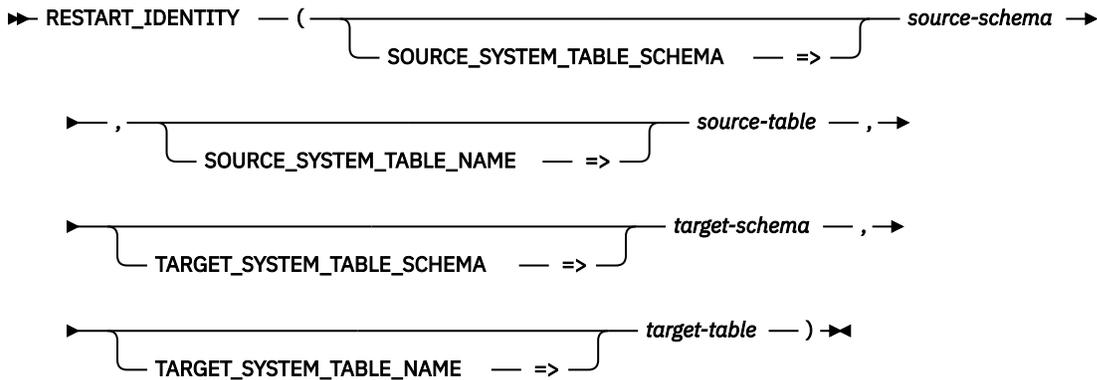

```
SELECT LEVEL, RO.*
FROM (VALUES('APPLIB', 'ORDERS')) I(IN_LIB, IN_FILE),
     TABLE(QSYS2.OBJECT_STATISTICS(IN_LIB, '*FILE', IN_FILE)),
     TABLE(SYSTOOLS.RELATED_OBJECTS(IN_LIB, IN_FILE)) RO
START WITH SOURCE_SCHEMA_NAME = OBJLONGSCHEMA AND
         SOURCE_SQL_NAME = OBJLONGNAME
CONNECT BY SOURCE_SQL_NAME = PRIOR SQL_NAME AND
         SOURCE_SCHEMA_NAME = PRIOR SCHEMA_NAME
ORDER BY 1, 2, 3;
```

RESTART_IDENTITY procedure

The RESTART_IDENTITY procedure examines the *source-table* and determines the identity column and its next value. The next value and column name are used to configure the *target-table* to use the same next value.

Authorization: The caller must have:

- *EXECUTE authority on the library containing the table being modified, and
- *OBJALTER authority on the table

The schema is QSYS2.

source-schema A character or graphic string for the schema name containing *source-file*. It must be a system schema name.

source-table A character or graphic string for the table name that has the identity value to copy. It must be a system table name. The table must contain an identity column.

target-schema A character or graphic string for the schema name containing *target-table*. It must be a system schema name.

target-table A character or graphic string for the table name that is to have its identity column value reset. It must be a system table name. The table must contain an identity column that has the same name as the identity column in *source-table*.

Example

Set the identity column in NEWTABLE to have the same next value as the identity column in OLDTABLE

```
CALL QSYS2.RESTART_IDENTITY(SOURCE_SYSTEM_TABLE_SCHEMA => 'OLDLIB',
                             SOURCE_SYSTEM_TABLE_NAME => 'OLDTABLE',
                             TARGET_SYSTEM_TABLE_SCHEMA => 'NEWLIB',
                             TARGET_SYSTEM_TABLE_NAME => 'NEWTABLE')
```

SWAP_DYNUSRPRF procedure

The SWAP_DYNUSRPRF procedure switches the SQL DYNUSRPRF setting for a program or service program. The possible values are *OWNER and *USER. Calling this procedure will change the value for a program or service program to the opposite setting. The switch will be performed for all modules in an ILE program or service program.

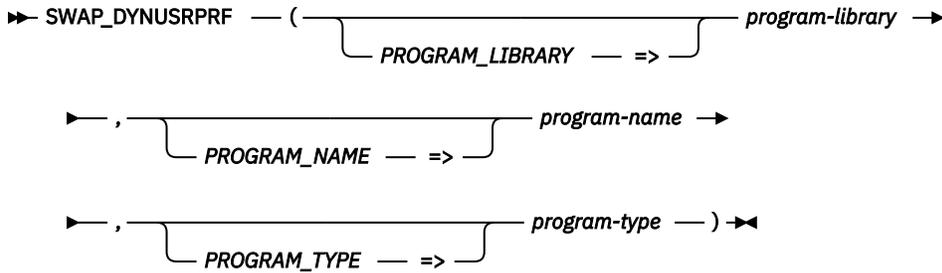

The following query shows the current value of the DYNUSRPRF setting for any modules that are part of an ILE program or service program:

```
SELECT SQL_DYNAMIC_USER_PROFILE FROM QSYS2.BOUND_MODULE_INFO
WHERE PROGRAM_LIBRARY = 'MYLIB' AND PROGRAM_NAME = 'MYPGM';
```

For an OPM program, run the following query:

```
SELECT SQL_DYNAMIC_USER_PROFILE FROM QSYS2.PROGRAM_INFO
WHERE PROGRAM_LIBRARY = 'MYLIB' AND PROGRAM_NAME = 'MYPGM';
```

Authorization: The caller must have *ALLOBJ special authority or be authorized to the QIBM_DB_SECADM function usage ID.

The schema is QSYS2.

program-library A character or graphic string containing the name of the library containing the program. Can be one of the following special values:

- *CURLIB** The job's current library is used.
- *LIBL** The library list is used.

program-name A character or graphic string containing the program name.

program-type The object type for *program-name*.

- *PGM** The object is a program.
- *SRVPGM** The object is a service program.

Example

Switch the value of the dynamic user profile for program MYLIB/MYPGM.

```
CALL QSYS2.SWAP_DYNUSRPRF('MYLIB', 'MYPGM', '*PGM');
```

SYSFILES view

The SYSFILES view contains information about database files. Additional information is available in the QSYS2.SYSTABLES view.

The information returned is similar to the detail seen from the Display File Description (DSPFD) command and the Retrieve Database File Description (QDBRTVFD) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the file, and
- *OBJOPR authority to the file.

The following table describes the columns in the view. The schema is QSYS2.

Table 81. SYSFILES view

Column Name	System Column Name	Data Type	Description
SYSTEM_TABLE_SCHEMA	LIB_NAME	VARCHAR(10)	The library containing the file.
SYSTEM_TABLE_NAME	FILE_NAME	VARCHAR(10)	The name of the file.
TABLE_SCHEMA	TABSHEMA	VARCHAR(128)	The SQL schema name of the library.

Table 81. SYSFILES view (continued)

Column Name	System Column Name	Data Type	Description
TABLE_NAME	TABNAME	VARCHAR(128)	The SQL name of the file.
IASP_NUMBER	IASPNUMBER	INTEGER	The independent auxiliary storage pool (IASP) number. 1 indicates the system ASP.
TEXT_DESCRIPTION	TEXT	VARGRAPHIC(50) CCSID 1200 Nullable	The descriptive text for the file. Contains the null value if there is no descriptive text.
NATIVE_TYPE	DDS_TYPE	VARCHAR(8)	Type of file. LOGICAL This is a DDS created logical file or an SQL view or index. PHYSICAL This is a physical file or an SQL table.
FILE_TYPE	FILETYPE	VARCHAR(6)	Type of file. DATA This is a data file. SOURCE This is a source physical file.
SQL_OBJECT_TYPE	SQL_TYPE	VARCHAR(5) Nullable	SQL object type. INDEX This is an SQL index. TABLE This is an SQL table. VIEW This is an SQL view. Contains the null value if this is not an SQL object.
LAST_ALTERED_TIMESTAMP	ALTEREDTS	TIMESTAMP(0)	Timestamp when the file was last altered or created.
FILE_LEVEL_ID	FILE_LVLID	CHAR(13)	File level identifier. This is the date of the file in CYYMMDDHHMMSS format.
LEVEL_CHECK	LVLCHK	VARCHAR(3)	Record format level check (LVLCHK). NO The record format level identifiers are not checked when the file is opened. YES The record format level identifiers are checked when the file is opened. See <i>Level checking</i> for some additional information about how level checking works.
FILE_OWNER	OWNER	VARCHAR(10) Nullable	The owner of the object. Contains the null value if the object owner is not available.
CREATE_PUBLIC_AUTHORITY	PUB_AUTH	VARCHAR(10)	The public authority that the file was created with (AUT). This is not the current public authority for the file. *ALL Public all authority *CHANGE Public change authority *EXCLUDE Public exclude authority *USE Public use authority authorization-list-name The name of the authorization list whose authority is used for the file.
NUMBER_MEMBERS	MEMBERS	INTEGER	Number of members.
MAXIMUM_MEMBERS	MAXMBRS	INTEGER Nullable	Maximum members (MAXMBRS). 1 to 32767 The maximum number of members for the file. Contains the null value if no maximum is specified; 32767 is used (*NOMAX).
MAXIMUM_RECORD_LENGTH	RECLENGTH	INTEGER	Maximum record length. This is the length of the record in the file's record format that contains the largest number of bytes.
NUMBER_KEY_FIELDS	KEY_FLDS	INTEGER	Number of key fields for the file.

Table 81. SYSFILES view (continued)

Column Name	System Column Name	Data Type	Description
MAXIMUM_KEY_LENGTH	KEY_LEN	INTEGER	Maximum key length for the file.
TRIGGER_COUNT	TRIG_CNT	INTEGER	Number of triggers.
CONSTRAINT_COUNT	CONSTR_CNT	INTEGER Nullable	Number of constraints for the file. Contains the null value if this is not a physical file.
NUMBER_BASED_ON_FILES	BASE_FILES	INTEGER Nullable	Number of files directly referenced by a logical file, view, or index. Contains the null value for physical files.
BASED_ON_FILES	BASED_ON	CLOB(35K) CCSID 1208 Nullable	A list of files directly referenced by this logical file, view, or index. This list is returned as an array within a JSON object. The array is identified by BASED_ON_FILES. Each entry in the JSON array identifies one file. Each array entry can contain information with the following keys: <ul style="list-style-type: none"> LIBRARY FILE MEMBER LF_FORMAT Contains the null value for physical files.
ALLOW_READ	ALWREAD	VARCHAR(3)	Allow read operation. NO Records are not allowed to be read from the file. YES Records are allowed to be read from the file.
ALLOW_WRITE	ALWWRITE	VARCHAR(3)	Allow write operation. NO Records are not allowed to be written to the file. YES Records are allowed to be written to the file.
ALLOW_UPDATE	ALWUPD	VARCHAR(3)	Allow update operation (ALWUPD). NO Records are not allowed to be updated in the file. YES Records are allowed to be updated in the file.
ALLOW_DELETE	ALWDLT	VARCHAR(3)	Allow delete operation (ALWDLT). NO Records are not allowed to be deleted from the file. YES Records are allowed to be deleted from the file.
MAXIMUM_FILE_WAIT_TIME	WAITFILE	INTEGER	Maximum file wait time (WAITFILE). -1 The default wait time specified in the class description is used (*CLS). 0 The program does not wait for the file; an immediate allocation is required (*IMMED). 1 through 32767 The maximum number of seconds a program waits for the file.
MAXIMUM_RECORD_WAIT_TIME	WAITRCD	INTEGER	Maximum record wait time (WAITRCD). -2 The default wait time allowed by the system is used. This is 32767 seconds (*NOMAX). -1 The program does not wait for the record, an immediate allocation is required (*IMMED). 1 through 32767 The maximum number of seconds a program waits for the record.

Table 81. SYSFILES view (continued)

Column Name	System Column Name	Data Type	Description
FORCE_WRITE_RATIO	FRCRATIO	INTEGER Nullable	Records to force a write (FRCRATIO). 1 through 32767 When the cumulative count of inserted, updated, and deleted records has reached this value, the changed records are forced to storage. Contains the null value if there is no force write ratio.
SELECT_OMIT	SELECTOMIT	VARCHAR(3)	Select/omit setting. NO The file is not a select/omit logical file. YES The file is a select/omit logical file.
PROGRAM_DESCRIBED	PGM_DESC	VARCHAR(3)	Program described file setting. NO The file is not program described. YES The file is program described.
DISTRIBUTED	DIST_FILE	VARCHAR(3)	Distributed file setting. NO The file is not distributed. YES The file is distributed.
FILE_VRM	FILE_VRM	CHAR(6)	File version, release, and modification level. VxRyMz, where x is the version, y the release, and z the modification level. This is the release where the file was created.
EARLIEST_POSSIBLE_RELEASE	MINRLS	CHAR(6) Nullable	Earliest supported version, release, and modification level. New database support used in the file will prevent the file from being saved to a prior version, release, and modification level. The value is formatted as VxRyMz, where x is the version, y the release, and z the modification level. Contains the null value if the value is prior to V2.
ALLOW_NULL_KEYS	ALWNULLK	VARCHAR(3) Nullable	Allow null value key setting (ALWNULL). NO Null value keys are not allowed. YES Null value keys are allowed. Contains the null value if ACCESS_PATH_KEYED is NO.
ALLOW_NULL_DATA	ALWNULLD	VARCHAR(3)	Allow null value data (ALWNULL). NO The file record format(s) do not allow null value fields. YES The file record format(s) allow null value fields.
PRIMARY_KEY	PRIKEY	VARCHAR(3)	Primary key (*PRIKEY). NO The access path for the file is not a primary key. YES The access path for the file is a primary key.
UNIQUE_CONSTRAINT	UNQCST	VARCHAR(3)	Unique constraint. NO The access path for the file is not a unique constraint. YES The access path for the file is a unique constraint.
VOLATILE	VOLATILE	VARCHAR(3)	SQL volatile table setting. NO The file is not an SQL volatile table. YES The file is an SQL volatile table.
KEEP_IN_MEMORY	KEEPINMEM	VARCHAR(3)	The memory preference of the file. NO The file does not have the keep in memory indication set. YES The file has the keep in memory indication set.

Table 81. SYSFILES view (continued)

Column Name	System Column Name	Data Type	Description
MEDIA_PREFERENCE	UNIT	VARCHAR(4)	Preferred storage unit for the file (UNIT). *ANY No storage media is preferred. Storage will be allocated from any available storage media. *SSD Solid state disk storage media is preferred. Storage may be allocated from solid state disk storage media, if available.
SOURCE_FILE_LIBRARY	SRCLIB	VARCHAR(10) Nullable	Library containing SOURCE_FILE. Contains the null value if a source file was not used.
SOURCE_FILE	SRCFILE	VARCHAR(10) Nullable	Name of the source file containing the DDS used to create the file. Contains the null value if a source file was not used.
SOURCE_FILE_MEMBER	SRCMBR	VARCHAR(10) Nullable	Source file member name within SOURCE_FILE used to create the file. Contains the null value if a source file was not used.
ACCESS_PATH_KEYED	ACCESSPATH	VARCHAR(3)	Whether the file has a keyed sequence access path. NO The file does not have a keyed sequence access path. The file is processed using arrival sequence. YES The file has a keyed sequence access path.
ACCESS_PATH_TYPE	AP_TYPE	VARCHAR(14) Nullable	Access path type. EVI Encoded vector with a 1-, 2-, or 4-byte vector. KEYED FCFO Keyed sequence access path with duplicate keys allowed. Duplicate keys are accessed in first-changed-first-out (FCFO) order. KEYED FIFO Keyed sequence access path with duplicate keys allowed. Duplicate keys are accessed in first-in-first-out (FIFO) order. KEYED LIFO Keyed sequence access path with duplicate keys allowed. Duplicate keys are accessed in last-in-first-out (LIFO) order. KEYED NO ORDER Keyed sequence access path with duplicate keys allowed. No order is guaranteed when accessing duplicate keys. KEYED UNIQUE Keyed sequence access path with no duplicate keys allowed (UNIQUE). Contains the null value if ACCESS_PATH_KEYED is NO.
ACCESS_PATH_MAINTENANCE	MAINT	VARCHAR(6) Nullable	Access path maintenance (MAINT). *DLY Delayed maintenance *IMMED Immediate maintenance *REBLD Rebuild maintenance Contains the null value if ACCESS_PATH_KEYED is NO.
ACCESS_PATH_SIZE	ACCPHSIZ	VARCHAR(7) Nullable	Access path size (ACCPHSIZ). *MAX1TB All access paths associated with this file will be allowed to occupy a maximum of 1 terabyte (1 099 511 627 776 bytes) of auxiliary storage *MAX4GB All access paths associated with this file will be allowed to occupy a maximum of 4 gigabytes (4 294 966 272 bytes) of auxiliary storage. Contains the null value if ACCESS_PATH_KEYED is NO.

Table 81. SYSFILES view (continued)

Column Name	System Column Name	Data Type	Description
LOGICAL_PAGE_SIZE	PAGESIZE	INTEGER Nullable	Access path page size. -1 Access path is a 4 gigabyte access path 0 System determines page size from the key length of the access path 8 Page size is 8 kilobytes 16 Page size is 16 kilobytes 32 Page size is 32 kilobytes 64 Page size is 64 kilobytes 128 Page size is 128 kilobytes 256 Page size is 256 kilobytes 512 Page size is 512 kilobytes Contains the null value if ACCESS_PATH_KEYED is NO.
FORCE_KEYED_ACCESS_PATH	FRCACCPH	VARCHAR(3) Nullable	Force keyed access path (FRCACCPH). NO The access path and changed records are not forced to auxiliary storage when the access path is changed. YES The access path and changed records are forced to auxiliary storage when the access path is changed (*YES). Contains the null value if ACCESS_PATH_KEYED is NO.
ACCESS_PATH_JOURNALED	JOURNALED	VARCHAR(3) Nullable	Access path journaled. NO The access path is not journaled. YES The access path is journaled. Contains the null value if ACCESS_PATH_KEYED is NO.
ACCESS_PATH_RECOVERY	RECOVER	VARCHAR(7) Nullable	Access path recovery (RECOVER). *AFTIPL The file access path is built after the IPL is completed. *IPL The file access path is built during the IPL. *NO The file access path is built when the file is next opened. Contains the null value if ACCESS_PATH_KEYED is NO.
SRTSEQ_IND	SRTSEQ_IND	INTEGER	Sort sequence table (SRTSEQ) indicators. 1 No sort sequence table is used for the file, and the hexadecimal value of the characters will be used to determine the sort sequence (*HEX). 2 A sort sequence table was specified for the file. 3 No sort sequence table for the file; however, an alternate collating sequence table was specified.
SORT_SEQUENCE_LIBRARY	SRTSEQ_LIB	VARCHAR(10) Nullable	The library containing the sort sequence table or alternate collating sequence table. Can contain the special value *LIBL. Contains the null value if SRTSEQ_IND is 1 or if there is no library.
SORT_SEQUENCE	SRTSEQ	VARCHAR(10) Nullable	The sort sequence table or alternate collating sequence table associated with the file. Contains the null value if SRTSEQ_IND is 1.
LANGUAGE_IDENTIFIER	LANGID	CHAR(3) Nullable	Language identifier (LANGID). Contains the null value if there is no language identifier.

Table 81. SYSFILES view (continued)

Column Name	System Column Name	Data Type	Description
ROUNDING_MODE	DECFLTRND	VARCHAR(8) Nullable	Rounding mode to be used for decimal floating point (DECFLOAT) calculations. CEILING DOWN FLOOR HALFDOWN HALFEVEN HALFUP UP Contains the null value if the file has no decimal floating point fields or this is not an SQL view, SQL index with a derived key expression, SQL materialized query table, or logical file.
DECFLOAT_WARNINGS	DECFLTWRN	VARCHAR(3) Nullable	Indicates whether warnings should be returned from decimal floating point calculations. NO Warnings are not returned. YES Warnings are returned. Contains the null value if the file has no decimal floating point fields or this is not an SQL view, SQL index with a derived key expression, SQL materialized query table, or logical file.
NUMBER_RECORD_FORMATS	FORMATS	INTEGER	Total number of record formats.
FORMAT_LEVEL_ID	FMTLVlid	CHAR(13) Nullable	The record format level ID. Contains the null value if file has more than one format or if no value is available.
FORMAT_NAME	FMT_NAME	VARCHAR(10) Nullable	The name of the record format. Contains the null value if file has more than one format.
RECORD_LENGTH	RCD_LEN	INTEGER Nullable	The length of the record format. Contains the null value if file has more than one format.
NUMBER_FIELDS	FIELDS	INTEGER Nullable	The number of fields in the record format. Contains the null value if file has more than one format.
COMMON_CCsID	CCSID	INTEGER Nullable	The CCSID used when all fields with a character, open, and graphic data type use the same CCSID. Contains the null value if file has more than one format or if all character, open, and graphic fields do not use the same CCSID.
CONTAINS_EXPLICIT_CCsID	EXPLICIT	VARCHAR(3) Nullable	Explicit CCSID setting. NO A CCSID was not specified for any character type fields in the format. YES A CCSID was specified for one or more character type fields in the format. Contains the null value if file has more than one format.
CONTAINS_MULTIPLE_CCsIDS	MULTIPLE	VARCHAR(3)	Multiple CCSID setting. NO The file has only one CCSID for its character type fields or the file has no character type fields. YES The file has more than one CCSID for its character type fields

Table 81. SYSFILES view (continued)

Column Name	System Column Name	Data Type	Description
CONTAINS_UNICODE	UNICODE	VARCHAR(3) Nullable	<p>Format contains UTF-8, UTF-16, or UCS-2 fields.</p> <p>NO The file record format does not contain UTF-8, UTF-16, or UCS-2 fields.</p> <p>YES The file record format contains UTF-8, UTF-16, or UCS-2 fields.</p> <p>Contains the null value if file has more than one format.</p>
CONTAINS_VARYING_LENGTH	VARLEN	VARCHAR(3)	<p>File contains variable length fields (VARLEN).</p> <p>NO The file record format does not contain variable length fields.</p> <p>YES The file record format contains variable length fields.</p>
CONTAINS_DATETIME	DATETIME	VARCHAR(3)	<p>File contains date/time/timestamp fields.</p> <p>NO The file record format does not contain date, time, or timestamp fields.</p> <p>YES The file record format contains date, time, or timestamp fields.</p>
CONTAINS_GRAPHIC	GRAPHIC	VARCHAR(3)	<p>File contains graphic fields.</p> <p>NO The file record format does not contain graphic fields.</p> <p>YES The file record format contains graphic fields.</p>
CONTAINS_LOB	LOB	VARCHAR(3)	<p>File contains large object fields. These are the SQL data types character large object (CLOB), double-byte character large object (DBCLOB), and binary large object (BLOB).</p> <p>NO The file record format does not have a large object field.</p> <p>YES The file record format has a large object field.</p>
CONTAINS_ROWID	ROWID	VARCHAR(3)	<p>File contains ROWID fields.</p> <p>NO The file record format does not have a ROWID column.</p> <p>YES The file record format has a ROWID column.</p>
CONTAINS_UDT	UDT	VARCHAR(3)	<p>File contains user-defined type fields.</p> <p>NO The file record format does not have a user-defined type field.</p> <p>YES The file record format has a user-defined type field.</p>
CONTAINS_DATA LINK	DATA LINK	VARCHAR(3)	<p>File contains DataLink fields.</p> <p>NO The file record format does not have a DataLink field.</p> <p>YES The file record format has a DataLink field.</p>
CONTAINS_DATA LINK_ FILE_LINK_CONTROL	DATA LINKFL	VARCHAR(3)	<p>File contains DataLink with FILE LINK CONTROL fields.</p> <p>NO The file record format does not have a DataLink field with FILE LINK CONTROL.</p> <p>YES The file record format has a DataLink field with FILE LINK CONTROL.</p>
CONTAINS_NULL	NULLABLE	VARCHAR(3) Nullable	<p>File contains null capable fields.</p> <p>NO The file record format does not have any null capable fields.</p> <p>YES The file record format has null capable fields.</p> <p>Contains the null value if file has more than one format.</p>

Table 81. SYSFILES view (continued)

Column Name	System Column Name	Data Type	Description
CONTAINS_DEFAULT	DFT	VARCHAR(3) Nullable	The physical file format contains fields with explicit default values. NO The file record format does not have any fields with explicit default values. YES The file record format has fields with explicit default values. Contains the null value if file has more than one format.
CONTAINS_IDENTITY	IDENTITY	VARCHAR(3)	File contains an identity column. NO The file record format does not have an identity column. YES The file record format has an identity column.
CONTAINS_ROW_CHANGE_TIMESTAMP	ROW_CHANGE	VARCHAR(3)	File contains a row change timestamp column. NO The file record format does not have a row change timestamp column. YES The file record format has a row change timestamp column.
CONTAINS_USER_DEFINED_FUNCTION	UDF	VARCHAR(3)	File contains a user-defined function. NO The file does not use a user-defined function. YES The file uses a user-defined function.
Values for the following columns are returned when NATIVE_TYPE is PHYSICAL. Otherwise, the columns will contain the null value.			
ALLOCATE_STORAGE	ALLOCATE	VARCHAR(3) Nullable	The allocate storage setting (ALLOCATE). NO New members added to the file allow the system to determine storage space that is allocated for the member (ALLOCATE(*NO)). YES New members added to the file use the initial number of records to determine storage space that is allocated for the member (ALLOCATE(*YES)).
CONTIGUOUS_STORAGE	CONTIG	VARCHAR(3) Nullable	The contiguous storage setting (CONTIG). NO Storage should not be attempted to be allocated contiguously (CONTIG(*NO)). YES Storage should be attempted to be allocated contiguously (CONTIG(*YES)). Contains the null value if ALLOCATE_STORAGE is NO.
MAXIMUM_DELETED_PERCENTAGE	DLTPCT	INTEGER Nullable	Maximum percentage of deleted records allowed (DLTPCT). 1 to 100 The threshold percentage of deleted records a member can contain before a message is sent to the history log. See Deleted records for additional information. Contains the null value if the number of deleted records is not checked when the member is closed (*NONE).
INITIAL_RECORDS	SIZE_INIT	INTEGER Nullable	Initial number of records (SIZE). This is the number of records that can be inserted before an automatic extension occurs. Contains the null value if the number of records that can be inserted into each member is not limited by the user. The system determines the maximum member size (*NOMAX).
INCREMENT_RECORDS	SIZE_INCR	INTEGER Nullable	Increment number of records (SIZE). This is the maximum number of records that can be inserted into the member after an automatic extension occurs. Contains the null value when INITIAL_RECORDS is null.

Table 81. SYSFILES view (continued)

Column Name	System Column Name	Data Type	Description
MAXIMUM_INCREMENTS	SIZE_MAX	INTEGER Nullable	Maximum number of increments (SIZE). This is the maximum number of automatic extensions that can be made to the member. Contains the null value when INITIAL_RECORDS is 0.
REUSE_DELETED_RECORDS	REUSEDLT	VARCHAR(3) Nullable	Reuse deleted records (REUSEDLT). NO Deleted records are not reused on subsequent writes or inserts. YES Deleted records can be reused on subsequent writes or inserts.
MATERIALIZED_QUERY_TABLE	MQT	VARCHAR(3) Nullable	SQL materialized query table setting. NO This is not an SQL materialized query table. YES This is an SQL materialized query table.
PARTITIONED_TABLE	PARTITION	VARCHAR(3) Nullable	Partitioned table setting. NO This is not a partitioned table. YES This is a partitioned table.
ROW_AND_COLUMN_ACCESS_CONTROL	RCAC	VARCHAR(3) Nullable	Row and column access control setting. NO Access controls are not defined for the file. YES Access controls are defined for the file. The QSYS2.SYSCONTROLS view contains detailed information about row and column access controls.
Values for the following columns are returned when NATIVE_TYPE is LOGICAL. Otherwise, the columns will contain the null value.			
TOTAL_SELECT_OMIT	TOTAL_SO	INTEGER Nullable	Total number of select/omit statements for all record formats.
FMTSLR_LIBRARY	FMTSLR_LIB	VARCHAR(10) Nullable	Record format selector program library (FMTSLR) Contains the null value if there is no record format selector program.
FMTSLR_PROGRAM	FMTSLR_PGM	VARCHAR(10) Nullable	Record format selector program (FMTSLR) Contains the null value if there is no record format selector program.
IS_JOIN_LOGICAL	JFILE	VARCHAR(3) Nullable	Join logical file setting (JFILE). NO The file is not a join logical file. YES The file is a join logical file.
DYNAMIC_SELECTION	DYNSLT	VARCHAR(3) Nullable	Dynamic selection setting (DYNSLT). NO The selection and omission tests specified for the file are done when the access path is updated. YES The selection and omission tests specified for the file are done when the file is read.
WITH_CHECK_OPTION	CHECK	VARCHAR(8) Nullable	With check option. CASCADED The cascaded check option was specified. NO No check option was specified or this is not an SQL view. LOCAL The local check option was specified.

Table 81. SYSFILES view (continued)

Column Name	System Column Name	Data Type	Description
PHYSICAL_LOB	PF_LOB	VARCHAR(3) Nullable	Whether this logical file has no large object fields, but the based-on physical file has a large object field. NO The logical file and based-on physical file either both have large object fields or both do not. YES The logical file has no large object fields, but the based-on physical file has a large object field.
PHYSICAL_DATA LINK	PF_DATA LINK	VARCHAR(3) Nullable	Whether this logical file has no DataLink fields, but the based-on physical file has a DataLink field. NO The logical file and based-on physical file either both have DataLink fields or both do not. YES The logical file has no DataLink fields, but the based-on physical file has a DataLink field.
INDEX_COLUMN_IS_EXPRESSION	IXEXP	VARCHAR(3) Nullable	If the SQL index key column is an expression. NO The key column is not an expression or this is not an SQL index. YES The key column is an expression.
INDEX_EXPRESSION_HAS_UDF	IXEXPUDF	VARCHAR(3) Nullable	If the SQL index key column is an expression and the expression contains a user-defined function (UDF). NO The key column is not an expression or the expression does not contain a user-defined function, or this is not an SQL index. YES The key column is an expression and the expression contains a UDF.
INDEX_HAS_SEARCH_CONDITION	SPARSE	VARCHAR(3) Nullable	If the index has a search condition. NO The index does not have a search condition, or this is not an SQL index YES The index has a search condition.
INDEX_SEARCH_CONDITION_HAS_UDF	SPARSE_UDF	VARCHAR(3) Nullable	If the index search condition contains a user-defined function. NO The index is not sparse or does not contain a user-defined function, or this is not an SQL index YES The index is sparse and the search condition contains a UDF.

Examples

- Examine all the files in APPLIB1.

```
SELECT * FROM QSYS2.SYSFILES WHERE LIB_NAME = 'APPLIB1';
```

- List the files that native logical files in APPLIB1 are based on.

```
WITH BASED_ONS (LF_NAME, BASED_ON_NAMES) AS (
  SELECT TABLE_NAME, BASED_ON_FILES
  FROM QSYS2.SYSFILES
  WHERE SYSTEM_TABLE_SCHEMA = 'APPLIB1' AND
        NATIVE_TYPE = 'LOGICAL' AND
        SQL_OBJECT_TYPE IS NULL
)
SELECT DISTINCT LF_NAME, LIBRARY AS BASED_ON_LIBRARY, FILE AS BASED_ON_FILE
FROM BASED_ONS, JSON_TABLE(
  BASED_ON_NAMES,
  '1ax $.BASED_ON_FILES'
  COLUMNS(
    LIBRARY CHAR(10), FILE CHAR(10)
  ))
order by 1, 2, 3;
```

SYSMEMBERSTAT view

The SYSMEMBERSTAT view contains one row for every table partition or table member, including rows for program described files.

The following table describes the columns in the SYSMEMBERSTAT view:

Table 82. SYSMEMBERSTAT view

Column name	System Column Name	Data Type	Description
TABLE_SCHEMA	TABSCHEMA	VARCHAR(128)	Name of the SQL schema that contains the table.
TABLE_NAME	TABNAME	VARCHAR(128)	Name of the table.
SYSTEM_TABLE_SCHEMA	SYS_DNAME	VARCHAR(10)	System schema name.
SYSTEM_TABLE_NAME	SYS_TNAME	VARCHAR(10)	System table name.
SYSTEM_TABLE_MEMBER	SYS_MNAME	VARCHAR(10)	System member name.
SOURCE_TYPE	SRCTYPE	VARCHAR(10) Nullable	Source type of a source member. Contains the null value if the table is not a source file.
LAST_SOURCE_UPDATE_TIMESTAMP	LASTSRCUPD	TIMESTAMP Nullable	Last source change timestamp to a source member. Contains the null value if the table is not a source file.
TEXT_DESCRIPTION	TEXT	VARGRAPHIC(50) CCSID 1200 Nullable	Text description for the member or partition. Contains the null value if there is no text description for the member.
CREATE_TIMESTAMP	CREATED	TIMESTAMP	Create timestamp of the member or partition.
LAST_CHANGE_TIMESTAMP	LASTCHG	TIMESTAMP	Timestamp of the last change that occurred to the member or partition.
LAST_SAVE_TIMESTAMP	LASTSAVE	TIMESTAMP Nullable	Timestamp of the last save of the member or partition. Contains the null value if the member or partition has never been saved.
LAST_RESTORE_TIMESTAMP	LASTRST	TIMESTAMP Nullable	Timestamp of the last restore of the member or partition. Contains the null value if the member or partition has never been restored.
LAST_USED_TIMESTAMP	LASTUSED	TIMESTAMP Nullable	Timestamp of the last time the member or partition was used directly by an application for native record I/O or SQL operations. Contains the null value if the member or partition has never been used.
DAYS_USED_COUNT	DAYSUSED	INTEGER	The number of days the member or partition was used directly by an application for native record I/O or SQL operations since the last time the usage statistics were reset. If the member or partition has never been used since the last time the usage statistics were reset, contains 0.
LAST_RESET_TIMESTAMP	LASTRESET	TIMESTAMP Nullable	The timestamp of the last time the usage statistics were reset for the table. For more information see the Change Object Description (CHGOBJD) command. Contains the null value if the member or partition's last used timestamp has never been reset.
TABLE_PARTITION	TABPART	VARCHAR(128)	Name of the table member or partition.
PARTITION_TYPE	PARTTYPE	CHAR(1)	The type of the table partitioning: blank The table is not partitioned. H This is data hash partitioning. R This is data range partitioning. D This is distributed database hash partitioning.

Table 82. SYSMEMBERSTAT view (continued)

Column name	System Column Name	Data Type	Description
PARTITION_NUMBER	PARTNBR	INTEGER Nullable	The partition number of this partition. Contains the null value if the table is a distributed table.
NUMBER_DISTRIBUTED_PARTITIONS	DSTPARTS	INTEGER Nullable	If the table is a distributed table, contains the total number of partitions. Contains the null value if the table is not a distributed table.
NUMBER_PARTITIONING_KEYS	NBRPKEYS	INTEGER Nullable	The number of partitioning keys. Contains the null value if the table is not partitioned.
PARTITIONING_KEYS	PARTKEYS	VARCHAR(2880) Nullable	The list of partitioning keys. Contains the null value if the table is not partitioned.
LOWINCLUSIVE	LOWINCL	CHAR(1) Nullable	Indicates whether the low key value for the partition is inclusive. N The low key value is not inclusive. Y The low key value is inclusive. Contains the null value if the table is not partitioned by range.
LOWVALUE	LOWVALUE	VARGRAPHIC(1024) CCSID 1200 Nullable	A string representation of the low key value for a range partition. Contains the null value if the table is not partitioned by range.
HIGHINCLUSIVE	HIGHINCL	CHAR(1) Nullable	Indicates whether the high key value for the partition is inclusive. N The high key value is not inclusive. Y The high key value is inclusive. Contains the null value if the table is not partitioned by range.
HIGHVALUE	HIGHVALUE	VARGRAPHIC(1024) CCSID 1200 Nullable	A string representation of the high key value for a range partition. Contains the null value if the table is not partitioned by range.
NUMBER_ROWS	CARD	BIGINT	Number of valid rows in the table member or partition.
NUMBER_PAGES	FPAGES	BIGINT	Number of 64K pages in the partition's data.
OVERFLOW	OVERFLOW	BIGINT	The estimated number of rows that have overflowed to variable length segments. If the table does not contain variable length or LOB columns, contains 0.
AVGROWSIZE	AVGROWSIZE	BIGINT	Average length (in bytes) of a row in this table. If the table has variable length or LOB columns, contains -1.
NUMBER_DELETED_ROWS	DELETED	BIGINT	Number of deleted rows in the table member or partition.
DATA_SIZE	SIZE	BIGINT	Total size (in bytes) of the data space in the member or partition.
VARIABLE_LENGTH_SIZE	VLSIZE	BIGINT	Size (in bytes) of the variable-length data space segments in the member or partition.
VARIABLE_LENGTH_SEGMENTS	VLSEGMENTS	BIGINT	The number of variable-length data space segments in the member or partition.
COLUMN_STATS_SIZE	CSTATSSIZE	BIGINT	Size (in bytes) of the column statistics in the member or partition.
MAINTAINED_TEMPORARY_INDEX_SIZE	MTISIZE	BIGINT	Size (in bytes) of all maintained temporary indexes over the member or partition.

Table 82. SYSMEMBERSTAT view (continued)

Column name	System Column Name	Data Type	Description
NUMBER_DISTINCT_INDEXES	DISTINCTIX	INTEGER	The number of distinct indexes built over the member or partition. This does not include maintained temporary indexes.
OPEN_OPERATIONS	OPENS	BIGINT	Number of full opens of the member or partition since the last IPL.
CLOSE_OPERATIONS	CLOSES	BIGINT	Number of full closes of the member or partition since the last IPL.
INSERT_OPERATIONS	INSERTS	BIGINT	Number of insert operations for the member or partition since the last IPL.
BLOCKED_INSERT_OPERATIONS	BLKIOPS	BIGINT	Number of blocked insert operations for the member or partition since the last IPL.
BLOCKED_INSERT_ROWS	BLKIROW	BIGINT	Number of rows inserted with blocked insert operations for the member or partition since the last IPL.
UPDATE_OPERATIONS	UPDATES	BIGINT	Number of update operations for the member or partition since the last IPL.
DELETE_OPERATIONS	DELETES	BIGINT	Number of delete operations for the member or partition since the last IPL.
CLEAR_OPERATIONS	DSCLEAR	BIGINT	Number of clear operations (CLRPFM operations) for the member or partition since the last IPL.
COPY_OPERATIONS	DSCOPIES	BIGINT	Number of data space copy operations (certain CPYxxx operations) for the member or partition since the last IPL.
REORGANIZE_OPERATIONS	DSREORGS	BIGINT	Number of data space reorganize operations (non-interruptible RGZPFM operations) for the member or partition since the last IPL.
INDEX_BUILDS	DSINXBLDS	BIGINT	Number of creates or rebuilds of indexes that reference the member or partition since the last IPL. This does not include maintained temporary indexes.
LOGICAL_READS	LGLREADS	BIGINT	Number of logical read operations for the member or partition since the last IPL.
PHYSICAL_READS	PHYREADS	BIGINT	Number of physical read operations for the member or partition since the last IPL.
SEQUENTIAL_READS	SEQREADS	BIGINT	Number of sequential read operations for the member or partition since the last IPL.
RANDOM_READS	RANREADS	BIGINT	Number of random read operations for the member or partition since the last IPL.
NEXT_IDENTITY_VALUE	NEXTVALUE	DECIMAL(31,0) Nullable	The next identity value. In some cases, this value may be an estimate. Contains the null value if the table does not have an identity column.
KEEP_IN_MEMORY	KEEPINMEM	CHAR(1)	Indicates whether the partition should be kept in memory: 0 No memory preference. 1 The partition should be kept in memory, if possible.
MEDIA_PREFERENCE	MEDIAPREF	SMALLINT	Indicates the media preference of the partition: 0 No media preference. 255 The partition should be allocated on Solid State Disk (SSD), if possible.
VOLATILE	VOLATILE	CHAR(1)	Indicates whether the table is volatile. 0 Table is not volatile. 1 Table is volatile.

Table 82. SYSMEMBERSTAT view (continued)

Column name	System Column Name	Data Type	Description
PARTIAL_TRANSACTION	PARTIALTX	CHAR(1)	Indicates whether the partition contains a partial transaction: N The partition does not contain a partial transaction. Y The partition was saved while active with a partial transaction. A subsequent restore of the partition contains the partial transaction. The user should apply changes from the journal to complete the transaction. R A rollback abnormally ended prior to completion. This left the partition with a partial set of rolled back rows.
APPLY_STARTING_RECEIVER_LIBRARY	APYRCVLIB	VARCHAR(10) Nullable	The library containing the starting journal receiver. Contains the null value if APPLY_STARTING_RECEIVER is null.
APPLY_STARTING_RECEIVER	APYRCVNAME	VARCHAR(10) Nullable	Indicates that the partition was saved and subsequently restored. If the table was journaled when the partition was saved, the starting journal receiver name will indicate the journal receiver to start with if APYJRNCHG is then used. Contains the null value if PARTIAL_TRANSACTION has a value of R. Once an APYJRNCHG is performed, the apply information is cleared.

Example

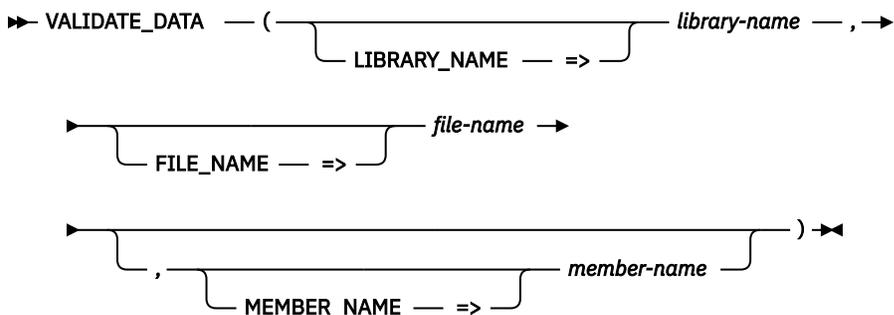

Examine some statistical information for all members of all files in APPLIB1.

```
SELECT TABLE_NAME, SYSTEM_TABLE_MEMBER, NUMBER_ROWS, NUMBER_DELETED_ROWS, LAST_USED_TIMESTAMP
FROM QSYS2.SYSMEMBERSTAT
WHERE TABLE_SCHEMA = 'APPLIB1';
```

VALIDATE_DATA, VALIDATE_DATA_FILE, and VALIDATE_DATA_LIBRARY table functions

The VALIDATE_DATA, VALIDATE_DATA_FILE, and VALIDATE_DATA_LIBRARY table functions examine the data in database physical file members to verify it is properly formed. This can be used to identify invalid data, such as invalid decimal values, that were inserted into a DDS-created physical file.

Authorization: See Note below.

library-name An character string expression that specifies the name of the library containing *file-name*.

- file-name** A character string expression that specifies the name of a database physical file.
- member-name** A character string expression that specifies the name of a member in *file-name*. The special values *FIRST and *LAST are supported. If this parameter is omitted, *FIRST is used.

The VALIDATE_DATA_FILE table function validates all members in a physical file. It is identical to VALIDATE_DATA except it only has *library-name* and *file-name* parameters.

The VALIDATE_DATA_LIBRARY table function validates all members in all physical files in a library. It is identical to VALIDATE_DATA except it only has a *library-name* parameter.

The result of the function is a table containing a row for each row in a member that has invalid data in at least one column. The columns of the result table are described in the following table. The result columns are nullable.

Table 83. VALIDATE_DATA, VALIDATE_DATA_FILE, and VALIDATE_DATA_LIBRARY table function

Column Name	Data Type	Description
VALIDATE_TIME	TIMESTAMP	The timestamp when this row was generated.
LIBRARY_NAME	VARCHAR(10)	The library containing the file.
FILE_NAME	VARCHAR(10)	The physical file containing the member.
MEMBER_NAME	VARCHAR(10)	The member with the invalid data.
RELATIVE_RECORD_NUMBER	BIGINT	The relative record number (RRN) of the row in MEMBER_NAME with the invalid data.
SQL_WARNING	INTEGER	The SQLCODE of the warning that indicated this error.
REASON_CODE	INTEGER	The reason code from the warning that indicated this error.
COLUMN_NAME	VARCHAR(128)	The name of the column with the invalid data.
WARNING_TEXT	VARCHAR(1000)	The text from the warning that indicated this error.

Note

This function is provided in the SYSTOOLS schema as an example of how to examine all the rows in a table by using an SQL table function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

- Validate the content of all members in FILE1. If no rows are returned, all the data appears to be good.

```
SELECT * FROM TABLE(SYSTOOLS.VALIDATE_DATA_FILE('APPLIB', 'FILE1'));
```

IBM i Services

There are many system services that can be accessed through system-provided SQL views, procedures, and functions. These provide an SQL interface to access, transform, order, and subset the information without needing to code to a system API.

Information about the supported IBM i releases, including the database PTF groups where each service was introduced or enhanced, is available in the IBM i Technology Updates wiki. See this page for all the details: <https://www.ibm.com/support/pages/node/1119123>

Application Services

These procedures, functions, and views provide interface information that can be used by applications.

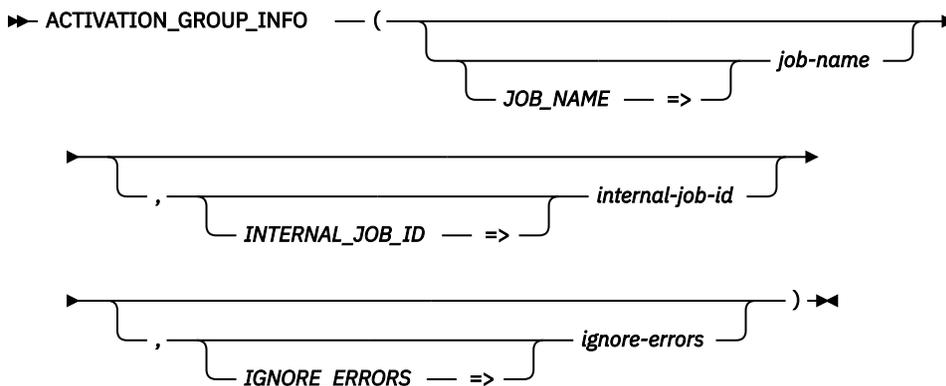

ACTIVATION_GROUP_INFO table function

The ACTIVATION_GROUP_INFO table function returns all the activation groups that are associated with a job and their attributes.

This information is similar to what can be accessed through the Display Job (DSPJOB) CL command and the Open List of Activation Group Attributes (QWVOLAGP) API.

Authorization: None required for a job where the caller's user profile is the same as the job user identity of the job for which the information is being returned.

Otherwise, the caller must have *JOBCTL special authority.

The schema is QSYS2.

job-name A character string that identifies the qualified name of a job in the form *job-number/**job-user/job-name*.

The special value of '*' indicates the current job.

If *job-name* is provided, *internal-job-id* must be omitted.

internal-job-id A binary string that contains an internal job identifier. This can be passed for quicker performance. This value is returned in the INTERNAL_JOB_ID column by the ACTIVE_JOB_INFO table function.

If *internal-job-id* is provided, *job-name* must be omitted.

ignore-errors A character string that identifies what to do when an error is encountered.

NO An error is returned.

YES A warning is returned.

No row is returned when an error is encountered. This is the default.

The result of the function is a table containing one row for every activation group for the job with the format shown in the following table. All columns are nullable.

Table 84. ACTIVATION_GROUP_INFO table function

Column Name	Data Type	Description
ACTIVATION_GROUP_NAME	VARCHAR(10)	The name of the activation group. Can contain one of the following special values: *DFACTGRP The activation group is one of the default activation groups. *NEW The activation group is *NEW.

Table 84. ACTIVATION_GROUP_INFO table function (continued)

Column Name	Data Type	Description
ACTIVATION_GROUP_NUMBER	DECIMAL(20,0)	The activation group number.
STORAGE_MODEL	VARCHAR(10)	The storage model of the activation group. *SINGLVL The activation group is single level store. *TERASPACE The activation group is teraspace.
STATE	VARCHAR(6)	The state of the activation group. SYSTEM The activation group is in system state. USER The activation group is in user state.
NUMBER_OF_ACTIVATIONS	INTEGER	The total number of program activations in this activation group.
PROGRAM_LIBRARY	VARCHAR(10)	The name of the library that contains the program that caused this activation group to be created. Contains the null value when PROGRAM is null.
PROGRAM	VARCHAR(10)	The name of the program that caused this activation group to be created. Contains the null value when the activation group is one of the default activation groups or if the program no longer exists in the system.
PROGRAM_TYPE	VARCHAR(6)	The type of program that caused this activation group to be created. JAVA A Java program. PGM A program. SRVPGM A service program. Contains the null value when PROGRAM is null.
SHARED_ACTIVATION_GROUP	VARCHAR(3)	Whether the activation group is shared. A shared activation group is an activation group that belongs to more than one job at the same time. NO The activation group is not shared with other jobs. YES The activation group is shared with other jobs.
IN_USE	VARCHAR(3)	Whether the activation group is eligible to be reclaimed. An activation group can be reclaimed using the Reclaim Activation Group (RCLACTGRP) command. NO The activation group is not in use and is eligible to be reclaimed. YES The activation group is in use and cannot be reclaimed.
STATIC_STORAGE_SIZE	DECIMAL(20,0)	The total amount of static storage allocated to the activation group, in bytes. If the size exceeds 4,294,967,295 bytes, 4,294,967,295 will be returned.
NUMBER_OF_HEAPS	INTEGER	The total number of heaps that are allocated by this activation group.
HEAP_STORAGE_SIZE	DECIMAL(20,0)	The total amount of heap storage that is allocated to the activation group, in bytes. If the size exceeds 4,294,967,295 bytes, 4,294,967,295 will be returned.

Example

- List the activation group information for the current job.

```
SELECT * FROM TABLE(QSYS2.ACTIVATION_GROUP_INFO('*'));
```

- List the activation group information for a job based on its internal job identifier.

```
SELECT * FROM TABLE(QSYS2.ACTIVATION_GROUP_INFO(
INTERNAL_JOB_ID => BX'00D10003007E3F00A784A7CBD6E89001'));
```

ADD_USER_INDEX_ENTRY and ADD_USER_INDEX_ENTRY_BINARY procedures

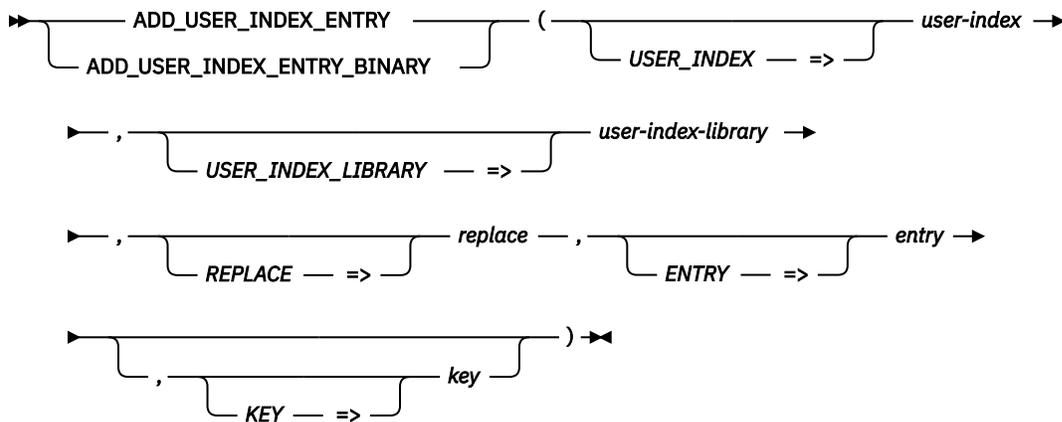

The ADD_USER_INDEX_ENTRY and ADD_USER_INDEX_ENTRY_BINARY procedures add a single entry to a user index (*USRIDX). The data to be added can be provided as either character or binary data.

For a fixed length index, the length of the new entry must exactly match the user index length or an error will occur.

The values used by the procedures are closely related to the values handled by the Add User Index Entries (QUSADDUI) API. Refer to the API documentation for additional behavior details.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the user index, and
- *CHANGE authority to the user index.

The schema is QSYS2.

user-index A character string containing the name of the user index where an entry is to be added.

user-index-library A character string containing the name of the library where the user index is located. Can be one of the following special values:

***CURLIB** The current library is used.

***LIBL** The library list is used.

replace The type of add to be performed.

NO For a non-keyed index, the new entry must be unique. If the entry is already in the index, an error is returned.

For a keyed index, insert the entry only if the key is not already in the user index. If the entry does not exist, the key and entry data will be inserted into the user index. If the entry is already in the index, an error is returned.

YES For a non-keyed index, this value is not supported.

For a keyed index, replace the entry portion of the index entry if the key is already in the user index. If the entry does not exist, the key and entry data will be inserted into the user index.

entry A string that specifies the data for the index entry. This parameter is required.

- For ADD_USER_INDEX_ENTRY, the input value is a character string.
- For ADD_USER_INDEX_ENTRY_BINARY, the input value will be considered a binary string.

key

A string that specifies the key for the index entry. This parameter must be provided for a keyed user index. The length of the key cannot exceed the defined key length.

- For ADD_USER_INDEX_ENTRY, the input value is a character string.
- For ADD_USER_INDEX_ENTRY_BINARY, the input value will be considered a binary string.

If the index is not keyed, this parameter must be omitted.

Example

- Add a new entry to a non-keyed user index.

```
CALL QSYS2.ADD_USER_INDEX_ENTRY(USER_INDEX => 'IX1',
                                USER_INDEX_LIBRARY => 'APPLIB',
                                REPLACE => 'NO',
                                ENTRY => 'Next entry');
```

- Add a new entry to a keyed user index. Allow the new entry to overwrite an existing entry if the key value already exists.

```
CALL QSYS2.ADD_USER_INDEX_ENTRY(USER_INDEX => 'USRIX1',
                                USER_INDEX_LIBRARY => 'APPLIB',
                                REPLACE => 'YES',
                                KEY => '00173',
                                ENTRY => 'New keyed entry');
```

BINDING_DIRECTORY_INFO view

The BINDING_DIRECTORY_INFO view returns information about the object entries in binding directories.

The values returned for the columns in the view are similar to the values returned by the Display Binding Directory (DSPBNDDIR) CL command

Authorization: The caller must have:

- *USE authority to the library containing the binding directory, and
- *OBJOPR and *READ authority to the binding directory.

To return the create timestamp for a binding directory entry, the caller must have:

- *EXECUTE authority to the library containing the binding directory entry, and
- Some authority to the binding directory entry.

The following table describes the columns in the view. The system name is BNDDIR_INF. The schema is QSYS2.

Table 85. BINDING_DIRECTORY_INFO view

Column Name	System Column Name	Data Type	Description
BINDING_DIRECTORY_LIBRARY	BNDDIR_LIB	VARCHAR(10)	The library containing the binding directory.
BINDING_DIRECTORY	BNDDIR	VARCHAR(10)	The binding directory name.
ENTRY_LIBRARY	ENTRY_LIB	VARCHAR(10)	The library containing ENTRY. Can contain the special value *LIBL.
ENTRY	ENTRY	VARCHAR(10)	The name of the binding directory entry.
ENTRY_TYPE	ENTRY_TYPE	VARCHAR(7)	The object type of the binding directory entry.
		*MODULE	The object is a module.
		*SRVPGM	The object is a service program.

Table 85. BINDING_DIRECTORY_INFO view (continued)

Column Name	System Column Name	Data Type	Description
ENTRY_ACTIVATION	ENTRY_ACT	VARCHAR(6) Nullable	The activation control of the bound service program. *DEFER Activation of the bound service program may be deferred until a function it exports is called. *IMMED Activation of the bound service program takes place immediately when the program or service program it is bound to is activated. Contains the null value if ENTRY_TYPE is *MODULE.
ENTRY_CREATE_TIMESTAMP	ENTRY_TS	TIMESTAMP(0) Nullable	The timestamp when the object was created. Contains the null value if the entry timestamp is not available.

Examples

- Return a list of the entries for all binding directories in library TESTLIB that start with 'TEST'.

```
SELECT * FROM QSYS2.BINDING_DIRECTORY_INFO
WHERE BINDING_DIRECTORY_LIBRARY = 'TESTLIB'
AND BINDING_DIRECTORY LIKE 'TEST%'
ORDER BY BINDING_DIRECTORY_LIBRARY,
BINDING_DIRECTORY,
ENTRY_LIBRARY,
ENTRY;
```

- List all of the binding directories that have the entry MYLIB/HELLO, type *MODULE.

```
SELECT BINDING_DIRECTORY,
BINDING_DIRECTORY_LIBRARY
FROM QSYS2.BINDING_DIRECTORY_INFO
WHERE ENTRY = 'HELLO'
AND ENTRY_LIBRARY = 'MYLIB'
AND ENTRY_TYPE = '*MODULE'
ORDER BY 1, 2;
```

BOUND_MODULE_INFO view

The BOUND_MODULE_INFO view returns information about modules bound into an ILE program or service program.

The values returned for the columns in the view are closely related to the values returned for *MODULE detail on the DSPPGM (Display Program) and DSPSRVPGM (Display Service Program) CL commands and the List ILE Program Information (QBNLPGMI) and the List Service Program Information (QBNLSPGM) APIs.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the program or service program, and
- *READ authority to the program or service program.

The following table describes the columns in the view. The system name is MODULE_INF. The schema is QSYS2.

Table 86. BOUND_MODULE_INFO view

Column Name	System Column Name	Data Type	Description
PROGRAM_LIBRARY	PGM_LIB	VARCHAR(10)	The library containing the program or service program.
PROGRAM_NAME	PGM_NAME	VARCHAR(10)	The program or service program containing the module.

Table 86. BOUND_MODULE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
OBJECT_TYPE	OBJ_TYPE	VARCHAR(7)	Object type for PROGRAM_NAME. *PGM A program. *SRVPGM A service program.
BOUND_MODULE_LIBRARY	BDMODLIB	VARCHAR(10)	The library containing the module bound into PROGRAM_NAME at bind time.
BOUND_MODULE	BDMOD	VARCHAR(10)	The module bound into PROGRAM_NAME. This is a copy of the module that was bound into PROGRAM_NAME. It is not the *MODULE object on the system.
MODULE_ATTRIBUTE	ATTRIBUTE	VARCHAR(10) Nullable	The language in which the module is written. Can contain the null value, for example, for a module created by a compilation process internal to IBM.
MODULE_CREATE_TIMESTAMP	CREATE_TS	TIMESTAMP(0) Nullable	The timestamp when the module was created. Contains the null value if no timestamp is available.
SOURCE_FILE_LIBRARY	SRCLIB	VARCHAR(10) Nullable	The name of the library that contains the source file used to create the module. Contains the null value if no source file was used to create the module.
SOURCE_FILE	SRCFILE	VARCHAR(10) Nullable	The name of the source file used to create the module. Contains the null value if no source file was used to create the module.
SOURCE_FILE_MEMBER	SRCMBR	VARCHAR(10) Nullable	The name of the member in the source file. Contains the null value if no source file was used to create the module.
SOURCE_STREAM_FILE_PATH	SRCSTMF	VARGRAPHIC(5000) CCSID 1200 Nullable	The absolute path to the source stream file that was used to create this module. If the stream file is contained the /QSYS.LIB file system, will contain the path to the stream file (e.g., /QSYS.LIB/library.LIB/filename.FILE/member.MBR) and the SOURCE_FILE, SOURCE_FILE_LIBRARY, and SOURCE_FILE_MEMBER will contain the database equivalent name. Contains the null value if no source file was used to create the module.
SOURCE_CHANGE_TIMESTAMP	SRC_CHGTS	TIMESTAMP(0) Nullable	The timestamp when the source that was used to create this module was last changed. Contains the null value if no source file was used to create the module.
MODULE_CCSID	TGTCCSID	INTEGER	The coded character set identifier (CCSID) for this module.
SORT_SEQUENCE_LIBRARY	SRTSEQ_LIB	VARCHAR(10) Nullable	The name of the library that contained the sort sequence table used when the module was compiled. This does not apply to SQL statements in the module. Can contain the following special values: *LIBL The sort sequence table is found in the library list when PROGRAM_NAME runs this module. *CURLIB The sort sequence table is found in the current library when PROGRAM_NAME runs this module. Contains the null value if SORT_SEQUENCE contains a special value or is null.

Table 86. BOUND_MODULE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SORT_SEQUENCE	SRTSEQ	VARCHAR(10) Nullable	<p>The name of the sort sequence table used when the module was compiled. This does not apply to SQL statements in the module. Can contain the following special values:</p> <p>*HEX No sort sequence is used.</p> <p>*JOBRUN The sort sequence value associated with the job at the time PROGRAM_NAME runs this module is used.</p> <p>*LANGIDSHR The shared sort sequence for the language identifier is used.</p> <p>*LANGIDUNQ The unique sort sequence for the language identifier is used.</p> <p>Contains the null value if the module does not contain any sort sequence information.</p>
LANGUAGE_ID	LANGID	VARCHAR(7) Nullable	<p>The language identifier used when the module was compiled. This does not apply to SQL statements in the module. Can contain the following special value:</p> <p>*JOBRUN The language identifier associated with the job at the time PROGRAM_NAME runs this module.</p> <p>Contains the null value if the module does not contain any language identification information.</p>
DEBUG_DATA	DEBUG_DATA	VARCHAR(4)	<p>Whether debug data was generated when this module was created. If debug data exists, the module may be debugged using the source debugger.</p> <p>*NO Debug data was not generated.</p> <p>*YES Debug data was generated.</p>
OPTIMIZATION_LEVEL	OPTIMIZE	INTEGER	<p>Optimization level for the module. Optimization improves the performance of a module, but reduces the ability to immediately change and accurately display the value of variables during debugging.</p> <p>10 No additional optimization is performed on the generated code. Variables can be displayed and changed when the program is being debugged. With no optimization of the code, this value provides the lowest level of module performance. 10 is also known as *NONE.</p> <p>20 Some optimization is performed on the generated code. When the module optimized at this level is being debugged, the variables can be displayed but not changed. 20 is also known as *BASIC.</p> <p>30 More optimization is performed in addition to those performed at optimization level 20. Variables cannot be changed but can be displayed while the program is being debugged. However, the displayed value of the variable during debugging may not be its actual value. 30 is also known as *FULL.</p> <p>40 Maximum level of optimization. This level includes all the optimizations performed at optimization level 30. In addition, it includes optimization that disables call and instruction tracing. Thus, tracing of modules created at this optimization level cannot be done.</p>

Table 86. BOUND_MODULE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
MAX_OPTIMIZATION_LEVEL	MAX_OPTLVL	INTEGER Nullable	The highest level of optimization this module could have at bind time. If observability has been removed from the module, this maximum optimization level value might not be the same as the one specified at module creation. The values are identical to the values for the OPTIMIZATION_LEVEL column. Contains the null value if the module is not restricted to a maximum optimization level. The module can be retranslated to any of the supported optimization levels.
OBJECT_CONTROL_LEVEL	OBJSSI	CHAR(8) Nullable	The object control level for the module at the time it was bound into PROGRAM_NAME. Contains the null value if there is no object control level for the module.
RELEASE_CREATED_ON	CREATE_ON	CHAR(6)	The version, release, and modification level of the operating system on which the module was created, in VxRxBx format.
TARGET_RELEASE	TGTRLS	CHAR(6)	The version, release, and modification level of the operating system for which the module was created, in VxRxBx format.
CREATION_DATA	CREATEDATA	VARCHAR(6)	Whether the bound module has all the creation data and if that data is observable or unobservable. *NO Not all the creation data is present in the bound module. *UNOBS The creation data is present in the bound module but not all of that data is observable. *YES The creation data is present in the bound module and all of that data is observable.
TERASPACE_STORAGE_ENABLED	TERASPACE	VARCHAR(4)	The teraspace storage capability for this bound module. *NO The module is not teraspace storage enabled. *YES The module is teraspace storage enabled.
STORAGE_MODEL	STGMDL	VARCHAR(10)	Where the automatic and static storage for this bound module is allocated at run time. *INHERIT Automatic and static storage are allocated from either single-level storage or teraspace, depending on the activation. *SINGLVL Automatic and static storage are allocated from single-level storage. *TERASPACE Automatic and static storage are allocated from teraspace.
NUMBER_PROCEDURES	PROCS	INTEGER	The number of procedures defined in the module. This number includes the program entry procedure (PEP), if one was generated by the compiler for this module.
NUMBER_PROCEDURES_BLOCK_REORDERED	PROCS_BRO	INTEGER	The number of procedures defined in the module that are block reordered. If the module does not have block-order profiling data applied, this value will be zero.

Table 86. BOUND_MODULE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
NUMBER_PROCEDURES_BLOCK_ORDER_MEASURED	PROCS_BOM	INTEGER	The number of procedures defined in the module that had block-order profiling data collected at the time block-order profiling data was applied. If the module does not have block-order profiling data applied, this value will be zero.
PROFILING_DATA	PRFDTA	VARCHAR(10)	The profiling data attribute for this bound module. *APYBLKORD Block-order profiling data is applied to the module. See NUMBER_PROCEDURES_BLOCK_REORDERED for the current number of procedures in this module that are block reordered. *COL The collection of profiling data is enabled. Any block-order profiling data has been removed for the module. *NOCOL The collection of profiling data is not enabled and block-order profiling data is not applied to the module.
ALLOW_RTVCLSRC	RTVCLSRC	VARCHAR(4)	Whether the module has CL source data that can be retrieved from the program. *NO There is no CL source for this module. *YES There is CL source for this module.
USER_MODIFIED	USER_MOD	VARCHAR(4) Nullable	Indicates whether the module was changed by the user at bind time. *NO The user did not change the module. *YES The user changed the module. Contains the null value if the information is not available.
LIC_OPTIONS	LICOPT	VARGRAPHIC(500) CCSID 1200 Nullable	The Licensed Internal Code options that are in use by the module. Contains the null value if no LIC options were used for the module.
LICENSED_PROGRAM	LICPGM	VARCHAR(13) Nullable	If the module was part of a licensed program at bind time, contains the product number and the level of the licensed program. Contains the null value if the module was not part of a licensed program at bind time.
PTF_NUMBER	PTF	CHAR(5) Nullable	The program temporary fix (PTF) that resulted in the creation of the module. Contains the null value for user-created modules.
APAR_ID	APAR_ID	CHAR(6) Nullable	The module was changed as the result of the authorized program analysis report (APAR) with this identification number. Contains the null value if the module was not changed at bind time.
SQL_STATEMENT_COUNT	NBRSTMTS	INTEGER	The number of SQL statements contained in the module. Contains 0 if there are no SQL statements in the module.

Table 86. BOUND_MODULE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SQL_RELATIONAL_DATABASE	RDB	VARCHAR(18) Nullable	<p>The default relational database that was specified on the SQL precompile. Can contain the following special value:</p> <p>*LOCAL The module can only access data on the local system.</p> <p>Contains the null value if no package was created for the module by the SQL precompiler or if the module does not contain SQL statements.</p>
SQL_COMMITMENT_CONTROL	ISOLATION	VARCHAR(5) Nullable	<p>The level of commitment control that was specified on the SQL precompile.</p> <p>*ALL Read stability. *CHG Uncommitted read. *CS Cursor stability. *NONE No commit. *RR Repeatable read.</p> <p>Contains the null value if the module does not contain SQL statements.</p>
SQL_NAMING	NAMING	VARCHAR(4) Nullable	<p>The convention used for naming objects in SQL statements.</p> <p>*SQL The SQL naming convention is used. *SYS The system naming convention is used.</p> <p>Contains the null value if the module does not contain SQL statements.</p>
SQL_DATE_FORMAT	DATFMT	VARCHAR(4) Nullable	<p>The date format attribute.</p> <p>*DMY Day/month/year format (dd/mm/yy). *EUR European format (dd.mm.yyyy). *ISO International Standards Organization format (yyyy-mm-dd). *JIS Japanese Industrial Standard format (yyyy-mm-dd). *JUL Julian format (yy/dds). *MDY Month/day/year format (mm/dd/yy). *USA USA format (mm/dd/yyyy). *YMD Year/month/day format (yy/mm/dd).</p> <p>Contains the null value if the module does not contain SQL statements.</p>
SQL_DATE_SEPARATOR	DATSEP	CHAR(1) Nullable	<p>The date separator attribute.</p> <p>Contains the null value if the module does not contain SQL statements.</p>
SQL_TIME_FORMAT	TIMFMT	VARCHAR(4) Nullable	<p>The time format attribute.</p> <p>*EUR European format (hh.mm.ss). *HMS Hours/minutes/seconds format (hh:mm:ss). *ISO International Standards Organization format (hh.mm.ss). *JIS Japanese Industrial Standard format (hh.mm.ss). *USA USA format (hh:mm a.m. or p.m.).</p> <p>Contains the null value if the module does not contain SQL statements.</p>

Table 86. BOUND_MODULE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SQL_TIME_SEPARATOR	TIMSEP	CHAR(1) Nullable	The time separator attribute. Contains the null value if the module does not contain SQL statements.
SQL_SORT_SEQUENCE_LIBRARY	SQL_SSEQLB	VARCHAR(10) Nullable	The name of the library that is used to locate the SQL sort sequence table. The following special values can be returned: *CURLIB The SQL sort sequence table is found by looking in the current library. *LIBL The SQL sort sequence table is found by looking in the library list. Contains the null value if SQL_SORT_SEQUENCE contains a special value or if the module does not contain SQL statements.
SQL_SORT_SEQUENCE	SQL_SRTSEQ	VARCHAR(10) Nullable	The sort sequence table name specified when the module was compiled. The following special values can be returned: *HEX No SQL sort sequence is used for the SQL statements. *JOBRUN The SQL sort sequence is the SRTSEQ value associated with the job at the time the SQL statements within the module are run. *LANGIDSHR The shared SQL sort sequence for the language identifier (LANGID) is used for the SQL statements. *LANGIDUNQ The unique SQL sort sequence for the language identifier (LANGID) is used for the SQL statements. Contains the null value if the module does not contain SQL statements.
SQL_LANGUAGE_ID	SQL_LANGID	VARCHAR(7) Nullable	The language identifier specified when the module was compiled. The following special value can be returned: *JOBRUN The language identifier is the LANGID associated with the job at the time the module is run. Contains the null value if the module does not contain SQL statements.
SQL_DEFAULT_SCHEMA	DFTRDBCOL	VARCHAR(10) Nullable	The schema name used for unqualified names of tables, views, indexes, and SQL packages in static statements. Contains the null value if there is no default schema name or if the module does not contain SQL statements.
SQL_PATH	SQLPATH	VARCHAR(3483) Nullable	The list of libraries used during resolution of functions, procedures, and data types within SQL statements. The list is in the form of repeating library names, each surrounded by double quotes and separated by commas. Contains the null value if the module does not contain SQL statements.

Table 86. BOUND_MODULE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SQL_DYNAMIC_USER_PROFILE	DYNUSRPRF	VARCHAR(10) Nullable	<p>The user profile used for dynamic SQL statements. The following special values can be returned:</p> <p>*OWNER Local dynamic SQL statements are run under the profile of the program or service program's owner. Distributed dynamic SQL statements are run under the profile of the SQL package's owner.</p> <p>*USER Local dynamic SQL statements are run under the profile of the job or thread. Distributed dynamic SQL statements are run under the profile of the application server job.</p> <p>Contains the null value if the module does not contain SQL statements.</p>
SQL_ALLOW_COPY_DATA	ALWCPYDTA	VARCHAR(9) Nullable	<p>Whether a copy of the data can be used in the implementation of an SQL query.</p> <p>*NO A copy of the data is not allowed.</p> <p>*OPTIMIZE A copy of the data is allowed whenever it might result is better performance.</p> <p>*YES A copy of the data is allowed, but only when necessary.</p> <p>Contains the null value if the module does not contain SQL statements.</p>
SQL_CLOSE_SQL_CURSOR	CLOSQCSR	VARCHAR(10) Nullable	<p>Specifies the CLOSQCSR attribute.</p> <p>*ENDACTGRP SQL cursors are closed, SQL prepared statements are implicitly discarded, and LOCK TABLE locks are released when the activation group ends.</p> <p>*ENDMOD SQL cursors are closed and SQL prepared statements are implicitly discarded when the module is exited. LOCK TABLE locks are released when the first SQL program on the call stack ends.</p> <p>Contains the null value if the module does not contain SQL statements.</p>
SQL_DELAY_PREPARE	DLYPRP	VARCHAR(4) Nullable	<p>Indicates the delay prepare attribute.</p> <p>*NO Dynamic statement validation is performed when the dynamic statements are prepared.</p> <p>*YES Dynamic statement validation is delayed until the dynamic statements are used.</p> <p>Contains the null value if the module does not contain SQL statements.</p>

Table 86. BOUND_MODULE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SQL_ALLOW_BLOCK	ALWBLK	VARCHAR(8) Nullable	<p>Whether blocking is used to improve the performance of certain SQL statements.</p> <p>*ALLREAD Rows are blocked for read-only cursors.</p> <p>*NONE Rows are not blocked for retrieval of data for cursors.</p> <p>*READ Rows are blocked for read-only retrieval of data for cursors when:</p> <ul style="list-style-type: none"> The commitment control value is *NONE. The cursor is declared with a FOR READ ONLY clause or there are no dynamic statements that could run a positioned UPDATE or DELETE statement for the cursor. <p>Contains the null value if the module does not contain SQL statements.</p>
SQL_PACKAGE_LIBRARY	SQLPKGLIB	VARCHAR(10) Nullable	<p>The name of the library the SQL package is in.</p> <p>Contains the null value if the module is not distributed or if the module does not contain SQL statements.</p>
SQL_PACKAGE	SQLPKG	VARCHAR(10) Nullable	<p>The name of the SQL package created on the relational database specified on the RDB parameter of the command that created this module.</p> <p>Contains the null value if the module is not distributed or if it does not contain SQL statements.</p>
SQL_RDB_CONNECTION_METHOD	RDBCNNMTH	VARCHAR(4) Nullable	<p>Specifies the semantics used for CONNECT statements:</p> <p>*DUW CONNECT (Type 2) semantics are used to support distributed unit of work.</p> <p>*RUW CONNECT (Type 1) semantics are used to support remote unit of work.</p> <p>Contains the null value if the module is not distributed or does not contain SQL statements.</p>

Examples

- Find any bound modules that include source changes from the last 7 days.

```
SELECT *
FROM QSYS2.BOUND_MODULE_INFO
WHERE PROGRAM_LIBRARY = 'QGPL'
AND SOURCE_CHANGE_TIMESTAMP > CURRENT_TIMESTAMP - 7 DAYS
ORDER BY SOURCE_CHANGE_TIMESTAMP DESC;
```

- Find bound modules in APPLIB that were built from source that does not reside in the integrated file system.

```
SELECT *
FROM QSYS2.BOUND_MODULE_INFO
WHERE PROGRAM_LIBRARY = 'APPLIB'
AND SOURCE_FILE_LIBRARY <> 'QTEMP'
AND SOURCE_STREAM_FILE_PATH IS NULL
ORDER BY SOURCE_FILE_LIBRARY, SOURCE_FILE, SOURCE_FILE_MEMBER;
```

BOUND_SRVPGM_INFO view

The BOUND_SRVPGM_INFO view returns information about service programs bound into an ILE program or service program.

The values returned for the columns in the view are closely related to the values returned for *SRVPGM detail on the DSPPGM (Display Program) and DSPSRVPGM (Display Service Program) CL commands and the List ILE Program Information (QBNLPGMI) and the List Service Program Information (QBNLSPGM) APIs.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the program or service program, and
- *READ authority to the program or service program.

The following table describes the columns in the view. The system name is SRVPGM_INF. The schema is QSYS2.

Table 87. BOUND_SRVPGM_INFO view

Column Name	System Column Name	Data Type	Description
PROGRAM_LIBRARY	PGM_LIB	VARCHAR(10)	Library containing the program or service program.
PROGRAM_NAME	PGM_NAME	VARCHAR(10)	Program or service program name.
OBJECT_TYPE	OBJ_TYPE	VARCHAR(7)	Object type for PROGRAM_NAME. *PGM A program. *SRVPGM A service program.
BOUND_SERVICE_PROGRAM_LIBRARY	BDSRVPGMLB	VARCHAR(10)	The name of the library containing the service program bound to PROGRAM_NAME at bind time. This is the library name in which the activation expects to find the service program at run time. Can contain the following special value: *LIBL Indicates the library list is used at the time the service program is needed.
BOUND_SERVICE_PROGRAM	BDSRVPGM	VARCHAR(10)	The name of the service program bound to PROGRAM_NAME.
BOUND_SERVICE_PROGRAM_SIGNATURE	SIGNATURE	BINARY(16)	The current signature of the service program at the time the service program was bound to PROGRAM_NAME.
BOUND_SERVICE_PROGRAM_ACTIVATION	SRVPGM_ACT	VARCHAR(6)	Specifies when the bound service program is activated. *DEFER The bound service program activation is deferred until a procedure it exports is called. *IMMED The bound service program activation happens when PROGRAM_NAME is activated.

Example

- Examine whether service programs in APPLIB are taking advantage of deferred service program activation.

```
SELECT BOUND_SERVICE_PROGRAM_ACTIVATION, COUNT(*) AS BOUND_SERVICE_PROGRAM_ACTIVATION_COUNT
FROM QSYS2.BOUND_SRVPGM_INFO
WHERE PROGRAM_LIBRARY = 'APPLIB'
GROUP BY BOUND_SERVICE_PROGRAM_ACTIVATION
ORDER BY 2 DESC;
```

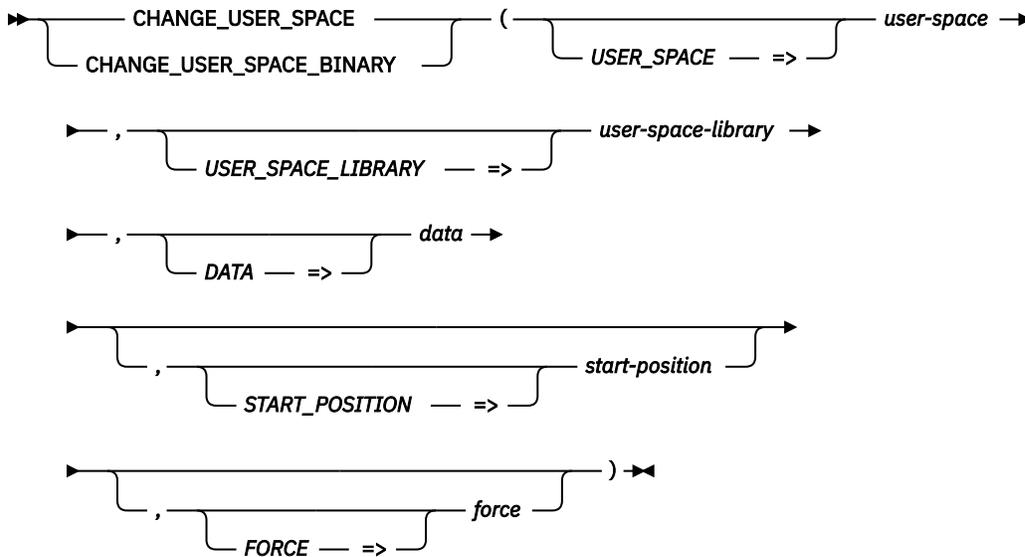

CHANGE_USER_SPACE and CHANGE_USER_SPACE_BINARY procedures

The CHANGE_USER_SPACE and CHANGE_USER_SPACE_BINARY procedures change the contents of a user space (*USRSPC) object by writing a specified amount of data to the object at a specified location. The data can be provided as either character or binary data.

The values used by the procedures are closely related to the values handled by the Change User Space (QUSCHGUS) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the user space, and
- *CHANGE authority to the user space.

The schema is QSYS2.

user-space A character string containing the name of the user space to be changed.

user-space-library A character string containing the name of the library containing the user space to be changed. Can be one of the following special values:

- ***CURLIB** The job's current library is used.
- ***LIBL** The library list is used.

data The data to be written to the user space. The string can be up to 16,773,120 bytes long.

- For CHANGE_USER_SPACE, the input value will be converted to a character string using the job CCSID.
- For CHANGE_USER_SPACE_BINARY, the input value will be considered a binary string.

start-position An integer value that indicates the position in the user space where *data* will be written. The first position in the user space is position 1. If this parameter is omitted, 1 will be used.

force A character string that indicates whether changes made to the user space should be forced to auxiliary storage.

ASYNCR Force changes asynchronously. This interrupts normal system management and ensures that the user space is written to auxiliary storage.

NO Do not force changes. Normal system management writes the changes to auxiliary storage. This is the default.

SYNC Force changes synchronously. This interrupts normal system management and ensures that the user space is written immediately to auxiliary storage.

Example

- Modify the content of user space USRSPC1 in APPLIB, placing the specified string starting at the 500th byte in the space.

```
CALL QSYS2.CHANGE_USER_SPACE(USER_SPACE => 'USRSPC1',
                             USER_SPACE_LIBRARY => 'APPLIB',
                             DATA => 'Overwrite with this new value',
                             START_POSITION => 500);
```

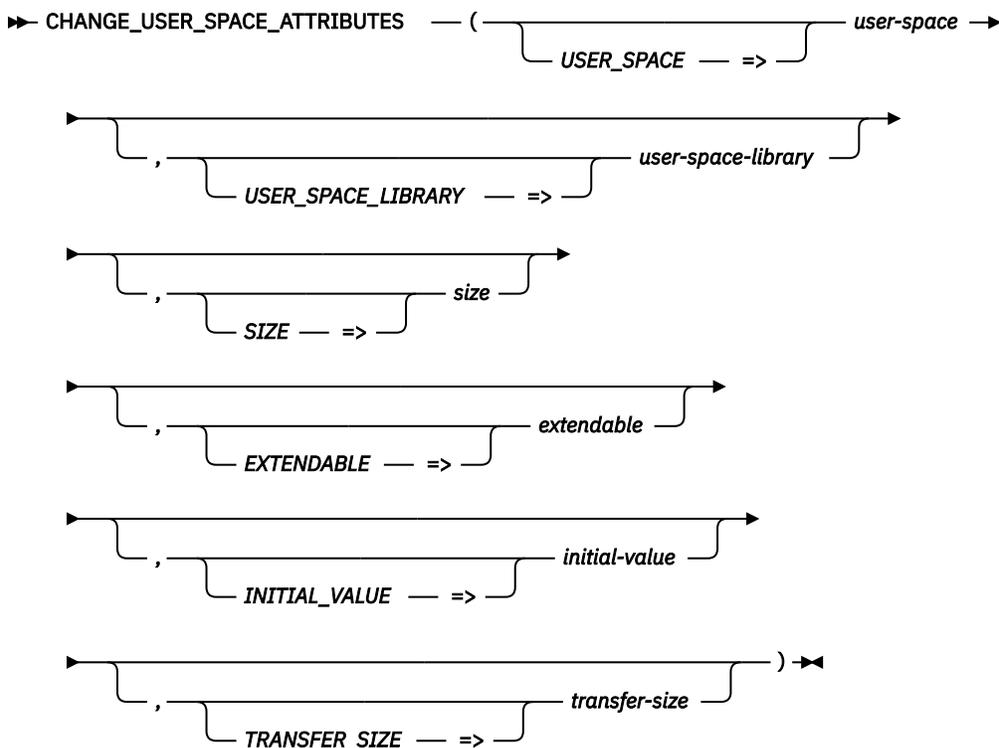

CHANGE_USER_SPACE_ATTRIBUTES procedure

The CHANGE_USER_SPACE_ATTRIBUTES procedure changes the attributes of a user space (*USRSPC) object.

The values used by the procedure are closely related to the values handled by the Change User Space Attributes (QUSCUSAT) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the user space, and
- *CHANGE and *OBJMGT authority to the user space.

The schema is QSYS2.

user-space A character string containing the name of the user space to be changed.

user-space-library A character string containing the name of the library containing the user space to be changed. Can be one of the following special values:

***CURLIB** The job's current library is used.

	*LIBL	The library list is used. This is the default.
size		An integer value specifying the size, in bytes, of the user space object. This value must be from 1 byte to 16,773,120 bytes. If the value is smaller than the current size of the space, the user space is truncated. If it is larger, the space is extended. If this parameter is omitted, the size is not changed.
extendable		An character string that indicates whether the user space can be automatically extended.
	NO	The user space is not automatically extendable.
	YES	The user space is automatically extendable.
		If this parameter is omitted, the automatic extend attribute is not changed.
initial-value		A one byte binary value containing the initial value to which future extensions of the user space will be set. The best performance is when this value indicates hexadecimal zeros (BX'00'). If this parameter is omitted, the initial value is not changed.
transfer-size		An integer value that indicates the number of pages to be transferred between main storage and auxiliary storage. This is only a request, as system processing can use a value of its choice in some circumstances. Allowable values are from 0 to 32 pages. A value of 0 indicates that the default transfer size for the user space should be used. A larger transfer size may allow for better performance of applications processing the user space. If this parameter is omitted, the transfer size is not changed.

Example

- Truncate user space USRSPC1 in APPLIB to a size of 200 bytes.

```
CALL QSYS2.CHANGE_USER_SPACE_ATTRIBUTES(USER_SPACE => 'USRSPC1',
                                         USER_SPACE_LIBRARY => 'APPLIB',
                                         SIZE => 200);
```

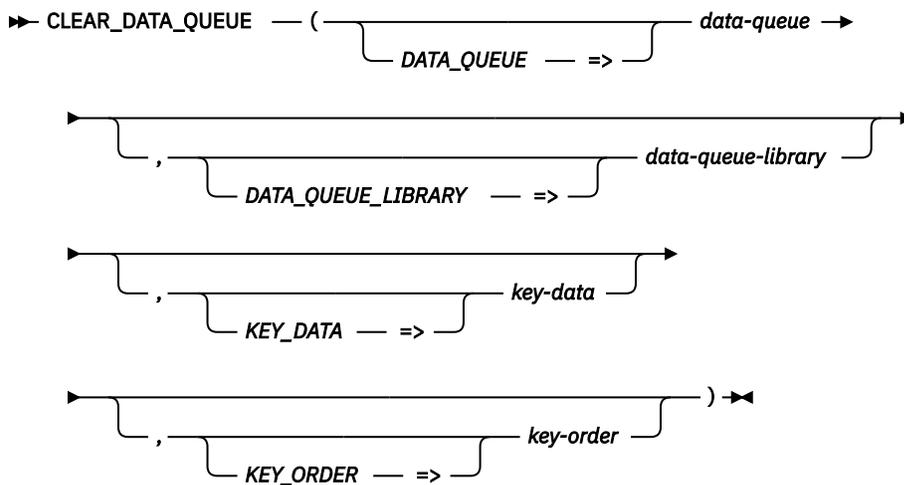

CLEAR_DATA_QUEUE procedure

The CLEAR_DATA_QUEUE procedure clears all messages from the specified data queue or clears messages that match the key provided.

This procedure provides function similar to the Clear Data Queue (QCLRDTAQ) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the data queue, and
- *OBJOPR and *READ authority to the data queue.

The schema is QSYS2.

data-queue A character or graphic string containing the name of the data queue.

data-queue-library A character or graphic string containing the name of the library containing the data queue. Can be one of the following special values:

- *CURLIB** The job's current library is used.
- *LIBL** The library list is used. This is the default.

key-data A character string containing the data to use as the key for selecting messages to be removed from the data queue. This parameter can only be specified for a keyed data queue. If this parameter is not specified, all messages will be cleared from the data queue.

The length of *key-data* must be the length specified on the KEYLEN parameter on the Create Data Queue (CRTDTAQ) command. The KEY_LENGTH column of the QSYS2.DATA_QUEUE_INFO view contains this value.

When this parameter is specified, *key-order* must also be specified.

key-order The comparison criteria between the keys of messages on the data queue and the *key-data* parameter. Valid values are:

- EQ** Equal
- GE** Greater than or equal
- GT** Greater than
- LE** Less than or equal
- LT** Less than
- NE** Not equal

This parameter is ignored if *key-data* is not specified.

Example

Clear all entries from data queue DQ1 in library TESTLIB.

```
CALL QSYS2.CLEAR_DATA_QUEUE('DQ1', 'TESTLIB');
```

COMMAND_INFO view

The COMMAND_INFO view returns information about all CL commands on the system.

The values returned for the result columns in the view are closely related to the values returned by the Display Command (DSPCMD) CL command and the Retrieve Command Information (QCRCMDI) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the command, and
- *USE authority to the command

The following table describes the columns in the view. The system name is CMD_INFO. The schema is QSYS2.

Table 88. COMMAND_INFO view

Column Name	System Column Name	Data Type	Description
COMMAND_LIBRARY	CMD_LIB	VARCHAR(10)	The name of the library in which the command resides.
COMMAND_NAME	CMD	VARCHAR(10)	The name of the command about which information is being returned.
PROXY_COMMAND	PROXY_CMD	VARCHAR(3)	Whether the command is a proxy command. NO This command is not a proxy command. YES This command is a proxy command.
PROXY_TARGET_COMMAND_LIBRARY	PRXTGT_LIB	VARCHAR(10) Nullable	The name of the library in which the proxy target command resides. Can contain the special value *LIBL. Contains the null value if PROXY_COMMAND is NO.
PROXY_TARGET_COMMAND	PRXTGT_CMD	VARCHAR(10) Nullable	The name of the proxy target command. This could be another proxy command. Contains the null value if PROXY_COMMAND is NO.
TEXT_DESCRIPTION	TEXT	VARCHAR(50) Nullable	The text description of the command. Contains the null value if there is no text description.
COMMAND_PROCESSING_PROGRAM_LIBRARY	CPP_LIB	VARCHAR(10) Nullable	The name of the library in which the command processing program resides. Can contain the special value *LIBL. Contains the null value if COMMAND_PROCESSING_PROGRAM contains the special value *REXX, or if PROXY_COMMAND is YES.
COMMAND_PROCESSING_PROGRAM	CPP_PGM	VARCHAR(10) Nullable	The name of the program that accepts parameters from the command and processes the command. Can contain the following special value: *REXX The command is processed by REXX. Contains the null value if PROXY_COMMAND is YES.
COMMAND_PROCESSING_PROGRAM_STATE	CPP_STATE	VARCHAR(7) Nullable	The state the command processing program is called from. *SYSTEM The command processing program is called from system state. *USER The command processing program is called from user state. Contains the null value if PROXY_COMMAND is YES.

Table 88. COMMAND_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SOURCE_FILE_LIBRARY	SRCLIB	VARCHAR(10) Nullable	The name of the library in which the source file resides. Contains the null value if a stream file was used to create the command, or if PROXY_COMMAND is YES.
SOURCE_FILE	SRCFILE	VARCHAR(10) Nullable	The name of the source file that contains the source file member used to create the command. Contains the null value if a stream file was used to create the command, or if PROXY_COMMAND is YES.
SOURCE_FILE_MEMBER	SRCMBR	VARCHAR(10) Nullable	The name of the source file member that contains the command definition statements used to create the command. Contains the null value if a stream file was used to create the command, or if PROXY_COMMAND is YES.
VALIDITY_CHECKING_PROGRAM_LIBRARY	VLD_LIB	VARCHAR(10) Nullable	The name of the library in which the validity checking program resides. Contains the null value if VALIDITY_CHECKING_PROGRAM contains the null value, or if PROXY_COMMAND is YES.
VALIDITY_CHECKING_PROGRAM	VLD_PGM	VARCHAR(10) Nullable	The name of a program that performs additional user-defined validity checking on the parameters in the command. Contains the null value if no validity checking program is defined, or if PROXY_COMMAND is YES.
VALIDITY_CHECKING_PROGRAM_STATE	VLD_STATE	VARCHAR(7) Nullable	The state the validity checking program is called from. *SYSTEM The validity checking program is called from the system state. *USER The validity checking program is called from the user state. Contains the null value if VALIDITY_CHECKING_PROGRAM contains the null value, or if PROXY_COMMAND is YES.
PROMPT_TEXT_MESSAGE_FILE_LIBRARY	PMT_LIB	VARCHAR(10) Nullable	The name of the library in which the prompt message file resides. Can contain the special value *LIBL. Contains the null value if PROMPT_TEXT_MESSAGE_FILE contains the null value, or if PROXY_COMMAND is YES.
PROMPT_TEXT_MESSAGE_FILE	PMT_MSGF	VARCHAR(10) Nullable	The name of the message file that contains the prompt text for this command. Contains the null value if no message file was specified for prompt text, or if PROXY_COMMAND is YES.

Table 88. COMMAND_INFO view (continued)

Column Name	System Column Name	Data Type	Description
RETRIEVE_PROMPT_MESSAGE	RTVPMTMSG	VARCHAR(8) Nullable	<p>Whether text messages used by the command are retrieved from the prompt message file when the command is prompted.</p> <p>*DYNAMIC When the command is prompted, the prompt text will be dynamically retrieved from PROMPT_TEXT_MESSAGE_FILE.</p> <p>*STATIC When the command is prompted, the prompt text will be retrieved from the static copies of the messages stored in the *CMD object when the command was created.</p> <p>Contains the null value if no message file was specified for prompt text, or if PROXY_COMMAND is YES.</p>
PROMPT_OVERRIDE_PROGRAM_LIBRARY	PMTOVR_LIB	VARCHAR(10) Nullable	<p>The name of the library in which the prompt override program resides.</p> <p>Contains the null value if PROMPT_OVERRIDE_PROGRAM contains the null value, or if PROXY_COMMAND is YES.</p>
PROMPT_OVERRIDE_PROGRAM	PMTOVR_PGM	VARCHAR(10) Nullable	<p>The name of the prompt override program that replaces default values (on the prompt display) with the current actual values for the parameter.</p> <p>Contains the null value if no prompt override program is specified, or if PROXY_COMMAND is YES.</p>
PROMPT_OVERRIDE_PROGRAM_STATE	PMTOVR_ST	VARCHAR(7) Nullable	<p>The state the prompt override program is called from.</p> <p>*SYSTEM The prompt override program is called from the system state.</p> <p>*USER The prompt override program is called from the user state.</p> <p>Contains the null value if PROMPT_OVERRIDE_PROGRAM contains the null value, or if PROXY_COMMAND is YES.</p>
MESSAGE_FILE_LIBRARY	MSGF_LIB	VARCHAR(10) Nullable	<p>The name of the library in which the message file resides. Can contain the special value *LIBL.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>
MESSAGE_FILE	MSGF	VARCHAR(10) Nullable	<p>The name of the message file from which messages identified on the Dependency (DEP) command definition statements are retrieved.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>
HELP_PANEL_GROUP_LIBRARY	PNLGRP_LIB	VARCHAR(10) Nullable	<p>The name of the library in which the panel group resides. Can contain the special value *LIBL.</p> <p>Contains the null value if HELP_PANEL_GROUP contains the null value, or if PROXY_COMMAND is YES.</p>
HELP_PANEL_GROUP	PNLGRP	VARCHAR(10) Nullable	<p>The name of the panel group in which the online help information exists for this command.</p> <p>Contains the null value if no help panel group is defined for this command, or if PROXY_COMMAND is YES.</p>
HELP_IDENTIFIER	HELP_ID	VARCHAR(10) Nullable	<p>The root name for all help section identifiers for this command. All help sections in the help panel group associated with this command will begin with this name.</p> <p>Contains the null value if no help identifier is specified, or if PROXY_COMMAND is YES.</p>

Table 88. COMMAND_INFO view (continued)

Column Name	System Column Name	Data Type	Description
HELP_SEARCH_INDEX_LIBRARY	HELP_LIB	VARCHAR(10) Nullable	The name of the library in which the help search index resides. Can contain the special value *LIBL. Contains the null value if HELP_SEARCH_INDEX is null, or if PROXY_COMMAND is YES.
HELP_SEARCH_INDEX	HELP_INDEX	VARCHAR(10) Nullable	The name of the help search index for this command. Contains the null value if no help search index is specified, or if PROXY_COMMAND is YES.
CURRENT_LIBRARY_NAME	CURLIB	VARCHAR(10) Nullable	The name of the library used as the current library during the processing of this command. Can contain the following special values: *CRTDFT No current library is active during processing of the command. *NOCHG The current library does not change for the processing of this command. Contains the null value if PROXY_COMMAND is YES.
PRODUCT_LIBRARY_NAME	PRODLIB	VARCHAR(10) Nullable	The name of the library that is used as the product library during the processing of the command. Can contain the following special value: *NOCHG The product library does not change for the processing of this command. Contains the null value if there is no product library used during the processing of the command, or if PROXY_COMMAND is YES.
MAXIMUM_POSITIONAL_PARAMETERS	MAXPOS	INTEGER Nullable	The maximum number of parameters that can be coded in a positional manner for this command. Contains the null value if no maximum positional coding limit was specified for the command, or if PROXY_COMMAND is YES.
ALLOW_LIMITED_USER	ALWLMTUSR	VARCHAR(3) Nullable	Whether a user whose profile is set for limited capabilities is allowed to use the command by typing it in the command line on a menu. NO This command cannot be entered in the command line on a menu by a user whose profile is set for limited capabilities. YES This command can be entered in the command line on a menu by a user whose profile is set for limited capabilities. Contains the null value if PROXY_COMMAND is YES.
DEBUG_MODE	DEBUG_MODE	VARCHAR(3) Nullable	Whether the command is valid for debug mode operations. NO The command is not valid for debug mode operations. YES The command is valid for debug mode operations. Contains the null value if PROXY_COMMAND is YES.

Table 88. COMMAND_INFO view (continued)

Column Name	System Column Name	Data Type	Description
PRODUCTION_MODE	PROD_MODE	VARCHAR(3) Nullable	<p>Whether the command is valid for production mode operations.</p> <p>NO The command is not valid for production mode operations.</p> <p>YES The command is valid for production mode operations.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>
SERVICE_MODE	SVC_MODE	VARCHAR(3) Nullable	<p>Whether the command is valid for service mode operations.</p> <p>NO The command is not valid for service mode operations.</p> <p>YES The command is valid for service mode operations.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>
ALLOW_RUN_INTERACTIVE	ALLOWINTER	VARCHAR(3) Nullable	<p>Whether the command can be processed interactively, external to a CL program.</p> <p>NO The command is not allowed to run in an interactive job.</p> <p>YES The command is allowed to run in an interactive job.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>
ALLOW_RUN_BATCH	ALLOWBATCH	VARCHAR(3) Nullable	<p>Whether the command can be processed in a batch input stream, external to a CL program.</p> <p>NO The command is not allowed to run in a batch job.</p> <p>YES The command is allowed to run in a batch job.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>
ALLOW_RUN_EXEC	ALLOWEXEC	VARCHAR(3) Nullable	<p>Whether the command can be used as a parameter on the CALL command and be passed as a character string to the system API programs QCMDEXC, QCAEXEC, and QCAPCMD for processing.</p> <p>NO The command is not allowed to run by using QCMDEXC, QCAEXEC, or QCAPCMD API programs.</p> <p>YES The command is allowed to run by using QCMDEXC, QCAEXEC, or QCAPCMD API programs.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>
ALLOW_RUN_BATCH_ENTRY	ALLOWBPGM	VARCHAR(3) Nullable	<p>Whether the command can be processed in a CL program that is called from batch entry.</p> <p>NO The command is not allowed to run in a batch program.</p> <p>YES The command is allowed to run in a batch program.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>

Table 88. COMMAND_INFO view (continued)

Column Name	System Column Name	Data Type	Description
ALLOW_RUN_INTERACTIVE_ENTRY	ALLOWIPGM	VARCHAR(3) Nullable	<p>Whether the command can be processed in a CL program that is called from interactive entry.</p> <p>NO The command is not allowed to run in an interactive program.</p> <p>YES The command is allowed to run in an interactive program.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>
ALLOW_RUN_BATCH_PGM	ALLOWBMOD	VARCHAR(3) Nullable	<p>Whether the command can be used in a batch ILE CL program.</p> <p>NO The command is not allowed to run in a batch ILE CL program.</p> <p>YES The command is allowed to run in a batch ILE CL program.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>
ALLOW_RUN_INTERACTIVE_PGM	ALLOWIMOD	VARCHAR(3) Nullable	<p>Whether the command can be used in an interactive ILE CL program.</p> <p>NO The command is not allowed to run in an interactive ILE CL program.</p> <p>YES The command is allowed to run in an interactive ILE CL program.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>
ALLOW_RUN_BATCH_REXX	ALLOWBREXX	VARCHAR(3) Nullable	<p>Whether the command can be used in a REXX procedure run in a batch job.</p> <p>NO The command is not allowed to run in a batch REXX job.</p> <p>YES The command is allowed to run in a batch REXX job.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>
ALLOW_RUN_INTERACTIVE_REXX	ALLOWIREXX	VARCHAR(3) Nullable	<p>Whether the command can be used in a REXX procedure run in an interactive job.</p> <p>NO The command is not allowed to run in an interactive REXX job.</p> <p>YES The command is allowed to run in an interactive REXX job.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>
CCSID	CCSID	INTEGER Nullable	<p>The value of the coded character set identifier (CCSID) associated with this command. It is the value of the job CCSID when this command was created.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>

Table 88. COMMAND_INFO view (continued)

Column Name	System Column Name	Data Type	Description
GUI_ENABLED	GUI_ENB	VARCHAR(3) Nullable	<p>Whether the command prompt panels are enabled for conversion to a graphical user interface.</p> <p>NO The command prompt panels are not enabled for conversion to a graphical user interface.</p> <p>YES The command prompt panels are enabled for conversion to a graphical user interface by including information about the panel content in the 5250 data stream.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>
THREADSAFE	THREADSAFE	VARCHAR(5) Nullable	<p>Whether the command can be used safely in a multithreaded job.</p> <p>*COND The command is threadsafe under certain conditions.</p> <p>*NO The command is not threadsafe and should not be used in a multithreaded job.</p> <p>*YES The command is threadsafe and can be used safely in a multithreaded job.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>
MULTITHREADED_JOB_ACTION	JOB_ACTION	VARCHAR(7) Nullable	<p>The action to take in a multithreaded job for this command.</p> <p>*MSG Send an informational message and run the command.</p> <p>*NORUN Send an escape message, and do not run the command.</p> <p>*RUN Run the command. Do not send a message.</p> <p>*SYSVAL Use the action specified in QMLTTHDACN system value.</p> <p>Contains the null value if PROXY_COMMAND is YES.</p>
TARGET_RELEASE	TGTRLS	CHAR(6) Nullable	<p>The version, release, and modification level to which this command is restricted in VxRxMx format. This applies only to a command used in a CL program. It must match the contents of the target release parameter on the Create CL Program (CRTCLPGM) command.</p> <p>Contains the null value if the current release is used, or if PROXY_COMMAND is YES.</p>

Example

- List all the proxy commands in QSYS.

```
SELECT *
  FROM QSYS2.COMMAND_INFO
 WHERE COMMAND_LIBRARY = 'QSYS'
    AND PROXY_COMMAND = 'YES';
```

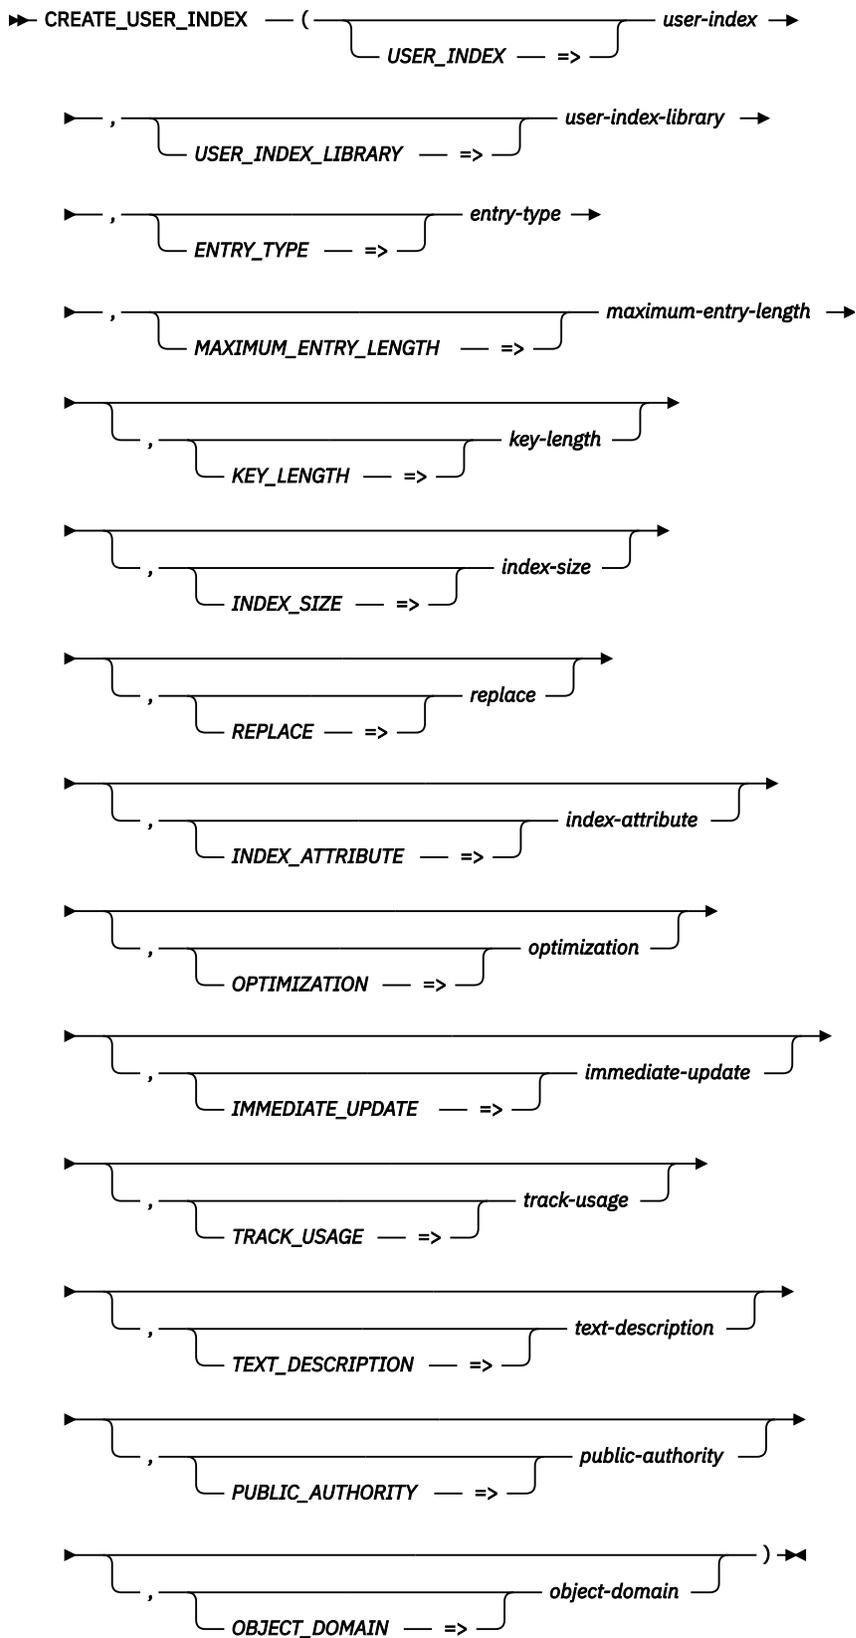

CREATE_USER_INDEX procedure

The CREATE_USER_INDEX procedure creates or replaces a user index (*USRIDX) object.

The values used by the procedure are closely related to the values handled by the Create User Index (QUSCRTUI) API.

Authorization: The caller must have:

- *READ and *ADD authority to the library where the user index is being created.
- If a user index is being replaced, the caller must have *OBJMGT, *OBJEXIST, and *READ authorities to the existing user index.

The schema is QSYS2.

user-index A character string containing the name of the user index to be created.

<i>user-index-library</i>	<p>A character string containing the name of the library where the user index is to be created. Can be the following special value:</p> <p>*CURLIB The current library is used.</p>
<i>entry-type</i>	<p>A character string that indicates the type of entries for the user index.</p> <p>FIXED Fixed-length entries.</p> <p>VARIABLE Variable-length entries.</p>
<i>maximum-entry-length</i>	<p>An integer value that specifies the length of entries in the user index. When <i>entry-type</i> is FIXED, valid values are 1 to 2000. When <i>entry-type</i> is VARIABLE, this parameter is ignored and the value 2000 is used.</p>
<i>key-length</i>	<p>An integer value that specifies the length of the key to be used for any insertions into the user index.</p> <p>To define a non-keyed index, the value must be 0. This is the default.</p> <p>To define a keyed index, the value can be 1 to <i>maximum-entry-length</i>.</p>
<i>index-size</i>	<p>A character string that indicates the maximum size of the user index.</p> <p>4 GB The maximum size of the user index is 4 gigabytes. This is the default.</p> <p>1 TB The maximum size of the user index is 1 terabyte.</p>
<i>replace</i>	<p>A character string that indicates whether an existing user index by this name is to be replaced.</p> <p>NO Do not replace an existing user index of the same name and library. This is the default.</p> <p>YES Replace an existing user index of the same name and library. If the user index already exists, it is replaced by a new user index with the same name and library and keeps the original object's authorities.</p>
<i>index-attribute</i>	<p>A character string that specifies the user-provided object attribute to assign to the user index. It can be up to ten characters long. The string will be folded to uppercase.</p>
<i>optimization</i>	<p>The optimization method used for user index maintenance.</p> <p>RANDOM Optimize for random references. This is the default.</p> <p>SEQUENTIAL Optimize for sequential references.</p>
<i>immediate-update</i>	<p>Whether the updates to the index are written to auxiliary storage on each update to the index.</p> <p>NO No immediate update. This is the default.</p> <p>YES Immediate update.</p>
<i>track-usage</i>	<p>The usage tracking setting for the user index. Usage tracking provides machine checkpoints to improve recognition that the index is bad. If a user index is found to be a state of partial change, it will be marked as damaged.</p> <p>NO Do not track usage. This is the default.</p> <p>YES Track usage.</p>
<i>text-description</i>	<p>A character string that describes the user index. It can be up to 50 characters long.</p>

public- authority

The authority given to a newly created user index for users who do not have a specific private or group authority to the user index. This option is ignored if *replace* has a value of YES and an existing user index is replaced.

- *ALL** The public authority allows users to perform all operations on the user index.
- authorization-list-name** The user index is secured by the specified authorization list, and its public authority is set to *AUTL.
- *CHANGE** The public authority provides users read, add, update, and delete authority for the user index and they can read the object description.
- *EXCLUDE** The public authority prevents users from accessing the user index in any way.
- *LIBCRTAUT** The public authority is taken from the CRTAUT value for the library when the object is created. This is the default.
- *USE** The public authority allows users to read the object description and contents but they cannot change the user index.

object-domain The domain into which the user space is created. Refer to the API documentation for more details.

- *DEFAULT** The system decides into which domain the object should be created. This is the default.
- *SYSTEM** Create the user index object into the system domain.
- *USER** Attempt to create the user index object into the user domain.
If the library you are creating the user index into does not appear in the QALWUSRDMN system value, the user index cannot be created into the user domain.

Example

- Create user space USRIX1 in APPLIB to contain variable-length entries. The key is 5 characters long. Assign *EXCLUDE public authority to the *USRIDX object.

```
CALL QSYS2.CREATE_USER_INDEX(USER_INDEX => 'USRIX1',  
                             USER_INDEX_LIBRARY => 'APPLIB',  
                             ENTRY_TYPE => 'VARIABLE',  
                             KEY_LENGTH => 5,  
                             PUBLIC_AUTHORITY => '*EXCLUDE');
```

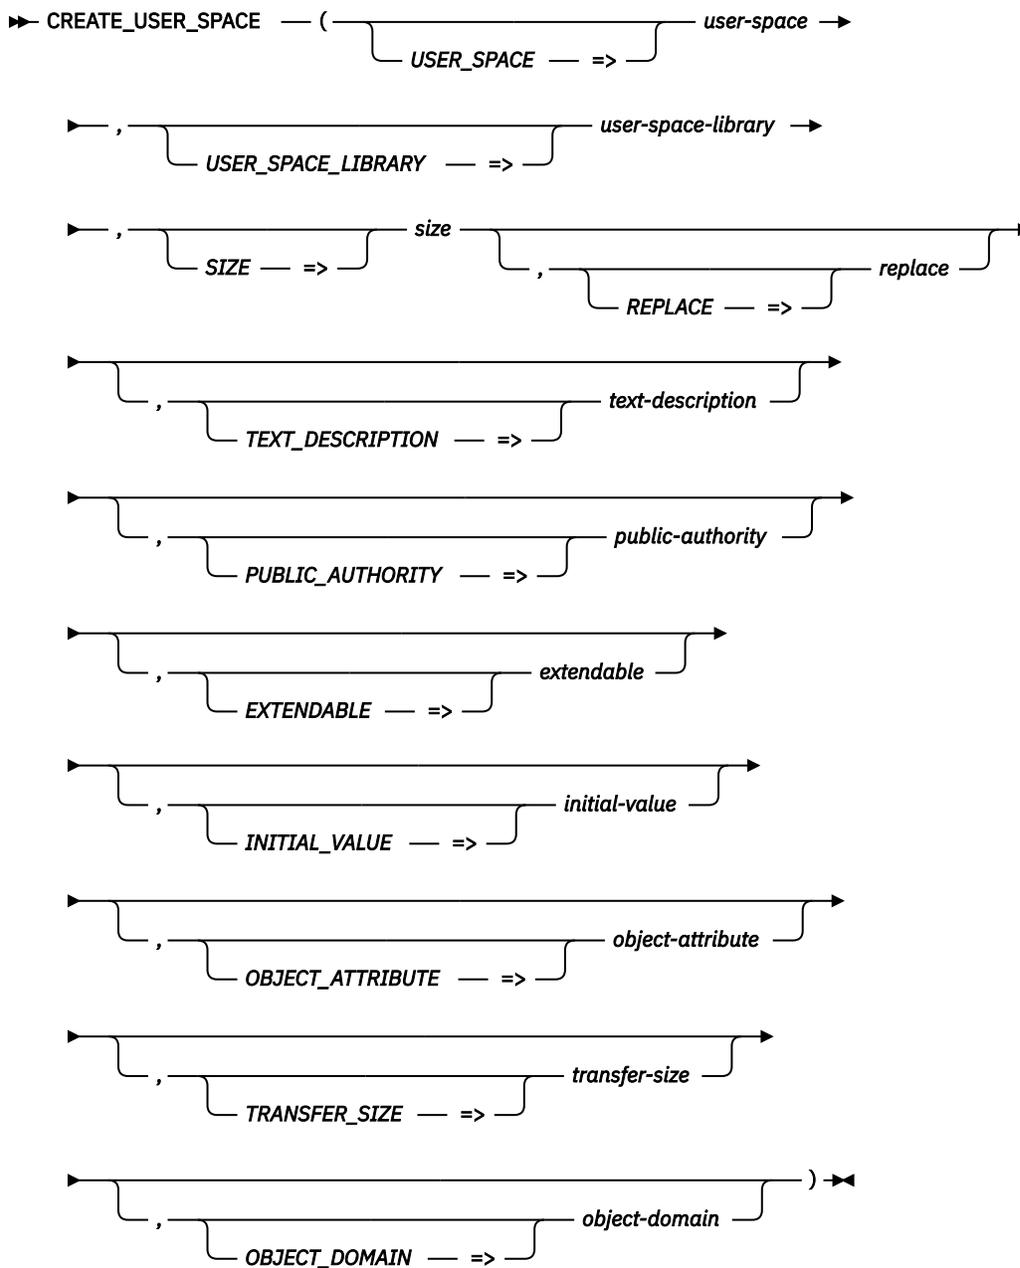

CREATE_USER_SPACE procedure

The CREATE_USER_SPACE procedure creates or replaces a user space (*USRSPC) object.

The values used by the procedure are closely related to the values handled by the Create User Space (QUSCRTUS) API.

Authorization: The caller must have:

- *READ and *ADD authority to the library where the user space is being created.
- If a user space is being replaced, the caller must have *OBJMGT, *OBJEXIST, and *READ authorities to the existing user space.

The schema is QSYS2.

- user-space** A character string containing the name of the user space to be created.
- user-space-library** A character string containing the name of the library where the user space is to be created. Can be the following special value:
 - *CURLIB** The job's current library is used.
- size** The initial size of the user space being created. This value must be from 1 byte to 16,773,120 bytes.
 - The size of the user space that is created could be larger than the specified value.
- replace** A character string that indicates whether an existing user space by this name is to be replaced.

- NO** Do not replace an existing user space of the same name and library. This is the default.
- YES** Replace an existing user space of the same name and library.
If the user space already exists, it is replaced by a new user space with the same name and library and keeps the original object's authorities.

**text-
description**

A character string that describes the user space. It can be up to 50 characters long.

**public-
authority**

The authority given to a newly created user space for users who do not have a specific private or group authority to the user space. This option is ignored if *replace* has a value of YES and an existing user space is replaced.

- *ALL** The public authority allows users to perform all operations on the user space.
- authorization-list-name** The user space is secured by the specified authorization list, and its public authority is set to *AUTL.
- *CHANGE** The public authority allows users to read the object description and provides read, add, update, and delete authority to the user space.
- *EXCLUDE** The public authority prevents users from accessing the user space in any way.
- *LIBCRTAUT** The public authority is taken from the CRTAUT value for the library when the object is created. This is the default.
- *USE** The public authority allows users to read the user space.

extendable

A character string that indicates whether the user space can be automatically extended.

- NO** The user space is not automatically extendable. The user space maximum size matches the initial size.
- YES** The user space is automatically extendable. The size of the user space automatically grows as data is written beyond its current size. This is the default.

initial-value

The initial value of all bytes in the user space as a binary value. A value of BX'00' will achieve the best performance. This is the default.

**object-
attribute**

A character string that specifies the user-provided object attribute to assign to the user space. It can be up to ten characters long. The string will be folded to uppercase.

transfer-size

An integer value that indicates the number of pages to be transferred between main storage and auxiliary storage. This is only a request, as system processing can use a value of its choice in some circumstances. Allowable values are from 0 to 32 pages. A value of 0 indicates that the default transfer size for the user space should be used. The default is 0.

A larger transfer size may allow for better performance of applications processing the user space.

**object-
domain**

The domain into which the user space is created.

- *DEFAULT** The system decides into which domain the object should be created. This is the default.
- *SYSTEM** Create the user space object into the system domain.
- *USER** Attempt to create the user space object into the user domain.

If the library you are creating the user space into does not appear in the QALWUSRDMN system value, the user space cannot be created into the user domain.

Example

- Create user space USRSPC1 in APPLIB with an initial size of 1000 bytes. Assign *EXCLUDE public authority to the *USRSPC object.

```
CALL QSYS2.CREATE_USER_SPACE(USER_SPACE => 'USRSPC1',
                             USER_SPACE_LIBRARY => 'APPLIB',
                             SIZE => 1000,
                             PUBLIC_AUTHORITY => '*EXCLUDE');
```

DATA_AREA_INFO table function

The DATA_AREA_INFO table function returns a row for the specified data area, including a data area in QTEMP or the *LDA, *PDA, or *GDA data areas.

The values returned are closely related to the values returned by the Retrieve Data Area (RTVDTAARA) CL command and the Retrieve Data Area (QWCRDTAA) API.

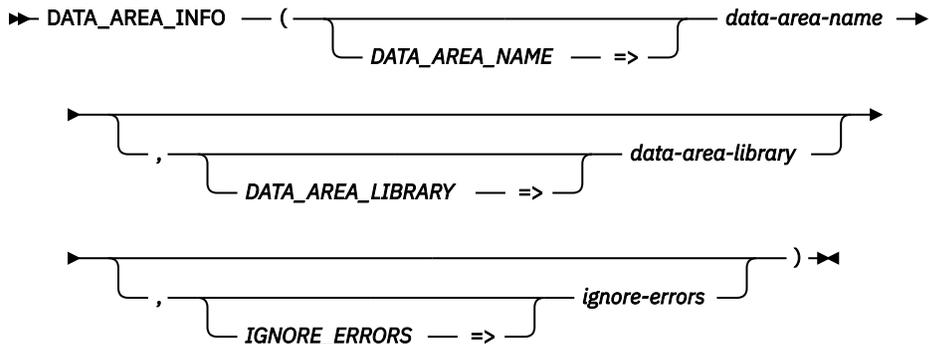

Authorization: The caller must have:

- *EXECUTE authority to the library containing the data area, and
- *USE authority to the data area.

For a DDM data area, the caller must be able to connect to the remote system.

To return information for the data area on the remote system, the caller must have:

- *EXECUTE authority to the library containing the data area, and
- *USE authority to the data area.

The schema is QSYS2.

data-area-name A character or graphic string expression that identifies the data area. Can contain the following special values:

- *GDA** Group data area.
- *LDA** Local data area.
- *PDA** Program initialization parameter data area.

data-area-library A character or graphic string expression that identifies the library containing the data area. If *data-area-library* is not specified, *LIBL is used. If *data-area-name* is one of the special values, *data-area-library* is ignored.

Can contain the following special values:

- *CURLIB** The current library is used.
- *LIBL** The library list is used.

ignore-errors

A character or graphic string expression that identifies what to do when an error is encountered.

NO An error is returned. This is the default.

YES A warning is returned.

A partial row is returned when an error is encountered. Columns other than the data area name (and the library name if explicitly specified as an input parameter) will be null.

The result of the function is a table containing one row with the format shown in the following table. All the columns are nullable.

Table 89. DATA_AREA_INFO table function

Column Name	Data Type	Description
DATA_AREA_LIBRARY	VARCHAR(10)	Library containing the data area. Contains the null value if this request is for *GDA, *LDA, or *PDA.
DATA_AREA_NAME	VARCHAR(10)	Name of the data area.
DATA_AREA_TYPE	VARCHAR(5)	The type of data area. <ul style="list-style-type: none"> *CHAR A character data area. *DEC A decimal data area. *LGL A logical data area.
LENGTH	INTEGER	Specifies the length of the data area. <ul style="list-style-type: none"> • For a character data area, it is the maximum number of characters. • For a decimal data area it is the total number of digits, including decimal positions. • For a logical data area, it is always 1.
DECIMAL_POSITIONS	INTEGER	Specifies the number of digits to the right of the decimal point for a decimal data area. Contains the null value if not a decimal data area.
DATA_AREA_VALUE	VARCHAR(2000)	The value currently assigned to the data area. For a decimal data area, the SQL default decimal point is used. See Decimal point .
DATA_AREA_BINARY_VALUE	VARBINARY(2000)	The value currently assigned to the data area as binary data.

Example

- Return the current value of the TESTDATA data area. Use the library list to locate the data area.

```
SELECT DATA_AREA_VALUE FROM TABLE(QSYS2.DATA_AREA_INFO(
    DATA_AREA_NAME => 'TESTDATA',
    DATA_AREA_LIBRARY => '*LIBL'));
```

DATA_AREA_INFO view

The DATA_AREA_INFO view returns the values of data areas.

The values returned for the columns in the view are closely related to the values returned by the Retrieve Data Area (RTVDTAARA) CL command and the Retrieve Data Area (QWCRDTAA) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the data area, and
- *USE authority to the data area.

For a DDM data area, the caller must be able to connect to the remote system.

To return information for the data area on the remote system, the caller must have:

- *EXECUTE authority to the library containing the data area, and
- *USE authority to the data area.

The following table describes the columns in the view. The system name is DTAARA_INF. The schema is QSYS2.

Table 90. DATA_AREA_INFO view

Column Name	System Column Name	Data Type	Description
DATA_AREA_LIBRARY	DTAARA_LIB	VARCHAR(10)	Library containing the data area.
DATA_AREA_NAME	DTAARA	VARCHAR(10)	Name of the data area.
DATA_AREA_TYPE	TYPE	VARCHAR(5) Nullable	The type of data area. *CHAR A character data area. *DEC A decimal data area. *LGL A logical data area. Contains the null value if this is a DDM data area that was unable to access the data.
LENGTH	LENGTH	INTEGER Nullable	Specifies the length of the data area. <ul style="list-style-type: none"> • For a character data area, it is the maximum number of characters. • For a numeric data area it is the total number of digits, including decimal positions. • For a logical data area, it is always 1. Contains the null value if this is a DDM data area that was unable to access the data.
DECIMAL_POSITIONS	SCALE	INTEGER Nullable	Specifies the number of digits to the right of the decimal point for a decimal data area. Contains the null value if not a decimal data area or if this is a DDM data area that was unable to access the data.
DATA_AREA_VALUE	VALUE	VARCHAR(2000) Nullable	The value currently assigned to the data area as character data. For a decimal data area, the SQL default decimal point is used. See Decimal point . Contains the null value if this is a DDM data area that was unable to access the data.
DATA_AREA_BINARY_VALUE	BIN_VALUE	VARBINARY(2000) Nullable	The value currently assigned to the data area as binary data. Contains the null value if this is a DDM data area that was unable to access the data.
SQL_SEQUENCE	SEQUENCE	VARCHAR(3)	This data area is defined as an SQL sequence. NO This is not an SQL sequence. YES This is an SQL sequence.
TEXT_DESCRIPTION	TEXT	VARCHAR(50) Nullable	The text description of the data area. Contains the null value if the data area has no description or if this is a DDM data area.

Example

- Return a list of values for all data areas in MYLIB.

```
SELECT DATA_AREA_NAME, DATA_AREA_VALUE FROM QSYS2.DATA_AREA_INFO
WHERE DATA_AREA_LIBRARY = 'MYLIB';
```

DATA_QUEUE_ENTRIES table function

The DATA_QUEUE_ENTRIES table function returns one or more messages from the specified data queue. The messages are not removed from the data queue. The message data is returned as character, UTF-8, and binary data.

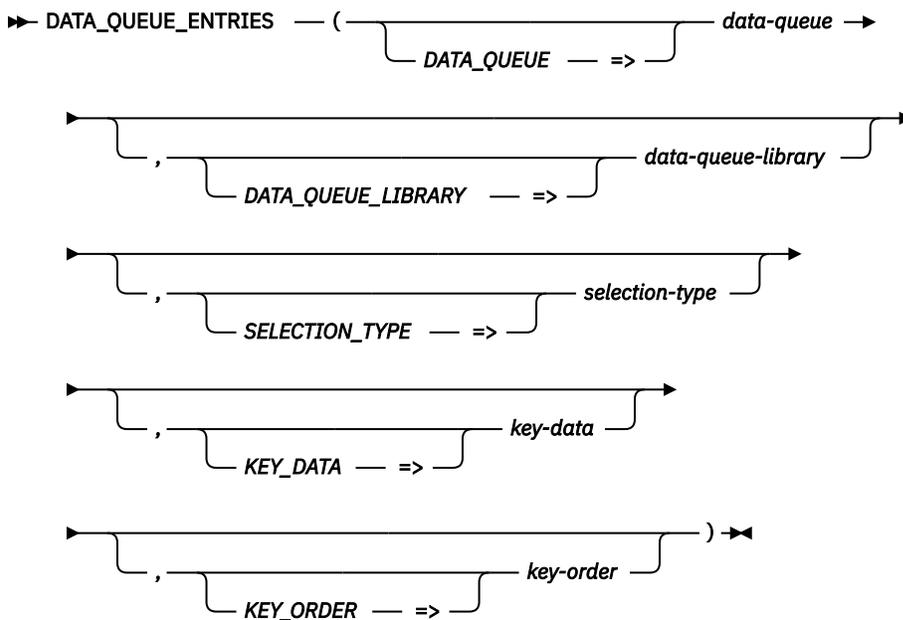

Distributed data management (DDM) data queues are not supported.

The MESSAGE_DATA, MESSAGE_DATA_UTF8, and MESSAGE_DATA_BINARY columns contain identical values. It is up to the user to determine which data type is most appropriate for working with the result data.

The values returned for the result columns of the table function are closely related to the values returned by the Retrieve Data Queue Message (QMHRDQM) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the data queue, and
- *OBJOPR and *READ authority to the data queue.

The schema is QSYS2.

data-queue A character or graphic string containing the name of the data queue.

data-queue-library A character or graphic string containing the name of the library containing the data queue. Can be one of the following special values:

- *CURLIB** The job's current library is used.
- *LIBL** The library list is used. This is the default.

selection-type A character string indicating how the messages are to be returned. If this parameter is omitted, ALL is used.

- ALL** All messages are to be returned in the order based on the type of data queue. FIFO queues are returned in FIFO order, LIFO queues are returned in LIFO order, and keyed queues are returned in ascending key order.

- FIRST** The first message is to be returned. This option is not allowed for a keyed data queue.
- KEY** Messages meeting the key criteria are to be returned. This option is only valid for a keyed data queue.
When this value is specified, *key-data* and *key-order* must also be specified.
- LAST** The last message is to be returned. This option is not allowed for a keyed data queue.
- REVERSE** All messages are to be returned in reverse order of the type of data queue. For example, LIFO queues are returned in FIFO order. This option is not allowed for a keyed data queue.

key-data A character string containing the data to use as the key for receiving a message from the data queue. This parameter is required for a keyed data queue. It must not be specified for a non-keyed data queue.

The length of *key-data* must be the length specified on the KEYLEN parameter on the Create Data Queue (CRTDTAQ) command. The KEY_LENGTH column of the QSYS2.DATA_QUEUE_INFO view contains this value.

When this parameter is specified, *key-order* must also be specified.

key-order The comparison criteria between the keys of messages on the data queue and the *key-data* parameter. Valid values are:

- EQ** All messages with a key equal to *key-data* are to be returned.
- GE** All messages with a key greater than or equal to *key-data* are to be returned.
- GT** All messages with a key greater than *key-data* are to be returned.
- LE** All messages with a key less than or equal to *key-data* are to be returned.
- LT** All messages with a key less than *key-data* are to be returned.
- NE** All messages with a key not equal to *key-data* are to be returned.

This parameter is ignored if *key-data* is not specified.

The result of the function is a table containing one or more rows with the format shown in the following table. If no messages are selected, no rows are returned. All the columns are nullable.

Table 91. DATA_QUEUE_ENTRIES table function

Column Name	Data Type	Description
ORDINAL_POSITION	INTEGER	The relative position of this row in the result data set.
DATA_QUEUE_LIBRARY	VARCHAR(10)	The library in which the data queue was found.
DATA_QUEUE	VARCHAR(10)	The name of the data queue.
MESSAGE_DATA	CLOB(64512)	The message received from the data queue as character data.
MESSAGE_DATA_UTF8	CLOB(64512) CCSID 1208	The message received from the data queue represented as character data in CCSID 1208.
MESSAGE_DATA_BINARY	BLOB(64512)	The message received from the data queue in binary form. This is the raw form of the data.
KEY_DATA	VARCHAR(256)	For a keyed data queue, the key value of the returned message. This is the actual key value, which could be different than the <i>key-data</i> parameter value. Contains the null value if this is not a keyed data queue.
MESSAGE_ENQUEUE_TIMESTAMP	TIMESTAMP(0)	The date and time that the message was placed on the data queue.
SENDER_JOB_NAME	VARCHAR(28)	The qualified job name of the sender. Contains the null value if no sender information is available for the message.

Table 91. DATA_QUEUE_ENTRIES table function (continued)

Column Name	Data Type	Description
SENDER_CURRENT_USER	VARCHAR(10)	The current user profile of the sender. Contains the null value if no sender information is available for the message.

Example

Look at all the messages in data queue DQ1 in TESTLIB.

```
SELECT * FROM TABLE(QSYS2.DATA_QUEUE_ENTRIES(
                                DATA_QUEUE => 'DQ1',
                                DATA_QUEUE_LIBRARY => 'TESTLIB'))
ORDER BY ORDINAL_POSITION;
```

DATA_QUEUE_INFO view

The DATA_QUEUE_INFO view returns a row for every data queue.

The information returned is similar to the information available through the Retrieve Data Queue Description (QMHQRDQD) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the data queue, and
- *OBJOPR and *READ authority to the data queue.

The following table describes the columns in the view. The system name is DTAQ_INFO. The schema is QSYS2.

Table 92. DATA_QUEUE_INFO view

Column name	System column name	Data type	Description
DATA_QUEUE_LIBRARY	DTAQ_LIB	VARCHAR(10)	Library containing the data queue.
DATA_QUEUE_NAME	DTAQ	VARCHAR(10)	Name of the data queue.
DATA_QUEUE_TYPE	DTAQ_TYPE	VARCHAR(8)	This will be set to one of the following values: DDM The data queue is a DDM data queue. DISPLAY The data queue is a display data queue. STANDARD The data queue is a standard data queue.
MAXIMUM_MESSAGE_LENGTH	MSG_LENGTH	INTEGER Nullable	The maximum length allowed for messages. This is the value that was specified with the MAXLEN keyword on the CRTDTAQ command. Contains the null value for a DDM data queue.
SEQUENCE	SEQUENCE	VARCHAR(5) Nullable	The sequence in which messages can be removed from the queue. FIFO First-in first-out KEYED Keyed LIFO Last-in first-out Contains the null value for a DDM data queue.
KEY_LENGTH	KEY_LENGTH	INTEGER Nullable	The length of the message reference key for a keyed data queue, in bytes. Values are from 1 to 256. Contains the null value if this is not a keyed queue or is a DDM data queue.

Table 92. DATA_QUEUE_INFO view (continued)

Column name	System column name	Data type	Description
INCLUDE_SENDER_ID	SENDER_ID	VARCHAR(3) Nullable	Indicates if the queue was created to include the sender ID with sent messages. NO The sender ID is not included when data is sent to the data queue. YES The sender ID is included when data is sent to the data queue. Contains the null value for a DDM data queue.
CURRENT_MESSAGES	CUR_MSGS	INTEGER Nullable	The number of messages currently on the data queue. Contains the null value for a DDM data queue.
MAXIMUM_MESSAGES	MAX_MSGS	INTEGER Nullable	The maximum number of messages that will fit into the data queue. Contains the null value for a DDM data queue.
SPECIFIED_MAXIMUM_MESSAGES	SPEC_MAX	INTEGER Nullable	The maximum number of messages that was specified on the SIZE keyword of the CRTDTAQ command. Can contain the following special values: -1 *MAX16MB was specified for the data queue size. -2 *MAX2GB was specified for the data queue size. Contains the null value for a DDM data queue.
INITIAL_MESSAGE_ALLOCATION	INIT_ALOC	INTEGER Nullable	The number of messages that will fit into the storage allocated for the data queue when it is created or when it is automatically reclaimed. Contains the null value for a DDM data queue.
CURRENT_MESSAGE_ALLOCATION	CUR_ALOC	INTEGER Nullable	The number of entries that will fit into the data queue before it is extended. When the queue is extended, additional storage is allocated for the queue. The data queue can be extended until it reaches the value for the maximum number of entries allowed. Contains the null value for a DDM data queue.
FORCE	FORCE	VARCHAR(3) Nullable	Whether the data queue is forced to auxiliary storage when entries are sent or received. NO The data queue is not forced to auxiliary storage after entries are sent or received. YES The data queue is forced to auxiliary storage after entries are sent or received. Contains the null value for a DDM data queue.
AUTOMATIC_RECLAIM	RECLAIM	VARCHAR(3) Nullable	Whether or not the data queue has the amount of storage allocated for the queue reclaimed when the queue is empty. NO Storage is not reclaimed. YES Storage is reclaimed when the queue is empty. The amount of storage allocated will be set to the initial number of entries. Contains the null value for a DDM data queue.
LAST_RECLAIM_TIMESTAMP	RECLAIM_TS	TIMESTAMP Nullable	The date and time that the last automatic reclaim was done. Contains the null value for a DDM data queue or when no reclaim has occurred for a STANDARD or DISPLAY data queue.

Table 92. DATA_QUEUE_INFO view (continued)

Column name	System column name	Data type	Description
ENFORCE_DATA_QUEUE_LOCKS	DTAQ_LOCKS	VARCHAR(3) Nullable	<p>Identifies whether IBM-supplied data queue operations will enforce a lock on the data queue. This attribute cannot be specified on the Create Data Queue (CRTDTAQ) CL Command. The default when a data queue is created is for locks to be ignored. A data queue can be locked with the Allocate Object (ALCOBJ) CL Command. When locks are enforced, performance can be degraded due to the additional locking performed by all data queue operations.</p> <p>NO Locks on the data queue are ignored by IBM-supplied data queue operations.</p> <p>YES Locks on the data queue are enforced by IBM-supplied data queue operations.</p> <p>Contains the null value for a DDM data queue.</p>
TEXT_DESCRIPTION	TEXT	VARCHAR(50) Nullable	<p>The text description of the data queue.</p> <p>Contains the null value if there is no text description.</p>
REMOTE_DATA_QUEUE_LIBRARY	RMT_DTAQL	VARCHAR(10) Nullable	<p>The name of the library for the remote data queue on the target system. This is the data queue name that was specified on the RMTDTAQ parameter of the CRTDTAQ command. Can contain the following special values:</p> <p>*CURLIB The current library will be used to find the data queue.</p> <p>*LIBL The library list will be used to find the data queue.</p> <p>Contains the null value for a STANDARD or DISPLAY data queue.</p>
REMOTE_DATA_QUEUE	RMT_DTAQ	VARCHAR(10) Nullable	<p>The name of the remote data queue on the target system. This is the data queue name that was specified on the RMTDTAQ parameter of the CRTDTAQ command.</p> <p>Contains the null value for a STANDARD or DISPLAY data queue.</p>
REMOTE_LOCATION	REMOTE_LOC	VARCHAR(8) Nullable	<p>The name of the remote location that is used with this object. This is the name that was specified on the RMTLOCNAME parameter of the CRTDTAQ command. Can contain the following special value:</p> <p>*RDB The remote location information from the relational database entry returned in the relational database entry name field is used to determine the remote system.</p> <p>Contains the null value for a STANDARD or DISPLAY data queue.</p>
RELATIONAL_DATABASE_NAME	RDBNAME	VARCHAR(18) Nullable	<p>The name of the relational database entry that identifies the target system or target ASP group. This is the name that was specified on the RDB parameter of the CRTDTAQ command.</p> <p>Contains the null value for a STANDARD or DISPLAY data queue or a data queue that is not an RDB type DDM data queue.</p>
APPC_DEVICE_DESCRIPTION	APPC_DEVD	VARCHAR(10) Nullable	<p>The name of the APPC device description on the source system that is used with this DDM data queue. This is the name that was specified on the DEV parameter of the CRTDTAQ command. Can contain the following special value:</p> <p>*LOC The device associated with the remote location is used.</p> <p>Contains the null value for a STANDARD or DISPLAY data queue and for RDB type DDM data queues.</p>

Table 92. DATA_QUEUE_INFO view (continued)

Column name	System column name	Data type	Description
LOCAL_LOCATION	LOCAL_LOC	VARCHAR(8) Nullable	The name of the local location. This is the name that was specified on the LCLLOCNAME parameter of the CRTDTAQ command. Can contain the following special values: *LOC The device associated with the remote location is used. *NETATR The LCLLOCNAME value specified in the system network attributes is used. Contains the null value for a STANDARD or DISPLAY data queue and for RDB type DDM data queues.
MODE	MODE	VARCHAR(8) Nullable	The mode name used with the remote location name to communicate with the target system. This is the name that was specified on the MODE parameter of the CRTDTAQ command. Can contain the following special value: *NETATR The mode name specified in the system network attributes is used. Contains the null value for a STANDARD or DISPLAY data queue and for RDB type DDM data queues.
REMOTE_NETWORK_ID	REMOTE_NET	VARCHAR(8) Nullable	The remote network identifier in which the remote location used to communicate with the target system. This is the name that was specified on the RMTNETID parameter of the CRTDTAQ command. Can contain the following special values: *LOC The remote network ID associated with the remote location is used. *NETATR The remote network ID value specified in the system network attributes is used. *NONE No remote network ID is used. Contains the null value for a STANDARD or DISPLAY data queue and for RDB type DDM data queues.

Example

Find the number of messages currently on data queue DQ1 in TESTLIB.

```
SELECT CURRENT_MESSAGES FROM QSYS2.DATA_QUEUE_INFO
WHERE DATA_QUEUE_LIBRARY = 'TESTLIB' AND DATA_QUEUE_NAME = 'DQ1';
```

DB_TRANSACTION_INFO view

The DB_TRANSACTION_INFO view returns one row for each commitment definition.

The values returned for the columns in the view are similar to the values returned by the Work with Commitment Definitions (WRKCMTDFN) CL command and by the Database Transactions and Global Transactions lists in ACS.

Authorization: None required when the creator of the commitment definition matches the effective user of the thread. Otherwise, the caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM or QIBM_DB_SYSMON function usage identifier.

The following table describes the columns in the view. The system name is TRANS_INFO. The schema is QSYS2.

Table 93. DB_TRANSACTION_INFO view

Column Name	System Column Name	Data Type	Description
COMMITMENT_DEFINITION	COMMIT_DFN	VARCHAR(10)	The name of the commitment definition.

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
COMMITMENT_DEFINITION_DESCRIPTION	TEXT	VARCHAR(50) Nullable	The text description of the commitment definition. Contains the null value if there is no text description.
COMMITMENT_DEFINITION_ID	CMTDEF_ID	VARCHAR(10) FOR BIT DATA	The ID associated with the commitment definition. Can contain the following special values: *DFACTGRP This is the commitment definition for the default activation group. *JOB The commitment definition is shared by activation groups within a job.
JOB_NAME	JOB_NAME	VARCHAR(28)	The qualified job name that is using commitment control.
THREAD_ASSOCIATION_STATUS	THD_STATUS	VARCHAR(11) Nullable	The thread association status of the *TNSOBJ scoped commitment definition. *ATTACHED There are threads attached to the *TNSOBJ scoped commitment definition. *UNATTACHED There are no threads attached to the *TNSOBJ scoped commitment definition. Contains the null value if the commitment definition is not a *TNSOBJ scoped commitment definition.
LOGICAL_UNIT_OF_WORK_ID	LUWID	VARCHAR(39)	The identifier (ID) of the current logical unit of work (LUW). This value can be used to find associated commitment definitions on this system and on other systems. The logical unit of work ID (LUWID) is a character string containing the network-qualified logical unit (LU) name, the instance number, and the sequence number. The network-qualified LU name consists of a network ID with a maximum of 8 characters, a period delimiter, followed by a LU name with a maximum of 8 characters. The instance number is a 12 character value, each character representing a single hexadecimal digit. The sequence number is a decimal value with values ranging from 1 through 65535.

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
LOGICAL_UNIT_OF_WORK_STATE	L UW_STATE	VARCHAR(20)	<p>The current state of the logical unit of work (LUW).</p> <p>COMMIT IN PROGRESS A commit operation is in progress. The system is attempting to commit the resources for this commitment definition and all downstream resources associated with this LUW.</p> <p>COMMITTED A commit operation is in progress. The resources for this commitment definition and all downstream resources associated with this LUW have been committed.</p> <p>LAST AGENT PENDING A commit operation is in progress. The resources for this commitment definition have been prepared and the system is waiting for the last agent selected by this commitment definition to return the commit or rollback decision.</p> <p>PREPARE IN PROGRESS A commit or prepare operation is in progress. The system is attempting to prepare the resources for this commitment definition and to prepare all downstream resources associated with this LUW.</p> <p>PREPARED A commit operation is in progress. The resources for this commitment definition and all downstream resources associated with this LUW have been prepared.</p> <p>RESET A commit, rollback, or prepare operation is not in progress for this commitment definition.</p> <p>ROLLBACK IN PROGRESS A rollback operation is in progress. The system is attempting to roll back the committable changes for this commitment definition and for all the committable changes associated with this commitment definition.</p> <p>ROLLBACK REQUIRED A rollback operation is required. The resources registered to this commitment definition cannot be used until the LUW is rolled back.</p> <p>VOTE READ ONLY A commit operation is in progress. The commitment definition had no changes to commit, the Vote Read Only commitment option is set to 'Yes', and all downstream locations voted read only. This commitment definition and any downstream locations will not participate in the committed wave during this commit operation.</p>
STATE_TIMESTAMP	STATE_TIME	TIMESTAMP(0) Nullable	<p>The timestamp when the logical unit of work started or became undecided.</p> <p>Contains the null value if the commitment definition has performed no work and is not undecided.</p>

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
LOCK_SPACE_ID	LOCKID	CHAR(20)	The lock space identifier for this commitment definition.
ACTIVATION_GROUP	ACTGRP	BIGINT Nullable	The activation group for this commitment definition. Contains the null value if the commitment definition is the job commitment definition (*JOB), an explicitly named commitment definition, or a commitment definition that represents an XA transaction branch with lock space scoped locks.
ASPGRP	ASPGRP	VARCHAR(10)	The ASP group for this commitment definition. If *SYSBAS, the commitment definition resides on the system auxiliary storage pool.
RESOURCE_LOCATION	RSC_LOC	VARCHAR(6)	Indicates whether local or remote resources are currently under commitment control. BOTH Both local and remote resources are under commitment control. LOCAL Local resources are under commitment control. NONE No resources are under commitment control. REMOTE Remote resources are under commitment control. API resources, and relational database resources with remote location name *ARDPGM, are considered to be local, even though they may represent objects on a remote system. Because these resources are accessed and updated by user programs, the system cannot determine whether these programs access objects on a remote system.
DEFAULT_LOCK_LEVEL	DFT_LCKL	VARCHAR(4)	The level of record locking on the records in each database file under commitment control for the commitment definition when files are opened using traditional system interfaces. For files opened using SQL interfaces, the effective isolation level for each SQL operation determines the level of record locking that is used. *ALL Every record that is accessed in a file under commitment control is locked until the logical unit of work is committed or rolled back. *CHG Every record that is changed in a file under commitment control is locked until the logical unit of work is committed or rolled back. *CS Every record that is changed in a file under commitment control is locked until the logical unit of work is committed or rolled back. Records that are accessed but not changed are locked only until a different record is accessed.
USER_NAME	USER_NAME	VARCHAR(10)	The user profile that started the transaction.

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
LOCAL_CHANGES_PENDING	LOCAL_PEND	VARCHAR(3)	<p>Indicates whether this commitment definition has local changes pending. A local pending change means:</p> <ul style="list-style-type: none"> • One or more record level changes are pending. SQL statements run against the relational database might or might not have committable changes to the local database. • One or more object level changes are pending. • An API resource is registered that does not allow save-while-active requests to perform normally or does not allow independent ASPs to be quiesced. <p>NO This commitment definition has no local changes pending.</p> <p>YES This commitment definition has local changes pending.</p>
LOCAL_JOURNAL_CHANGES_PENDING	LOCAL_JRN	VARCHAR(3)	<p>Indicates this commitment definition has journals with changes pending.</p> <p>This means that one or more local journals have changes pending.</p> <p>NO This commitment definition has no local journal changes pending.</p> <p>YES This commitment definition has local journal changes pending.</p>
LOCAL_RECORD_CHANGES_PENDING	LOCAL_RCD	VARCHAR(3)	<p>Indicates whether this commitment definition has records with changes pending.</p> <p>This means that one or more local records have insert, update, or delete changes pending.</p> <p>NO This commitment definition has no local record level changes pending.</p> <p>YES This commitment definition has local record level changes pending.</p>
LOCAL_OBJECT_CHANGES_PENDING	LOCAL_OBJ	VARCHAR(3)	<p>Indicates whether this commitment definition has objects with changes pending.</p> <p>This means that one or more local objects have changes pending.</p> <p>NO This commitment definition has no local object level changes pending.</p> <p>YES This commitment definition has local object level changes pending.</p>
LOCAL_API_CHANGES_PENDING	LOCAL_API	VARCHAR(3)	<p>Indicates whether this commitment definition has local API changes pending.</p> <p>This means that one or more API resources are registered that do not allow save-while-active requests to perform normally or do not allow independent ASPs to be quiesced.</p> <p>NO This commitment definition has no local API resource changes pending.</p> <p>YES This commitment definition has local API resource changes pending.</p>

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
LOCAL_RDB_CHANGES_PENDING	LOCAL_RDB	VARCHAR(3)	<p>Indicates whether this commitment definition has local RDB changes pending.</p> <p>This means that one or more record or object level changes are pending for a local RDB resource. SQL statements run against the relational database may or may not have committable changes to the local database.</p> <p>NO This commitment definition has no local RDB changes pending.</p> <p>YES This commitment definition has local RDB changes pending.</p>
REMOTE_CHANGES_PENDING	RMT_PEND	VARCHAR(3)	<p>Indicates whether this commitment definition has remote changes pending. A remote pending change means:</p> <ul style="list-style-type: none"> • One or more record or object level changes are pending for an RDB resource. SQL statements run against the relational database may or may not have committable changes to the remote database. • One or more record or object level changes are pending for a TCP/IP connection resource. • One or more record or object level changes are pending for a remote file resource. • One or more record or object level changes are pending for a conversation resource. <p>NO This commitment definition has no remote changes pending.</p> <p>YES This commitment definition has remote changes pending.</p>
REMOTE_RDB_CHANGES_PENDING	RMT_RDB	VARCHAR(3)	<p>Indicates whether this commitment definition has remote RDB changes pending. This means:</p> <ul style="list-style-type: none"> • One or more record or object level changes are pending for a remote RDB resource. SQL statements run against the relational database may or may not have committable changes to the remote database. • One or more record or object level changes are pending for a TCP/IP connection resource. <p>NO This commitment definition has no remote RDB changes pending.</p> <p>YES This commitment definition has remote RDB changes pending.</p>
REMOTE_FILE_CHANGES_PENDING	RMT_FILE	VARCHAR(3)	<p>Indicates whether this commitment definition has remote file changes pending. This means that one or more record or object level changes are pending for a remote file resource.</p> <p>NO This commitment definition has no remote file changes pending.</p> <p>YES This commitment definition has remote file changes pending.</p>

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
REMOTE_CONVERSATION_CHANGES_PENDING	RMT_CONV	VARCHAR(3)	<p>Indicates whether this commitment definition has remote conversation changes pending. This means that one or more record or object level changes are pending for a conversation resource. SQL statements run against the relational database may or may not have committable changes to the remote database.</p> <p>NO This commitment definition has no remote conversation changes pending.</p> <p>YES This commitment definition has remote conversation changes pending.</p>
ROLE	ROLE	VARCHAR(19) Nullable	<p>Indicates the role that this location is playing in the transaction program network.</p> <p>AGENT This location is a leaf in the transaction program network and it has no subordinate locations.</p> <p>CASCADER This location is an intermediate node in the transaction program network and it has subordinate locations. The commit or rollback operation did not start at this location.</p> <p>INITIATOR This location started the commit or rollback operation and is at the root of the transaction program network.</p> <p>LAST AGENT This location is a leaf in the transaction program network and it is the last agent, which decides whether to commit or to roll back the logical unit of work.</p> <p>LAST AGENT CASCADER This location is a middle node in the transaction program network and it is the last agent, which decides whether the logical unit of work is committed or rolled back. This location also can delegate another location of its choice to be the last agent.</p> <p>LOCAL This location is the only location with resources registered to the commitment definition.</p> <p>X/OPEN AGENT This location is a leaf in the transaction program network. The commit operation was initiated by an X/Open transaction manager.</p> <p>X/OPEN CASCADER This location is a middle node in the transaction program network. The commit operation was initiated by an X/Open transaction manager and this location has subordinate locations.</p> <p>Contains the null value if the role is not recognized.</p>
RESYNC_IN_PROGRESS	RESYNCING	VARCHAR(3)	<p>Indicates whether this commitment definition is resynchronizing resources that are associated with the logical unit of work.</p> <p>NO This commitment definition is not resynchronizing resources.</p> <p>YES This commitment definition is resynchronizing resources.</p>

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
HEURISTIC_OPERATION	HEUR_OPER	VARCHAR(20) Nullable	<p>The user-specified operation (resulting from a heuristic decision) performed against this commitment definition's resources and against all of the downstream resources associated with the logical unit of work.</p> <p>COMMIT IN PROGRESS The user forced a commit operation that has not yet completed.</p> <p>FORCED COMMIT The user forced a commit operation.</p> <p>FORCED ROLLBACK The user forced a rollback operation.</p> <p>ROLLBACK IN PROGRESS The user forced a rollback operation that has not yet completed.</p> <p>Contains the null value if the user has not specified a heuristic operation.</p>
MIRROR_ACTIVE	MIRROR_ACT	VARCHAR(3)	<p>Indicates whether the commitment definition has a Db2 Mirror resource registered under commitment control.</p> <p>NO The commitment definition has no Db2 Mirror resource registered under commitment control.</p> <p>YES The commitment definition has Db2 Mirror resource registered under commitment control.</p>
MIRROR_ERROR	MIRROR_ERR	VARCHAR(19) Nullable	<p>Indicates whether commitment control has detected a Db2 Mirror error.</p> <p>BLOCKED The Db2 Mirror state was BLOCKED when the error was detected.</p> <p>COMMUNICATION ERROR A communication error was detected.</p> <p>NO ERROR No error has been detected.</p> <p>TRACKING The Db2 Mirror state was TRACKING when the error was detected.</p> <p>Contains the null value if MIRROR_ACTIVE is NO.</p>
MIRROR_ERROR_IASP	MIRROR_EI	INTEGER Nullable	<p>The IASP number of the IASP where commitment control detected a Db2 Mirror error.</p> <p>Contains the null value if MIRROR_ACTIVE is NO or if commitment control has not detected a Db2 Mirror error for an IASP.</p>
MIRROR_TRACKING_IASP	MIRROR_TI	INTEGER Nullable	<p>The IASP number of the IASP where commitment control detected the Db2 Mirror state was TRACKING.</p> <p>Contains the null value if MIRROR_ACTIVE is NO or if commitment control has not detected an IASP where the Db2 Mirror state is TRACKING.</p>

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
JOB_ACTIVE	JOB_ACTIVE	VARCHAR(6)	<p>Indicates whether this commitment definition is part of an active job.</p> <p>NO This commitment definition is not part of an active job. The job was ended before all logical units of work were complete.</p> <p>SERVER The job that the commitment definition was part of has ended, and the commitment definition has been made part of a database server job. The SERVER_JOB_NAME column contains the name of the database server job.</p> <p>YES This commitment definition is part of an active job.</p>
SERVER_JOB_NAME	SERVER_JOB	VARCHAR(28) Nullable	<p>Qualified job name of the database server job of which this commitment definition is a part.</p> <p>Contains the null value if the commitment definition is not part of a database server job.</p>
LOCK_SCOPE	LOCK_SCOPE	VARCHAR(7) Nullable	<p>Indicates where the locks acquired on behalf of the commitment definition are scoped.</p> <p>*ACTGRP The commitment definition has an activation group level scope.</p> <p>*EXPL The commitment definition is explicitly named scope.</p> <p>*JOB The commitment definition has a job level scope.</p> <p>*TNSOBJ The commitment definition has a transaction object level scope (XA).</p> <p>Contains the null value if the lock scope is not recognized.</p>
LOCK_WAIT_TIME	LOCK_WAIT	INTEGER	<p>The maximum number of seconds that the system waits to acquire a lock requested on behalf of this commitment definition. Lock wait time values that are specified or defaulted using system interfaces other than the xa_open API are used if they are smaller than this value, or if this value is zero.</p>
LOCK_LIMIT	LOCK_LIMIT	BIGINT	<p>Indicates the maximum number of records which can be locked within a transaction. If multiple journals are involved in the transaction, this limit applies to each journal, not the transaction as a whole.</p> <p>The COMMITMENT_CONTROL_LOCK_LIMIT QAQQINI option can be used to configure this value before commitment control is started.</p>
NESTING_LEVEL_DEPTH	NEST_LEVEL	INTEGER	<p>The current nesting depth of all nested transactions for this commitment definition.</p>
NUMBER_SAVEPOINTS	SAVEPOINTS	INTEGER	<p>The number of active savepoints.</p>
COMMIT_ROLLBACK_END	CR_END	VARCHAR(3)	<p>Indicates if COMMIT, ROLLBACK, and ENDCMTCTL are allowed to be executed.</p> <p>NO COMMIT, ROLLBACK, and ENDCMTCTL are not allowed.</p> <p>YES COMMIT, ROLLBACK, and ENDCMTCTL are allowed.</p>

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
EXPLICIT_COMMIT_ROLLBACK	EXPL_CR	VARCHAR(3)	<p>Indicates if an explicit COMMIT or ROLLBACK was executed.</p> <p>NO An explicit COMMIT or ROLLBACK has not been executed.</p> <p>YES An explicit COMMIT or ROLLBACK has been executed.</p>
SQL_DYNAMIC_COMMIT	SQL_DYNC	VARCHAR(3)	<p>Indicates if an SQL Dynamic COMMIT was executed.</p> <p>NO An SQL dynamic COMMIT has not been executed.</p> <p>YES An SQL dynamic COMMIT has been executed.</p>
SQL_DYNAMIC_ROLLBACK	SQL_DYNR	VARCHAR(3)	<p>Indicates if an SQL Dynamic ROLLBACK was executed.</p> <p>NO An SQL dynamic ROLLBACK has not been executed.</p> <p>YES An SQL dynamic ROLLBACK has been executed.</p>
SQL_HOLD_COMMIT	SQL_HOLD	VARCHAR(3)	<p>Indicates the SQL HOLD value used on the call to COMMIT.</p> <p>NO SQLHOLD(NO) specified on COMMIT call.</p> <p>YES SQLHOLD(YES) specified on COMMIT call.</p>
COMMIT_DURABLE	DURABLE	VARCHAR(3)	<p>Indicates whether commit operations are guaranteed to be durable.</p> <p>NO The commit operation is not durable. Atomicity of the transaction is guaranteed, but one or more transactions may be lost in the event of a system failure.</p> <p>YES The commit operation is durable. When the transaction is committed, the transaction is guaranteed to persist on the system.</p>
NUMBER_COMMITS	COMMIT_OPS	BIGINT Nullable	<p>The total number of commit operations performed since this commitment definition was created. This number includes commit operations initiated by both the user and the operating system. Returns 2,147,483,648 if the number of commits has exceeded 2,147,483,647.</p> <p>Contains the null value if an IPL has been performed on the system since the commitment definition was created.</p>
NUMBER_ROLLBACKS	ROLLB_OPS	BIGINT Nullable	<p>The total number of rollback operations performed since this commitment definition was created. This number includes rollback operations initiated by both the user and the operating system. Returns 2,147,483,648 if the number of rollbacks has exceeded 2,147,483,647.</p> <p>Contains the null value if an IPL has been performed on the system since the commitment definition was created.</p>
DEFAULT_JOURNAL_LIBRARY	DFT_JRNLIB	VARCHAR(10) Nullable	<p>The name of the library in which the default journal is located.</p> <p>Contains the null value if there is no default journal.</p>

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
DEFAULT_JOURNAL_NAME	DFT_JRN	VARCHAR(10) Nullable	The name of the default journal that was specified when the commitment definition was created. All logical unit of work (LUW) entries are placed in this journal. Contains the null value if there is no default journal.
NOTIFY_OBJECT_TYPE	NOTIFY_TYP	VARCHAR(7) Nullable	Type of notify object for the commitment definition. *DTAARA The notify object is a data area. *FILE The notify object is a database file member *MSGQ The notify object is a message queue. Contains the null value if there is no notification object.
NOTIFY_OBJECT_LIBRARY	NOTIFY_LIB	VARCHAR(10) Nullable	The name of the library in which the notify object for the commitment definition can be located. Contains the null value if there is no notification object.
NOTIFY_OBJECT	NOTIFY_OBJ	VARCHAR(10) Nullable	The name of the object to which notification is sent regarding the status of the commitment definition. Contains the null value if there is no notification object.
NOTIFY_OBJECT_MEMBER	NOTIFY_MBR	VARCHAR(10) Nullable	The name of the database file member that is the notify object for the commitment definition. Contains the null value if there is no notification object or NOTIFY_OBJECT_TYPE is not *FILE.

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
WAIT_FOR_OUTCOME	WAIT_OUTC	VARCHAR(17) Nullable	<p>This commitment option indicates how this system handles resynchronization if a communications or remote system failure occurs during a commit or rollback operation. This value is set to WAIT when commitment control is started and can be changed using the Change Commitment Options (QTNCHGCO) API. Note: If the commitment definition has a Wait for Outcome value of WAIT or inherits a value of WAIT, the value of the ACCEPT_VOTE_RELIABLE commitment option is ignored, and the system behaves as though the ACCEPT_VOTE_RELIABLE commitment option is NO.</p> <p>INHERIT OR NOWAIT When this system is the initiator of the commit or rollback operation, the INHERIT OR NOWAIT value has the same effect as the NOWAIT value. When this system is not the initiator and the initiator supports the presumed abort protocol, the Wait for Outcome value is inherited from the initiator. When this system is not the initiator and the initiator does not support the presumed abort protocol, the INHERIT OR NOWAIT value has the same effect as the NOWAIT value.</p> <p>INHERIT OR WAIT When this system is the initiator of the commit or rollback operation, the INHERIT OR WAIT value has the same effect as the WAIT value. When this system is not the initiator and the initiator supports the presumed abort protocol, the Wait for Outcome value is inherited from the initiator. When this system is not the initiator and the initiator does not support the presumed abort protocol, the INHERIT OR WAIT value has the same effect as the WAIT value.</p> <p>NOWAIT This system attempts to resynchronize one time before allowing the commit or rollback operation to complete. If the initial attempt fails, the resynchronization is completed in a database server job, and the application is not notified of the result of the resynchronization. Resynchronizations required with the last agent location always wait regardless of the current status of the wait for outcome option.</p> <p>WAIT This system completes resynchronization before allowing the commit or rollback operation to complete.</p> <p>Contains the null value if the Wait for Outcome option was not specified for the commitment definition.</p>

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
PROBLEM_ACTION	ACTION	VARCHAR(8)	<p>Indicates what this system does if another system, which controls whether the logical unit of work should commit or rollback, sends this system an unrecognized message or detects damage in the logical unit of work. This value is set to ROLLBACK when commitment control is started and can be changed using the Change Commitment Options (QTNCHGCO) API.</p> <p>COMMIT The changes associated with this logical unit of work are committed.</p> <p>ROLLBACK The changes associated with this logical unit of work are rolled back.</p>
VOTE_READ_ONLY_PERMITTED	VOTE_RO	VARCHAR(3)	<p>Indicates whether this system can vote read-only in response to a commit operation started on another system. Note: If this system votes read-only, control is not returned to the application until this system receives a message from the starting system containing an indicator that the next logical unit of work has started. The length of the delay in regaining control depends on the application running on the starting system. This value is set to NO when commitment control is started and can be changed using the Change Commitment Options (QTNCHGCO) API.</p> <p>NO This system cannot vote read-only.</p> <p>YES This system can vote read-only.</p>
END_JOB_ACTION	ENDJOB_ACT	VARCHAR(8) Nullable	<p>Indicates what this system does if the logical unit of work is in an undecided state and the job is ending abnormally. This value is set to WAIT when commitment control is started and can be changed using the Change Commitment Options (QTNCHGCO) API.</p> <p>COMMIT This system commits the changes made to the logical of work.</p> <p>ROLLBACK This system rolls back the changes made to the logical unit of work.</p> <p>WAIT The system gets the commit or rollback decision from the system that started the operation. Based on that decision, this system commits or rolls back the changes made to the logical unit of work before ending the job. Heuristic operations can be performed if the time spent waiting is unacceptable.</p> <p>Contains the null value if the end job action is not known.</p>
LAST_AGENT_PERMITTED	LAST_AGENT	VARCHAR(6) Nullable	<p>Indicates whether a last agent can be selected when one is eligible to be selected during a commit operation. A last agent is eligible to be selected at the location that initiates a commit operation, and at locations that are selected as a last agent by the location that propagates the commit operation to that location. This value is set to SYSTEM when commitment control is started and can be changed using the Change Commitment Options (QTNCHGCO) API.</p> <p>NO The system is not allowed to select a last agent.</p> <p>SYSTEM The system is allowed to select a last agent.</p> <p>Contains the null value if the last agent permitted value is not known.</p>

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
LEAVE_OUT_OK	LEAVE_OUT	VARCHAR(3)	<p>The commitment option that indicates whether it is OK to leave this system out of a commit operation initiated at another system. If this system indicates it can be left out, no communications flows are sent to this system during subsequent commit or rollback operations until a data flow is received from the initiator. Also, control is not returned to the application until the data flow is received. This value is set to NO when commitment control is started and can be changed using the Change Commitment Options (QTNCHGCO) API.</p> <p>NO This system may not be left out of subsequent logical units of work.</p> <p>YES This system may be left out of subsequent logical units of work.</p>
ACCEPT_VOTE_RELIABLE	ACCEPT_VR	VARCHAR(3)	<p>Indicates whether this system accepts the vote reliable indicator if it is received from its agents during the prepare wave of a commit operation. The vote reliable indicator indicates that it is unlikely that a heuristic decision will be made at the agent if a failure occurs before the committed wave completes. If an agent sends the vote reliable indicator, and this location accepts it, performance is improved because one communications flow is eliminated and control is returned to the application before the committed wave is completed for that agent. However, if a heuristic decision is made at that agent which causes heuristic damage, the application at this location will not receive an error message if the Accept vote reliable commitment option is set to YES. This value is set to YES when commitment control is started and can be changed using the Change Commitment Options (QTNCHGCO) API.</p> <p>If the commitment definition has a Wait for outcome value of Wait or inherits a value of Wait, the value of the Accept vote reliable commitment option is ignored, and the system behaves as though the Accept vote reliable commitment option is No.</p> <p>NO This system does not accept the vote reliable indicator.</p> <p>YES This system accepts the vote reliable indicator.</p>
RECYCLE_COUNT	RECYCLECNT	INTEGER	<p>The number of times that this commitment definition has been recycled as a spare.</p>

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
RECEIVED_DRDA_SYNCTYPE	RCV_SYNC	VARCHAR(17) Nullable	<p>The two-phase commitment control synchronization type received by commitment control on the target-side of a DRDA connection.</p> <p>COMMITTED The application requester committed its unit or work.</p> <p>FORGET The application requester issued a forget request.</p> <p>MIGRATE The application requester issued a migrate request.</p> <p>NEW UNIT OF WORK The application requester is requesting a new unit of work.</p> <p>PREPARE TO COMMIT The application requester is requesting the unit of work be prepared to commit.</p> <p>REQUEST TO COMMIT The application requester is requesting the unit of work be committed.</p> <p>ROLLBACK The application requester is requesting the unit of work be rolled back.</p> <p>Contains the null value if no two-phase commitment control requests have been received.</p>
RETURNED_DRDA_SYNCTYPE	RET_SYNC	VARCHAR(17) Nullable	<p>The two-phase commitment control synchronization type returned by commitment control on the target-side of a DRDA connection.</p> <p>COMMITTED The application server committed its unit or work.</p> <p>FORGET The application server returned a forget request.</p> <p>MIGRATE The application server returned a migrate request.</p> <p>REQUEST TO COMMIT The application server is returning the unit of work be committed.</p> <p>ROLLBACK The application server is returning the unit of work be rolled back.</p> <p>Contains the null value if no two-phase commitment control requests have been returned.</p>
XA_CONNECTION_TYPE	XA_TYPE	VARCHAR(8) Nullable	<p>Indicates whether this commitment definition was created in an SQL Server Job for the purposes of running XA transactions.</p> <p>CLI The XA transactions are being performed in an SQL Server Job over a CLI connection.</p> <p>EMBEDDED The XA transactions are being performed in an SQL Server Job over an embedded SQL connection.</p> <p>NONE The XA transactions are not performed in an SQL Server Job.</p> <p>Contains the null value if the commitment definition is not a *TNSOBJ scoped commitment definition.</p>

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description										
XA_RMID	XA_RMID	INTEGER Nullable	The resource manager ID (RMID). The unique number is assigned by the transaction manager to identify this instance of the XA resource manager within the thread of control. This RMID is passed on subsequent calls to XA routines to identify the resource manager. The identifier remains constant until the transaction manager in this thread closes the resource manager. Contains the null value if the commitment definition is not a *TNSOBJ scoped commitment definition.										
XA_TRANSACTION_MANAGER	XA_MANAGER	VARCHAR(10) Nullable	The name of the transaction manager that started the XA transaction branch represented by this commitment definition. Contains the null value if the commitment definition is not a *TNSOBJ scoped commitment definition or if the transaction manager name was not specified for the commitment definition.										
XA_RDB_NAME	XA_RDB	VARCHAR(18) Nullable	The relational database name (RDB) associated with the XA transaction represented by this commitment definition. Contains the null value if the commitment definition is not a *TNSOBJ scoped commitment definition.										
XA_TRANSACTION_BRANCH_STATE	XA_STATE	VARCHAR(23) Nullable	Indicates the state of the XA transaction branch represented by this commitment definition. <table border="0"> <tr> <td>ACTIVE</td> <td>One or more threads of control are actively associated with the transaction branch.</td> </tr> <tr> <td>IDLE</td> <td>No threads of control are actively associated with the transaction branch.</td> </tr> <tr> <td>PREPARED</td> <td>The transaction branch has been prepared.</td> </tr> <tr> <td>ROLLBACK ONLY</td> <td>The transaction branch is required to roll back.</td> </tr> <tr> <td>HEURISTICALLY COMPLETED</td> <td>The transaction branch has been heuristically committed or rolled back.</td> </tr> </table> Contains the null value if the commitment definition is not a *TNSOBJ scoped commitment definition.	ACTIVE	One or more threads of control are actively associated with the transaction branch.	IDLE	No threads of control are actively associated with the transaction branch.	PREPARED	The transaction branch has been prepared.	ROLLBACK ONLY	The transaction branch is required to roll back.	HEURISTICALLY COMPLETED	The transaction branch has been heuristically committed or rolled back.
ACTIVE	One or more threads of control are actively associated with the transaction branch.												
IDLE	No threads of control are actively associated with the transaction branch.												
PREPARED	The transaction branch has been prepared.												
ROLLBACK ONLY	The transaction branch is required to roll back.												
HEURISTICALLY COMPLETED	The transaction branch has been heuristically committed or rolled back.												
XA_XID_FORMAT_ID	XA_FMTID	VARBINARY(4) Nullable	The hex value of the format identifier portion of the XA transaction identifier (XID). Contains the null value if the commitment definition is not a *TNSOBJ scoped commitment definition.										
XA_XID_GLOBAL_TRANSACTION_ID	XA_GTRID	VARBINARY(64) Nullable	The hex value of the global transaction identifier (GTRID) portion of the XA transaction identifier (XID). Contains the null value if the commitment definition is not a *TNSOBJ scoped commitment definition.										
XA_XID_BRANCH_QUALIFIER	XA_BQUAL	VARBINARY(64) Nullable	The hex value of the branch qualifier (BQUAL) portion of the XA transaction identifier (XID). Contains the null value if the commitment definition is not a *TNSOBJ scoped commitment definition.										

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
XA_OPEN_SQL_HOLD	XA_SQLHOLD	CHAR(1) Nullable	<p>Indicates how SQL cursors are affected by some XA operations. Specified on the db2xa_open() API xainfo string SQLHOLD keyword.</p> <p>A</p> <ul style="list-style-type: none"> • db2xa_commit() and db2xa_rollback(): Cursors are not affected since db2xa_end() already closed them. • db2xa_end() : All cursors are closed. <p>C</p> <ul style="list-style-type: none"> • db2xa_commit() and db2xa_rollback(): Cursors declared WITH HOLD are held open. Cursors not declared WITH HOLD are closed. • db2xa_end(): All cursors are held open. <p>E</p> <ul style="list-style-type: none"> • db2xa_commit(): Cursors declared WITH HOLD are held open. Cursors not declared WITH HOLD are closed. • db2xa_rollback(): All cursors are closed. • db2xa_end(): Cursors declared WITH HOLD are held open. Cursors not declared WITH HOLD are closed. <p>L</p> <ul style="list-style-type: none"> • db2xa_commit(): If the relational database resides on an IBM i, all cursors are left open. Otherwise, cursors declared WITH HOLD are left open and cursors not declared WITH HOLD are closed. • db2xa_rollback(): If the relational database resides on an IBM i, all cursors are left open. Otherwise, all cursors are closed. • db2xa_end(): All cursors are held open. <p>N</p> <ul style="list-style-type: none"> • db2xa_commit(): Cursors declared WITH HOLD are held open. Cursors not declared WITH HOLD are closed. • db2xa_rollback(): All cursors are closed. • db2xa_end(): All cursors are held open. <p>Y</p> <ul style="list-style-type: none"> • db2xa_commit() and db2xa_rollback(): If the relational database resides on an IBM i, all cursors are left open. Otherwise, the operation will fail. • db2xa_end(): All cursors are held open. <p>Contains the null value if the commitment definition is not a *TNSOBJ scoped commitment definition or it is a *TNSOBJ scoped commitment definition but not one where SQLHOLD was specified on the db2xa_open() API.</p>

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
XA_OPEN_TBLCS	XA_TBLCS	CHAR(1) Nullable	<p>Indicates whether loosely coupled threads of control (those working on transaction branches with the same global transaction identifier (GTRID), but different branch qualifiers (BQUALS)), share locks. This is what was specified on xa_open() API.</p> <p>N Locks are not shared. Resource deadlock may occur between the transaction branches.</p> <p>S Locks are shared. Resource deadlock will not occur between the transaction branches.</p> <p>Contains the null value if the commitment definition is not a *TNSOBJ scoped commitment definition or it is a *TNSOBJ scoped commitment definition but not one where TBLCS was specified on the xa_open() API.</p>
XA_THREAD_OF_CONTROL	XA_THDCTL	VARCHAR(10) Nullable	<p>The thread of control for the XA transaction branch represented by this commitment definition.</p> <p>CONNECTION The SQL connection is the XA thread of control. The XA transaction branch represented by this commitment definition was started by the SQLSetConnectAttr API or by a remote system that established an SQL connection to this system. All SQL work requested using the connection that started the transaction branch becomes part of the transaction branch regardless of requesting thread.</p> <p>THREAD The thread is the XA thread of control. The XA transaction branch represented by this commitment definition was started by the xa_start or db2xa_start API. All SQL work requested by the thread that started the transaction branch becomes part of the transaction branch regardless of which SQL connection is used to perform that work.</p> <p>Contains the null value if the commitment definition is not a *TNSOBJ scoped commitment definition.</p>
XA_THREAD_ASSOCIATION_COUNT	XA_THDCNT	BIGINT Nullable	<p>The number of threads or SQL connections currently associated with the XA transaction branch represented by this commitment definition. The associations may be active or suspended.</p> <p>Contains the null value if the commitment definition is not a *TNSOBJ scoped commitment definition.</p>

Table 93. DB_TRANSACTION_INFO view (continued)

Column Name	System Column Name	Data Type	Description
XA_LOCK_SHARING	XA_LOCKSHR	VARCHAR(3) Nullable	Specifies whether locks are shared with loosely coupled transaction branches. A loosely coupled transaction branch is one with a transaction identifier (XID) that has the same global transaction identifier (GTRID) but a different branch qualifier (BQUAL). NO This commitment definition does not share locks with loosely coupled transaction branches. YES This commitment definition shares locks with loosely coupled transaction branches. Contains the null value if the commitment definition is not a *TNSOBJ scoped commitment definition.
XA_LOCK_SPACE_HANDLE	XA_LOCKSP	INTEGER Nullable	The lock space associated space handle. Contains the null value if the commitment definition is not a *TNSOBJ scoped commitment definition.
XA_TRANSACTION_TIMEOUT	XA_TIMEOUT	INTEGER Nullable	The number of seconds that an XA transaction is allowed to exist before being automatically rolled back by the system. Contains the null value if the commitment definition is not a *TNSOBJ scoped commitment definition or if the number of seconds is 0.

Example

- Show all jobs that have local work that has not been committed. The rows that are returned are not ordered.

```
SELECT *
FROM QSYS2.DB_TRANSACTION_INFO
WHERE LOCAL_CHANGES_PENDING = 'YES';
```

- Show all jobs that have a commitment definition. Order the returned rows by job name, then job user, then by job number.

```
SELECT *
FROM QSYS2.DB_TRANSACTION_INFO
ORDER BY SUBSTR(SUBSTR(JOB_NAME,8),POSSTR(SUBSTR(JOB_NAME,8),'/')+1), --job name
SUBSTR(JOB_NAME,8,POSSTR(SUBSTR(JOB_NAME,8),'/')-1), -- job user
SUBSTR(JOB_NAME,1,6) -- job number
;
```

DB_TRANSACTION_JOURNAL_INFO table function

The DB_TRANSACTION_JOURNAL_INFO table function returns the status of journal resources under commitment control for a commitment definition.

The information returned is similar to the values shown by Display Journal Status within the Work with Commitment Definitions (WRKCMTDFN) CL command.

Authorization: None required when the creator of the commitment definition matches the effective user of the thread. Otherwise, the caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM or QIBM_DB_SYSMON function usage identifier.

►► DB_TRANSACTION_JOURNAL_INFO ((LOCK_SPACE_ID => lock-space-id)) ◄◄

The schema is QSYS2.

lock-space-id A character string that contains the lock space identifier of the commitment definition to be returned.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 94. DB_TRANSACTION_JOURNAL_INFO table function

Column Name	Data Type	Description
JOURNAL_LIBRARY	VARCHAR(10)	The name of the library that contains the journal.
JOURNAL_NAME	VARCHAR(10)	The name of the journal.
COMMIT_CYCLE	DECIMAL(21,0)	The commit cycle identifier of the current logical unit of work (LUW) for this journal. The commit cycle identifier is the sequence number of the journal entry that corresponds to the beginning of the current LUW for the commitment definition. Contains the null value if no changes have been made to local database files under commitment control, and no user journal entries have been sent to this journal on behalf of an API resource that is journaled to this journal during this LUW.
RECORD_LOCKS	BIGINT	The number of record locks held by this commitment definition for files journaled to this journal. This number is kept current during the entire transaction. When a commit or rollback is requested, the number will decrease to show progress as locks are released.
PENDING_CHANGES	BIGINT	The number of changes that have yet to be committed or rolled back for the journal. This number is kept current during the entire transaction. When a rollback is requested, the number will decrease to show progress as the rollback occurs.
RECORD_ROLLBACK_STARTED	TIMESTAMP(0)	The timestamp when record level rollback started for the journal. Contains the null value if a rollback has not started.
RECORD_ROLLBACK_PERCENT	INTEGER	The percentage of record level rollback processing that has completed for the journal. A value of 100 means record level rollback has completed for this journal, but other steps in the current commit or rollback operation may still be in progress for this or other journals related to this commitment definition. Contains the null value if no rollback is in progress, or rollback has not yet started for this journal.
INDEX_ENTRIES	INTEGER	The number of index entries in internal indexes used by this commitment definition. This number is kept current during the entire transaction. When a rollback is requested, the number will decrease to show progress as the rollback occurs.
INDEX_CLEANUP_STARTED	TIMESTAMP(0)	The timestamp when the index cleanup started for the journal. Contains the null value if cleanup has not started.
INDEX_CLEANUP_PERCENT	INTEGER	The percentage of index cleanup that has completed for the journal. A value of 100 means cleanup has completed for this journal, but other steps in the current commit or rollback operation are still in progress for this or other journals related to this commitment definition. Contains the null value if no cleanup is in progress, or cleanup has not yet started for this journal.
RECORD_UNLOCK_STARTED	TIMESTAMP(0)	The timestamp when the record unlock processing started for the journal. Contains the null value if unlock processing has not started.

Table 94. DB_TRANSACTION_JOURNAL_INFO table function (continued)

Column Name	Data Type	Description
RECORD_UNLOCK_PERCENT	INTEGER	The percentage of record unlock processing that has completed for the journal. A value of 100 means unlock processing has completed for this journal, but other steps in the current commit or rollback operation are still in progress for this or other journals related to this commitment definition. Contains the null value if no record unlock processing is in progress, or it has not yet started for this journal.

Example

- Show the status of journal resources under commitment control for a specific lock space ID.

```
SELECT * FROM TABLE(QSYS2.DB_TRANSACTION_JOURNAL_INFO('UDB_010000000000A07F'));
```

DB_TRANSACTION_OBJECT_INFO table function

The DB_TRANSACTION_OBJECT_INFO table function returns the object level status of objects under commitment control for a commitment definition.

An object can appear in the result more than once if it was changed more than once during the current logical unit of work.

The information returned is similar to the values shown by Display Object Level Status within the Work with Commitment Definitions (WRKCMDFN) CL command.

Authorization: None required when the creator of the commitment definition matches the effective user of the thread. Otherwise, the caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM or QIBM_DB_SYSMON function usage identifier.

➤ DB_TRANSACTION_OBJECT_INFO ((LOCK_SPACE_ID =>) lock-space-id) ➤

The schema is QSYS2.

lock-space-id A character string that contains the lock space identifier of the commitment definition to use.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 95. DB_TRANSACTION_OBJECT_INFO table function

Column Name	Data Type	Description
ORDINAL_POSITION	INTEGER	The relative position of this row in the result data set. This indicates the order in which the object changed, with 1 being the oldest row.
OBJECT_LIBRARY	VARCHAR(10)	The name of the library that contains the object.
OBJECT_NAME	VARCHAR(10)	The name of the object under commitment control for the commitment definition.
OBJECT_TYPE	VARCHAR(7)	The type of object.
OPERATION	VARCHAR(42)	A description of the command or operation that caused a committable change to be made to the object.

Example

- View all the objects associated with a given commit definition.

```
SELECT * FROM TABLE(QSYS2.DB_TRANSACTION_OBJECT_INFO('UDB_010000000000001'))
ORDER BY ORDINAL_POSITION;
```

DB_TRANSACTION_RECORD_INFO table function

The DB_TRANSACTION_RECORD_INFO table function returns the record level status of local database files under commitment control for a commitment definition.

The information returned is similar to the values shown by Display Record Level Status within the Work with Commitment Definitions (WRKCMDFN) CL command.

Authorization: None required when the creator of the commitment definition matches the effective user of the thread. Otherwise, the caller must have *JOBCTL special authority or be authorized to the QIBM_DB_SQLADM or QIBM_DB_SYSMON function usage identifier.

►► DB_TRANSACTION_RECORD_INFO (LOCK_SPACE_ID => lock-space-id) ►►

The schema is QSYS2.

lock-space-id A character string that contains the lock space identifier of the commitment definition to use.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 96. DB_TRANSACTION_RECORD_INFO table function

Column Name	Data Type	Description
LIBRARY_NAME	VARCHAR(10)	The name of the library that contains the file.
FILE_NAME	VARCHAR(10)	The name of the local database file under commitment control for the commitment definition.
MEMBER_NAME	VARCHAR(10)	The name of the member in the file.
FILE_CHANGES_COMMITTED	BIGINT	The total number of record level changes to the file that have been committed. Returns the value 32768 when more than 32767 changes have been committed. Contains the null value if an IPL has been performed on the system since the commitment definition was created.
FILE_CHANGES_ROLLED_BACK	BIGINT	The total number of record level changes to the file that have been rolled back. Returns the value 32768 when more than 32767 changes have been rolled back. Contains the null value if an IPL has been performed on the system since the commitment definition was created.
FILE_CHANGES_PENDING	BIGINT	The total number of record level changes to the file that are pending a commit or rollback for the commitment definition. Returns the value 32,768 when more than 32767 changes are pending. Contains the null value if an IPL has been performed on the system since the commitment definition was created.

Table 96. DB_TRANSACTION_RECORD_INFO table function (continued)

Column Name	Data Type	Description
LOCK_LEVEL	VARCHAR(5)	<p>The level of record locking for this file.</p> <p>*ALL Records that are read, updated, deleted, and inserted are locked until the logical unit of work is committed or rolled back. Uncommitted changes in other jobs cannot be seen.</p> <p>*CHG Records that are updated, deleted, and inserted are locked until the logical unit of work is committed or rolled back. Uncommitted changes in other jobs can be seen.</p> <p>*CS Records that are updated, deleted, and inserted are locked until the logical unit of work is committed or rolled back. A record that is read but not updated is locked until the next record is read. Uncommitted changes in other jobs cannot be seen.</p> <p>*CSKL Records that are updated, deleted, and inserted are locked until the logical unit of work is committed or rolled back. A record that is read but not updated is locked until the completion of the SQL statement, or the cursor is closed, or the logical unit of work is committed or rolled back. Uncommitted changes in other jobs cannot be seen.</p> <p>*RR Records that are updated, deleted, and inserted are locked until the logical unit of work is committed or rolled back. Uncommitted changes in other jobs cannot be seen. All tables referred to in SELECT, UPDATE, DELETE, and INSERT statements are locked exclusively until the logical unit of work is committed or rolled back.</p> <p>*RREL Records that are read, updated, deleted, and inserted are locked exclusively until the logical unit of work is committed or rolled back. Uncommitted changes in other jobs cannot be seen. All tables referred to in SELECT, UPDATE, DELETE, and INSERT statements are locked exclusively until the logical unit of work is committed or rolled back.</p> <p>*RSEL Records that are read, updated, deleted, and inserted are locked exclusively until the logical unit of work is committed or rolled back. Uncommitted changes in other jobs cannot be seen.</p> <p>Contains the null value if the file is closed.</p>
STATUS	VARCHAR(13)	<p>File status.</p> <p>CLOSED The file has been closed with pending changes that have not been committed or rolled back.</p> <p>OPEN The file is open under commitment control.</p> <p>PSEUDO-CLOSED The file has been pseudo-closed. This is an SQL cursor that is not currently in use, but remains open under commitment control for reuse to minimize performance impacts.</p>

Table 96. DB_TRANSACTION_RECORD_INFO table function (continued)

Column Name	Data Type	Description
CONCURRENT_ACCESS_RESOLUTION	VARCHAR(7)	<p>The concurrent access resolution setting for this file.</p> <p>*CURCMT The database manager can use the currently committed version of the data for applicable scans when it is in the process of being updated or deleted. Rows in the process of being inserted can be skipped.</p> <p>*SKIP The database manager will skip data on which incompatible locks are held by other transactions.</p> <p>*WAIT The database manager will wait for the commit or rollback when encountering data in the process of being updated or deleted. Rows encountered that are in the process of being inserted are not skipped.</p> <p>Contains the null value if the file is closed.</p>
JOURNAL_LIBRARY	VARCHAR(10)	<p>The library that contains the journal.</p> <p>Contains the null value if JOURNAL_NAME is *MULTIPLE.</p>
JOURNAL_NAME	VARCHAR(10)	<p>The journal in which changes to the file are recorded. Can contain the following special value:</p> <p>*MULTIPLE Logical files based on physical files are not all journaled to the same journal.</p>
COMMIT_CYCLE	DECIMAL(21,0)	<p>The commit cycle identifier of the current logical unit of work (LUW) for this file's journal. The commit cycle identifier is the sequence number of the journal entry that corresponds to the beginning of the current LUW for the commitment definition.</p> <p>Contains the null value if no changes have been made to local database files under commitment control, and no user journal entries have been sent to this journal on behalf of an API resource that is journaled to the file's journal during this LUW.</p>

Example

- View all the files associated with a given commit definition.

```
SELECT * FROM TABLE(QSYS2.DB_TRANSACTION_RECORD_INFO('UDB_0100000000000001'));
```

- View all the files with pending changes for a given commit definition.

```
SELECT * FROM TABLE(QSYS2.DB_TRANSACTION_RECORD_INFO('UDB_0100000000000001'))
WHERE FILE_CHANGES_PENDING > 0;
```

ENVIRONMENT_VARIABLE_INFO view

The ENVIRONMENT_VARIABLE_INFO view contains information about environment variables.

The values returned for the columns in the view are similar to the values returned by the WRKENVVAR CL command or [Get All System-Level Environment Variables API](#). Refer to the API for more detailed information.

Authorization: None required.

The following table describes the columns in the view. The system name is ENV_VARS. The schema is QSYS2.

Table 97. ENVIRONMENT_VARIABLE_INFO view

Column Name	System Column Name	Data Type	Description
ENVIRONMENT_VARIABLE_TYPE	VAR_TYPE	VARCHAR(6)	The type of environment variable. SYSTEM Defined as a system level environment variable. JOB Defined as a job level environment variable. This variable and value only apply to the current connection. PASE Defined as an IBM Portable Application Solutions Environment for i (PASE for i) environment variable. This variable and value only apply to the current job. PASE variables are not returned unless the PASE environment has been started.
ENVIRONMENT_VARIABLE_NAME	VAR_NAME	VARGRAPHIC(128) CCSID 1200	The name of the environment variable. If the name is longer than 128 characters, it will be truncated with no warning. If ENVIRONMENT_VARIABLE_CCSID is 65535, the content of this column is set using the job default CCSID.
ENVIRONMENT_VARIABLE_VALUE	VAR_VALUE	VARGRAPHIC(1024) CCSID 1200 Nullable	The current value of the environment variable. If the value is longer than 1024 characters, it will be truncated with no warning. If ENVIRONMENT_VARIABLE_CCSID is 65535, the content of this column is set using the job default CCSID. Contains null if there is no value.
ENVIRONMENT_VARIABLE_BINARY_NAME	VAR_BNAME	VARBINARY(128)	The name of the environment variable in binary form. This is the raw value for the name. If the name is longer than 128 characters, it will be truncated with no warning.
ENVIRONMENT_VARIABLE_BINARY_VALUE	VAR_BVALUE	VARBINARY(1024) Nullable	The current value of the environment variable. This is the raw value for the value. If the value is longer than 1024 characters, it will be truncated with no warning. Contains null if there is no value.
ENVIRONMENT_VARIABLE_CCSID	VAR_CCSID	INTEGER	The CCSID value associated with the environment variable.

Example

Look at all system level environment variables and their values for this connection:

```
SELECT ENVIRONMENT_VARIABLE_NAME, ENVIRONMENT_VARIABLE_VALUE
FROM QSYS2.ENVIRONMENT_VARIABLE_INFO
WHERE ENVIRONMENT_VARIABLE_TYPE = 'SYSTEM'
```

ERRNO_INFO scalar function

The ERRNO_INFO scalar function returns descriptive text that corresponds to an errno value.

The function requires that Option 13 (System Openness Includes) of the IBM i operating system is installed.

Authorization: See Note below.

►► ERRNO_INFO (*errno*) ►►
└── ERRNO ── => ─┘

The schema is SYSTOOLS.

errno An integer representing an errno value returned from an API call.

The result of the function is VARCHAR(256). If no descriptive text for the errno is found, the null value is returned.

Note

This function is provided in the SYSTOOLS schema as an example of how to embed a C language interface in an SQL scalar function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

Return information for errno 3025.

```
VALUES SYSTOOLS.ERRNO_INFO(3025);
```

EXIT_POINT_INFO view

The EXIT_POINT_INFO view returns information about exit points.

The values returned for the columns in the view are closely related to the values returned by the Work with Registration Information (WRKREGINF) CL command and by the Retrieve Exit Information (QUSRTVEI, QusRetrieveExitInformation) API.

Authorization: None required.

The following table describes the columns in the view. The system name is EXIT_POINT. The schema is QSYS2.

Table 98. EXIT_POINT_INFO view

Column Name	System Column Name	Data Type	Description
EXIT_POINT_NAME	EXIT_NAME	VARCHAR(20)	The name of the exit point.
EXIT_POINT_FORMAT	EXIT_FMT	CHAR(8)	The format name associated with the exit point.
REGISTERED	REGISTERED	VARCHAR(3)	Whether the exit point is registered with the registration facility. NO The exit point is unregistered. YES The exit point is registered.
ALLOW_DEREGISTRATION	DEREGISTER	VARCHAR(3)	Whether the exit point can be deregistered. NO The exit point cannot be deregistered. YES The exit point can be deregistered.
ALLOW_CHANGE	CHANGE	VARCHAR(3)	Whether the exit point controls can be changed. NO The exit point controls cannot be changed. YES The exit point controls can be changed.
EXIT_PROGRAMS	EXIT_PGMS	INTEGER	The current number of exit programs associated with the exit point.

Table 98. EXIT_POINT_INFO view (continued)

Column Name	System Column Name	Data Type	Description
MAXIMUM_EXIT_PROGRAMS	MAX_PGMS	INTEGER Nullable	The maximum number of exit programs that the exit point allows. Contains the null value if the maximum number of exit programs is *NOMAX.
TEXT_DESCRIPTION	TEXT	VARCHAR(132) Nullable	The descriptive text for the exit point. Contains the null value if no descriptive text is available.
ADD_EXIT_PROGRAM_LIBRARY	ADD_LIB	VARCHAR(10) Nullable	The library in which ADD_EXIT_PROGRAM resides. Contains the null value if no add exit program is defined.
ADD_EXIT_PROGRAM	ADD_PGM	VARCHAR(10) Nullable	The preprocessing exit program name that is called by the registration facility when the Add Exit Program API is called for the exit point. Contains the null value if no add exit program is defined.
ADD_EXIT_PROGRAM_FORMAT	ADD_FMT	CHAR(8) Nullable	The format name for ADD_EXIT_PROGRAM. Contains the null value if no add exit program is defined.
REMOVE_EXIT_PROGRAM_LIBRARY	RMV_LIB	VARCHAR(10) Nullable	The library in which REMOVE_EXIT_PROGRAM resides. Contains the null value if no remove exit program is defined.
REMOVE_EXIT_PROGRAM	RMV_PGM	VARCHAR(10) Nullable	The preprocessing exit program name that is called by the registration facility when the Remove Exit Program API is called for the exit point. Contains the null value if no remove exit program is defined.
REMOVE_EXIT_PROGRAM_FORMAT	RMV_FMT	CHAR(8) Nullable	The format name for REMOVE_EXIT_PROGRAM. Contains the null value if no remove exit program is defined.
RETRIEVE_EXIT_PROGRAM_LIBRARY	RTV_LIB	VARCHAR(10) Nullable	The library in which RETRIEVE_EXIT_PROGRAM resides. Contains the null value if no retrieve exit program is defined.
RETRIEVE_EXIT_PROGRAM	RTV_PGM	VARCHAR(10) Nullable	The preprocessing exit program name that is called by the registration facility when the Retrieve Exit Information API is called for the exit point. Contains the null value if no retrieve exit program is defined.
RETRIEVE_EXIT_PROGRAM_FORMAT	RTV_FMT	CHAR(8) Nullable	The format name for RETRIEVE_EXIT_PROGRAM. Contains the null value if no retrieve exit program is defined.

Example

- List all the security exit points.

```
SELECT *
FROM QSYS2.EXIT_POINT_INFO
WHERE EXIT_POINT_NAME LIKE 'QIBM_QSY%';
```

EXIT_PROGRAM_INFO view

The EXIT_PROGRAM_INFO view returns information about exit programs.

The values returned for the columns in the view are closely related to the values returned by the Work with Registration Information (WRKREGINF) CL command and by the Retrieve Exit Information (QUSRTVEI, QusRetrieveExitInformation) API.

Authorization: None required.

The following table describes the columns in the view. The system name is EXIT_PGM. The schema is QSYS2.

Table 99. EXIT_PROGRAM_INFO view

Column Name	System Column Name	Data Type	Description
EXIT_POINT_NAME	EXIT_NAME	VARCHAR(20)	The exit point name.
EXIT_POINT_FORMAT	EXIT_FMT	CHAR(8)	The exit point format name associated with the exit point.
REGISTERED	REGISTERED	VARCHAR(3)	Whether the exit point is registered with the registration facility. NO The exit point is unregistered. YES The exit point is registered.
COMPLETE	COMPLETE	VARCHAR(3)	Whether the information returned for the exit point is complete and accurate. Incomplete information may occur when the exit point's retrieve preprocessing program indicates that the information it returned is incomplete or inaccurate. NO The exit point entry information is not complete or accurate. The remaining columns should be ignored. YES The exit point entry information is complete and accurate.
EXIT_PROGRAM_NUMBER	NUMBER	INTEGER	The exit program number associated with the exit program. This number determines the processing sequence of exit programs associated with an exit point, where the lowest number is processed first.
EXIT_PROGRAM_LIBRARY	LIBRARY	VARCHAR(10)	The library in which EXIT_PROGRAM resides.
EXIT_PROGRAM	PROGRAM	VARCHAR(10)	The name of the exit program.
TEXT_DESCRIPTION	TEXT	VARCHAR(132) Nullable	The descriptive text for the exit program . Contains the null value if no descriptive text is available.
EXIT_PROGRAM_DATA	DATA	VARCHAR(2048) Nullable	The data that is associated with the exit program. Contains the null value when there is no exit program data.
EXIT_PROGRAM_DATA_CCSD	DATA_CCSD	INTEGER Nullable	The coded character set identifier (CCSID) to use for working with the exit program data. Contains the null value when EXIT_PROGRAM_DATA is null.
THREADSAFE	THREADSAFE	VARCHAR(3) Nullable	The thread safety status of the exit program entry. NO The exit program entry is not threadsafe. YES The exit program entry is threadsafe. Contains the null value when the threadsafe status of the exit program entry is not known.

Table 99. EXIT_PROGRAM_INFO view (continued)

Column Name	System Column Name	Data Type	Description
MULTITHREADED_JOB_ACTION	JOB_ACTION	VARCHAR(6)	<p>The action to take when calling an exit program in a multithreaded job.</p> <p>*MSG Run the exit program in the current multithreaded job, but send an informational message. CPI3C80 can be used as the informational message.</p> <p>*NORUN Do not run the exit program in the current multithreaded job. Depending on the exit point, do one of the following:</p> <ol style="list-style-type: none"> 1. Send an escape message and do not call the exit program. CPF3C80 can be used as the escape message. 2. Send an informational message and do not call the exit program. CPF3C80 can be used as the informational message. 3. Call the exit program in a non-multithreaded job. <p>*RUN Run the exit program in the current multithreaded job.</p>
QMLTTHDACN_SYSTEM_VALUE	QMLTTHDACN	VARCHAR(3)	<p>Indicates whether the QMLTTHDACN system value was used in determining the multithreaded job action.</p> <p>NO The QMLTTHDACN system value was not used to determine the multithreaded job action.</p> <p>YES The QMLTTHDACN system value was used to determine the multithreaded job action.</p>

Example

- List all the exit programs associated with security exit points.

```
SELECT *
FROM QSYS2.EXIT_PROGRAM_INFO
WHERE EXIT_POINT_NAME LIKE 'QIBM_QSY%'
ORDER BY EXIT_POINT_NAME, EXIT_PROGRAM_NUMBER;
```

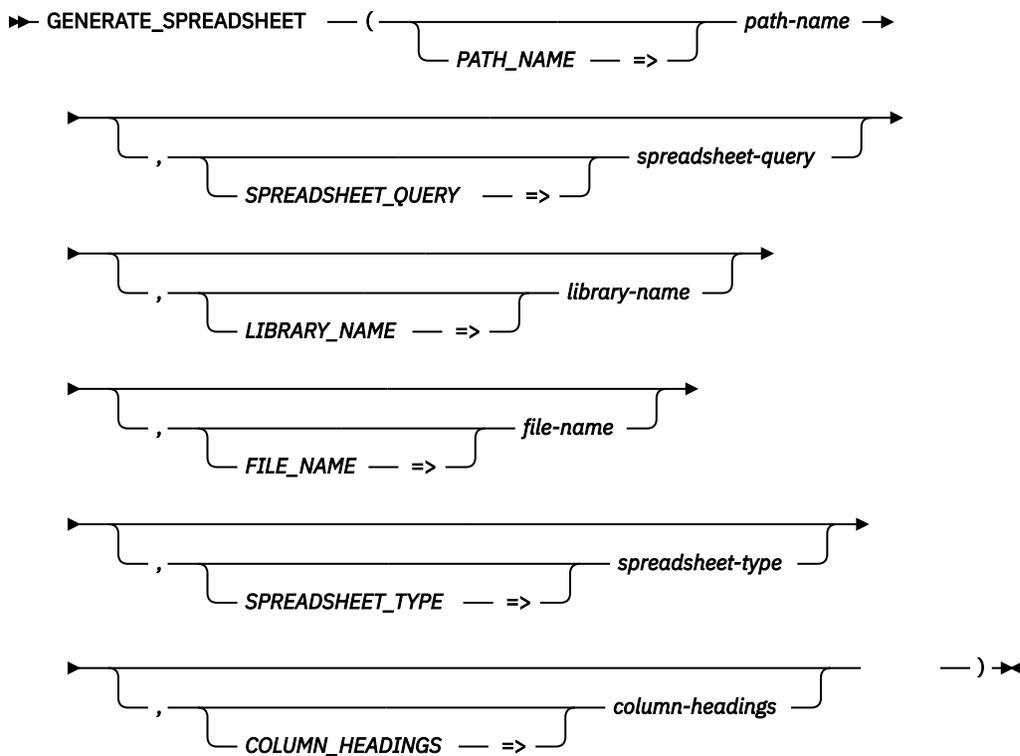

GENERATE_SPREADSHEET scalar function

The GENERATE_SPREADSHEET scalar function generates a file in the integrated file system containing a spreadsheet based on either the results of a query or the complete content of a database file.

This scalar function relies upon the CLDownload feature provided by the IBM i Access Client Solutions (ACS) jar that ships on every IBM i. The ACS jar is delivered via the IBM HTTP SERVER FOR i PTF Group, and is found at this path: **/QIBM/proddata/Access/ACS/Base/acsbundle.jar**

CLOB, BLOB, DBCLOB, and XML data is not supported by CLDownload. It can be returned by casting the column to a non-LOB string data type.

Authorization: See Note below.

The schema is SYSTOOLS.

- path-name*** A character string containing the name of the path where the result spreadsheet file is to be written. An existing file is overwritten.
- spreadsheet-query*** A character string containing a query to run that identifies the rows to be included in the spreadsheet. The query can be up to 4000 characters long. Objects referenced in the query cannot be in QTEMP and must be fully qualified.
If this parameter is omitted, *library-name* and *file-name* must be specified.
- library-name*** The name of the library containing *file-name*. QTEMP, *LIBL, and *CURLIB are not supported.
- file-name*** A character string containing the name of the database file that contains the rows and columns of data to include in the spreadsheet. The file must be in SYSBASE.
If *spreadsheet-query* is specified, values for *library-name* and *file-name* are ignored.
- spreadsheet-type*** A character string containing the type of spreadsheet to generate. The supported values are csv, ods, txt, xls, and xlsx. These values must be provided in lower case.
If this parameter is omitted, csv is used.
- column-headings*** A character string that specifies whether a heading row is included in the spreadsheet result.
 - COLUMN** The column names are used as the heading.
 - LABEL** The column labels are used as the heading. If no column label exists, the column name is used.
 - NONE** No heading row is returned. This is the default.

The result of the function is an integer. If the function is successful, it returns a value of 1. If the function encounters an error, it returns a value of -1.

Note

This function is provided in the SYSTOOLS schema as an example of invoking a Qshell command from within an SQL scalar function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

- Create a spreadsheet that contains the data from MYLIB/A.

```
VALUES SYSTOOLS.GENERATE_SPREADSHEET(  
    PATH_NAME      => '/usr/fileA_spreadsheet',  
    FILE_NAME     => 'A',  
    LIBRARY_NAME  => 'MYLIB');
```

- Create a spreadsheet that contains the data from a query. Return column names in the first row of the spreadsheet.

```
VALUES SYSTOOLS.GENERATE_SPREADSHEET(  
    PATH_NAME      => '/usr/query_spreadsheet',  
    SPREADSHEET_QUERY => 'select order_number, customer, balance  
from orders where shipped = 'YES'',  
    COLUMN_HEADINGS => 'COLUMN');
```

GETENV scalar function

The GETENV scalar function retrieves the value of an environment variable for the current job.

The function is implemented using the getenv() API. The result is similar to the QSYS2.ENVIRONMENT_VARIABLE_INFO view and the Work with Environment Var (WRKENVVAR) CL command.

The function requires that Option 13 (System Openness Includes) of the IBM i operating system is installed.

Authorization: See Note below.

► GETENV (ENVIRONMENT_VARIABLE_NAME => *environment-variable-name*) ►

The schema is SYSTOOLS.

environment-variable-name An expression that returns the name of an environment variable.

The result of the function is a variable-length character string that contains the value of the environment variable, from 0 to 1024 characters in length. If the environment variable is not found, the function returns the null value.

Note

This function is provided in the SYSTOOLS schema as an example of how to embed a C interface within SQL PL code. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

- Get the value of MY_ENVVAR for the current job.

```
VALUES SYSTOOLS.GETENV('MY_ENVVAR');
```

LPRINTF procedure

The LPRINTF procedure writes an informational message to the joblog. It is severity 0 and has no message identifier.

Authorization: See Note below.

➔ LPRINTF — (————— *print-string* —) ➔
 PRINT_STRING — =>

The schema is SYSTOOLS.

print-string A character or graphic string containing the information to be written to the joblog. It can be up to 30,720 characters long.

Note

This procedure is provided in the SYSTOOLS schema as an example of how to write to the joblog using an SQL procedure. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar procedures, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

Write a message to the joblog.

```
CALL SYSTOOLS.LPRINTF('This message sent on '
                      CONCAT DAYOFWEEK(CURRENT DATE) CONCAT ' at '
                      CONCAT CURRENT TIME);
```

Results in this string in the joblog:

```
This message sent on Saturday at 04:21 PM
```

PROGRAM_EXPORT_IMPORT_INFO view

The PROGRAM_EXPORT_IMPORT_INFO view returns the data and procedure that are exported or imported for an ILE program or service program.

The values returned for the columns in the view are closely related to the values returned for *PROCEXP, *DTAEXP, *ACTGRPEXP, and *ACTGRPIMP detail on the DSPSRVPGM (Display Service Program) CL command and *ACTGRPEXP and *ACTGRPIMP detail on the DSPPGM (Display Program) CL command. It is similar to the information returned by the List Service Program Information (QBNLSPGM) and List Program Information (QBNLPGMI) APIs.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the program or service program, and
- *READ authority to the program or service program.

The following table describes the columns in the view. The system name is EXPIMP_INF. The schema is QSYS2.

Table 100. PROGRAM_EXPORT_IMPORT_INFO view

Column Name	System Column Name	Data Type	Description
PROGRAM_LIBRARY	PGM_LIB	VARCHAR(10)	The library containing the program or service program.
PROGRAM_NAME	PGM_NAME	VARCHAR(10)	The program or service program to which this export or import applies.
OBJECT_TYPE	OBJ_TYPE	VARCHAR(7)	Object type for PROGRAM_NAME. *PGM A program. *SRVPGM A service program.
SYMBOL_NAME	NAME	VARGRAPHIC(8192) CCSID 1200	The name of a procedure or data export or import.
SYMBOL_USAGE	USAGE	VARCHAR(10)	The type of export or import. *ACTGRPEXP The data export to the activation group. *ACTGRPIMP A data import that is resolved by a weak export that had been exported to the activation group. *DTAEXP A data item exported from this service program. *PROCEXP A procedure exported from this service program.
ARGUMENT_OPTIMIZATION	ARGOPT	VARCHAR(4) Nullable	Whether the service program procedure export uses argument optimization. *NO The procedure export does not use argument optimization. *YES The procedure export uses argument optimization. Contains the null value if SYMBOL_USAGE is not *PROCEXP.
DATA_ITEM_SIZE	DATA_SIZE	INTEGER Nullable	The size of the data item export, in bytes. Contains the null value if SYMBOL_USAGE is not *ACTGRPEXP.

Example

- Show all the procedure exports for service program APP_PGM1 in APPLIB.

```
SELECT *
FROM QSYS2.PROGRAM_EXPORT_IMPORT_INFO
WHERE PROGRAM_LIBRARY = 'APPLIB' AND
      PROGRAM_NAME     = 'APP_PGM1' AND
      OBJECT_TYPE      = '*SRVPGM' AND
      SYMBOL_USAGE     = '*PROCEXP';
```

- Find the service program in QSYS that exports printf to joblog (Qp0zLprintf).

```
SELECT *
FROM QSYS2.PROGRAM_EXPORT_IMPORT_INFO
WHERE PROGRAM_LIBRARY = 'QSYS' AND SYMBOL_NAME = 'Qp0zLprintf';
```

PROGRAM_INFO view

The PROGRAM_INFO view returns information about programs.

The values returned for the columns in the view are closely related to the values returned by the DSPPPGM (Display Program) and DSPSRVPGM (Display Service Program) CL commands (the *BASIC, *SIZE, *SIGNATURE, and *COPYRIGHT details for ILE programs and service programs) and the Retrieve Program Information (QCLRPGMI) and Retrieve Service Program Information (QBNRSPGM) APIs.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the program or service program, and
- *READ authority to the program or service program.

The following table describes the columns in the view. The first set of columns, through CONVERSION_DETAIL, apply to all ILE and OPM programs and service programs. The next group of columns apply to only ILE programs and service programs. The final group of columns apply to only OPM programs. The system name is PGM_INFO. The schema is QSYS2.

Table 101. PROGRAM_INFO view

Column Name	System Column Name	Data Type	Description
PROGRAM_LIBRARY	PGM_LIB	VARCHAR(10)	The library containing the program or service program.
PROGRAM_NAME	PGM_NAME	VARCHAR(10)	The program or service program.
PROGRAM_TYPE	PGM_TYPE	VARCHAR(3)	The type of program or service program. ILE An Integrated Language Environment® program or service program. OPM An original program model program.
OBJECT_TYPE	OBJ_TYPE	VARCHAR(7)	Object type for PROGRAM_NAME. *PGM A program. *SRVPGM A service program.
CREATE_TIMESTAMP	CREATE_TS	TIMESTAMP(0)	The timestamp when the program or service program was created.
TEXT_DESCRIPTION	TEXT	VARCHAR(50) Nullable	The user text, if any, used to briefly describe the program or service program. Contains the null value if there is no text description.
PROGRAM_OWNER	OWNER	VARCHAR(10) Nullable	The name of the program or service program owner's user profile. Contains the null value if no program owner is available.
PROGRAM_ATTRIBUTE	ATTRIBUTE	VARCHAR(10) Nullable	For an ILE program, the ILE language used for the module containing the program entry procedure (PEP). For a service program, the language in which the modules of the service program are written. For an OPM program, the language the program is written in. Contains the null value if there is no attribute value or if a service program contains modules generated by different compilers.

Table 101. PROGRAM_INFO view (continued)

Column Name	System Column Name	Data Type	Description
USER_PROFILE	USRPRF	VARCHAR(6)	<p>The value specified for the USRPRF option on the command used to create the program or service program.</p> <p>*OWNER The program or service program runs under both the current user's and the owner's user profiles.</p> <p>*USER The program or service program runs under the current user's user profile.</p>
USE_ADOPTED_AUTHORITY	USEADPAUT	VARCHAR(4)	<p>The value specified for the USEADPAUT option on the command used to change the program or service program.</p> <p>*NO Does not use program adopted authority from previous call levels when this program or service program is running</p> <p>*YES Uses program adopted authority from previous call levels when this program or service program is running.</p>
PROGRAM_STATE	STATE	VARCHAR(8)	<p>The state of the program or service program.</p> <p>*INHERIT The program or service program runs under (inherits) the same state as its caller.</p> <p>*SYSTEM The program or service program can call user-domain or system-domain programs.</p> <p>*USER The program or service program can call only user-domain programs.</p>
PROGRAM_DOMAIN	DOMAIN	VARCHAR(7)	<p>The domain of the program or service program.</p> <p>*SYSTEM The program or service program can be called by system-state programs.</p> <p>*USER The program can be called by user-state or system-state programs.</p>
EARLIEST_POSSIBLE_RELEASE	EARLY_REL	CHAR(6)	<p>The version, release, and modification level of the earliest release the program or service program is allowed to run on, in VvRrMm format. The target release (TGTRLS) parameter of the command can affect this value.</p>
RELEASE_CREATED_ON	CREATE_ON	CHAR(6) Nullable	<p>The version, release, and modification level of the operating system, in VvRrMm format, on which the program or service program was created.</p> <p>Contains the null value for OPM programs.</p>
TARGET_RELEASE	TGTRLS	CHAR(6) Nullable	<p>This is the release specified on the target release (TGTRLS) parameter of the command.</p> <p>Contains the null value for OPM programs.</p>
MINIMUM_NUMBER_PARMS	MIN_PARMS	INTEGER Nullable	<p>The minimum number of parameters that is to be received by the program when it is called.</p> <p>Contains the null value if this is a service program or if the information is not available.</p>
MAXIMUM_NUMBER_PARMS	MAX_PARMS	INTEGER Nullable	<p>The maximum number of parameters that may be received by the program when it is called.</p> <p>Contains the null value if this is a service program or if the information is not available.</p>
ASSOCIATED_SPACE_SIZE	ASSOC_SIZE	INTEGER	<p>The size (in bytes) of the associated space used by this program or service program.</p>

Table 101. PROGRAM_INFO view (continued)

Column Name	System Column Name	Data Type	Description
PAGING_POOL	POOL	VARCHAR(8)	The paging pool used for the program or service program object. *BASE Use the base pool. *MACHINE Use the machine pool. *USER Use the user pool.
PAGING_AMOUNT	PAGEAMOUNT	VARCHAR(8)	The paging behavior for the program or service program. *BLOCK Page the program or service program in multiple-page blocks. *NOBLOCK Page the program or service program one page at a time.
ALLOW_RTVCLSRC	ALWRTVSRC	VARCHAR(4) Nullable	Value of the ALWRTVSRC parameter if this program was created using the Create CL Program (CRTCLPGM) command. *NO Source for the CL program is not saved with the program. *YES Source is saved. Contains the null value if this is not a CL program.
CONVERSION_REQUIRED	CONVREQ	VARCHAR(4)	Indicates whether the program or service program has been converted to the format required by the machine or if conversion is still required. *NO Conversion is not required. *YES Conversion is required.
CONVERSION_DETAIL	CONVDETAIL	VARCHAR(8)	Indicates details about the conversion status. *COMMON The object is compatible and requires only features common to all systems supported by this release. *COMPAT The object is compatible, but requires features not present on all systems supported by this release. *FEATURE The object is not compatible. The format is current, but the object requires features not present on the current machine implementation. *FORMAT The object is not compatible because it is in an older format.
The following columns apply to ILE programs and service programs. They will contain the null value for OPM programs.			
PROGRAM_ENTRY_PROCEDURE_MODULE_LIBRARY	PEP_LIB	VARCHAR(10) Nullable	The library name that contained the module that contained the program entry procedure for this program when the bind was done. Contains the null value if this is a service program.
PROGRAM_ENTRY_PROCEDURE_MODULE	PEP_MODULE	VARCHAR(10) Nullable	The module name that contains the program entry procedure for this program. Contains the null value if this is a service program.

Table 101. PROGRAM_INFO view (continued)

Column Name	System Column Name	Data Type	Description
ACTIVATION_GROUP	ACTGRP	VARCHAR(10) Nullable	<p>The name of the activation group in which this program or service program runs. If the activation group already exists when the program or service program is called, it runs in the existing activation group. If the activation group does not exist, a new activation group is created and the program or service program runs in it. Can contain the following special values:</p> <p>*CALLER The program or service program runs in the activation group of the calling program.</p> <p>*DFACTGRP The program uses one of two existing activation groups created when the process is started. One default activation group is reserved for system-state programs. The other default activation group is reserved for user-state programs.</p> <p>*NEW A new unnamed activation group is created when this program is called. The program runs in this activation group.</p>
SHARED_ACTIVATION_GROUP	SHARED_AG	VARCHAR(4) Nullable	<p>Whether the program or service program runs in a shared activation group.</p> <p>*NO The activation group is not shared.</p> <p>*YES The activation group is shared.</p>
OBSERVABLE_INFO_COMPRESSED	OBS_COMP	VARCHAR(4) Nullable	<p>Whether the observable information associated with the program or service program is compressed.</p> <p>*NO The observable information is not compressed.</p> <p>*YES The observable information is compressed.</p>
RUNTIME_INFO_COMPRESSED	RUN_COMP	VARCHAR(4) Nullable	<p>Whether the run-time information associated with the program or service program is compressed.</p> <p>*NO The run-time information is not compressed.</p> <p>*YES The run-time information is compressed.</p>
ALLOW_UPDATE	ALWUPD	VARCHAR(4) Nullable	<p>Whether the Update Program (UPDPGM) or Update Service Program (UPDSRVPGM) command is allowed on this program or service program.</p> <p>*NO The update command cannot be run.</p> <p>*YES The update command can be run.</p>
ALLOW_BOUND_SRPVGM_LIBRARY_UPDATE	ALWLIBUPD	VARCHAR(4) Nullable	<p>Whether the Update Program (UPDPGM) or Update Service Program (UPDSRVPGM) command is allowed to change the bound *SRVPGM library names on this program or service program.</p> <p>*NO The update command cannot specify a library name for the SRVPGMLIB parameter.</p> <p>*YES The update command can specify a library name for the SRVPGMLIB parameter.</p>

Table 101. PROGRAM_INFO view (continued)

Column Name	System Column Name	Data Type	Description
ALL_CREATION_DATA	ALL_CREATE	VARCHAR(6) Nullable	<p>Whether the program or service program has all creation data and if that data is observable or unobservable. All observable creation data is needed to re-create the program or service program using the Change Program (CHGPGM) or Change Service Program (CHGSRVPGM) command. All creation data (either observable or unobservable) is needed to convert the program or service program during restore.</p> <p>*NO Not all of the creation data is present.</p> <p>*UNOBS All the creation data is present but not all of that data is observable.</p> <p>*YES All the creation data is present and all of that data is observable.</p>
PROFILING_DATA	PRF_DATA	VARCHAR(10) Nullable	<p>Specifies the profiling data attribute for this program or service program.</p> <p>*APYALL Block order and procedure order profiling data are applied to this program or service program. The collection of profiling data is no longer enabled.</p> <p>*APYBLKORD Block order profiling data has been applied to at least one module bound into this program or service program.</p> <p>*APYPRCORD Procedure order profiling data has been applied to this program or service program.</p> <p>*COL The collection of profiling data is enabled for at least one module bound into this program or service program. Any applied profiling data has been removed.</p> <p>*NOCOL The collection of profiling data is not enabled and profiling data is not applied.</p>
TERASPACE_STORAGE_ENABLED_MODULES	TERA_MOD	VARCHAR(5) Nullable	<p>The teraspace storage capability of the modules bound to this program or service program.</p> <p>*ALL All modules bound to this program or service program are teraspace storage enabled.</p> <p>*NONE No modules bound to this program or service program are teraspace storage enabled.</p> <p>*SOME One or more modules bound to this program or service program are teraspace storage enabled.</p>
TERASPACE_STORAGE_ENABLED_PEP	TERA_PEP	VARCHAR(4) Nullable	<p>Indicates whether the Program Entry Procedure (PEP) is teraspace enabled.</p> <p>*NO The PEP module is not teraspace storage enabled.</p> <p>*YES The PEP module is teraspace storage enabled.</p> <p>Contains the null value if this is a service program.</p>

Table 101. PROGRAM_INFO view (continued)

Column Name	System Column Name	Data Type	Description
STORAGE_MODEL	STGMDL	VARCHAR(10) Nullable	Where the automatic and static storage for this program or service program is allocated at run time. *INHERIT Automatic and static storage are allocated from either single-level storage or teraspace, depending on the activation. *SNGLVL Automatic and static storage are allocated from single-level storage. *TERASPACE Automatic and static storage are allocated from teraspace.
ARGUMENT_OPTIMIZATION	ARGOPT	VARCHAR(4) Nullable	Whether argument optimization was done during program or service program creation. *NO Argument optimization was not performed. *YES Argument optimization was performed.
NUMBER_OF_UNRESOLVED_REFERENCES	UNRESOLVED	INTEGER Nullable	The number of symbols that could not be resolved at Create Program (CRTPGM) or Create Service Program (CRTSRVPGM) command time.
ALLOW_STATIC_STORAGE_REINIT	ALWRINZ	VARCHAR(4) Nullable	Whether program or service program static storage can be reinitialized. *NO Static storage cannot be reinitialized. *YES Static storage can be reinitialized.
MINIMUM_STATIC_STORAGE_SIZE	MIN_STATIC	BIGINT Nullable	The minimum static storage size, in bytes, that this program or service program needs in order to run.
MAXIMUM_STATIC_STORAGE_SIZE	MAX_STATIC	BIGINT Nullable	The maximum static storage size, in bytes, that this program or service program may need in order to run.
AUXILIARY_STORAGE_SEGMENTS	NBR_AUX	INTEGER Nullable	The number of auxiliary storage segments in this program or service program.
MAXIMUM_AUXILIARY_STORAGE_SEGMENTS	MAX_AUX	INTEGER Nullable	The maximum number of auxiliary storage segments an ILE program or service program can have.
PROGRAM_SIZE	PGM_SIZE	INTEGER Nullable	The total size of the program or service program, in kilobytes.
MAXIMUM_PROGRAM_SIZE	MAXPGMSIZE	INTEGER Nullable	The maximum size that an ILE program or service program can be, in kilobytes.
MODULES	MODULES	INTEGER Nullable	The number of modules bound into this program or service program.
MAXIMUM_MODULES	MAXMODS	INTEGER Nullable	The maximum number of modules that can be bound into an ILE program or service program.
SERVICE_PROGRAMS	SRVPGMS	INTEGER Nullable	The number of service programs bound to this program or service program.
MAXIMUM_SERVICE_PROGRAMS	MAXSRVPGMS	INTEGER Nullable	The maximum number of service programs that can be bound to an ILE program or service program.
STRING_DIRECTORY_SIZE	STRDIRSIZE	INTEGER Nullable	The program or service program's string directory size.

Table 101. PROGRAM_INFO view (continued)

Column Name	System Column Name	Data Type	Description
MAXIMUM_STRING_DIRECTORY_SIZE	MAXSTRDIR	INTEGER Nullable	The maximum size that the string directory can be in an ILE program or service program.
COPYRIGHTS	COPYRIGHTS	INTEGER Nullable	The number of copyrights in this program or service program.
COPYRIGHT_STRINGS	COPYR_JSON	CLOB(16M) CCSID 1208 Nullable	A list of copyrights. The value is returned as an array within a JSON object. It is formatted as: {"COPYRIGHT":["first-string", "second-string",...]} Contains the null value if COPYRIGHTS is 0.
COPYRIGHT_STRING_SIZE	CPYRSTRSIZ	INTEGER Nullable	The program or service program's copyright string size.
MAXIMUM_COPYRIGHT_STRING_SIZE	MAXCPYRSTR	INTEGER Nullable	The maximum size of the copyright string in an ILE program or service program.
EXPORT_SOURCE_LIBRARY	EXP_SRCLIB	VARCHAR(10) Nullable	The name of the library that contains the export source file. Can contain the following special value: *LIBL The library list. Contains the null value if EXPORT_SOURCE_FILE is null.
EXPORT_SOURCE_FILE	EXP_SRCF	VARCHAR(10) Nullable	The name of the export source file that contains the export source file member. Contains the null value if this is not a service program, if there is no export source, if the export source was not specified using a source file, or if you are not authorized to this information.
EXPORT_SOURCE_FILE_MEMBER	EXP_SRCM	VARCHAR(10) Nullable	The name of the member in the export source file that was used to create this service program. Contains the null value if EXPORT_SOURCE_FILE is null.
EXPORT_SOURCE_STREAM_FILE	EXP_STMF	VARGRAPHIC(5000) CCSID 1200 Nullable	The path name of the stream file that contains the export source for this service program. Contains the null value if this is not a service program or if the export source was not specified using a stream file.
PROCEDURE_EXPORTS	PROCEXP	INTEGER Nullable	The number of procedures exported from this service program. Contains the null value if this is not a service program.
MAXIMUM_PROCEDURE_EXPORTS	MAXPROCEXP	INTEGER Nullable	The maximum number of procedures that can be exported by a service program. Contains the null value if this is not a service program.
DATA_EXPORTS	DATAEXP	INTEGER Nullable	The number of data items exported from this service program. Contains the null value if this is not a service program.
MAXIMUM_DATA_EXPORTS	MAXDATAEXP	INTEGER Nullable	The maximum number of data items that can be exported by a service program. Contains the null value if this is not a service program.
SIGNATURES	SIGNATURES	INTEGER Nullable	The number of signatures for this service program. This is the number of entries returned in EXPORT_SIGNATURES. Contains the null value if this is not a service program.

Table 101. PROGRAM_INFO view (continued)

Column Name	System Column Name	Data Type	Description
EXPORT_SIGNATURES	EXP_SIG	BLOB(557038) Nullable	The list of export signatures for this service program. Each signature is a binary string with a length of 16. A single hexadecimal 00 character separates values. The current export signature of this service program is the first one in the list. Contains the null value if this is not a service program.
MAXIMUM_SIGNATURES	MAXSIGS	INTEGER Nullable	The maximum number of signatures that can be in a service program. Contains the null value if this is not a service program.
The following columns apply to OPM programs. They will contain the null value for ILE programs and service programs.			
SOURCE_FILE_LIBRARY	SRCLIB	VARCHAR(10) Nullable	The name of the library that contains the source file used to create the program.. Contains the null value if no source file was used to create the program.
SOURCE_FILE	SRCFILE	VARCHAR(10) Nullable	The name of the source file used to create the program. Contains the null value if no source file was used to create the program.
SOURCE_FILE_MEMBER	SRCMBR	VARCHAR(10) Nullable	The name of the member in the source file. Contains the null value if no source file was used to create the program.
SOURCE_FILE_CHANGE_TIMESTAMP	SRCF_CHGTS	TIMESTAMP(0) Nullable	The timestamp of when the member in the source file was last updated. Contains the null value if no source file was used to create the program.
SORT_SEQUENCE_LIBRARY	SRTSEQ_LIB	VARCHAR(10) Nullable	The name of the library that contained the sort sequence table used when the module was compiled. This does not apply to SQL statements in the module. Can contain the following special values: *LIBL The sort sequence table is found in the library list when PROGRAM_NAME runs this module. *CURLIB The sort sequence table is found in the current library when PROGRAM_NAME runs this module. Contains the null value if SORT_SEQUENCE contains a special value or is null.
SORT_SEQUENCE	SRTSEQ	VARCHAR(10) Nullable	The name of the sort sequence table used when the program was compiled. This does not apply to SQL statements in the program. Can contain the following special values: *HEX No sort sequence is used. *JOB RUN The sort sequence value associated with the job at the time the program runs. *LANGIDSHR The shared sort sequence for the language identifier is used. *LANGIDUNQ The unique sort sequence for the language identifier is used. Contains the null value if the program does not contain any sort sequence information.

Table 101. PROGRAM_INFO view (continued)

Column Name	System Column Name	Data Type	Description
LANGUAGE_ID	LANGID	VARCHAR(7) Nullable	<p>The language identifier used when the program was compiled. This does not apply to SQL statements in the program. Can contain the following special value:</p> <p>*JOBRUN The language identifier associated with the job at the time the program is run.</p> <p>Contains the null value if the program does not contain any language identification information.</p>
OBSERVABLE	OBSERVABLE	VARCHAR(6) Nullable	<p>Whether the OPM program contains creation data and if that data is observable or unobservable. All observable creation data is needed to re-create the program using CHGPGM. All creation data (either observable or unobservable) is needed to convert the program during restore.</p> <p>*ALL The program has all creation data and that data is observable.</p> <p>*NONE The program does not have all creation data.</p> <p>*UNOBS The program has all creation data but not all of that data is observable.</p>
OPTIMIZATION	OPTIMIZE	VARCHAR(11) Nullable	<p>Indicates what was specified on the OPTIMIZE parameter when the program was created or changed.</p> <p>*NOOPTIMIZE *NOOPTIMIZE was specified.</p> <p>*OPTIMIZE *OPTIMIZE was specified.</p>
LOG_COMMANDS	LOGCMD	VARCHAR(4) Nullable	<p>The value specified for the LOG parameter of the CRTCLPGM command.</p> <p>*JOB Logging of commands in a running CL program depends on the status of the job's logging flag.</p> <p>*NO Commands are not logged.</p> <p>*YES Commands are logged in all cases.</p> <p>Contains the null value if the program is not a CL program.</p>
FIX_DECIMAL_DATA	FIXDECDATA	VARCHAR(4) Nullable	<p>Whether decimal data that is not valid is corrected or an error is signaled.</p> <p>*NO An error is signaled to the program without correcting the data that is not valid.</p> <p>*YES Decimal data that is not valid is corrected.</p>
UPDATE_PASA	UPDPASA	VARCHAR(10) Nullable	<p>The compiler may have allowed you to control this attribute through the GENOPT parameter of the command used to create the program.</p> <p>*NOUPDPASA Do not update internal program automatic storage area (PASA) stack information.</p> <p>*UPDPASA Update internal PASA stack information.</p>
CLEAR_PASA	CLRPASA	VARCHAR(10) Nullable	<p>The compiler may have allowed you to control this attribute through the GENOPT parameter of the command used to create the program.</p> <p>*CLRPASA Clear PASA storage.</p> <p>*NOCLRPASA Do not clear PASA storage.</p>

Table 101. PROGRAM_INFO view (continued)

Column Name	System Column Name	Data Type	Description
COMPILER_ID	COMPILER	VARCHAR(14) Nullable	The licensed program identifier, version, release, and modification level of the compiler. The value has a ppppppbVvRrMm format, where: pppppp The licensed program identifier. b A blank character. Vv The character V is followed by a 1-character version number. Rr The character R is followed by a 1-character release level. Mm The character M is followed by a 1-character modification level.
TERASPACE_STORAGE_ENABLED_PROGRAM	TS_PGM	VARCHAR(4) Nullable	The teraspace storage capability of the program. A program must be teraspace storage enabled to access teraspace storage. *NO This program is not teraspace storage enabled. *YES This program is teraspace storage enabled.
OPM_PROGRAM_SIZE	OPMPGMSIZE	INTEGER Nullable	The size (in bytes) of this program.
STATIC_STORAGE_SIZE	STATIC_STG	INTEGER Nullable	The size (in bytes) of the static storage used by the program.
AUTOMATIC_STORAGE_SIZE	AUTO_STG	INTEGER Nullable	The size (in bytes) of the automatic storage used by this program.
NUMBER_MI_INSTRUCTIONS	MI_INSTR	INTEGER Nullable	The number of machine interface (MI) instructions used by this program. Contains the null value if the program is not observable.
NUMBER_MI_ODT_ENTRIES	MI_ODT	INTEGER Nullable	The number of ODT (object definition table) entries for the program. There is a limit of 32767 ODT entries in a program. Contains the null value if the program is not observable.
SQL_STATEMENT_COUNT	NBRSTMTS	INTEGER Nullable	The number of SQL statements contained in the program. Contains 0 if there are no SQL statements in the program.
SQL_RELATIONAL_DATABASE	RDB	VARCHAR(18) Nullable	The default relational database that was specified on the SQL precompile. Can contain the following special value: *LOCAL The program can only access data on the local system. Contains the null value if no package was created for the program by the SQL precompiler or if the program does not contain SQL statements.

Table 101. PROGRAM_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SQL_COMMITMENT_CONTROL	ISOLATION	VARCHAR(5) Nullable	<p>The level of commitment control that was specified on the SQL precompile.</p> <p>*ALL Read stability.</p> <p>*CHG Uncommitted read.</p> <p>*CS Cursor stability.</p> <p>*NONE No commit.</p> <p>*RR Repeatable read.</p> <p>Contains the null value if the program does not contain SQL statements.</p>
SQL_NAMING	NAMING	VARCHAR(4) Nullable	<p>The convention used for naming objects in SQL statements.</p> <p>*SQL The SQL naming convention is used.</p> <p>*SYS The system naming convention is used.</p> <p>Contains the null value if the program does not contain SQL statements.</p>
SQL_DATE_FORMAT	DATFMT	VARCHAR(4) Nullable	<p>The date format attribute.</p> <p>*DMY Day/month/year format (dd/mm/yy).</p> <p>*EUR European format (dd.mm.yyyy).</p> <p>*ISO International Standards Organization format (yyyy-mm-dd).</p> <p>*JIS Japanese Industrial Standard format (yyyy-mm-dd).</p> <p>*JUL Julian format (yy/dds).</p> <p>*MDY Month/day/year format (mm/dd/yy).</p> <p>*USA USA format (mm/dd/yyyy).</p> <p>*YMD Year/month/day format (yy/mm/dd).</p> <p>Contains the null value if the program does not contain SQL statements.</p>
SQL_DATE_SEPARATOR	DATSEP	CHAR(1) Nullable	<p>The date separator attribute.</p> <p>Contains the null value if the program does not contain SQL statements.</p>
SQL_TIME_FORMAT	TIMFMT	VARCHAR(4) Nullable	<p>The time format attribute.</p> <p>*EUR European format (hh.mm.ss).</p> <p>*HMS Hours/minutes/seconds format (hh:mm:ss).</p> <p>*ISO International Standards Organization format (hh.mm.ss).</p> <p>*JIS Japanese Industrial Standard format (hh.mm.ss).</p> <p>*USA USA format (hh:mm a.m. or p.m.).</p> <p>Contains the null value if the program does not contain SQL statements.</p>
SQL_TIME_SEPARATOR	TIMSEP	CHAR(1) Nullable	<p>The time separator attribute.</p> <p>Contains the null value if the program does not contain SQL statements.</p>

Table 101. PROGRAM_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SQL_SORT_SEQUENCE_LIBRARY	SQL_SSEQLB	VARCHAR(10) Nullable	<p>The name of the library that is used to locate the SQL sort sequence table. The following special values can be returned:</p> <p>*CURLIB The SQL sort sequence table is found by looking in the current library.</p> <p>*LIBL The SQL sort sequence table is found by looking in the library list.</p> <p>Contains the null value if SQL_SORT_SEQUENCE contains a special value or if the program does not contain SQL statements.</p>
SQL_SORT_SEQUENCE	SQL_SRTSEQ	VARCHAR(10) Nullable	<p>The sort sequence table name specified when the program was compiled. The following special values can be returned:</p> <p>*HEX No SQL sort sequence is used for the SQL statements.</p> <p>*JOBRUN The SQL sort sequence is the SRTSEQ value associated with the job at the time the SQL statements within the program are run.</p> <p>*LANGIDSHR The shared SQL sort sequence for the language identifier (LANGID) is used for the SQL statements.</p> <p>*LANGIDUNQ The unique SQL sort sequence for the language identifier (LANGID) is used for the SQL statements.</p> <p>Contains the null value if the program does not contain SQL statements.</p>
SQL_LANGUAGE_ID	SQL_LANGID	VARCHAR(7) Nullable	<p>The language identifier specified when the program was compiled. The following special value can be returned:</p> <p>*JOBRUN The language identifier is the LANGID associated with the job at the time the program is run.</p> <p>Contains the null value if the program does not contain SQL statements.</p>
SQL_DEFAULT_SCHEMA	DFTRBCOL	VARCHAR(10) Nullable	<p>The schema name used for unqualified names of tables, views, indexes, and SQL packages in static statements.</p> <p>Contains the null value if there is no default schema name or if the program does not contain SQL statements.</p>
SQL_PATH	SQLPATH	VARCHAR(3483) Nullable	<p>The list of libraries used during resolution of functions, procedures, and data types within SQL statements. The list is in the form of repeating library names, each surrounded by double quotes and separated by commas.</p> <p>Contains the null value if the program does not contain SQL statements.</p>

Table 101. PROGRAM_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SQL_DYNAMIC_USER_PROFILE	DYNUSRPRF	VARCHAR(10) Nullable	<p>The user profile used for dynamic SQL statements. The following special values can be returned:</p> <p>*OWNER Local dynamic SQL statements are run under the profile of the program's owner. Distributed dynamic SQL statements are run under the profile of the SQL package's owner.</p> <p>*USER Local dynamic SQL statements are run under the profile of the job or thread. Distributed dynamic SQL statements are run under the profile of the application server job.</p> <p>Contains the null value if the program does not contain SQL statements.</p>
SQL_ALLOW_COPY_DATA	ALWCPYDTA	VARCHAR(9) Nullable	<p>Whether a copy of the data can be used in the implementation of an SQL query.</p> <p>*NO A copy of the data is not allowed.</p> <p>*OPTIMIZE A copy of the data is allowed whenever it might result is better performance.</p> <p>*YES A copy of the data is allowed, but only when necessary.</p> <p>Contains the null value if the program does not contain SQL statements.</p>
SQL_CLOSE_SQL_CURSOR	CLOSQCSR	VARCHAR(10) Nullable	<p>Specifies the CLOSQCSR attribute.</p> <p>*ENDJOB SQL cursors remain open between calls and can be fetched without running another OPEN statement. The programs higher on the call stack do not need to have run SQL statements. SQL cursors are left open, SQL prepared statements are preserved, and LOCK TABLE locks are held when the first SQL program on the call stack ends. SQL cursors are closed, SQL prepared statements are discarded, and LOCK TABLE locks are released when the job ends.</p> <p>*ENDPGM SQL cursors are closed and SQL prepared statements are discarded when the program ends. LOCK TABLE locks are released when the first SQL program on the call stack ends.</p> <p>*ENDSQL SQL cursors remain open between calls and rows can be fetched without running another OPEN statement. One of the programs higher on the call stack must have run at least one SQL statement. The SQL cursors are closed, SQL prepared statements are discarded, and LOCK TABLE locks are released when the first SQL program on the call stack ends. If you specify *ENDSQL for a program that is the first SQL program called (the first SQL program on the call stack), the program is treated as if *ENDPGM was specified.</p> <p>Contains the null value if the program does not contain SQL statements.</p>

Table 101. PROGRAM_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SQL_DELAY_PREPARE	DLYPRP	VARCHAR(4) Nullable	Indicates the delay prepare attribute. *NO Dynamic statement validation is performed when the dynamic statements are prepared. *YES Dynamic statement validation is delayed until the dynamic statements are used. Contains the null value if the program does not contain SQL statements.
SQL_ALLOW_BLOCK	ALWBLK	VARCHAR(8) Nullable	Whether blocking is used to improve the performance of certain SQL statements. *ALLREAD Rows are blocked for read-only cursors. *NONE Rows are not blocked for retrieval of data for cursors. *READ Rows are blocked for read-only retrieval of data for cursors when: <ul style="list-style-type: none"> • The commitment control value is *NONE. • The cursor is declared with a FOR READ ONLY clause or there are no dynamic statements that could run a positioned UPDATE or DELETE statement for the cursor. Contains the null value if the program does not contain SQL statements.
SQL_PACKAGE_LIBRARY	SQLPKGLIB	VARCHAR(10) Nullable	The name of the library the SQL package is in. Contains the null value if the program is not distributed or if the program does not contain SQL statements.
SQL_PACKAGE	SQLPKG	VARCHAR(10) Nullable	The name of the SQL package created on the relational database specified on the RDB parameter of the command that created this program. Contains the null value if the program is not distributed or if it does not contain SQL statements.
SQL_RDB_CONNECTION_METHOD	RDBCNNMTH	VARCHAR(4) Nullable	Specifies the semantics used for CONNECT statements: *DUW CONNECT (Type 2) semantics are used to support distributed unit of work. *RUW CONNECT (Type 1) semantics are used to support remote unit of work Contains the null value if the program is not distributed or if it does not contain SQL statements.

Examples

- Summarize the activation group usage for all ILE programs in APPLIB.

```
SELECT ACTIVATION_GROUP, COUNT(*) AS ACTIVATION_GROUP_NAME_COUNT
FROM QSYS2.PROGRAM_INFO
WHERE PROGRAM_LIBRARY = 'APPLIB'
      AND PROGRAM_TYPE = 'ILE'
GROUP BY ACTIVATION_GROUP
ORDER BY 2 DESC;
```

- Examine the ownership of programs and service programs in APPLIB.

```
SELECT PROGRAM_OWNER, OBJECT_TYPE, COUNT(*) AS APPLICATION_OWNER_COUNT
FROM QSYS2.PROGRAM_INFO
WHERE PROGRAM_LIBRARY = 'APPLIB'
GROUP BY PROGRAM_OWNER, OBJECT_TYPE
ORDER BY 2, 3 DESC;
```

- List all the copyrights for ILE programs in APPLIB.

```
SELECT PROGRAM_LIBRARY, PROGRAM_NAME, PROGRAM_TYPE, COPYRIGHT
FROM QSYS2.PROGRAM_INFO,
     JSON_TABLE(COPYRIGHT_STRINGS, 'lax $.COPYRIGHTS'
                COLUMNS (COPYRIGHT VARCHAR(500) PATH 'lax $[*]' ))
WHERE PROGRAM_LIBRARY = 'APPLIB';
```

PUTENV scalar function

The PUTENV scalar function changes the value of an environment variable for the current job.

The function is implemented using the putenv() API. The result is similar to using the Add Environment Variable (ADDENVVVAR) or Change Environment Variable (CHGENVVAR) CL commands.

The function requires that Option 13 (System Openness Includes) of the IBM i operating system is installed.

Authorization: See Note below.

➤ PUTENV — (ENVIRONMENT_VARIABLE_NAME ⇒ *environment-variable-name* →
 , ENVIRONMENT_VARIABLE_VALUE ⇒ *environment-variable-value* —) ➤

The schema is SYSTOOLS.

<i>environment-variable-name</i>	An expression that returns the name of an environment variable. If it does not exist, it will be created.
<i>environment-variable-value</i>	An expression that returns the value to assign to <i>environment-variable-name</i> .

The result of the function is an integer. The function returns the following values:

- 0** The operation was successful.
- non-zero** The operation failed. The return value corresponds to the *errno* value from the API which describes the failure.

Note

This function is provided in the SYSTOOLS schema as an example of how to embed a C interface within SQL PL code. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

- Set the value of MY_ENVVVAR for the current job.

```
VALUES SYSTOOLS.PUTENV('MY_ENVVVAR', 'My job's value for the environment variable');
```

QCMDEXC procedure

The QCMDEXC procedure executes a CL command.

Authorization: Any authority requirements for the CL command apply to the use of this function.

►► QCMDEXC — (— *CL-command-string* —) ►►

The schema is QSYS2.

CL-command-string A character string expression containing a CL command.

The *CL-command-string* will be run as a CL command.

Examples

- Add a library to the library list.

```
CALL QSYS2.QCMDEXC('ADDLIBLE PRODLIB2');
```

- Add a library to the library list using an expression.

```
DECLARE V_LIBRARY_NAME VARCHAR(10);  
SET V_LIBRARY_NAME = 'PRODLIB2';  
CALL QSYS2/QCMDEXC('ADDLIBLE ' CONCAT V_LIBRARY_NAME);
```

QCMDEXC scalar function

The QCMDEXC scalar function executes a CL command.

Authorization: Any authority requirements for the CL command apply to the use of this function.

►► QCMDEXC — (— *command* —) ►►

└── *COMMAND* — => ─┘

The schema is QSYS2.

command A character string containing a CL command. The maximum length is 32000 characters.

The result of the function is an integer. If the command is successful, the function returns a value of 1. If the command execution fails, the function returns a value of -1.

Example

Hold any jobs that started running an SQL statement more than 2 hours ago.

```
SELECT JOB_NAME,  
       CASE WHEN QSYS2.QCMDEXC('HLDJOB ' CONCAT JOB_NAME) = 1 THEN 'Job Held'  
            ELSE 'Job not held'  
            END AS HLDJOB_RESULT  
FROM TABLE (QSYS2.ACTIVE_JOB_INFO (DETAILED_INFO=> 'ALL'))  
WHERE SQL_STATEMENT_START_TIMESTAMP < CURRENT_TIMESTAMP - 2 HOURS;
```

RECEIVE_DATA_QUEUE table function

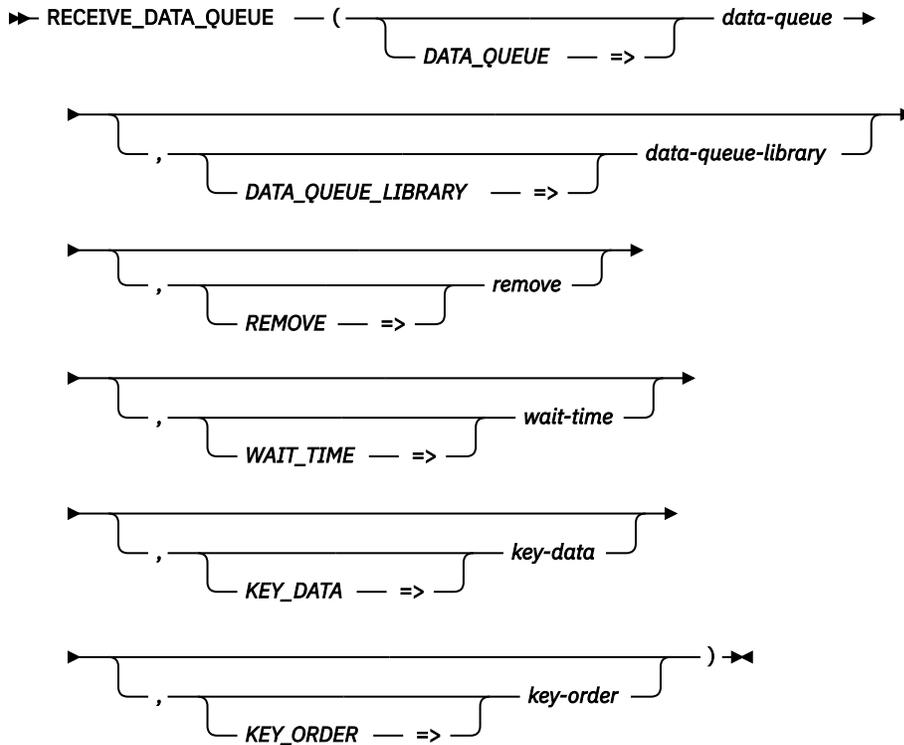

The RECEIVE_DATA_QUEUE table function returns a message from the specified data queue. The message data is returned as character, UTF-8, and binary data.

The MESSAGE_DATA, MESSAGE_DATA_UTF8, and MESSAGE_DATA_BINARY columns contain identical values. It is up to the user to determine which data type is most appropriate for working with the result of the receive data queue operation.

The values returned for the result columns of the table function are closely related to the values returned by the Receive Data Queue (QRCVDTAQ) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the data queue, and
- *OBJOPR and *READ authority to the data queue.

The schema is QSYS2.

- data-queue** A character or graphic string containing the name of the data queue.
- data-queue-library** A character or graphic string containing the name of the library containing the data queue. Can be one of the following special values:
- *CURLIB** The job's current library is used.
 - *LIBL** The library list is used. This is the default.
- remove** A character or graphic string indicating whether the message is to be removed from the data queue after it is received.
- NO** The message is not removed from the data queue.
 - YES** The message is removed from the data queue. This is the default.
- wait-time** The amount of time to wait, in seconds and milliseconds, if no entries exist on the data queue. The value can be from -99999 to 99999.000.
- Any value less than zero indicates to wait forever.
 - A value of zero means to continue processing immediately. This is the default.
 - A positive value indicates the length of time to wait. The milliseconds part of the time is ignored for any value over 100 and for DDM data queues.

key-data A character string containing the data to use as the key for receiving a message from the data queue. This parameter is required for a keyed data queue. It must not be specified for a non-keyed data queue.

The length of *key-data* must be the length specified on the KEYLEN parameter on the Create Data Queue (CRTDTAQ) command. The KEY_LENGTH column of the QSYS2.DATA_QUEUE_INFO view contains this value.

When this parameter is specified, *key-order* must also be specified.

key-order The comparison criteria between the keys of messages on the data queue and the *key-data* parameter. When the system searches for the requested key, the entries are searched in ascending order from the lowest value key to the highest value key until a match is found. If there are entries with duplicate keys, the entry that was put on the queue first is received. Valid values are:

EQ	Equal
GE	Greater than or equal
GT	Greater than
LE	Less than or equal
LT	Less than
NE	Not equal

This parameter is ignored if *key-data* is not specified.

The result of the function is a table containing one row or no rows with the format shown in the following table. All the columns are nullable.

Table 102. RECEIVE_DATA_QUEUE table function

Column Name	Data Type	Description
MESSAGE_DATA	CLOB(64512)	The message received from the data queue as character data.
MESSAGE_DATA_UTF8	CLOB(64512) CCSID 1208	The message received from the data queue represented as character data in CCSID 1208.
MESSAGE_DATA_BINARY	BLOB(64512)	The message received from the data queue in binary form. This is the raw form of the data.
KEY_DATA	VARCHAR(256)	For a keyed data queue, the key value of the returned message. This is the actual key value, which could be different than the <i>key-data</i> parameter value. Contains the null value if this is not a keyed data queue.
SENDER_JOB_NAME	VARCHAR(28)	The qualified job name of the sender. Contains the null value if no sender information is available for the message.
SENDER_CURRENT_USER	VARCHAR(10)	The current user profile of the sender. Contains the null value if no sender information is available for the message.

Example

Get the message from data queue DQ1 in TESTLIB with key 456.

```
SELECT * FROM TABLE(QSYS2.RECEIVE_DATA_QUEUE(
    DATA_QUEUE => 'DQ1',
    DATA_QUEUE_LIBRARY => 'TESTLIB',
    KEY_DATA => '456',
    KEY_ORDER => 'EQ'));
```

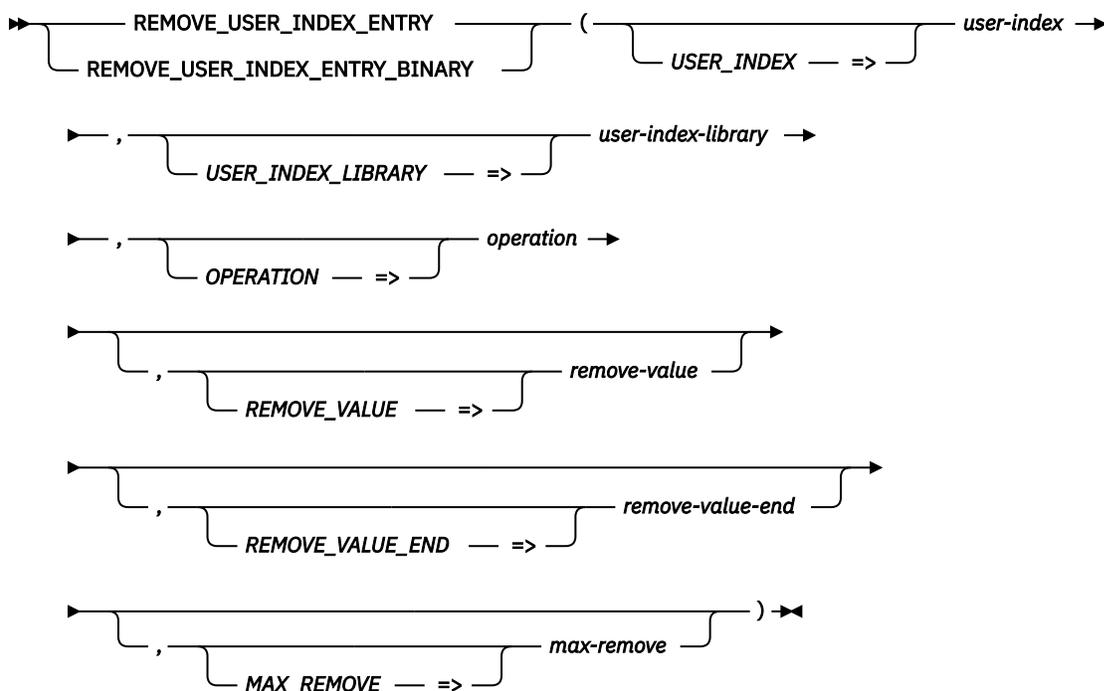

REMOVE_USER_INDEX_ENTRY and REMOVE_USER_INDEX_ENTRY_BINARY table functions

The REMOVE_USER_INDEX_ENTRY and REMOVE_USER_INDEX_ENTRY_BINARY table functions remove one or more entries from a user index (*USRIDX).

The values used by the table functions are closely related to the values handled by the Remove User Index Entries (QUSRMVUI) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the user index, and
- *CHANGE authority to the user index.

The schema is QSYS2.

user-index A character string containing the name of the user index for the removal of entries.

user-index-library A character string containing the name of the library where the user index is located. Can be one of the following special values:

***CURLIB** The current library is used.

***LIBL** The library list is used.

operation The operation to be used for comparing *remove-value* and *remove-value-end* and the index value.

If the index is keyed, the complete entry consists of the key followed by the entry data. If the length of *remove-value* is less than or equal to the length of the key, the comparison only applies to the key. If the length of *remove-value* is greater than the key, the comparison will include some or all of the entry data as well.

If the index is not keyed, the comparison applies to the value of the entry data.

EQ Remove entries that match *remove-value* or start with *remove-value*.

GE Remove entries that are greater than or equal to *remove-value*.

GT Remove entries that are greater than *remove-value*.

- LE** Remove entries that are less than or equal to *remove-value*.
- LT** Remove entries that are less than *remove-value*.
- BETWEEN** Remove entries that are greater than or equal to *remove-value* and less than or equal to *remove-value-end*.
- FIRST** Remove the first *n* entries from the user index, where *n* is the *max-remove* value. If *max-remove* is not specified, all index entries are removed. *remove-value* and *remove-value-end* are ignored.
- LAST** Remove the last *n* entries from the user index, where *n* is the *max-remove* value. If *max-remove* is not specified, all index entries are removed. *remove-value* and *remove-value-end* are ignored.

remove-value A string that specifies the value to compare with the index value to determine whether an index entry is to be removed.

- For REMOVE_USER_INDEX_ENTRY, the input value will be converted to a character string using the job CCSID.
- For REMOVE_USER_INDEX_ENTRY_BINARY, the input value will be considered a binary string.

This parameter is ignored when *operation* is FIRST or LAST. It is required for all other *operation* values.

remove-value-end A string that specifies the value to compare with the index value as the upper bound for BETWEEN. The lengths of *remove-value* and *remove-value-end* must be the same.

- For REMOVE_USER_INDEX_ENTRY, the input value will be converted to a character string using the job CCSID.
- For REMOVE_USER_INDEX_ENTRY_BINARY, the input value will be considered a binary string.

This parameter is ignored when *operation* is not BETWEEN. It is required when *operation* is BETWEEN.

max-remove An integer value that specifies the maximum number of user index entries satisfying the remove comparison that should be removed. A value of -1 can be used to remove all index entries that satisfy the remove comparison. The default is -1.

The result of the function is a table containing one row for each index entry that was removed with the format shown in the following table. All columns are nullable.

Table 103. REMOVE_USER_INDEX_ENTRY table function

Column Name	Data Type	Description
ORDINAL_POSITION	INTEGER	The relative position of this row in the set of removed index entries.
USER_INDEX_LIBRARY	VARCHAR(10)	The name of the library where the user index was found.
USER_INDEX	VARCHAR(10)	The name of the user index.
REMOVED_ENTRY	VARCHAR(2000)	The data for the index entry that was removed, in character form. The value includes both the key and the entry data.
REMOVED_ENTRY_BINARY	VARBINARY(2000)	The data for the index entry that was removed, in binary form. This is the raw bytes of data. The value includes both the key and the entry data.

Example

- Remove all index entries with a key value less than '00173'.

```
SELECT * FROM TABLE(QSYS2.REMOVE_USER_INDEX_ENTRY(USER_INDEX => 'USR1X1',
                                                    USER_INDEX_LIBRARY => 'APPLIB',
```

```
OPERATION => 'LT',
REMOVE_VALUE => '00173'));
```

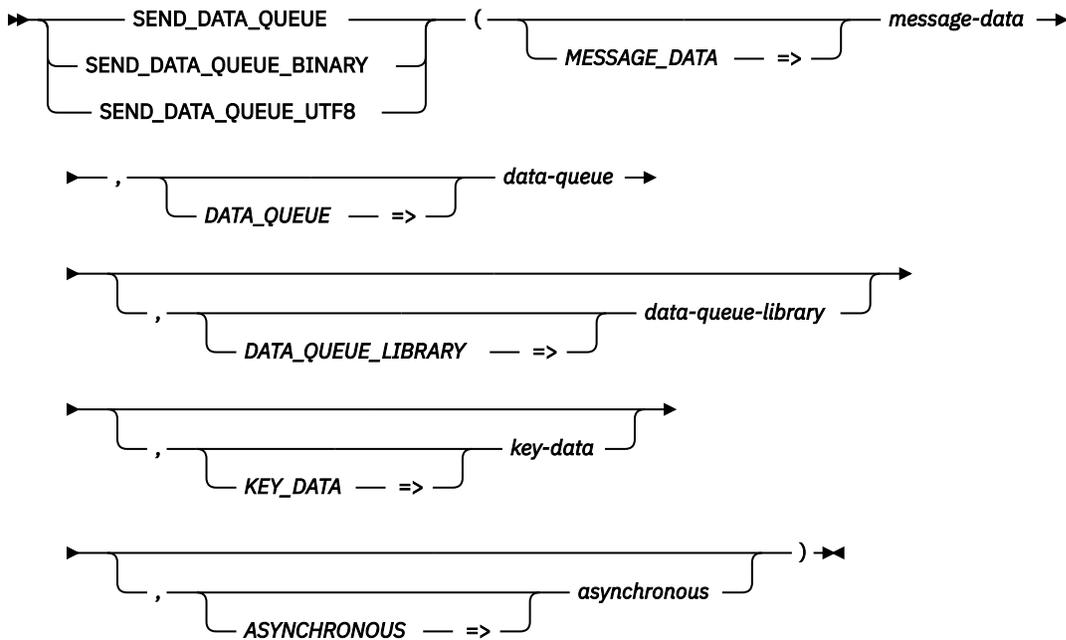

SEND_DATA_QUEUE, SEND_DATA_QUEUE_BINARY, and SEND_DATA_QUEUE_UTF8 procedures

The SEND_DATA_QUEUE, SEND_DATA_QUEUE_BINARY, and SEND_DATA_QUEUE_UTF8 procedures send a message to the specified data queue. The message data can be sent as character, UTF-8, or binary data.

This procedure provides function similar to the Send Data Queue (QSNDDTAQ) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the data queue, and
- *OBJOPR and *ADD authority to the data queue.

The schema is QSYS2.

message-data The data to send to the message queue. The string can be up to 64512 characters long.

- For SEND_DATA_QUEUE, the input value will be converted to a character string with the job CCSID.
- For SEND_DATA_QUEUE_BINARY, the input value will be converted to a binary string.
- For SEND_DATA_QUEUE_UTF8, the input value will be converted to a UTF-8 string.

data-queue A character or graphic string containing the name of the data queue.

data-queue-library A character or graphic string containing the name of the library containing the data queue. Can be one of the following special values:

- *CURLIB** The job's current library is used.
- *LIBL** The library list is used. This is the default.

key-data A character string containing the key data to send to the data queue. This parameter is required for a keyed data queue. It must not be specified for a non-keyed data queue.

The length of the key must match the length specified on the KEYLEN parameter on the Create Data Queue (CRTDTAQ) command.

asynchronous

Indicates whether the send request to a DDM data queue should be processed asynchronously. Valid values are:

NO The request should not be processed asynchronously. This is the default.

YES The request should be processed asynchronously. This can only be specified for a DDM data queue.

If an error occurs during an asynchronous operation, the error will not be detected until the next time the data queue is accessed synchronously.

Example

Send a message to data queue DQ1 in TESTLIB with key 456.

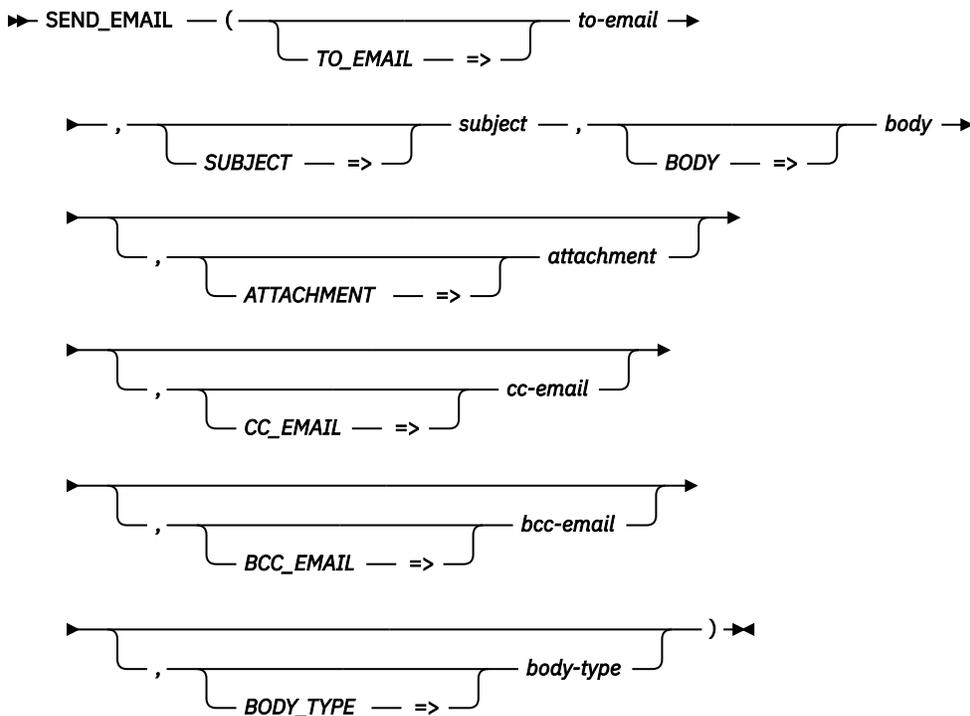

```
CALL QSYS2.SEND_DATA_QUEUE(MESSAGE_DATA => 'This is the message data',
                           DATA_QUEUE => 'DQ1',
                           DATA_QUEUE_LIBRARY => 'TESTLIB',
                           KEY_DATA => '456');
```

SEND_EMAIL scalar function

The SEND_EMAIL scalar function sends an email to a one or more recipients. This is done by using the SNDSMTPEMM (Send SMTP E-mail Message) CL command.

This function assumes that the user invoking this function has been registered to the SMTP server by using the ADDUSRSMTMP (Add User SMTP) CL command. If the SMTP server is not active, this function will attempt to start it before sending the email.

Authorization: See Note below.

The schema is SYSTOOLS.

- to-email** A character string containing one or more email addresses. Addresses must be separated by a comma. Blanks included before or after each comma are ignored.
The total number of email addresses provided with the *to-email*, *cc-email*, and *bcc-email* parameters cannot exceed 20.
- subject** A character string up to 255 characters long containing the subject of the email.
- body** A character string up to 5000 characters long containing the body of the email.
- attachment** A character string containing up to 10 path names of integrated file system files to be sent as attachments to the email. Each absolute path name can be up to 200 characters long. Path names must be separated by a comma. Blanks included before or after each comma are ignored.
If this parameter is omitted, no attachment is sent with the email.
- cc-email** A character string containing one or more email addresses to be included in the carbon copy list. Addresses must be separated by a comma. Blanks included before or after each comma are ignored.
The total number of email addresses provided with the *to-email*, *cc-email*, and *bcc-email* parameters cannot exceed 20.
If this parameter is omitted, no carbon copy list included for the email.
- bcc-email** A character string containing one or more email addresses to be included in the blind carbon copy list. Addresses must be separated by a comma. Blanks included before or after each comma are ignored.
The total number of email addresses provided with the *to-email*, *cc-email*, and *bcc-email* parameters cannot exceed 20.
If this parameter is omitted, no blind carbon copy list included for the email.
- body-type** The content type for *body*. Accepted values are *PLAIN, *HTML, and *XML. The default is *PLAIN.

The result of the function is an integer. If the command is successful, the function returns a value of 1. If the command returns an error, the function returns a value of -1.

Note

This function is provided in the SYSTOOLS schema as an example of how send an email using the SNDSMTPEMM CL command in an SQL scalar function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Examples

- Send an email to a user with an attachment.

```
VALUES SYSTOOLS.SEND_EMAIL(TO_EMAIL => 'someuser@gmail.com',
                           SUBJECT  => 'Status for last week',
                           BODY     => 'Attached is the status information for last
week.',
                           ATTACHMENT => '/home/myuser/status.log');
```

- Send an email to multiple users with 2 attachments.

```
VALUES SYSTOOLS.SEND_EMAIL(TO_EMAIL => 'someuser@gmail.com, mymanager@xyz.com',
                           CC_EMAIL  => 'anotheruser@gmail.com',
                           SUBJECT   => 'Status and future plans',
                           BODY      => 'Attached is the status for last week and the
```

```
future plan.',
```

```
ATTACHMENT => '/home/myuser/status.log, /home/myuser/plan.docx');
```

SERVICES_INFO table

The SERVICES_INFO table returns information about system-supplied services.

Authorization: The caller must have:

- *EXECUTE authority to QSYS2, and
- *OBJOPR and *READ authority to the QSYS2/SERV_INFO file.

The following table describes the columns in the table. The system name is SERV_INFO. The schema is QSYS2.

Table 104. SERVICES_INFO table

Column Name	System Column Name	Data Type	Description
SERVICE_CATEGORY	CATEGORY	VARCHAR(40)	Classification of the service. <ul style="list-style-type: none">• APPLICATION• BACKUP AND RECOVERY• COMMUNICATION• CONFIGURATION• DATABASE-APPLICATION• DATABASE-PERFORMANCE• DATABASE-PLAN CACHE• DATABASE-UTILITY• IFS• JAVA• JOURNAL• LIBRARIAN• MESSAGE HANDLING• MIGRATE WHILE ACTIVE• MIRROR-COMMUNICATION• MIRROR-PRODUCT• MIRROR-RECLONE• MIRROR-REPLICATION• MIRROR-RESYNCHRONIZATION• MIRROR-SERVICEABILITY• PERFORMANCE• PRODUCT• PTF• SECURITY• SPOOL• STORAGE• SYSTEM HEALTH• WORK MANAGEMENT
SERVICE_SCHEMA_NAME	SYS_NAME	VARCHAR(128)	Name of the schema containing the service.
SERVICE_NAME	SERVNAME	VARCHAR(128)	Name of the service.
SQL_OBJECT_TYPE	SQLTYPE	VARCHAR(15)	The type of object. <ul style="list-style-type: none">• GLOBAL VARIABLE• PROCEDURE• SCALAR FUNCTION• TABLE• TABLE FUNCTION• VIEW

Table 104. SERVICES_INFO table (continued)

Column Name	System Column Name	Data Type	Description
OBJECT_TYPE	OBJTYPE	VARCHAR(7) Nullable	The system object type of the service. <ul style="list-style-type: none"> *FILE *SRVPGM Contains null for procedures, functions, and global variables.
SYSTEM_OBJECT_NAME	SYS_ONAME	VARCHAR(10) Nullable	The system name of the service. Contains null for procedures, functions, and global variables.
LATEST_DB2_GROUP_LEVEL	GROUPLVL	INTEGER Nullable	The Db2 for i PTF Group level which most recently changed this service. Contains null if the service has not been enhanced in a PTF in this release.
INITIAL_DB2_GROUP_LEVEL	INITIALVL	INTEGER Nullable	The Db2 for i PTF Group level where this service was introduced. Contains null if this service was available in the base for this release.
EARLIEST_POSSIBLE_RELEASE	MINRLS	VARCHAR(6)	The earliest release, in VxRxMx format, where a version of this service is available.
EXAMPLE	EXAMPLE	VARCHAR(5000)	An example SQL script that uses this service.

Example

Show all the available PTF services:

```
SELECT * FROM QSYS2.SERVICES_INFO
WHERE SERVICE_CATEGORY = 'PTF'
```

Db2 PTF Group dependencies

To complement the Db2 PTF Group level information provided by the SERVICES_INFO catalog table, you can determine the Db2 PTF Group dependency level for every static SQL statement within a module, program, or service program. The QSYS2.SYSPROGRAMSTMTSTAT catalog contains one row for every static SQL statement. The Db2 PTF Group dependency information is surfaced in two columns:

SQL_DB2_GROUP_LEVEL

Indicates the use of SQL language features. For example, new SQL statements or query clauses surface as dependencies upon having a certain Db2 PTF Group level (or higher) installed before the statement can be run.

This is an SQL syntax level and is an accurate indication of the dependency level.

SERVICES_DB2_GROUP_LEVEL

Indicates the consumption of IBM i Services. For example, queries that reference Db2 for i provided views, functions, procedures, or global variables can surface possible dependencies upon having a certain Db2 PTF Group level (or higher) installed before executing the statement. If multiple services are used within a single SQL statement, the highest dependency level is returned.

The services that are instrumented are documented in [“IBM i Services”](#) on page 419 and [Db2 for i Services](#). SQL built-in functions and built-in global variables are also tracked.

This is not an exact indication of the Db2 PTF Group that is needed. It depends on how the service is being used in your application. The information is provided based solely on the name of the service and the knowledge of when the latest enhancement was added for

that service. If the name of an IBM-provided service matches an unqualified name in an SQL statement, it will be tracked as the IBM service. Based on the reported use of these services, you will need to determine whether the reported Db2 PTF Group is actually required.

To check all programs in APPLIB for potential SQL syntax and IBM i Service dependencies, execute the following query. Only programs created after the SERVICES_INFO table was introduced will report this information.

```
SELECT PROGRAM_NAME, SQL_DB2_GROUP_LEVEL, SERVICES_DB2_GROUP_LEVEL
FROM QSYS2.SYSPROGRAMSTMTSTAT
WHERE PROGRAM_SCHEMA = 'APPLIB' AND
      (SQL_DB2_GROUP_LEVEL IS NOT NULL OR
       SERVICES_DB2_GROUP_LEVEL IS NOT NULL);
```

To see more detailed information about which services are used in a program, including the name of each service and the Db2 PTF Group level required for the service, perform the following steps:

1. STRDBG UPDPROD(*YES)
2. Precompile your program or build your SQL procedure, function, or trigger.
 - To have informational messages written to the listing, add SET OPTION OUTPUT=*PRINT to your SQL routine or specify the OUTPUT(*PRINT) parameter on the CRTSQLxxx or RUNSQLSTM CL commands
3. For each reference to a service, message SQL7901 will be written to the joblog and, optionally, to the precompile listing.

If you precompile with a TGTRLS of 7.1 or later, a message will be issued for each of the earlier releases as well with an indication of the Db2 PTF Group level that is needed on that release. If the service is not supported for a release, message SQL795B will be issued.

This information can be used to determine whether your application contains any content that might require a certain level of Db2 PTF Group. If you need to deploy your application to a different partition or an earlier release, this feedback can alert you to potential dependencies.

After you have created one or more objects using the steps above, you can query your job log to see if any messages were issued that might need to be addressed.

```
SELECT MESSAGE_ID, MESSAGE_TEXT
FROM TABLE(QSYS2.JOBLOG_INFO('*')) X
WHERE MESSAGE_ID IN ('SQL7901', 'SQL795B')
ORDER BY ORDINAL_POSITION;
```

Here is one more query to help tie this information together. It will tell you the Db2 PTF Group level that is on a partition.

```
SELECT MAX(PTF_GROUP_LEVEL) AS DB2_PTF_LEVEL FROM QSYS2.GROUP_PTF_INFO
WHERE PTF_GROUP_NAME LIKE 'SF9970%' AND PTF_GROUP_STATUS = 'INSTALLED';
```

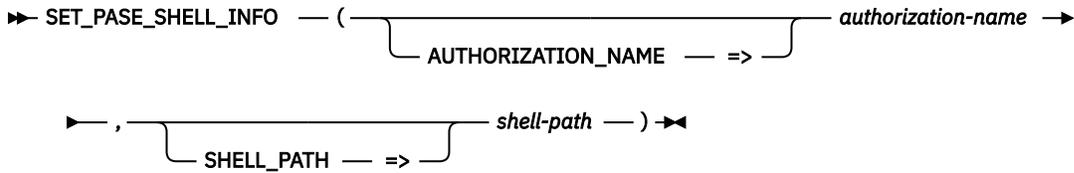

SET_PASE_SHELL_INFO procedure

The SET_PASE_SHELL_INFO procedure provides the ability to set the path to the PASE shell for the specified user or the path to the default shell returned for users that do not have a configured shell.

The path set by this procedure is returned in the pw_shell field in struct pw from PASE APIs such as Get User Information for User Name (getpwnam) and Get User Information for User ID (getpwuid). It is also returned by the QSYS2.USER_INFO view. If a user does not have a path set, the default shell path is returned; if the default shell is not set, an empty string is returned. The pw_shell field is used by PASE applications that need to execute shells for a user, such as the OpenSSH server. The OpenSSH server will start this application as the initial program when the user logs in. If it is not set it will use /QOpenSys/usr/bin/bsh instead.

Authorization:

- If AUTHORIZATION_NAME is *CURRENT or matches the caller of this procedure, no authorization is needed.
- Otherwise, the caller must have:
 - *SECADM special authority, and
 - *OBJMGT and *USE authorities to the user profile identified by AUTHORIZATION_NAME.

The schema is QSYS2.

authorization-name A character or graphic string expression that identifies an existing user profile name. Can also be one of the following special values:

- *CURRENT** Set the current user's shell.
- *DEFAULT** Set the PASE shell to be used by any user that does not have an explicit value set. The default does not apply to IBM supplied profiles. The default is saved in the QSYS user profile. This is equivalent to specifying 'QSYS' for *authorization-name*.

shell-path A character or graphic string expression that specifies the path to a PASE shell. The string must begin with a forward slash (/).
If *shell-path* is blanks, the empty string, or NULL, the shell path is removed for the user. Once the path is removed, the value specified for *DEFAULT (if any) will apply to this user.

Examples

- Set the current user's shell to BASH shipped by 5733-OPS.

```
CALL QSYS2.SET_PASE_SHELL_INFO('*CURRENT',
                               '/QOpenSys/QIBM/ProdData/OPS/tools/bin/bash');
```

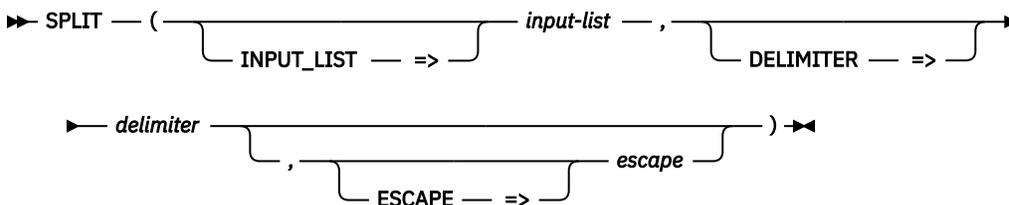

- Set the default shell to be ksh for any users that do not have an explicit shell set.

```
CALL QSYS2.SET_PASE_SHELL_INFO('*DEFAULT', '/QOpenSys/usr/bin/ksh');
```

SPLIT table function

The SPLIT table function returns a result table that contains one row for each substring of *input-list* that is separated by *delimiter*.

Authorization: None required.

input-list An expression that contains a list to be deconstructed. The value is cast to CLOB(2G).

delimiter A character string expression that defines the separator between list elements. The value is cast to VARCHAR(32672).

escape A character string expression with a length of 1 that defines a character that is used to escape a delimiter sequence. If this parameter is provided, any delimiter sequence of characters immediately preceded by this character will not be interpreted as a delimiter. The escape character will be removed from the returned element value.

The table function returns one row for each substring of *input-list* containing the characters between *delimiter* strings. If *input-list* contains two adjacent *delimiter* strings, an empty string is returned to represent an element with no content. If a *delimiter* string starts at position 1 of *input-list*, a row containing a zero length string is returned as the first element. If a *delimiter* string ends at the last position of *input-list*, a row containing a zero length string is returned as the last element. Substrings of *input-list* that match *delimiter* are not included in the result.

If *input-list* is null, the result contains no rows. If *delimiter* is null, the empty string, or a string that is not found, *input-list* is returned.

The result of the function is a table containing a row for each substring of *input-list*. The columns of the result table are described in the following table. The result columns are nullable.

Table 105. SPLIT table function

Column Name	Data Type	Description
ORDINAL_POSITION	INTEGER	The relative position of this element in the input string. The first row has a value of 1.
ELEMENT	CLOB(2G)	The value of the element.

Note

This function is provided in the SYSTOOLS schema as an example of how to break a string apart at a delimiting character by using an SQL table function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Example

- Return a list of all authorities collected for all users for objects in the APP1 schema. First, a common table expression breaks the detailed authority lists into separate rows for each authority using the SPLIT table function. Then, all the authorities for the object are recombined into a single list for each user, removing duplicate authorities and listing them alphabetically, using the LISTAGG aggregate function.

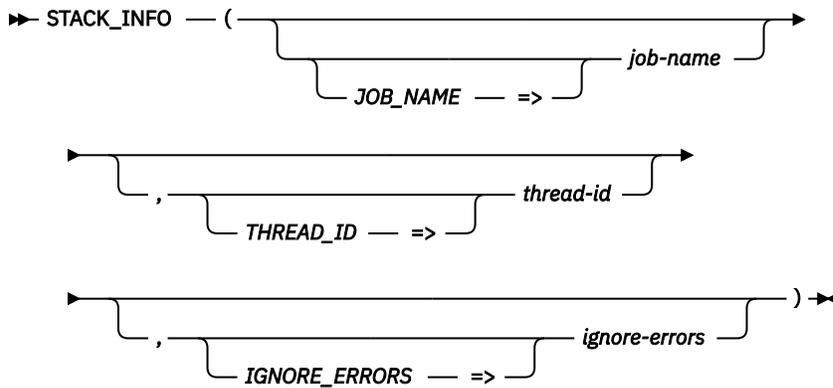

```
WITH EXPANDED_AUTHS AS (  
  SELECT AUTHORIZATION_NAME, OBJECT_NAME, VARCHAR(TRIM(ELEMENT), 10) AS AUTH  
    FROM QSYS2.AUTHORITY_COLLECTION,  
         TABLE(SYSTOOLS.SPLIT(DETAILED_REQUIRED_AUTHORITY, ' '))  
   WHERE OBJECT_SCHEMA = 'APP1'  
         AND CHECK_ANY_AUTHORITY = 0)  
SELECT AUTHORIZATION_NAME, OBJECT_NAME,  
       LISTAGG(DISTINCT AUTH, ' ') WITHIN GROUP(ORDER BY AUTH)  
  FROM EXPANDED_AUTHS  
 GROUP BY AUTHORIZATION_NAME, OBJECT_NAME  
 ORDER BY AUTHORIZATION_NAME, OBJECT_NAME;
```

STACK_INFO table function

The STACK_INFO table function returns one row for each entry in the call stack for either a specific thread or for every thread of the specified job. It returns information similar to what can be accessed through the Display Job (DSPJOB) CL command and the Retrieve Call Stack (QWVRCSTK) API.

Authorization: None required to see information for jobs where the caller's user profile is the same as the job user identity of the job for which the information is being returned. Otherwise, the caller must have *JOBCTL special authority or be authorized to the QIBM_SERVICE_THREAD function usage identifier.

If the caller has *SERVICE special authority, the returned call stack information will include Licensed Internal Code (LIC) stack entries.

The schema is QSYS2.

job-name The qualified job name to return stack information. Can contain the following special value:

- * The current job name is used.

If *job-name* is not specified, the default is *.

thread-id A numeric expression indicating the thread identifier to return information for. Can contain one of the following special values:

- ALL** Information for all the threads in the job is returned.
- INITIAL** Information for the initial thread of the job is returned.

If *thread-id* is not specified:

- If *job-name* is *, the default is the value of the QSYS2.THREAD_ID global variable.
- Otherwise, the default is INITIAL.

ignore-errors A character or graphic string expression that identifies what to do when an error is encountered.

- NO** An error is returned.
- YES** A warning is returned.
- No rows are returned when an error is encountered. This is the default.

The result of the function is a table containing multiple rows with the format shown in the following table. All the columns are nullable.

Table 106. STACK_INFO table function

Column Name	Data Type	Description
THREAD_ID	BIGINT	The identifier for the specific thread.
THREAD_TYPE	VARCHAR(6)	Specifies how the thread was initiated. SYSTEM The thread was initiated by the operating system. USER The thread was initiated by a user process. Contains the null value unless ALL was specified for the <i>thread-id</i> input parameter.
ORDINAL_POSITION	INTEGER	A unique number for each row corresponding to a thread where 1 is the first invocation entry for this thread and the highest number is the most recent invocation entry for this thread.

Table 106. STACK_INFO table function (continued)

Column Name	Data Type	Description
ENTRY_TYPE	VARCHAR(4)	<p>The type of stack entry.</p> <p>ILE This entry returns ILE program information. The columns specific to JAVA, PASE, and LIC contain the null value.</p> <p>JAVA This entry returns JAVA information. The columns specific to ILE and OPM, PASE, and LIC contain the null value.</p> <p>LIC This entry returns Licensed Internal Code (LIC) information. The columns specific to ILE and OPM, JAVA, and PASE contain the null value.</p> <p>OPM This entry returns OPM program information. The columns specific to JAVA, PASE, and LIC contain the null value.</p> <p>PASE This entry returns PASE information. The columns specific to ILE and OPM, JAVA, and LIC contain the null value.</p>
--- ILE and OPM information -----		
PROGRAM_NAME	VARCHAR(10) Nullable	<p>The name of the program or service program.</p> <p>Contains the null value if the program name is not available.</p>
PROGRAM_LIBRARY_NAME	VARCHAR(10) Nullable	<p>The name of the library in which the program is located.</p> <p>Contains the null value if the program is not located in a library or if the program library name is not available.</p>
STATEMENT_IDENTIFIERS	VARCHAR(109) Nullable	<p>The high-level language statement identifier. If this column contains the character representation of a number, the number is right-adjusted and padded on the left with zeros (for example, '000000246'). If the call stack entry is for an integrated language environment (ILE) procedure, more than one statement identifier may exist. If more than one statement identifier is returned, each identifier will be ten characters long with a single blank between them. Up to ten identifiers will be returned.</p> <p>Returns the null value if a statement identifier cannot be determined.</p>
REQUEST_LEVEL	INTEGER Nullable	<p>The level of the request-processing program or procedure.</p> <p>Contains the null value if the program or procedure has not received a request message or incomplete information is available.</p>
CONTROL_BOUNDARY	VARCHAR(3) Nullable	<p>Whether a control boundary exists for a program or procedure. A control boundary is defined as any ILE call stack entry for which the immediately preceding call stack entry is for an ILE procedure or program object in a different activation group.</p> <p>NO No control boundary is active.</p> <p>YES A control boundary is active.</p> <p>Contains the null value if information is not available or incomplete information is available.</p>
PROGRAM_ASP_NAME	VARCHAR(10) Nullable	<p>The name of the auxiliary storage pool (ASP) device in which the program is located. Can contain the following special value:</p> <p>*SYSBAS The program is located in the system ASP or a basic user ASP</p> <p>Contains the null value if the name of the ASP cannot be determined.</p>
PROGRAM_ASP_NUMBER	INTEGER Nullable	<p>The numeric identifier of the ASP containing the program.</p> <p>1 The program is in the system ASP.</p> <p>2-32 The program is in a basic user ASP.</p> <p>33-255 The program is in an independent ASP.</p> <p>Contains the null value if the ASP device cannot be determined.</p>
MODULE_NAME	VARCHAR(10) Nullable	<p>The module containing the integrated language environment (ILE) procedure.</p> <p>Contains the null value if this is not an ILE program or if the module name is not available.</p>

Table 106. STACK_INFO table function (continued)

Column Name	Data Type	Description
MODULE_LIBRARY_NAME	VARCHAR(10) Nullable	The name of the library in which the module is located. Contains the null value if this is not an ILE program or if the module library name is not available.
PROCEDURE_NAME	VARCHAR(4096) Nullable	The name of the procedure at this level of the call stack. Returns the null value if this is not an ILE program or if the procedure name cannot be determined.
ACTIVATION_GROUP_NUMBER	DECIMAL(20,0) Nullable	The number of the activation group within which the program or procedure is running. This is an internal number that uniquely identifies the activation group within the job. Contains the null value if this is not an ILE program or incomplete information is available.
ACTIVATION_GROUP_NAME	VARCHAR(10) Nullable	The name of the activation group within which the program or procedure is running. Can contain the following special values: *DFTACTGRP The activation group does not have a specific name. The activation group is one of the default activation groups for the system. *NEW The activation group does not have a specific name. The activation group was created when the program was called. Contains the null value if this is not an ILE program or incomplete information is available.
MI_INSTRUCTION_NUMBER	INTEGER Nullable	The current machine instruction number in the program. Contains the null value if this is not an OPM program.
--- JAVA information -----		
JAVA_LINE_NUMBER	INTEGER Nullable	The line number where the invocation was interrupted. Contains the null value if no line number can be determined.
JAVA_BYTE_CODE_OFFSET	INTEGER Nullable	The offset in bytes from the beginning of the Java method byte codes to the resume point for the invocation. Contains the null value if no Java byte code offset can be determined.
JAVA_METHOD_TYPE	VARCHAR(9) Nullable	The type of Java method. DE The method is a direct execution Java method. The Java method has been precompiled by the Java Transformer. GLUE The invocation is a Java Virtual Machine glue frame used either to perform a call from the JVM to a Java method or perform a call to a Java native method. INTERPRET The method is an interpreted Java method. The Java method is being interpreted by the Java Interpreter. JIT The method is a JIT compiled Java method. The Java method has been compiled by the Java Just In Time Compiler. MMI The method is a MMI interpreted Java method. The Java method is being interpreted by the Mixed Mode Java Interpreter. Contains the null value if there is no information.
JAVA_CLASS_NAME	DBCLOB(64000) CCSID 1200 Nullable	The name of the Java class at this level of the call stack. Returns the null value if the class name cannot be determined.
JAVA_METHOD_NAME	DBCLOB(64000) CCSID 1200 Nullable	The name of the Java method at this level of the call stack. Returns the null value if the method name cannot be determined.
JAVA_METHOD_SIGNATURE	DBCLOB(64000) CCSID 1200 Nullable	The signature of the Java method at this level of the call stack. Returns the null value if the signature cannot be determined.

Table 106. STACK_INFO table function (continued)

Column Name	Data Type	Description
JAVA_FILE_NAME	DBCLOB(64000) CCSID 1200 Nullable	The name of the Java file and directory that provides the location of where the Java class was loaded at this level of the call stack. If the Java class was loaded from a .jar or .zip file, then the location will be the path to and the name of the .jar or .zip file. If the class was loaded from a .class file, then the location will be the directory from which the class was loaded. Returns the null value if the file name cannot be determined.
JAVA_SOURCE_FILE_NAME	DBCLOB(64000) CCSID 1200 Nullable	The name of the Java source file at this level of the call stack. Returns the null value if the source file name cannot be determined.
--- PASE information -----		
PASE_LINE_NUMBER	BIGINT Nullable	The line number where the invocation was interrupted. Contains the null value if no line number can be determined.
PASE_INSTRUCTION_ADDRESS	DECIMAL(20,0) Nullable	The IBM PASE for i memory address for the instruction that will run when execution resumes for the invocation.
PASE_INSTRUCTION_OFFSET	BIGINT Nullable	The offset in bytes from the beginning of the start of the procedure to the instruction that is either the suspend point for the invocation or the resume point for the invocation.
PASE_KERNEL_CODE	VARCHAR(3) Nullable	Whether the invocation is running IBM PASE for i kernel code. NO The current invocation is not IBM PASE for i kernel code. YES The current invocation is IBM PASE for i kernel code. Contains the null value if there is no information.
PASE_BIT_CODE	INTEGER Nullable	Whether the invocation is running 32-bit or 64-bit IBM PASE for i code. 32 The invocation is running 32-bit IBM PASE for i code. 64 The invocation is running 64-bit IBM PASE for i code. Contains the null value if PASE_KERNEL_CODE is YES.
PASE_ALTERNATE_RESUME_POINT	VARCHAR(3) Nullable	Whether the current entry is a second entry for a given invocation. This flag is only used when the system can not reliably determine which of two possible resume points will be used when an invocation resumes execution. NO The current invocation does not have an alternate resume point. YES The current invocation has an alternate resume point. Contains the null value if there is no information.
PASE_PROCEDURE_NAME	DBCLOB(4000) CCSID 1200 Nullable	The name of the procedure at this level of the call stack. Returns the null value if the procedure name cannot be determined.
PASE_LOAD_MODULE_NAME	DBCLOB(1000) CCSID 1200 Nullable	The name of the load module at this level of the call stack. Returns the null value if the load module name cannot be determined.
PASE_LOAD_MODULE_PATH	DBCLOB(4000) CCSID 1200 Nullable	The path to the load module at this level of the call stack. Returns the null value if the load module path cannot be determined.
PASE_SOURCE_PATH_AND_FILE	DBCLOB(1000) CCSID 1200 Nullable	The path and name for the source file used to create the procedure. Returns the null value if the path and name for the source file cannot be determined.
--- LIC information -----		
LIC_INSTRUCTION_OFFSET	BIGINT Nullable	The offset in bytes from the beginning of the start of the procedure to the instruction that is either the suspend point for the invocation or the resume point for the invocation.

Table 106. STACK_INFO table function (continued)

Column Name	Data Type	Description
LIC_PROCEDURE_NAME	VARCHAR(4096) Nullable	The name of the procedure at this level of the call stack. Returns the null value if the procedure name cannot be determined.
LIC_LOAD_MODULE_NAME	VARCHAR(64) Nullable	The name of the load module at this level of the call stack. Returns the null value if the load module name cannot be determined.

Example

- Find out whether ILE program MYPGM is on the stack for the current thread.

```
SELECT * FROM TABLE(QSYS2.STACK_INFO('*')) A
WHERE PROGRAM_NAME = 'MYPGM';
```

- Create a table that contains the stack for all of the threads in a specific job.

```
CREATE TABLE STACK_DUMP AS (
  SELECT * FROM TABLE(QSYS2.STACK_INFO('358788/QLIWISVR/ADMIN1', 'ALL')) AS X
) WITH DATA;
```

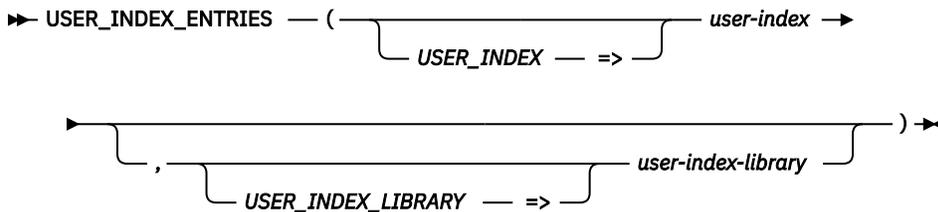

USER_INDEX_ENTRIES table function

The USER_INDEX_ENTRIES table function returns the entries of the specified user index (*USRIDX). The data is returned as character and binary data.

The values returned for the result columns of the table function are closely related to the values returned by the Retrieve User Index Entries (QUSRTVUI) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the user index, and
- *USE authority to the user index.

The schema is QSYS2.

user-index A character or graphic string containing the name of the user index.

user-index-library A character or graphic string containing the name of the library containing the user index. Can be one of the following special values:

***CURLIB** The job's current library is used.

***LIBL** The library list is used. This is the default.

The result of the function is a table containing one or more rows with the format shown in the following table. All the columns are nullable.

Table 107. USER_INDEX_ENTRIES table function

Column Name	Data Type	Description
ORDINAL_POSITION	INTEGER	The relative position of this row in the result data set.
USER_INDEX_LIBRARY	VARCHAR(10)	The library in which the user index was found.
USER_INDEX	VARCHAR(10)	The name of the user index.

Table 107. USER_INDEX_ENTRIES table function (continued)

Column Name	Data Type	Description
KEY	VARCHAR(2000)	The key for the index entry in character form. Contains the null value if the user index is not keyed.
KEY_BINARY	VARBINARY(2000)	The key for the index entry in binary form. This is the raw form of the data. Contains the null value if the user index is not keyed.
ENTRY	VARCHAR(2000)	The data for the index entry in character form. Contains the null value if the entry contains only a key value.
ENTRY_BINARY	VARBINARY(2000)	The data for the index entry in binary form. This is the raw form of the data. Contains the null value if the entry contains only a key value.

Example

Look at all the entries in user index IX1 in TESTLIB.

```
SELECT * FROM TABLE(QSYS2.USER_INDEX_ENTRIES(
    USER_INDEX => 'IX1',
    USER_INDEX_LIBRARY => 'TESTLIB'))
ORDER BY ORDINAL_POSITION;
```

USER_INDEX_INFO view

The USER_INDEX_INFO view returns the attributes of user indexes.

The values returned for the columns in the view are closely related to the values returned by the Retrieve User Index Attributes (QUSRUIAT) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the user index, and
- *USE authority to the user index.

The following table describes the columns in the view. The system name is USRIDX_INF. The schema is QSYS2.

Table 108. USER_INDEX_INFO view

Column Name	System Column Name	Data Type	Description
USER_INDEX_LIBRARY	USRIDX_LIB	VARCHAR(10)	Library containing the user index.
USER_INDEX	USRIDX	VARCHAR(10)	Name of the user index.
ENTRY_TYPE	TYPE	VARCHAR(8)	The type of entries in the user index. FIXED Fixed-length entries VARIABLE Variable-length entries
ENTRY_LENGTH	LENGTH	INTEGER	When ENTRY_TYPE is FIXED, the length of each index entry. When ENTRY_TYPE is VARIABLE, the length of the longest entry that has ever been inserted into the index. Valid values are from 1 through 2000.
MAXIMUM_ENTRY_LENGTH	MAX_LENGTH	INTEGER	The maximum entry length any user index entry can have.
INDEX_SIZE	SIZE	CHAR(4)	The maximum size of the user index. 4 GB The maximum size of the user index is 4 gigabytes. 1 TB The maximum size of the user index is 1 terabyte.

Table 108. USER_INDEX_INFO view (continued)

Column Name	System Column Name	Data Type	Description
IMMEDIATE_UPDATE	IMMEDIATE	VARCHAR(3)	Whether updates to the index are written to auxiliary storage on each update to the index. NO No immediate update YES Immediate update
OPTIMIZATION	OPTIMIZE	VARCHAR(10)	The optimization method used for user index maintenance. RANDOM Random references SEQUENTIAL Sequential references
KEY_INSERTION	KEYED	VARCHAR(3)	Whether inserts into the index are by key. NO No insertion by key YES Insertion by key
KEY_LENGTH	KEY_LENGTH	INTEGER Nullable	The length of the key. Contains the null value when KEY_INSERTION is NO.
ENTRY_TOTAL	TOTAL	INTEGER	The number of entries currently in the index.
ENTRIES_ADDED	ADDED	INTEGER	The number of entries added to the user index.
ENTRIES_REMOVED	REMOVED	INTEGER	The number of entries removed from the user index.
OBJECT_DOMAIN	DOMAIN	VARCHAR(7)	The domain of the object. *SYSTEM The object is in the system domain. *USER The object is in the user domain.
TEXT_DESCRIPTION	TEXT	VARCHAR(50) Nullable	The text description of the user index. Contains the null value if the user index has no description.

Example

- Return a list of attributes for all user indexes in MYLIB.

```
SELECT * FROM QSYS2.USER_INDEX_INFO
WHERE USER_INDEX_LIBRARY = 'MYLIB';
```

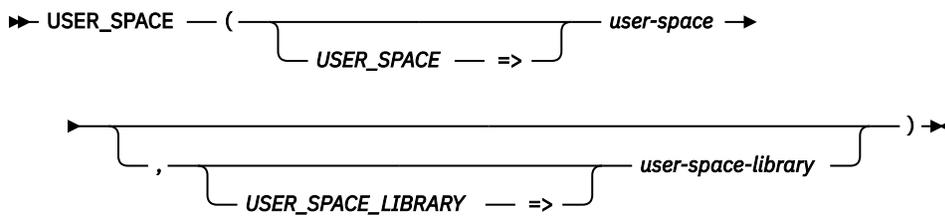

USER_SPACE table function

The USER_SPACE table function returns the contents of the specified user space (*USRSPC). The data is returned as character and binary data.

The values returned for the result columns of the table function are closely related to the values returned by the Retrieve User Space (QUSRTVUS) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the user space, and
- *USE authority to the user space.

The schema is QSYS2.

user-space A character or graphic string containing the name of the user space.

user-space-library A character or graphic string containing the name of the library containing the user space. Can be one of the following special values:

- *CURLIB** The job's current library is used.
- *LIBL** The library list is used. This is the default.

The result of the function is a table containing one row with the format shown in the following table. All the columns are nullable.

Table 109. USER_SPACE table function

Column Name	Data Type	Description
USER_SPACE_LIBRARY	VARCHAR(10)	The library in which the user space was found.
USER_SPACE	VARCHAR(10)	The name of the user space.
DATA	CLOB(16M)	The data from the user space as character data.
DATA_BINARY	BLOB(16M)	The data from the user space in binary form. This is the raw form of the data.

Example

Look at the untranslated contents of user space USERSPC1 in TESTLIB.

```
SELECT DATA_BINARY FROM TABLE(QSYS2.USER_SPACE(
    USER_SPACE => 'USRSPACE1',
    USER_SPACE_LIBRARY => 'TESTLIB'));
```

USER_SPACE_INFO view

The `USER_SPACE_INFO` view returns the attributes of user spaces.

The values returned for the columns in the view are closely related to the values returned by the Retrieve User Space Attributes (QUSRUSAT) API.

Authorization: The caller must have:

- *EXECUTE authority to the library containing the user space, and
- *USE authority to the user space.

The following table describes the columns in the view. The system name is USRSPC_INF. The schema is QSYS2.

Table 110. USER_SPACE_INFO view

Column Name	System Column Name	Data Type	Description
USER_SPACE_LIBRARY	USRSPC_LIB	VARCHAR(10)	Library containing the user space.
USER_SPACE	USRSPC	VARCHAR(10)	Name of the user space.
SIZE	SIZE	INTEGER	The size of the user space object in bytes.

Table 110. USER_SPACE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
EXTENDABLE	EXTENDABLE	VARCHAR(3)	Whether the space is extended automatically by the system when the end of the space is encountered. NO Space is not automatically extendable YES Space is automatically extendable
INITIAL_VALUE	INITIAL	BINARY(1)	The initial value to which future extensions of the user space will be set.
OBJECT_DOMAIN	DOMAIN	VARCHAR(7)	The domain of the object. *SYSTEM The object is in the system domain. *USER The object is in the user domain.
TEXT_DESCRIPTION	TEXT	VARCHAR(50) Nullable	The text description of the user space. Contains the null value if the user space has no description.

Example

- Return a list of user spaces in MYLIB.

```
SELECT USER_SPACE, SIZE, TEXT_DESCRIPTION FROM QSYS2.USER_SPACE_INFO
WHERE USER_SPACE_LIBRARY = 'MYLIB';
```

WATCH_DETAIL table function

The WATCH_DETAIL table function returns the details for watched messages, LIC logs, and PALs for a specific session identifier.

The values returned for the columns in the table function are closely related to the values returned by the WRKWCH (Work with Watches) CL command and by the Retrieve Watch Information (QSCRWCHI) API.

Authorization: The caller must have:

- *USE authority to the QSYS/QSCRWCHI program, and
 - *SERVICE special authority, or
 - Authorization to the QIBM_SERVICE_WATCH and QIBM_SERVICE_TRACE function usage identifiers.

►► WATCH_DETAIL ((SESSION_ID =>) session-id) ◄◄

The schema is QSYS2.

session-id A character or graphic string expression that contains the session identifier that the watch details are returned for.

The result of the function is a table containing rows with the format shown in the following table. All columns are nullable.

Table 111. WATCH_DETAIL table function

Column Name	Data Type	Description
DETAIL_TYPE	VARCHAR(7)	The type of detail information returned by this row. LICLOG This row is for a watched LIC log. MESSAGE This row is for a watched message. PAL This row is for a watched PAL.

Table 111. WATCH_DETAIL table function (continued)

Column Name	Data Type	Description
COMPARISON_DATA_CCSID	INTEGER	The CCSID that pertains to each of the xxx_COMPARISON_DATA columns. Contains the null value if this row has no comparison data.
The following columns apply when DETAIL_TYPE is MESSAGE. They will contain the null value when DETAIL_TYPE is LICLOG or PAL.		
MESSAGE_ID	VARCHAR(7)	The message to be watched. message-id The 7-character message identifier of the message to be watched. generic-name The generic name of the message to be watched. A generic name is a character string of one or more characters followed by an asterisk (*); for example, ABC*. The asterisk substitutes for any valid characters. A generic message name specifies all messages with identifiers that begin with the generic prefix. *ALL All messages are to be watched. This includes stored messages and immediate messages. *IMMED All immediate or impromptu messages will be watched.
MESSAGE_TYPE	VARCHAR(6)	The message type assigned to the message to be watched. ALL All the message types are to be watched. This includes completion, command, diagnostic, escape, informational, inquiry, notify, reply, request, sender's copy, scope and status message types. COMP A completion message is to be watched. DIAG A diagnostic message is to be watched. ESCAPE An escape message is to be watched. INFO An informational message is to be watched. INQ An inquiry message is to be watched. NOTIFY A notify message is to be watched. SCOPE A scope message is to be watched. STATUS A status message is to be watched.
MESSAGE_QUEUE_LIBRARY	VARCHAR(10)	The name of the library where the message queue is located. Contains the null value if MESSAGE_QUEUE is *JOBLOG.
MESSAGE_QUEUE	VARCHAR(10)	The name of the message queue to watch. Can contain the following special value: *JOBLOG Watch messages added to the job logs of the jobs specified for the watched job field.
MESSAGE_JOB_NAME	VARCHAR(10)	The job name of the job to be watched. Can contain the following special values: generic-name The generic name of the job to be watched. A generic name is a character string of one or more characters followed by an asterisk (*); for example, ABC*. The asterisk substitutes for any valid characters. A generic job name specifies all jobs with job names that begin with the generic prefix. *ALL All jobs with the specified job user name are watched. Contains the null value if MESSAGE_QUEUE is not *JOBLOG.

Table 111. WATCH_DETAIL table function (continued)

Column Name	Data Type	Description
MESSAGE_JOB_USER	VARCHAR(10)	<p>The user name of the job to be watched. Can contain the following special values:</p> <p>generic-name The generic name of the user name of the job to be watched. A generic name is a character string of one or more characters followed by an asterisk (*); for example, ABC*. The asterisk substitutes for any valid characters. A generic user name specifies all jobs with the specified job name and with user names that begin with the generic prefix.</p> <p>*ALL All jobs with the specified job name are watched.</p> <p>Contains the null value if MESSAGE_QUEUE is not *JOBLOG.</p>
MESSAGE_JOB_NUMBER	VARCHAR(6)	<p>The job number to further qualify the job name and user name. Can contain the following special value:</p> <p>*ALL All jobs with the specified job name and user name are watched.</p> <p>Contains the null value if a generic job name or a generic user name qualifier is specified, or if MESSAGE_QUEUE is not *JOBLOG.</p>
MESSAGE_SEVERITY	INTEGER	<p>The severity code, ranging from 0 through 99, of the message to be watched.</p>
MESSAGE_RELATIONAL_OPERATOR	CHAR(3)	<p>The relational operator against which the message severity code is compared.</p> <p>*EQ Equal</p> <p>*GE Greater than or equal</p> <p>*GT Greater than</p> <p>*LE Less than or equal</p> <p>*LT Less than</p>
MESSAGE_COMPARISON_DATA	VARCHAR(72) CCSID 65535	<p>The comparison data to be used if a message matching the specified message is added to the specified message queue or log. If the message data, the "From program" or the "To program" includes the specified text, the watched for condition is true.</p> <p>Contains the null value if no message comparison data was specified.</p>
MESSAGE_COMPARE_AGAINST	VARCHAR(8)	<p>The part of the message the data specified in MESSAGE_COMPARISON_DATA is to be compared against.</p> <p>*FROMPGM The message comparison data will be compared against the name of the program sending the message, or the name of the ILE program that contains the procedure sending the message.</p> <p>*MSGDTA The message comparison data will be compared against the message replacement data.</p> <p>*TOPGM The message comparison data will be compared against the name of the program the message was sent to, or the name of the ILE program that contains the procedure the message was sent to.</p> <p>Contains the null value if no message comparison data was specified.</p>
<p>The following columns apply when DETAIL_TYPE is LICLOG. They will contain the null value when DETAIL_TYPE is MESSAGE or PAL.</p>		
LIC_MAJOR_CODE	CHAR(4)	<p>The LIC log major code to be watched. A hexadecimal digit or a question mark can be specified for each character in the four-digit code. A question mark is a wildcard character that will match any digit in that position. Up to three wildcard characters can be specified. Can contain the following special value:</p> <p>*ALL Any LIC log entry major code will be considered to be a match.</p>

Table 111. WATCH_DETAIL table function (continued)

Column Name	Data Type	Description
LIC_MINOR_CODE	CHAR(4)	<p>The LIC log minor code to be watched. A hexadecimal digit or a question mark can be specified for each character in the four-digit code. A question mark is a wildcard character that will match any digit in that position. Up to three wildcard characters can be specified. Can contain the following special value:</p> <p>*ALL Any LIC log entry minor code will be considered to be a match.</p>
LIC_COMPARISON_DATA	VARCHAR(72) CCSID 65535	<p>The comparison data to be used if a log entry matching the specified major and minor codes is added to the licensed internal code (LIC) log. If this text is found in the LIC log entry data field specified by the LIC log compare against field, the watched for condition is true. This text is case sensitive. If *ALL is specified in the LIC log compare against field, the LIC log fields which will be compared are TDE number, task name, server type, job name, user ID, job number, thread ID, exception ID, LIC module compile binary timestamp, module offset, LIC module RU name, LIC module name, LIC module entry point name. The comparison data cannot be used to match across two fields, and can match an entire field or a substring of any field. The prefix MCH may be specified to compare only against the exception ID field and avoid possible substring matches with the other fields.</p> <p>Contains the null value if no LIC log comparison data was specified.</p>

Table 111. WATCH_DETAIL table function (continued)

Column Name	Data Type	Description
LIC_COMPARE_AGAINST	VARCHAR(10)	The part of the LIC log the data specified in LIC_COMPARISON_DATA is to be compared against.
		<p>*ALL The LIC log comparison data will be compared against all the fields described below.</p> <p>*EXCPID The LIC log comparison data will be compared against the exception that caused the LIC log entry to be requested. This is a 2-byte hexadecimal field formed by concatenating to the high-order 1-byte exception group number a low-order 1-byte exception subtype number. Exception identifier is binary zeros if the LIC log entry is not requested as a result of an exception.</p> <p>*JOBNAME The LIC log comparison data will be compared against the name of the job which requested the LIC log entry. LIC job name is blank (hex 40s) if the LIC log entry is not requested by a job.</p> <p>*JOBNBR The LIC log comparison data will be compared against the job number (000001-999999) to further qualify the job name and user name of the job which requested the LIC log entry. LIC job number is blank (hex 40s) if the LIC log entry is not requested by a job.</p> <p>*JOBUSR The LIC log comparison data will be compared against the user name of the job which requested the LIC log entry. LIC user name is blank (hex 40s) if the LIC log entry is not requested by a job.</p> <p>*MODEPNAME The LIC log comparison data will be compared against the name of the entry point which requested the LIC log entry. If the entry point name is greater than 128 characters, the LIC module entry point name is truncated to 128 characters.</p> <p>*MODNAME The LIC log comparison data will be compared against the LIC module name which requested the LIC log entry. If the module name is greater than 64 characters, the LIC module name is truncated to 64 characters.</p> <p>*MODOFFSET The LIC log comparison data will be compared against the byte offset into the LIC module text which requested the LIC log entry.</p> <p>*MODRUNAME The LIC log comparison data will be compared against the LIC module replacement unit name. LIC module RU name is always in upper case EBCDIC.</p> <p>*MODTSP The LIC log comparison data will be compared against the timestamp of when the LIC module was compiled. The format for this field is the system timestamp format.</p> <p>*SVRTYPE The LIC log comparison data will be compared against the type of server that requested the LIC log entry. Server type is blank (hex 40s) if the LIC log entry is not requested by a server.</p> <p>*TASKNAME The LIC log comparison data will be compared against the name of the task which requested the LIC log entry. Task name is blank (hex 40s) if the LIC log entry is not requested by a task.</p> <p>*TDENBR The LIC log comparison data will be compared against the number of the task dispatching element (TDE) which requested the LIC log entry.</p> <p>*THDID The LIC log comparison data will be compared against the thread which requested the LIC log entry. Thread identifier is binary zeros if the LIC log entry is not requested by a thread</p>
		Contains the null value if no LIC log comparison data was specified.

The following columns apply when **DETAIL_TYPE** is **PAL**. They will contain the null value when **DETAIL_TYPE** is **MESSAGE** or **LICLOG**.

Table 111. WATCH_DETAIL table function (continued)

Column Name	Data Type	Description
PAL_SYSTEM_REFERENCE_CODE	VARCHAR(8)	<p>The system reference code to be watched. A hexadecimal digit or a question mark can be specified for each character in the eight-digit code. A question mark is a wildcard character that will match any digit in that position. Up to seven wildcard characters can be specified. A generic name that is a character string of one or more characters followed by an asterisk (*) can also be specified; for example, ABC*. The asterisk substitutes for any valid characters. A generic name specifies all PALs with system reference codes that begin with the generic prefix. Can contain the following special value:</p> <p>*ALL Any PAL system reference code will be considered to be a match.</p>
PAL_COMPARISON_DATA	VARCHAR(10) CCSID 65535	<p>The comparison data to be used if a PAL entry matching the specified system reference code was created. If the data specified by PAL compare against field matches the specified text, the watched for condition is true. This text is case sensitive. Question marks (?) and asterisk (*) wildcard characters can be specified in the text string. A question mark is a single-character wildcard character and will match any character in the same position. For example, '??123' will match any value that is five characters long and ends with '123'. Multiple question mark wildcard characters can be specified for the comparison data value. An asterisk is a multiple-character wildcard character. A single asterisk wildcard character can be specified at the end of the comparison data value. For example, 'ABC*' will match any value that begins with the letters 'ABC'.</p> <p>Contains the null value if no PAL comparison data was specified.</p>
PAL_COMPARE_AGAINST	VARCHAR(9)	<p>The part of the PAL the data specified in PAL_COMPARISON_DATA is to be compared against.</p> <p>*RSCMODEL The PAL comparison data will be compared against the resource model.</p> <p>*RSCNAME The PAL comparison data will be compared against the resource name.</p> <p>*RSCTYPE The PAL comparison data will be compared against the resource type.</p> <p>Contains the null value if no PAL comparison data was specified.</p>

Example

- List all the watches that my user profile started with the STRWCH command including the detailed information.

```
SELECT *
FROM QSYS2.WATCH_INFO W, TABLE(QSYS2.WATCH_DETAIL(W.SESSION_ID)) D
WHERE W.WATCH_SESSION_TYPE = '*STRWCH' AND
      W.USER_ID = USER;
```

WATCH_INFO view

The WATCH_INFO view returns information about watch sessions on the system.

The values returned for the columns in the view are closely related to the values returned by the WRKWCH (Work with Watches) CL command and by the Retrieve Watch List (QSCRWCHL) and Retrieve Watch Information (QSCRWCHI) API.

Authorization: The caller must have:

- *USE authority to the QSYS/QSCRWCHL and QSYS/QSCRWCHI programs, and
- *SERVICE special authority, or
 - Authorization to the QIBM_SERVICE_WATCH and QIBM_SERVICE_TRACE function usage identifiers.

The following table describes the columns in the view. The system name is WATCH_INFO. The schema is QSYS2.

Table 112. WATCH_INFO view

Column Name	System Column Name	Data Type	Description
SESSION_ID	SESSION_ID	VARCHAR(10)	The session identifier for the watch.
ORIGIN	ORIGIN	VARCHAR(9)	The name of the command or the API that started the watch. QSCSWCH Session started by Start Watch (QSCSWCH) API. STRCMNTRC Session started by Start Communications Trace (STRCMNTRC) command. STRTRC Session started by Start Trace (STRTRC) command. STRWCH Session started by Start Watch (STRWCH) command. TRCCNN Session started by Trace Connection (TRCCNN) command. TRCINT Session started by Trace Internal (TRCINT) command. TRTCPAPP Session started by Trace TCP/IP Application (TRTCPAPP) command.
ORIGIN_JOB	ORIGIN_JOB	VARCHAR(28)	The qualified job name that started the watch session.
START_TIMESTAMP	WCH_START	TIMESTAMP	The timestamp of when the watch was started.
USER_ID	USER_ID	VARCHAR(10)	The name of the user that started the watch session.
WATCH_SESSION_TYPE	WCH_TYPE	VARCHAR(7)	Identifies the type of watch according to its origin. *SRVMON Watch session started using the Service Monitor function of the operating system. *STRWCH Watch session started using the Start Watch (STRWCH) command or Start Watch (QSCSWCH) API. *TRCCMD Watch session started using Start Communications Trace (STRCMNTRC), Start Trace (STRTRC), Trace Internal (TRCINT), Trace Connection (TRCCNN), or Trace TCP/IP Application (TRTCPAPP) commands.
STATUS	STATUS	VARCHAR(6)	The status of the watch session. ACTIVE Session is in ACTIVE status ENDING Session is in ENDING status
JOB_RUN_PRIORITY	PRIORITY	INTEGER	The priority for the job where the watch session work will be run.
WATCHED_MESSAGE_COUNT	MSG_COUNT	INTEGER	The number of messages being watched.
WATCHED_LIC_LOG_COUNT	LIC_COUNT	INTEGER	The number of LIC logs being watched.
WATCHED_PAL_COUNT	PAL_COUNT	INTEGER	The number of PALs being watched.
WATCH_PROGRAM_LIBRARY	WCH_PGMLIB	VARCHAR(10) Nullable	The name of the library where the watch program is located. Contains the null value if WATCH_PROGRAM is null.
WATCH_PROGRAM	WCH_PGM	VARCHAR(10) Nullable	The name of the program called to notify that a specified watch event occurred. Contains the null value if a watch program is not specified or not found.

Table 112. WATCH_INFO view (continued)

Column Name	System Column Name	Data Type	Description
WATCH_PROGRAM_CALL_START	CALL_START	VARCHAR(3) Nullable	Whether the watch program will be called before starting watching for any event. NO The watch program will not be called before starting watching for any event. YES The watch program will be called before starting watching for any event. Contains the null value if WATCH_PROGRAM is null.
WATCH_PROGRAM_CALL_END	CALL_END	VARCHAR(3) Nullable	Whether the watch program will be called when the watch session is ending. NO The watch program will not be called when the watch session is ending. YES The watch program will be called when the watch session is ending. Contains the null value if WATCH_PROGRAM is null.
TIME_LIMIT	TIME_LIMIT	INTEGER Nullable	The time limit, in minutes, for watching for a message, a LIC log entry, or a PAL entry. A non-null value is only returned for watch sessions started by a trace command. When the specified amount of time has elapsed, the program identified by the WATCH_PROGRAM column is called, the watch is ended, and message CPI3999 is sent to the history log. Contains the null value if the watch session was started by a trace command and did not specify a time limit or for sessions not started by a trace command.
TIME_INTERVAL	INTERVAL	INTEGER Nullable	The interval of time, in seconds, of how often the trace exit program is called. Contains the null value if the watch session was started by a trace command and did not specify an interval or for sessions not started by a trace command.

Example

- List all the service monitor watches that are currently active.

```
SELECT *
FROM QSYS2.WATCH_INFO
WHERE WATCH_SESSION_TYPE = '*SRVMON' AND
STATUS = 'ACTIVE';
```

Backup and Recovery Services

These table functions and views provide information about backup and recovery.

Backup, Recovery, and Media Services (BRMS) Services

These table functions and views provide information about BRMS.

BRMS SQL Services

MEDIA_LIBRARY_INFO view

The MEDIA_LIBRARY_INFO view returns information that can also be seen through the Work with Media Library Status (WRKMLBSTS) command interface.

Authorization: None required.

The following table describes the columns in the view. The system name is MEDIA_INFO. The schema is QSYS2.

Table 113. MEDIA_LIBRARY_INFO view

Column Name	System Column Name	Data Type	Description
DEVICE_NAME	DEVICE	VARCHAR(10)	The name of the device.
DEVICE_STATUS	DEVICE_STS	VARCHAR(20)	The status of the device. The most common values are: VARIED ON The media library device is varied on. VARIED OFF The media library device is varied off. ACTIVE The resource is currently in use by a job under this media library. See List Configuration Descriptions API for a complete list of status values.
DEVICE_TYPE	DEVICE_TYP	VARCHAR(10)	The type of device. Contains the special value *RSRCNAME if the device type is determined by the resource in the RESOURCE_NAME column.
DEVICE_MODEL	DEVICE_MDL	VARCHAR(10)	The model number of the device. Contains the special value *RSRCNAME if the device model is determined by the resource in the RESOURCE_NAME column.
RESOURCE_NAME	RESOURCE	VARCHAR(10) Nullable	The name of the resource. Contains the null value if the DEVICE_STATUS column has a value of VARIED_OFF, or if the tape library does not have any associated tape resources.
RESOURCE_STATUS	RSRC_STS	VARCHAR(11) Nullable	The status of the resource. OPERATIONAL The resource is working and the system can address the tape drive resource. ACTIVE The resource is currently in use by a job under this media library. UNAVAILABLE The resource is currently not available because it may be in use by another object, another client, or DST. FAILED The resource is not operational and the system can no longer communicate with that resource. A hardware problem may have occurred. Contains the null value if the DEVICE_STATUS column has a value of VARIED_OFF, or if the tape library does not have any associated tape resources.

Table 113. MEDIA_LIBRARY_INFO view (continued)

Column Name	System Column Name	Data Type	Description
RESOURCE_ALLOCATION_STATUS	ALLOCATION	VARCHAR(11) Nullable	<p>Current allocation status for the resource.</p> <p>ALLOCATED For a tape media library device the resource is exclusively assigned to this system and cannot be accessed by another system. For an optical media library device the drive is available for use by this media library.</p> <p>UNPROTECTED A tape resource is not exclusively assigned to this system. This resource can be assigned to this system when no other system has already assigned the resource.</p> <p>DEALLOCATED For a tape media library the resource is not assigned to this system and is not available to respond to requests. For an optical media library the device is not available for use by this media library.</p> <p>STAND-ALONE A tape resource is not available. The tape resource is reserved by a varied on stand-alone tape device description for non-library mode use.</p> <p>*UNKNOWN An optical media library is varied off or failed. The current allocation for a resource cannot be determined.</p> <p>Contains the null value if the DEVICE_STATUS column has a value of VARIED_OFF, or if the tape library does not have any associated tape resources.</p>
RESOURCE_ALLOCATION_PRIORITY	ALLOC_PRTY	VARCHAR(4)	<p>The priority of a job when requesting a resource. 1 is highest priority, 99 is lowest. Can contain the following special value:</p> <p>*JOB The priority of the job is used as the resource allocation priority.</p>
INITIAL_MOUNT_WAIT_TIME	INIT_WAIT	VARCHAR(6)	<p>The maximum amount of time a request will wait for allocation of a tape resource for the initial mount. Contains either a numeric string representing the number of minutes or one of the following special values:</p> <p>*JOB The allocation wait time is determined by the default wait time attribute of the job requesting the allocation, rounded up to the nearest minute.</p> <p>*IMMED The request will not wait for a tape resource to become available.</p> <p>*NOMAX The request will wait until a tape resource is available.</p>
END_OF_VOLUME_MOUNT_WAIT_TIME	END_WAIT	VARCHAR(6)	<p>The maximum amount of time a request will wait for allocation of a tape resource for the end of volume mount. Contains either a numeric string representing the number of minutes or one of the following special values:</p> <p>*JOB The allocation wait time is determined by the default wait time attribute of the job requesting the allocation, rounded up to the nearest minute.</p> <p>*IMMED The request will not wait for a tape resource to become available.</p> <p>*NOMAX The request will wait until a tape resource is available.</p>
DEVICE_DESCRIPTION	DEVICE_DES	VARCHAR(50)	The text description of the device.

Example

Return information about all media library devices.

```
SELECT * FROM QSYS2.MEDIA_LIBRARY_INFO
```

SAVE_FILE_INFO view

The SAVE_FILE_INFO view returns general information about save files. Detailed information for save files that contain integrated file system data is not returned.

The information returned is similar to the detail available through the Display Save File (DSPSAVF) CL command and the List Save File (QSRLSAVF) API.

Authorization: The caller must have:

- *USE authority to the library containing the save file, and
- *USE authority to the save file.

The following table describes the columns in the view. The system name is SAVF_INFO. The schema is QSYS2.

Table 114. SAVE_FILE_INFO view

Column Name	System Column Name	Data Type	Description
SAVE_FILE_LIBRARY	SAVF_LIB	VARCHAR(10)	Name of the library that contains the save file.
SAVE_FILE	SAVF	VARCHAR(10)	Name of the save file.
OBJECTS_SAVED	OBJECTS	INTEGER	The number of objects saved for the library.
MEMBERS_SAVED	MEMBERS	INTEGER	The number of members saved for the library.
ACCESS_PATHS_SAVED	ACC_PATHS	INTEGER	The number of logical file access paths saved for the library.
SPOOLED_FILES_SAVED	SPLFS	INTEGER	The number of spooled files saved in the save file.
SAVE_COMMAND	SAVE_CMD	VARCHAR(9) Nullable	The save command that was used for the save operation. QSYS Contents of the save file were created by the operating system by using a function other than the CL commands. SAV Save directories and integrated file system objects. Information about the content of this save file is not returned. SAVCFG Save configuration information. SAVCHGOBJ Save objects that changed since the date and time specified on the referenced date parameter. SAVDLO Save documents or folders located in library QDOC. SAVLIB Save a library. SAVLICPGM Save licensed programs. SAVOBJ Save an object or group of objects from the same library. SAVSECDTA Save objects required for the security function. Contains the null value if the save file is empty.
SAVE_TIMESTAMP	SAVED	TIMESTAMP(0) Nullable	The date and time when the objects were saved. Contains the null value if the save file is empty or SAVE_COMMAND is SAV.
DATA_COMPRESSED	COMPRESSED	VARCHAR(3) Nullable	Whether the data was saved in compressed format. NO The data is not compressed. YES The data is compressed. Contains the null value if the save file is empty or SAVE_COMMAND is SAV.

Table 114. SAVE_FILE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SAVE_WHILE_ACTIVE	SAVEACTIVE	VARCHAR(8) Nullable	<p>Whether objects in the library were allowed to be updated while they were being saved.</p> <p>*LIB Objects in the library were allowed to be saved while they were in use by another job. All objects in the library reached a checkpoint together. They were saved in a consistent state in relationship to each other.</p> <p>*NO Objects in the library were not allowed to be saved while they were in use by another job.</p> <p>*SYNCLIB Objects in the library were saved while in use by another job. All of the objects and all of the libraries in the save operation reached a checkpoint together. The objects and the libraries were saved in a consistent state in relationship to each other.</p> <p>*SYSDFN Objects that were in use were saved if they were released within the time specified on the SAVACTWAIT parameter. Objects in the library may have reached a checkpoint at different times. They might not be in a consistent state in relationship to each other. Objects in the library were saved while in use by another job.</p> <p>*YES Document library objects were allowed to be saved while they were in use by another job.</p> <p>Contains the null value if the save file is empty or SAVE_COMMAND is SAV.</p>
SYNCHRONIZATION_ID	SYNC_ID	VARCHAR(10) Nullable	<p>The name that was used to synchronize checkpoints for more than one save while active operation.</p> <p>Contains the null value if the save file is empty, SAVE_COMMAND is SAV, or if no synchronization name was used for the save.</p>
EARLIEST_POSSIBLE_RELEASE	EARLY_REL	CHAR(6) Nullable	<p>The earliest release level of the operating system on which the objects can be restored in VxRxMx format.</p> <p>Contains the null value if the save file is empty or SAVE_COMMAND is SAV.</p>
LIBRARY_NAME	LIBRARY	VARCHAR(10) Nullable	<p>The name of the library from which the objects were saved.</p> <p>Contains the null value if the save file is empty or SAVE_COMMAND is SAV.</p>
PRIVATE_AUTHORITIES	PRIV_AUTHS	VARCHAR(3) Nullable	<p>Whether the save operation specified that private authorities should be saved with the objects.</p> <p>NO Objects were saved without their private authorities.</p> <p>YES Objects were saved with their private authorities.</p> <p>Contains the null value if the save file is empty or SAVE_COMMAND is SAV.</p>
SERIAL_NUMBER	SERIAL	VARCHAR(8) Nullable	<p>The serial number of the system on which the save was performed.</p> <p>Contains the null value if the serial number is not available or the save file is empty or SAVE_COMMAND is SAV.</p>
SAVE_FILE_RECORDS	SAVF_REC	BIGINT Nullable	<p>The number of records used to contain the saved information in the save file.</p> <p>Contains the null value if SAVE_COMMAND is SAV.</p>

Table 114. SAVE_FILE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
IASP_NUMBER	IASPNUMBER	INTEGER Nullable	The auxiliary storage pool (ASP) of the library when it was saved. 1 indicates the system ASP. Contains the null value if the save file is empty or SAVE_COMMAND is SAV.
IASP_NAME	IASPNAME	VARCHAR(10) Nullable	The name of the independent auxiliary storage pool (ASP) device of the library when it was saved. Can contain the special value *SYSBAS. Contains the null value if the save file is empty or SAVE_COMMAND is SAV.

Example

- Find all the save files in library BACKUP used to save objects from APPLIB.

```
SELECT SAVE_FILE_LIBRARY, SAVE_FILE, SAVE_TIMESTAMP, OBJECTS_SAVED
FROM QSYS2.SAVE_FILE_INFO
WHERE SAVE_FILE_LIBRARY = 'BACKUP' AND
LIBRARY_NAME = 'APPLIB';
```

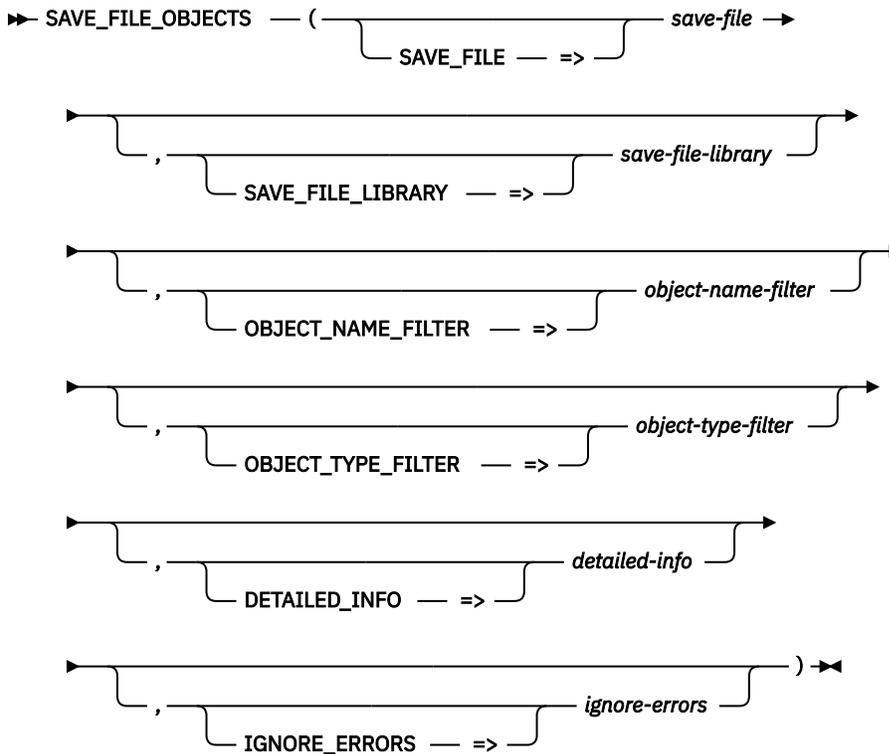

SAVE_FILE_OBJECTS table function

The SAVE_FILE_OBJECTS table function returns information about the objects in a save file. Information about integrated file system objects is not returned.

The information returned is similar to the detail available through the Display Save File (DSPSAVF) CL command and the List Save File (QSRLSAVF) API.

Authorization: The caller must have:

- *USE authority to the library containing the save file, and
- *USE authority to the save file.

The schema is QSYS2.

- save-file** A character or graphic string expression that identifies the name of the save file containing the objects.
- save-file-library** A character or graphic string expression that identifies the name of the library that contains *save-file*.
The string can contain the following special values:
- *CURLIB** The current library is used.
 - *LIBL** The library list is used. This is the default.
- object-name-filter** A character or graphic string expression that identifies the object name to be returned. The name can be a generic name.
The string can contain the following special value:
- *ALL** All objects are returned.
- If this parameter is not specified, information for all objects is returned.
- object-type-filter** A character or graphic string expression that contains a system object type for the objects to be returned.
The string can contain the following special value:
- *ALL** All object types are returned.
- If this parameter is not specified, information for all object types is returned.
- detailed-info** A character or graphic string expression that indicates the type of information to be returned.
- NONE** Only information about the object is returned. This is the default.
 - FILE** Additional information is returned for *FILE objects. For every file, one row is returned for each member.
 - OUTQ** Additional information is returned for *OUTQ objects. For every output queue, one row is returned for each spooled file.
 - ALL** Additional information is returned for *FILE and *OUTQ objects.
For a file, one row is returned for each member in the file.
For an output queue, one row is returned for each spooled file in the output queue.
- ignore-errors** A character or graphic string expression that identifies what to do when an error is encountered.
- NO** An error is returned.
 - YES** A warning is returned.
No row is returned when an error is encountered. This is the default.

The result of the function is a table containing multiple rows with the format shown in the following table. All the columns are nullable.

Table 115. SAVE_FILE_OBJECTS table function

Column Name	Data Type	Description
SAVE_FILE_LIBRARY	VARCHAR(10)	Name of the library that contains the save file.
SAVE_FILE	VARCHAR(10)	Name of the save file.
LIBRARY_NAME	VARCHAR(10)	The name of the library from which the object was saved.

Table 115. SAVE_FILE_OBJECTS table function (continued)

Column Name	Data Type	Description
OBJECT_NAME	VARCHAR(10)	The name of the saved object. Contains the system name for a DLO object.
OBJECT_TYPE	VARCHAR(7)	The type of object.
OBJECT_ATTRIBUTE	VARCHAR(10)	Extended information about the object type. Contains the null value if there is no object attribute.
TEXT_DESCRIPTION	VARCHAR(50)	The text description of the object. Contains the null value if there is no text description.
SAVE_TIMESTAMP	TIMESTAMP(0)	The date and time at which the object was saved.
OBJECT_SIZE	BIGINT	The size of the object, in bytes. This value will be a rounded value for an object larger than 999,999,999 bytes.
DATA_SAVED	VARCHAR(3)	Whether the data for this object was saved with the object. NO The data was not saved. The object's storage was freed by a previous save command before this save operation. YES The data was saved. The object's storage was not freed by a previous save command before this save operation.
OBJECT_OWNER	VARCHAR(10)	The owner of the object.
DLO_NAME	VARCHAR(20)	The name of the document, folder, or mail object that was saved. Contains the null value if there is no document library object.
FOLDER_PATH	VARCHAR(63)	The name of the folder that was saved. Contains the null value if this is not a *FLR or *DOC object, or if there is no folder path.
IASP_NUMBER	INTEGER	The auxiliary storage pool (ASP) of the library when the object was saved. 1 indicates the system ASP.
IASP_NAME	VARCHAR(10)	The name of the independent auxiliary storage pool (ASP) device of the library when the object was saved.
Member information		
MEMBERS	INTEGER	The number of members saved for the file. Contains the null value if DETAILED_INFO is NO or OUTQ or if OBJECT_TYPE is not *FILE.
MEMBER_NAME	VARCHAR(10)	The name of the file member that was saved. Contains the null value if DETAILED_INFO is NO or OUTQ or if OBJECT_TYPE is not *FILE.
Spooled file information		
SPOOLED_FILE_NAME	VARCHAR(10)	The name of the spooled file. Contains the null value if DETAILED_INFO is NO or FILE or if OBJECT_NAME is not an output queue.
SPOOLED_FILE_NUMBER	INTEGER	The number of the spooled file in the job that owns it. Contains the null value if DETAILED_INFO is NO or FILE or if OBJECT_TYPE is not *OUTQ.
QUALIFIED_JOB_NAME	VARCHAR(28)	The fully-qualified job name that owns the spooled file. Contains the null value if DETAILED_INFO is NO or FILE or if OBJECT_TYPE is not *OUTQ.
JOB_NAME	VARCHAR(10)	The name of the job that owns the spooled file. Contains the null value if DETAILED_INFO is NO or FILE or if OBJECT_TYPE is not *OUTQ.
JOB_USER	VARCHAR(10)	The name of the user who owns the spooled file. Contains the null value if DETAILED_INFO is NO or FILE or if OBJECT_TYPE is not *OUTQ.

Table 115. SAVE_FILE_OBJECTS table function (continued)

Column Name	Data Type	Description
JOB_NUMBER	VARCHAR(6)	The number of the job that owns the spooled file. Contains the null value if DETAILED_INFO is NO or FILE or if OBJECT_TYPE is not *OUTQ.
SYSTEM_NAME	VARCHAR(8)	The name of the system where the job that owns the spooled file ran. Contains the null value if DETAILED_INFO is NO or FILE or if OBJECT_TYPE is not *OUTQ.
CREATE_TIMESTAMP	TIMESTAMP(0)	The date and time when the spooled file was created. Contains the null value if DETAILED_INFO is NO or FILE or if OBJECT_TYPE is not *OUTQ.

Example

- List all the spooled files saved in the MYLIB/SAVF1 save file.

```
SELECT LIBRARY_NAME CONCAT '/' CONCAT OBJECT_NAME AS OUTPUT_QUEUE, SPOOLED_FILE_NAME,
SPOOLED_FILE_NUMBER, CREATE_TIMESTAMP
FROM TABLE (QSYS2.SAVE_FILE_OBJECTS(SAVE_FILE => 'SAVF1', SAVE_FILE_LIBRARY => 'MYLIB',
OBJECT_TYPE_FILTER => '*OUTQ', DETAILED_INFO => 'ALL'));
```

SAVE_FILE_OBJECTS view

The SAVE_FILE_OBJECTS view returns information about the objects in a save file. Information about integrated file system objects is not returned.

The SAVE_FILE_OBJECTS table function can be used to return detailed information about database file (*FILE) members and output queue (*OUTQ) spooled files that were saved.

The information returned is similar to the detail available through the Display Save File (DSPSAVF) CL command and the List Save File (QSRLSAVF) API.

Authorization: The caller must have:

- *USE authority to the library containing the save file, and
- *USE authority to the save file.

The following table describes the columns in the view. The system name is SAVF_OBJ. The schema is QSYS2.

Table 116. SAVE_FILE_OBJECTS view

Column Name	System Column Name	Data Type	Description
SAVE_FILE_LIBRARY	SAVF_LIB	VARCHAR(10)	Name of the library that contains the save file.
SAVE_FILE	SAVF	VARCHAR(10)	Name of the save file.
LIBRARY_NAME	LIBNAME	VARCHAR(10)	The name of the library from which the object was saved.
OBJECT_NAME	NAME	VARCHAR(10)	The name of the saved object. Contains the system name for a DLO object.
OBJECT_TYPE	OBJ_TYPE	VARCHAR(7)	The type of object.
OBJECT_ATTRIBUTE	OBJ_ATTR	VARCHAR(10) Nullable	Extended information about the object type. Contains the null value if there is no object attribute.
TEXT_DESCRIPTION	TEXT	VARCHAR(50) Nullable	The text description of the object. Contains the null value if there is no text description.
SAVE_TIMESTAMP	SAVED	TIMESTAMP(0)	The date and time at which the object was saved.
OBJECT_SIZE	OBJ_SIZE	BIGINT	The size of the object, in bytes. This value will be a rounded value for an object larger than 999,999,999 bytes.

Table 116. SAVE_FILE_OBJECTS view (continued)

Column Name	System Column Name	Data Type	Description
DATA_SAVED	DATA	VARCHAR(3)	Whether the data for this object was saved with the object. NO The data was not saved. The object's storage was freed by a previous save command before this save operation. YES The data was saved. The object's storage was not freed by a previous save command before this save operation.
OBJECT_OWNER	OBJ_OWNER	VARCHAR(10)	The owner of the object.
DLO_NAME	DLO_NAME	VARCHAR(20) Nullable	The name of the document, folder, or mail object that was saved. Contains the null value if there is no document library object.
FOLDER_PATH	FOLDER	VARCHAR(63) Nullable	The name of the folder that was saved. Contains the null value if this is not a *FLR or *DOC object, or if there is no folder path.
IASP_NUMBER	IASPNUMBER	INTEGER	The auxiliary storage pool (ASP) of the library when the object was saved. 1 indicates the system ASP.
IASP_NAME	IASP_NAME	VARCHAR(10)	The name of the independent auxiliary storage pool (ASP) device of the library when the object was saved.

Example

- Find all the save files used to save any *FILE objects with names that begin with 'CUST'. Since this can be a long-running query, submit it as a batch job. The RUNSQL CL command is used to run the SQL statement and return the results in a table in MYLIB.

```
SBMJOB CMD(RUNSQL
SQL('CREATE TABLE MYLIB.SAVF_CUST AS (
      SELECT SAVE_FILE_LIBRARY, SAVE_FILE, LIBRARY_NAME, OBJECT_NAME, SAVE_TIMESTAMP
      FROM QSYS2.SAVE_FILE_OBJECTS
      WHERE OBJECT_NAME LIKE ''CUST%'') WITH DATA')
COMMIT(*NONE)) JOB(SAVFLIST)
```

TAPE_CARTRIDGE_INFO view

The TAPE_CARTRIDGE_INFO view returns information about tape cartridges.

This information is similar to the information available through the Display Tape Cartridge (DSPTAPCTG) CL command and the Retrieve Cartridge Information (QTARCTGI) API.

Authorization: The caller must have *USE authority to the device description.

The following table describes the columns in the view. If a device cannot be allocated to access its information, a row containing only the device name is returned. The system name is TAPE_INFO. The schema is QSYS2.

Table 117. TAPE_CARTRIDGE_INFO view

Column Name	System Column Name	Data Type	Description
DEVICE_NAME	DEVICE	VARCHAR(10)	The name of the tape library device.
CARTRIDGE_ID	CTG_ID	VARCHAR(6)	The identifier of the cartridge.
CARTRIDGE_ID_SOURCE	CTG_ID_SRC	VARCHAR(9)	The type of cartridge ID. BAR CODE The cartridge ID was read from the bar code label on the cartridge. SYSTEM The cartridge ID is generated by the system. VOLUME ID The volume identifier is used for the cartridge ID.

Table 117. TAPE_CARTRIDGE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
VOLUME_ID	VOLUME_ID	VARCHAR(6) Nullable	The volume identifier for the cartridge that was read from the tape volume labels. Can contain the following special value: *NL The volume is a non-labeled tape. Contains the null value if the volume ID is not known.
MEDIA_TYPE	MEDIA_TYPE	VARCHAR(2) Nullable	The media type read from the bar code label on the cartridge. Contains the null value if the media type is not available.
CATEGORY	CATEGORY	VARCHAR(10)	The category assigned to the cartridge.
CATEGORY_SYSTEM	CAT_SYSTEM	VARCHAR(8) Nullable	The name of the system that owns the category assigned to the cartridge. Contains the null value if the cartridge is assigned to a category that does not have an owner.
STATUS	STATUS	VARCHAR(13)	The status of the cartridge. AVAILABLE The cartridge is available for use. DUPLICATE The cartridge identifier exists more than once in the library device. One of the cartridges must be physically removed before the other can be used in the library device. EJECTED The cartridge ID is in the *EJECT category or it was manually ejected from the library device. ERROR The status of the cartridge ID is unknown. The cartridge cannot be found or is not in a usable condition. INSERTED The cartridge is inserted into the library. The Add Tape Cartridge (ADDTAPCTG) command must be issued to move the cartridge to available status. MOUNTED The cartridge is mounted in a tape device or in the queue ready to be loaded. NOT AVAILABLE The cartridge is present but not available for use.
CHANGE_TIMESTAMP	CHANGED	TIMESTAMP(0) Nullable	The timestamp when the cartridge was last used for output operations. Contains the null value if a change timestamp is not available.
REFERENCE_TIMESTAMP	REFERENCED	TIMESTAMP(0) Nullable	The timestamp the cartridge was last used for input or output operations. Contains the null value if the cartridge has not been used.
LOCATION	LOCATION	VARCHAR(10) Nullable	The current location of the cartridge. This can be either a slot number or a tape resource name. Contains the null value if the cartridge is located in a storage slot but the slot number is not known, or if the cartridge is located in a tape drive but the drive location is not known.
LOCATION_INDICATOR	LOC_IND	VARCHAR(6)	Where the tape cartridge is located. *DRIVE The cartridge is located in a tape drive. *SLOT The cartridge is located in a storage slot.
OWNER_ID	OWNER_ID	VARCHAR(17) Nullable	The owner ID specified when the tape was initialized. This information is read from the tape volume labels. Can contain the following special values: *BLANK The owner ID in the tape labels is blank. *NL The cartridge is a non-labeled tape. Contains the null value if the owner ID is not known.

Table 118. ACTIVE_DB_CONNECTIONS table function

Column Name	Data Type	Description
CONNECTION_USAGE	VARCHAR(21)	The connection usage of the local server (<i>job-name</i>) side of the connection. APPLICATION REQUESTER The remote job is the application requester, often called the client. APPLICATION SERVER The remote job is the application server, often called the server.
REMOTE_HOST_NAME	VARCHAR(255)	The name of the remote system for this connection.
REMOTE_JOB_NAME	VARCHAR(28)	The qualified job name of the remote job that is connected to <i>job-name</i> . Contains the null value if the remote server is not an IBM i.
REMOTE_USER	VARCHAR(255)	User name for the remote connection.
CLIENT_RDB	VARCHAR(18)	The RDB name of the application requester. Can contain the null value if the connection is only used for a DDM file operation.
SERVER_RDB	VARCHAR(18)	The RDB name of the application server. Can contain the null value if the connection is only used for a DDM file operation.
CONNECTION_TIME	TIMESTAMP	Timestamp for when the connection was established.
CONNECTION_TIME_UTC	TIMESTAMP	Timestamp for when the connection was established, in Universal Time Coordinated (UTC).
CONNECTION_TYPE	VARCHAR(11)	The type of connection established between <i>job-name</i> and REMOTE_JOB_NAME. DB2 MIRROR This connection is a Db2 Mirror connection. OPTICONNECT This connection is an OptiConnect connection. SNA This connection is an SNA connection. TCP/IP This connection is a TCP/IP connection.
NRG_NAME	VARCHAR(15)	The Network Redundancy Group (NRG) used for this connection. Contains the null value if CONNECTION_TYPE is not DB2 MIRROR.
CLIENT_PORT	INTEGER	The client host port number.
CLIENT_ADDRESS	VARCHAR(45)	IP address of the client. This is shown in IPv6 address format.
SERVER_PORT	INTEGER	The server host port number.
SERVER_ADDRESS	VARCHAR(45)	IP address of the server. This is shown in IPv6 address format.
SNA_DEVICE_NAME	VARCHAR(10)	The name of the device used to communicate with the remote location. Contains the null value if CONNECTION_TYPE is not SNA.
SNA_MODE_NAME	VARCHAR(8)	The name of the mode to be used to communicate between the local location and remote location. Contains the null value if CONNECTION_TYPE is not SNA.
SNA_LOCAL_LOCATION_NAME	VARCHAR(8)	Indicates the local location name by which this system is identified to the system on which the RDB is located. Contains the null value if CONNECTION_TYPE is not SNA.
SNA_REMOTE_LOCATION_NAME	VARCHAR(8)	The name of the remote location where the remote file exists. Contains the null value if CONNECTION_TYPE is not SNA.

Table 118. ACTIVE_DB_CONNECTIONS table function (continued)

Column Name	Data Type	Description
SNA_REMOTE_NETWORK_ID	VARCHAR(8)	Indicates the remote network identifier of the system on which the RDB is located. Contains the null value if CONNECTION_TYPE is not SNA.
SNA_TRANSACTION_PROGRAM_NAME	VARCHAR(19)	Indicates the transaction program name (TPN) specified in the RDB directory entry. The value is returned as a hex string in the form X'aabbcc'. Contains the null value if CONNECTION_TYPE is not SNA.
SSL	VARCHAR(3)	Indicates whether this connection uses SSL. NO The connection does not use SSL. YES The connection uses SSL.
THREE_PART_NAMING	VARCHAR(3)	Indicates whether this connection was established using an SQL statement with 3-part naming. NO This connection was not established using an SQL statement with 3-part naming. YES This connection was established using an SQL statement with 3-part naming. Contains the null value if CONNECTION_USAGE is APPLICATION SERVER.
XA	VARCHAR(3)	Indicates whether this connection is used for XA. NO This is not an XA connection. YES This is an XA connection. Contains the null value if CONNECTION_USAGE is APPLICATION SERVER.
ACTIVATION_GROUP_NUMBER	BIGINT	Activation group number for job making the connection. Contains the null value if CONNECTION_USAGE is APPLICATION SERVER.
ACTIVATION_GROUP_NAME	VARCHAR(10)	Activation group name for job making the connection. Contains the null value if the activation group has no name or if CONNECTION_USAGE is APPLICATION SERVER.
THREAD_ID	BIGINT	The thread ID for the connection. Contains the null value if CONNECTION_USAGE is APPLICATION SERVER.
SCOPE	VARCHAR(16)	Scope of the connection. ACTIVATION GROUP The connection is scoped to the activation group. JOB The connection is scoped to the job. Contains the null value if CONNECTION_USAGE is APPLICATION SERVER.
COMMIT_PROTOCOL	VARCHAR(9)	The commitment control protocol used for this connection. ONE-PHASE The connection uses one-phase commitment control. TWO-PHASE The connection uses two-phase commitment control. Contains the null value if CONNECTION_USAGE is APPLICATION SERVER.
REMOTE_CLASS	VARCHAR(255)	The class of the remote server. Some common values are: QAS Db2 for i QDB2 Db2 for z/OS® QDB2/xxx Db2 for LUW

Table 118. ACTIVE_DB_CONNECTIONS table function (continued)

Column Name	Data Type	Description
REMOTE_RELEASE	VARCHAR(255)	The release level of the remote server.
ERROR	VARCHAR(3)	Indicates whether the connection is currently in an error state. For example, a communication failure occurred. NO The connection is not in an error state. YES The connection is in an error state.
SUSPEND_PROCESSING_START	TIMESTAMP	The timestamp, in Universal Time Coordinated (UTC), when the most recent Db2 Mirror suspend state change processing started for this job. The timestamp is not cleared when the state change processing is complete. Contains the null value if no prior suspend state change has occurred for this job.
SUSPEND_PROCESSING_END	TIMESTAMP	The timestamp, in Universal Time Coordinated (UTC), when the most recent Db2 Mirror suspend state change processing ended for this job. The timestamp is not cleared when the state change processing is complete. Contains the null value if no prior suspend state change has occurred for this job.

Example

- List all the connections that are active for a specific job.

```
SELECT * FROM TABLE (QSYS2.ACTIVE_DB_CONNECTIONS('900239/SKALSKY/QPADEV000F'));
```

ADD_TIME_SERVER procedure

The ADD_TIME_SERVER procedure adds a Network Time Protocol (NTP) server to the NTP configuration list.

The ADD_TIME_SERVER procedure requires 5770SS1 Option 33 - Portable Application Solutions Environment (PASE).

Authorization: The caller must have:

- *IOSYSCFG special authority, and
- *RW authority to /QIBM/UserData/OS400/TCP/IP/NTP/ntp.conf

```
➤ ADD_TIME_SERVER ( ( time-server →
                    { TIME_SERVER ⇒ }
                    , { PREFERRED_INDICATOR ⇒ }
                    preferred-indicator → ) ➤
```

The schema is QSYS2.

time-server A character or graphic string that identifies the DNS name of the NTP server to be added to the configuration.

preferred-indicator A character or graphic string that indicates whether this NTP server should be considered a preferred time server.

NO This is not a preferred time server.

YES This is a preferred time server.

Example

- Add time.domain.name.com as a preferred time server

```
CALL QSYS2.ADD_TIME_SERVER(TIME_SERVER =>'time.domain.name.com',  
                           PREFERRED_INDICATOR => 'YES');
```

CHANGE_OBJECTCONNECT procedure

The CHANGE_OBJECTCONNECT procedure changes, starts, or stops the ObjectConnect over IP server.

The procedure is similar to the Change ObjectConnect Attrs (CHGOBJCA) CL command.

If the subsystem description parameter is changed while the ObjectConnect over IP server is running, the change takes effect the next time the server is restarted.

This procedure requires that Option 22 of the IBM i operating system is installed.

Authorization: The caller must have *IOSYSCFG special authority.

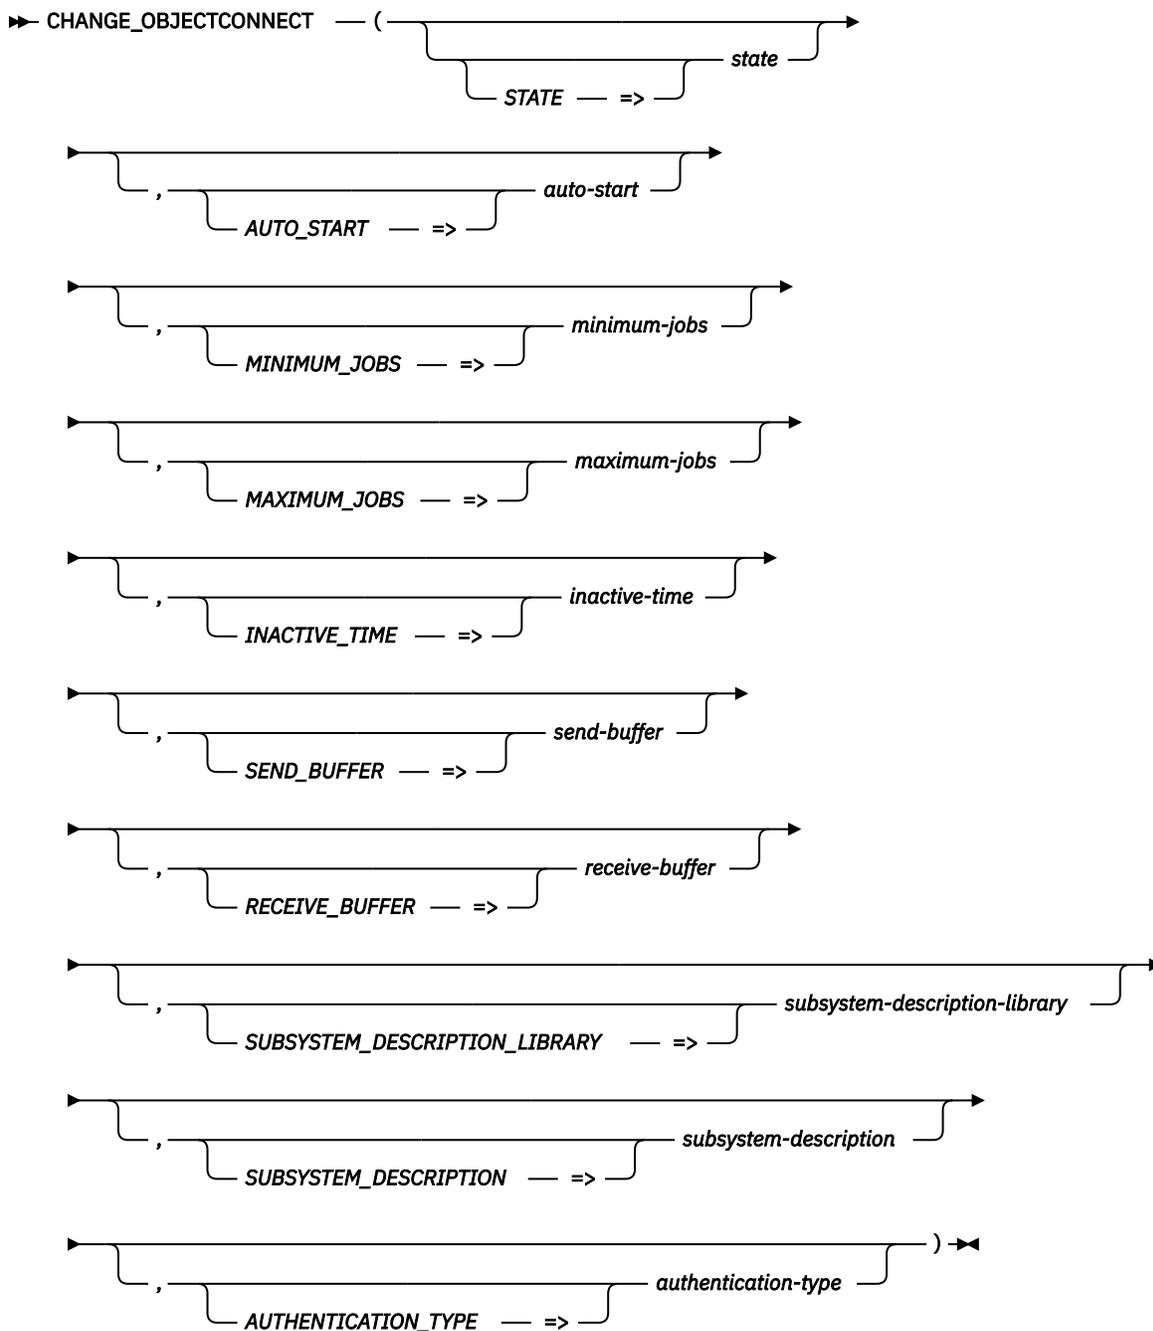

The caller must have *USE authority to the QSYS/STRTCPSVR command when changing STATE to 'START'.

The caller must have *USE authority to the QSYS/ENDTCPSVR command when changing STATE to 'END'.

The caller must have additional authority when changing SUBSYSTEM_DESCRIPTION_LIBRARY or SUBSYSTEM_DESCRIPTION.

- The caller must have *READ, *ADD, and *EXECUTE authorities to the library containing the subsystem description.
- If the subsystem description does not exist, the caller must have *USE authority to the QSYS/CRTSBSD CL command.
- If the subsystem description exists, the caller must have *READ, *OBJMGT and *OBJOPR authorities to the subsystem description.
- If the job queue referenced by the subsystem description exists, the caller must have *READ, *OBJMGT and *OBJOPR authorities to the job queue.

If the subsystem description and job queue exist, the QOBJC user profile will be granted *USE authority to these objects.

The schema is QSYS2.

state A character or graphic string that indicates how to change the state of the ObjectConnect over IP server. If this parameter is omitted, the state of the ObjectConnect over IP server does not change.

END End the ObjectConnect over IP server.

START Start the ObjectConnect over IP server.

auto-start A character or graphic string that indicates how to start the ObjectConnect over IP server. If this parameter is omitted, the auto start setting does not change. The initial configuration default value is YES.

NO Do not start the ObjectConnect over IP server automatically.

YES Start the ObjectConnect over IP server automatically.

<i>minimum-jobs</i>	An integer value that specifies the minimum number of server jobs that are started by the ObjectConnect receiver job to accept client connections. If this parameter is omitted, the minimum number of server jobs does not change. The initial configuration default value is 1 and the maximum value is 999.
<i>maximum-jobs</i>	An integer value that specifies the maximum number of server jobs that are started by the ObjectConnect receiver job to accept client connections. If this parameter is omitted, the maximum number of server jobs does not change. The initial configuration default value is 5 and the maximum value is 32767.
<i>inactive-time</i>	An integer value that specifies the length of time in minutes a server job will stay inactive before ending. If this parameter is omitted, the server inactive time does not change. The initial configuration default value is 30 and the maximum value is 1440.
<i>send-buffer</i>	An integer value that specifies the size of the TCP send buffer, in bytes, that the data connection will use to send data over the network. If this parameter is omitted, the TCP send buffer size does not change. The initial configuration default value is 262144, the minimum value is 512 and maximum value is 8388608.
<i>receive-buffer</i>	An integer value that specifies the size of the TCP receive buffer, in bytes, that the data connection will use to receive data from the network. If this parameter is omitted, the TCP receive buffer size does not change. The initial configuration default value is 8388608, the minimum value is 512 and maximum value is 8388608.
<i>subsystem-description-library</i>	A character or graphic string that contains the library name where <i>subsystem-description</i> resides. The library can be QSYS for IBM shipped subsystem QUSRWRK or any user library. The library must exist. If this parameter is omitted, the subsystem library does not change.
<i>subsystem-description</i>	<p>A character or graphic string that indicates the subsystem where the ObjectConnect server will run in. The subsystem can be IBM shipped subsystem QSYS/QUSRWRK or a user-provided subsystem description. When the <i>subsystem-description</i> parameter is provided, the <i>subsystem-description-library</i> parameter must also be provided.</p> <p>If the user-provided subsystem description exists, the QOBJC user profile will be granted *USE authority to the object. If the subsystem description does not exist, it will be created along with a job queue having same name. If this parameter is omitted, the subsystem does not change. The initial configuration default value is QSYS/QUSRWRK.</p>
<i>authentication-type</i>	<p>A character or graphic string that indicates which authentication type can be used by the ObjectConnect over IP server to authenticate the incoming ObjectConnect connection request. If this parameter is omitted, the authentication type does not change. The initial configuration default value is ANY.</p> <p>ANY The ObjectConnect over IP server can use any of the supported authentication types to authenticate an incoming ObjectConnect connection request.</p> <p>KERBEROS The ObjectConnect over IP server can use Kerberos to authenticate an incoming ObjectConnect connection request.</p> <p>PASSWORD The ObjectConnect over IP server can use the user profile and password to authenticate an incoming ObjectConnect connection request.</p>

Example

- Start the ObjectConnect over IP server.

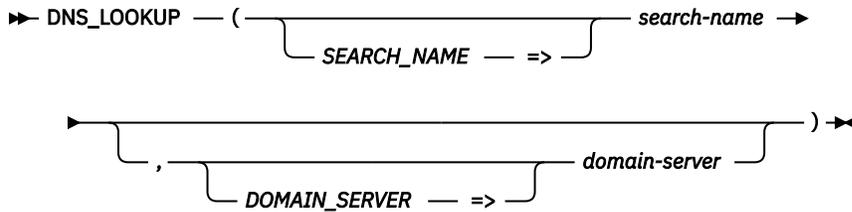

```
CALL QSYS2.CHANGE_OBJECTCONNECT(STATE => 'START');
```

DNS_LOOKUP table function

The DNS_LOOKUP table function queries a domain name server for IP address information about a hostname.

Authorization: If the HOSTALIASES environment variable is set, the caller must have:

- Execute (*X) data authority to each directory in the path of the host aliases file specified by the HOSTALIASES environment variable, and
- Read (*R) data authority to the host aliases file.

The schema is QSYS2.

search-name A character string containing the fully qualified domain name of the host to be resolved.

domain-server A character string containing either a host name or an IP address for the domain name server, or an IP address string for it.

If this parameter is omitted, the IPv4 or IPv6 configured name servers from CHGTCPDMN are used.

The result of the function is a table containing rows with the format shown in the following table. All columns are nullable.

Table 119. DNS_LOOKUP table function

Column Name	Data Type	Description
ADDRESS_SPACE_TYPE	CHAR(4)	The IP address space type for IP_ADDRESS IPV4 The address is specified using the IPv4 address space type. IPV6 The address is specified using the IPv6 address space type.
IP_ADDRESS	VARCHAR(45)	The IP address. When ADDRESS_SPACE_TYPE is IPV4, the address is in IPv4 format. When ADDRESS_SPACE_TYPE is IPV6, the address is in IPv6 format.
AUTHORITATIVE	VARCHAR(3)	Indicates whether the DNS response containing the IP address was an authoritative answer. NO The DNS response was a non-authoritative answer. YES The DNS response was an authoritative answer.
AUTHENTICATED_DATA	VARCHAR(3)	Whether the data was authenticated. NO Data was not DNSSEC authenticated YES Data was DNSSEC authenticated.

Example

- Determine the IP address for the `ibm.com`® hostname.

```
SELECT * FROM TABLE(QSYS2.DNS_LOOKUP('ibm.com'));
```

DNS_LOOKUP_IP scalar function

The DNS_LOOKUP_IP scalar function returns a hostname for a specified IP address.

Authorization: None required.

➤ DNS_LOOKUP_IP (*IP_ADDRESS* => *ip-address*) ➤

The schema is QSYS2.

ip-address A character string containing the IP address to be resolved to a hostname. The IP address can be in either IPv4 or IPv6 format.

The result of the function is a varying length character string that contains the corresponding hostname. If a hostname cannot be determined, the null value is returned.

Example

- Determine the hostname for IP address 129.42.38.10.

```
VALUES QSYS2.DNS_LOOKUP_IP('129.42.38.10');
```

ENV_SYS_INFO view

The ENV_SYS_INFO view contains information about the current server.

Authorization: None required.

The following table describes the columns in the view. The system name is ENVSYSINFO. The schema is SYSIBMADM.

Table 120. ENV_SYS_INFO view

Column Name	System Column Name	Data Type	Description
OS_NAME	OS_NAME	VARCHAR(256) Nullable	Operating system name.
OS_VERSION	OS_VERSION	VARCHAR(256) Nullable	Operating system version.
OS_RELEASE	OS_RELEASE	VARCHAR(256) Nullable	Operating system release.
HOST_NAME	HOST_NAME	VARCHAR(256) Nullable	Name of the system.
TOTAL_CPUS	TOTAL_CPUS	INTEGER Nullable	The maximum number of virtual processors defined within the LPAR configuration.
CONFIGURED_CPUS	CONFIGCPUS	INTEGER Nullable	The number of virtual processors currently available to the partition.
CONFIGURED_MEMORY	CONFIGMEM	BIGINT Nullable	Total amount of configured memory on the system, in megabytes.
TOTAL_MEMORY	TOTAL_MEM	INTEGER Nullable	Total amount of memory on the system, in megabytes.

Example

Return information about the current server.

```
SELECT * FROM SYSIBMADM.ENV_SYS_INFO
```

HTTP_SERVER_INFO view

The HTTP_SERVER_INFO view returns information for HTTP Server for IBM i (powered by Apache). Only information for enabled and active functions is returned.

The values returned for the result columns of the table function are similar to the values shown by Real Time Server Statistics in the IBM Web Administration for i GUI.

Authorization: None required.

The following table describes the columns in the view. The system name is HTTP_SRVR. The schema is QSYS2.

Table 121. HTTP_SERVER_INFO view

Column Name	System Column Name	Data Type	Description
SERVER_NAME	SERVER	VARCHAR(10)	The name of the HTTP server instance.
JOB_NAME	JOB_NAME	VARCHAR(28)	Qualified job name for the server.
SERVER_START_TIME	START_T	TIMESTAMP(0)	Time the server was started.
SERVER_RESTART_TIME	RESTART_T	TIMESTAMP(0) Nullable	Time the server was restarted. Contains the null value if the server has never been restarted.
SERVER_CURRENT_TIME	CURRENT_T	TIMESTAMP(0)	Current time.
SERVER_NORMAL_CONNECTIONS	NORM_CONN	BIGINT	Total number of normal (non-secure) connections to the server.
SERVER_SSL_CONNECTIONS	SSL_CONN	BIGINT	Total number of SSL (secure) connections to the server.
SERVER_ACTIVE_THREADS	ACT_THRD	INTEGER	Number of active threads.
SERVER_IDLE_THREADS	IDLE_THRD	INTEGER	Number of idle threads.
SERVER_TOTAL_REQUESTS	TOT_REQ	BIGINT	Total number of requests to the server since the server was started.
SERVER_TOTAL_REQUESTS_REJECTED	TOT_REQREJ	BIGINT	Total number of rejected requests issued by the server since the server was started.
SERVER_TOTAL_RESPONSES	TOT_RESP	BIGINT	Total number of responses from the server since the server was started.

Table 121. HTTP_SERVER_INFO view (continued)

Column Name	System Column Name	Data Type	Description
HTTP_FUNCTION	HTTP_FUNC	VARCHAR(20)	HTTP server function or associated server for the remaining statistical information columns. A row is only returned for a function if the function is enabled. CGI Common Gateway Interface (CGI) CUSTOMER MODULE A customer or third-party module FRCA PROXY Fast Response Cache Accelerator (FRCA) proxy FRCA STATS Fast Response Cache Accelerator (FRCA) PROXY Proxy SERVER HANDLED Server transactions. This includes static HTML pages, HTML pages containing Server Side Includes (SSI), and images. SSL Secure Sockets Layer (SSL) WEBSPPHERE WebSphere Application Server
REQUESTS	REQUESTS	BIGINT	Number of requests received.
RESPONSES	RESPONSES	BIGINT	Number of responses sent.
ERROR_RESPONSES	ERR_RESP	BIGINT	Number of error responses.
NONCACHE_RESPONSES	NC_RESP	BIGINT	Number of responses that did not come from cache.
BYTES_RECEIVED	BYTES_RCV	BIGINT	Total number of bytes received for all requests.
BYTES_SENT	BYTES_SENT	BIGINT	Total number of bytes sent for all requests.
NONCACHE_PROCESSING_TIME	NC_TIME	DECIMAL(20,3)	Processing time for non-cached requests, in seconds.
CACHE_PROCESSING_TIME	C_TIME	DECIMAL(20,3)	Processing time for cached requests, in seconds.

Example

- Examine information about the server functions associated with the ADMIN server.

```
SELECT * FROM QSYS2.HTTP_SERVER_INFO
WHERE SERVER_NAME = 'ADMIN';
```

NETSTAT_INFO view

The NETSTAT_INFO view returns information about IPv4 and IPv6 network connections.

The values returned for the columns in the view are closely related to the values returned by [List Network Connections API](#) and [Retrieve Network Connection Data API](#). Refer to the APIs for more detailed information.

Authorization: None required.

The following table describes the columns in the view. The system name is NS_INFO. The schema is QSYS2.

Table 122. NETSTAT_INFO view

Column Name	System Column Name	Data Type	Description
CONNECTION_TYPE	CONN_TYPE	CHAR(4)	The type of connection. IPV4 The connection is an IPv4 connection. IPV6 The connection is an IPv6 connection.
REMOTE_ADDRESS	RMT_ADDR	VARCHAR(45)	The internet address of the remote host. For IPv4: <ul style="list-style-type: none"> The address is in IPv4 address format. A value of 0.0.0.0 indicates that either the system is waiting for a connection to open or that a UDP socket is being used. A value of 0 means that the connection is a listening or UDP socket so this field does not apply. For IPv6: <ul style="list-style-type: none"> The address is in IPv6 address format. A value of :: means that the connection is a listening socket so this field does not apply.
REMOTE_PORT	RMT_PORT	INTEGER	The remote host port number. A value of 0 means that the connection is a listening or UDP socket, so this field does not apply.
REMOTE_PORT_NAME	RMT_NAME	VARGRAPHIC(14) CCSID 1200 Nullable	The remote host well-known port name or the name from the service table entry. Contains null if there is no well-known port name.
LOCAL_ADDRESS	LOCAL_ADDR	VARCHAR(45)	The local address of this connection on this system. For IPv4: <ul style="list-style-type: none"> The address is in IPv4 address format. A value of 0.0.0.0 indicates that either the system is waiting for a connection to open or that a UDP socket is being used. For IPv6: <ul style="list-style-type: none"> The address is in IPv6 address format. A value of :: means the local application specified that any local internet address can be used.
LOCAL_PORT	LOCAL_PORT	INTEGER	The local system port number.
LOCAL_PORT_NAME	LOCAL_NAME	VARGRAPHIC(14) CCSID 1200 Nullable	The local system well-known port name or the name from the service table entry. Contains null if there is no well-known port name.
PROTOCOL	PROTOCOL	VARCHAR(3)	Identifies the type of connection protocol. TCP A Transmission Control Protocol (TCP) connection or socket. UDP A User Datagram Protocol (UDP) socket.

Table 122. NETSTAT_INFO view (continued)

Column Name	System Column Name	Data Type	Description
TCP_STATE	STATE	VARCHAR(12) Nullable	<p>The state of the connection.</p> <p>CLOSED This connection has ended.</p> <p>CLOSE-WAIT Waiting for an end connection request from the local user.</p> <p>CLOSING Waiting for an end connection request acknowledgment from the remote host.</p> <p>ESTABLISHED The normal state in which data is transferred.</p> <p>FIN-WAIT-1 Waiting for the remote host to acknowledge the local system request to end the connection.</p> <p>FIN-WAIT-2 Waiting for the remote host request to end the connection.</p> <p>LAST-ACK Waiting for the remote host to acknowledge an end connection request.</p> <p>LISTEN Waiting for a connection request from any remote host.</p> <p>SYN-RECEIVED Waiting for a confirming connection request acknowledgment.</p> <p>SYN-SENT Waiting for a matching connection request after having sent a connection request.</p> <p>TIME-WAIT Waiting to allow the remote host enough time to receive the local system's acknowledgment to end the connection.</p> <p>Contains null if PROTOCOL is UDP.</p>
IDLE_TIME	IDLE_TIME	DECIMAL(19,3)	The length of time, in seconds, since the last activity on this connection.
BIND_USER	BIND_USER	VARCHAR(10)	The user profile of the job on the local system which first performed a sockets API bind() of the socket.
BYTES_SENT_REMOTELY	BYTES_OUT	BIGINT	The number of bytes sent to the remote host.
BYTES_RECEIVED_LOCALLY	BYTES_IN	BIGINT	The number of bytes received from the remote host.
NETWORK_CONNECTION_TYPE	NET_TYPE	VARCHAR(4)	<p>The type of connection or socket.</p> <p>*TCP Identifies a transmission control protocol (TCP) connection socket.</p> <p>*UDP Identifies a User Datagram Protocol (UDP) socket.</p> <p>For IPv4, the following additional value can be returned.</p> <p>*IPS Identifies an Internet Protocol (IP) over SNA connection or socket.</p>
CONNECTION_OPEN_TYPE	OPN_TYPE	VARCHAR(7) Nullable	<p>The type of open for the connection.</p> <p>ACTIVE The local system opens the connection.</p> <p>PASSIVE A remote host opens the connection.</p> <p>Contains null if PROTOCOL is UDP.</p>
NUMBER_OF_ASSOCIATED_JOBS	NUM_JOBS	INTEGER	The number of jobs associated with this connection.
LINE_DESCRIPTION	LINE_DES	VARCHAR(10) Nullable	<p>The local system line description associated with this connection.</p> <p>Contains null if this is an IPv4 connection or if the connection is not bound to a link local unicast interface.</p>
VIRTUAL_LAN_ID	LAN_ID	VARCHAR(4) Nullable	<p>The virtual LAN identifier associated with this connection. Can also contain the following special value:</p> <p>NONE No virtual LAN identifier is associated with this connection.</p> <p>Contains null if this is an IPv4 connection or if the connection is not bound to a link local unicast interface.</p>

Table 122. NETSTAT_INFO view (continued)

Column Name	System Column Name	Data Type	Description
CONNECTION_TRANSPORT_LAYER	CNNTRANSP	VARCHAR(5)	The transport that a connection is using. Values are: <ul style="list-style-type: none"> • IPS • TCPIP
IP_OPTIONS	IP_OPTIONS	BINARY(40) Nullable	The hex value of IP datagram options that may have been specified for a connection. Contains null if this is an IPv6 connection or if no IP datagram options have been specified.
ROUND_TRIP_TIME	ROUND_TRIP	BIGINT Nullable	The smoothed round-trip time interval in milliseconds. This is a measure of the time required for a segment on the connection to arrive at its destination, to be processed, and to return an acknowledgment to the client. Contains null if PROTOCOL is UDP.
ROUND_TRIP_VARIANCE	ROUND_VAR	BIGINT Nullable	The variance in milliseconds from the previous round-trip time. Contains null if PROTOCOL is UDP.
CURRENT_RETRANSMISSIONS	CT_RETRANS	BIGINT Nullable	The number of times the local system retransmitted the current segment without receiving an acknowledgment. Contains null if PROTOCOL is UDP.
TOTAL_RETRANSMISSIONS	TL_RETRANS	BIGINT Nullable	The total number of times the local system retransmitted a segment because an acknowledgement was not received. This is a cumulative count of all segments resent during the entire time the connection has been active. Contains null if PROTOCOL is UDP.
TCP_CONNECTIONS_CURRENTLY_ESTABLISHED	TCPCONN	BIGINT Nullable	The number of TCP connections for which the current state is either ESTABLISHED or CLOSE-WAIT. Contains null if PROTOCOL is UDP.
TCP_ACTIVE_OPENS	TCPACTOPN	BIGINT Nullable	The number of times TCP connections have made a direct transition to the SYN-SENT state from the CLOSED state. This number is an indication of the number of times this local system opened a connection to a remote system. Contains null if PROTOCOL is UDP.
TCP_PASSIVE_OPENS	TCPPSVOPN	BIGINT Nullable	The number of times TCP connections have made a direct transition to the SYN-RECEIVED state from the LISTEN state. This number is an indication of the number of times a remote system opened a connection to this system. Contains null if PROTOCOL is UDP.
TCP_FAILED_OPENS	TCPFAILOPN	BIGINT Nullable	The total number of times TCP connections have made direct transitions to a CLOSED state from either the SYN-SENT state or the SYN-RECEIVED state and/or to LISTEN from SYN-RECEIVED. Contains null if PROTOCOL is UDP.
TCP_ESTABLISHED_AND_THEN_RESET	TCPESTRST	BIGINT Nullable	The number of times TCP connections have made a direct transition to the CLOSED state from either the ESTABLISHED state or the CLOSE-WAIT state. Contains null if PROTOCOL is UDP.
TCP_SEGMENTS_SENT	TCPSEGSNT	BIGINT Nullable	The total number of segments sent, including those on current connections but excluding those containing only retransmitted octets. Contains null if PROTOCOL is UDP.
TCP_SEGMENTS_RETRANSMITTED	TCPSEGRTRN	BIGINT Nullable	The number of TCP segments transmitted containing one or more previously transmitted octets. Contains null if PROTOCOL is UDP.
TCP_SEGMENTS_RESET	TCPSEGRST	BIGINT Nullable	The number of TCP segments sent containing the RST flag. Contains null if PROTOCOL is UDP.

Table 122. NETSTAT_INFO view (continued)

Column Name	System Column Name	Data Type	Description
TCP_SEGMENTS_RECEIVED	TCPSEGRCV	BIGINT Nullable	The total number of segments received, including those received in error. This count includes segments received on currently established connections. Contains null if PROTOCOL is UDP.
TCP_SEGMENTS_RECEIVED_ERROR	TCPSEGRCVE	BIGINT Nullable	The total number of segments received in error (for example, bad TCP checksums). Contains null if PROTOCOL is UDP.
OUTGOING_BYTES_BUFFERED	BYTES_OUTB	BIGINT Nullable	The current number of bytes that an application has requested to send, but TCP has not yet sent. If TCP has sent the bytes to the remote system but has not yet received an acknowledgment, the bytes are considered 'not sent'. They are included in this count. Contains null if PROTOCOL is UDP.
USER_SEND_NEXT	USRSNDNXT	BIGINT Nullable	The sequence number of the next byte of data to be sent by the client application. Contains null if PROTOCOL is UDP.
SEND_NEXT	SEND_NEXT	BIGINT Nullable	The sequence number of the next byte of data that the local TCP application sends to the remote TCP application. Contains null if PROTOCOL is UDP.
SEND_UNACKNOWLEDGED	SNDUNACK	BIGINT Nullable	The sequence number of the last segment sent that was not acknowledged. This is the smallest sequence number of the send window. Contains null if PROTOCOL is UDP.
OUTGOING_PUSH_NUMBER	OUTPSHNBR	BIGINT Nullable	The sequence number of the last byte of push data in the outgoing stream. This value is zero if no push data is in the outgoing data stream. Contains null if PROTOCOL is UDP.
OUTGOING_URGENCY_NUMBER	OUTURGNBR	BIGINT Nullable	The sequence number of the last byte of urgent data in the outgoing data stream. This value is zero if no urgent data is in the outgoing data stream. Contains null if PROTOCOL is UDP.
OUTGOING_WINDOW_NUMBER	OUTWINNBR	BIGINT Nullable	The largest sequence number in the send window of the connection. The local TCP application cannot send data bytes with sequence numbers greater than the outgoing window number. Contains null if PROTOCOL is UDP.
INCOMING_BYTES_BUFFERED	BYTES_INB	BIGINT Nullable	The current number of bytes that are received and buffered by TCP. These bytes are available to be read by an application. Contains null if PROTOCOL is UDP.
RECEIVE_NEXT	RCVNEXT	BIGINT Nullable	The next sequence number the local TCP is expecting to receive. Contains null if PROTOCOL is UDP.
USER_RECEIVE_NEXT	USRRCVNXT	BIGINT Nullable	The sequence number of the next byte to be passed to the application by TCP. Contains null if PROTOCOL is UDP.
INCOMING_PUSH_NUMBER	INPSHNBR	BIGINT Nullable	The sequence number of the last byte of pushed data in the incoming data stream. This value is zero if no push data is in the incoming data stream. Contains null if PROTOCOL is UDP.
INCOMING_URGENCY_NUMBER	INURGNBR	BIGINT Nullable	The sequence number of the last byte of urgent data in the incoming data stream. This value is zero if no urgent data is in the incoming data stream. Contains null if PROTOCOL is UDP.
INCOMING_WINDOW_NUMBER	INWINNBR	BIGINT Nullable	The largest sequence number in the incoming window of this connection. Data bytes in the incoming stream having sequence numbers larger than this number are not accepted. Contains null if PROTOCOL is UDP.

Table 122. NETSTAT_INFO view (continued)

Column Name	System Column Name	Data Type	Description
MAXIMUM_WINDOW_SIZE	MAXWINSIZ	BIGINT Nullable	The largest size of the send window, in bytes, during the entire time the connection has been active. Contains null if PROTOCOL is UDP.
CURRENT_WINDOW_SIZE	CURWINSIZ	BIGINT Nullable	The current send window size in bytes. Contains null if PROTOCOL is UDP.
LAST_UPDATE	LSTUPD	BIGINT Nullable	The sequence number of the incoming segment used for the last window update that occurred on the connection. Contains null if PROTOCOL is UDP.
LAST_UPDATE_ACKNOWLEDGED	LSTUPDACK	BIGINT Nullable	The acknowledgment number of the incoming segment used for the last window update that occurred on the connection. Contains null if PROTOCOL is UDP.
CONGESTION_WINDOW	CONGESTWIN	BIGINT Nullable	The number of segments that are sent on the next transmission. If an acknowledgment is not received, the number is reset to the smallest allowable number. Contains null if PROTOCOL is UDP.
SLOW_START_THRESHOLD	SLWSTRTHR	BIGINT Nullable	The value of the slow-start threshold. Contains null if PROTOCOL is UDP.
MAXIMUM_SEGMENT_SIZE	MAXSEGSIZ	BIGINT Nullable	The size in bytes of the largest segment that may be transmitted on this connection. Contains null if PROTOCOL is UDP.
INITIAL_SEND_SEQUENCE_NUMBER	SNDSEQNBR	BIGINT Nullable	The first sequence number sent on this connection. Contains null if PROTOCOL is UDP.
INITIAL_RECEIVE_SEQUENCE_NUMBER	RCVSEQNBR	BIGINT Nullable	The first sequence number received on this connection. Contains null if PROTOCOL is UDP.
UDP_DATAGRAMS_SENT	UDPSENT	BIGINT Nullable	The total number of UDP datagrams sent from all connections since TCP/IP was started. Contains null if PROTOCOL is TCP.
UDP_DATAGRAMS_RECEIVED	UDPRCV	BIGINT Nullable	The total number of UDP datagrams received, including those received in error. This count includes datagrams received on currently established connections. Contains null if PROTOCOL is TCP.
UDP_DATAGRAMS_NOT_DELIVERED_PORT_NOT_FOUND	UDPNDPNF	BIGINT Nullable	The total number of received UDP datagrams for UDP users for which there was no application at the destination port. Contains null if PROTOCOL is TCP.
UDP_DATAGRAMS_NOT_DELIVERED_OTHER	UDPNDOTHER	BIGINT Nullable	The number of received UDP datagrams that could not be delivered for reasons other than the lack of an application at the destination port. Contains null if PROTOCOL is TCP.
SOCKET_STATE	SOCSTATE	VARCHAR(13)	The current state of the socket. Values are: <ul style="list-style-type: none"> • BOUND • CONNECTED • CONNECTING • DISCONNECTED • ERROR • LISTENING • UNBOUND • UNINITIALIZED

Table 122. NETSTAT_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SOCKET_BROADCAST	SOCBROAD	VARCHAR(3) Nullable	Indicates if messages can be sent to the broadcast address. NO Messages cannot be sent to the broadcast address. YES Messages can be sent to the broadcast address. Contains null if value is not specified or if socket is not an address family of AF_INET and type SOCK_DGRAM or SOCK_RAW.
SOCKET_BYPASS_ROUTE	SOCBYPASS	VARCHAR(3) Nullable	Indicates if the normal routing mechanism is being bypassed. NO The normal routing mechanism is being used. YES The normal routing mechanism is being bypassed. Contains null if value is not specified or if socket is not an address family of AF_INET or AF_INET6.
SOCKET_DEBUG	SOCDEBUG	VARCHAR(3) Nullable	Indicates if low-level debugging is active. NO Low-level debugging is not active. YES Low-level debugging is active. Contains null if value is not specified.
SOCKET_ERROR	SOCERROR	INTEGER Nullable	Indicates if there any pending errors in the socket. A value of zero indicates no pending errors. Otherwise, the value indicates the error number. Contains null if value is not specified.
SOCKET_KEEP_ALIVE	SOCALIVE	VARCHAR(3) Nullable	Indicates if the connection is being kept up by periodic transmissions. NO The connection is not being kept up by periodic transmissions. YES The connection is being kept up by periodic transmissions. Contains null if value is not specified or if socket is not an address family of AF_INET or AF_INET6 and type SOCK_STREAM.
SOCKET_LINGER	SOCLINGER	VARCHAR(3) Nullable	Indicates whether the system attempts to deliver any buffered data or if the system discards it when a close() is issued. NO The system attempts to send buffered data with an infinite wait time. YES The system attempts to send buffered data for SOCKET_LINGER_TIME seconds. If the data is not deliverable within that period of time, it is discarded. Contains null if value is not specified.
SOCKET_LINGER_TIME	SOCLTIME	BIGINT Nullable	The time, in seconds, the system will wait to send buffered data. Contains null if value is not specified or if SOCKET_LINGER is NO.
SOCKET_OUT_OF_BAND_DATA	SOCOUTBAND	VARCHAR(3) Nullable	Indicates if out-of-band data is received inline with normal data. NO Out-of-band data is not received inline with normal data. YES Out-of-band data is received inline with normal data. Contains null if value is not specified or if socket is not an address family of AF_INET or AF_INET6.
SOCKET_RECEIVE_BUFFER_SIZE	SOCRCVBUF	BIGINT Nullable	The size of the receive buffer. Contains null if value is not specified.
SOCKET_RECEIVE_LOW_WATER_MARK_SIZE	SOCRCVSZ	BIGINT Nullable	The size of the receive low-water mark. The default size is 1. Contains null if value is not specified or if socket is not type SOCK_STREAM.

Table 122. NETSTAT_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SOCKET_REUSE_ADDRESS	SOCKREUSE	VARCHAR(3)	Indicates if the local socket address can be reused.
		Nullable	<p>NO The local socket address cannot be reused.</p> <p>YES The local socket address can be reused.</p> <p>Contains null if value is not specified or if socket is not an address family of AF_INET or AF_INET6 and type SOCK_STREAM or SOCK_DGRAM.</p>
SOCKET_SEND_BUFFER_SIZE	SOCKSENDUF	BIGINT	The size of the send buffer.
		Nullable	Contains null if value is not specified.
SOCKET_TYPE	SOCTYPE	VARCHAR(14)	The socket type. Values are:
		Nullable	<p>SOCK_DGRAM Datagram type.</p> <p>SOCK_RAW Raw type.</p> <p>SOCK_SEQPACKET Sequential packet type.</p> <p>SOCK_STREAM Stream type.</p> <p>Contains null if value is not specified.</p>
SOCKET_LOOPBACK	SOCKLOOPBK	VARCHAR(3)	Indicates if the loopback feature is being used.
		Nullable	<p>NO The loopback feature is not being used.</p> <p>YES The loopback feature is being used.</p> <p>Contains null if value is not specified.</p>
SOCKET_RECEIVE_TIMEOUT	SOCKRCVTO	BIGINT	The receive timeout value.
		Nullable	Contains null if value is not specified.
SOCKET_SEND_LOW_WATER_MARK_SIZE	SOCKSENDSZ	BIGINT	The size of the send low-water mark.
		Nullable	Contains null if value is not specified.
SOCKET_SEND_TIMEOUT	SOCKSENDTO	BIGINT	The send timeout value.
		Nullable	Contains null if value is not specified.

Example

Return information about all network connections for user QLWISVR.

```
SELECT * FROM QSYS2.NETSTAT_INFO
WHERE BIND_USER = 'QLWISVR'
```

Related information

[Internet Protocol version 6](#)

NETSTAT_INTERFACE_INFO view

The NETSTAT_INTERFACE_INFO view returns information about IPv4 and IPv6 interfaces.

The values returned for the columns in the view are closely related to the values returned by [List Network Interfaces API](#). Refer to the API for more detailed information.

Authorization: None required.

The following table describes the columns in the view. The system name is NS_INTER. The schema is QSYS2.

Table 123. NETSTAT_INTERFACE_INFO view

Column Name	System Column Name	Data Type	Description
CONNECTION_TYPE	CONN_TYPE	CHAR(4)	<p>The type of connection.</p> <p>IPV4 The connection is an IPv4 connection.</p> <p>IPV6 The connection is an IPv6 connection.</p>
INTERNET_ADDRESS	INT_ADDR	VARCHAR(45)	<p>The internet address of the interface.</p> <p>For IPv4:</p> <ul style="list-style-type: none"> The address is in IPv4 address format. <p>Can contain the special value:</p> <p>*IP4DHCP The interface has been configured to use DHCP to obtain an IPv4 address.</p> <p>For IPv6:</p> <ul style="list-style-type: none"> The address is in IPv6 address format. <p>Can contain the special value:</p> <p>*IP6SAC This interface will use Stateless Address Auto-configuration to obtain an IPv6 address.</p>
NETWORK_ADDRESS	NET_ADDR	VARCHAR(45)	<p>The internet address of the IP network or subnetwork to which the interface is attached.</p> <p>For IPv4:</p> <ul style="list-style-type: none"> The address is in IPv4 address format. <p>For IPv6:</p> <ul style="list-style-type: none"> The address is in IPv6 address format.
SUBNET_MASK	SUBNET_MSK	VARCHAR(15) Nullable	<p>The subnet mask for the network, subnet, and host address fields of the internet address that defines the subnetwork for an interface.</p> <p>Contains null if this is an IPv6 connection.</p>
PREFIX_LENGTH	PRE_LEN	INTEGER Nullable	<p>The prefix length defines how many bits of the IPv6 internet address are in the prefix. It specifies how many of the left-most bits of the address make up the prefix. The prefix length is used to generate network and host addresses.</p> <p>Contains null if this is an IPv4 connection.</p>
LINE_DESCRIPTION	LINE_DES	VARCHAR(10)	<p>The name of the communications line description that identifies the physical network associated with an interface. Can contain the following special values:</p> <p>*LOOPBACK This is the loopback interface. Processing associated with a loopback interface does not extend to a physical line.</p> <p>*VIRTUALIP The virtual interface is a circuitless interface.</p> <p>For IPv4, the following additional values can be returned.</p> <p>*IPS The interface is used by Internet Protocol (IP) over SNA.</p> <p>*OPC The interface is attached to the optical bus (OptiConnect).</p>

Table 123. NETSTAT_INTERFACE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
INTERFACE_LINE_TYPE	LINE_TYPE	VARCHAR(6)	<p>The type of line used by the interface. Only supported line types are listed here; obsolete values could be returned for inactive configurations.</p> <p>ASYNC Asynchronous communications protocol.</p> <p>ELAN Ethernet local area network protocol.</p> <p>L2TP Layer Two Tunneling protocol.</p> <p>PPP Point-to-Point protocol.</p> <p>PPPOE Point-to-Point over Ethernet protocol.</p> <p>VETH Virtual Ethernet protocol.</p> <p>Can also contain one of the following special values:</p> <p>ERROR A system error other than those for NOTFND was received while trying to determine the link type for an interface.</p> <p>NONE Line is not defined. This value is used for the following interfaces: *LOOPBACK, *VIRTUALIP, *OPC. There is no line type value for this interface.</p> <p>NOTFND Not found. The line description object for this interface cannot be found.</p>
INTERFACE_STATUS	STATUS	VARCHAR(12)	<p>The current status of the logical interface.</p> <p>ACTIVE The interface has been started and is running.</p> <p>DOD This interface is being used for Point-to-Point (PPP) Dial-on-Demand.</p> <p>ENDING The operating system is processing the request to end this interface.</p> <p>FAILED The line description associated with this interface has entered the failed state.</p> <p>FAILED (TCP) An error was detected in the IBM TCP/IP Licensed Internal Code.</p> <p>INACTIVE The interface has not been started.</p> <p>RCYCNL A hardware failure has occurred and the line description associated with this interface is in the recovery canceled (RCYCNL) state.</p> <p>RCYPND An error with the physical line associated with this interface was detected by the system. The line description associated with this interface is in the recovery pending (RCYPND) state.</p> <p>STARTING The operating system is processing the request to start this interface.</p> <p>For IPv4, the following additional value can be returned.</p> <p>ACQUIRING The operating system is attempting to obtain an IP address from a Dynamic Host Configuration Protocol (DHCP) server.</p> <p>For IPv6, the following additional value can be returned.</p> <p>DEPRECATED The interface address preferred lifetime has expired but the valid lifetime has not yet expired.</p>

Table 123. NETSTAT_INTERFACE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
INTERFACE_SOURCE	SOURCE	VARCHAR(9) Nullable	Specifies how this interface was added to the protocol stack. LOOPBACK The interface was added by the protocol stack as the loopback address. STATELESS The interface was added by IPv6 address autoconfiguration. STATEFUL The interface was added by Dynamic Host Configuration Protocol version 6 (DHCPv6) configuration. MANUAL The interface was added by manual configuration. Contains null if this is an IPv4 connection.
SERVICE_TYPE	SRVC_TYPE	VARCHAR(9) Nullable	The type of service that defines how the internet hosts and routers should make trade-offs between throughput, delay, reliability, and cost. MAXRLB A higher level of effort to ensure delivery is important for datagrams with the maximize reliability indication. MAXTHRPUT High data rate is important for datagrams with the maximize throughput indication. MINCOST Lower cost is important for datagrams with the minimize monetary cost indication. MINDELAY Prompt delivery is important for datagrams with the minimize delay indication. NORMAL Normal service is used for delivery of datagrams. OTHER An Internet Protocol (IP) over SNA interface. Contains null if this is an IPv6 connection.
VIRTUAL_LAN_ID	LAN_ID	VARCHAR(4)	The virtual LAN to which this interface belongs according to IEEE standard 802.1Q. Can also contain the following special value: NONE The interface does not belong to a virtual LAN.
MAXIMUM_TRANSMISSION_UNIT	MTU	VARCHAR(10)	The maximum transmission unit (MTU) value specified for this interface. Either an integer value or this special value: LIND The interface is not currently active and the MTU was specified as *LIND. For IPv4, the following additional value can be returned. OTHER An Internet Protocol (IP) over SNA interface.
CONFIGURED_MAXIMUM_TRANSMISSION_UNIT	CFG_MTU	VARCHAR(10)	The configured maximum transmission unit value specified for this interface. Either an integer value or this special value: LIND The interface is not currently active and the MTU was specified as *LIND.
AUTOSTART	AUTOSTART	VARCHAR(3)	Specifies whether the interface is automatically started when the protocol stack is activated. NO This interface is not automatically started. YES This interface is automatically started.
DAD_MAX_TRANSMITS	DAD_MAX	BIGINT Nullable	The maximum number of duplicate address detection (DAD) transmissions the protocol stack will send out on this interface. Contains null if this is an IPv4 connection.

Table 123. NETSTAT_INTERFACE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
HOST_ADDRESS	HOST_ADDR	VARCHAR(45)	Host portion of the internet address. For IPv4: <ul style="list-style-type: none"> Host portion of the Internet address, in dotted decimal notation, as determined by the subnet mask specified for this interface. For IPv6: <ul style="list-style-type: none"> Host portion of the Internet address, in IPv6 address format, as determined by the prefix length configured for this interface.
DIRECTED_BROADCAST_ADDRESS	DIRBRDADR	VARCHAR(15) Nullable	The Internet address, in dotted decimal notation, used to broadcast to all systems attached to the same network or subnetwork as this interface. Contains null if this is an IPv6 connection or if interface is attached to a network that does not support a broadcast operation.
ASSOCIATED_LOCAL_INTERFACE	ASCLCLINT	VARCHAR(15) Nullable	The Internet address, in dotted decimal notation, of the local interface that has been associated with this interface. Contains null if this is an IPv6 connection or if no association has been made between this interface and another local interface.
CHANGE_STATUS	CHGSTS	VARCHAR(6) Nullable	The status of the most recent change to this interface in the dynamic tables used by the TCP/IP protocol stack. ADD Add interface request processed. CHANGE Change interface request processed. END End interface request processed. START Start interface request processed. Contains null if this is an IPv6 connection.
PACKET_RULES	PKT_RULES	VARCHAR(17) Nullable	The kind of packet rules data available for this line. NONE No filters and no NAT are loaded for this line. NAT NAT is enabled for this line. FILTERS Filters are defined for this line. NAT_FILTERS NAT enabled and filters defined for this line. FILTERS_IPSEC Filters and IPSec filters are defined for this line. NAT_FILTERS_IPSEC NAT enabled and Filters and IPsec filters defined for this line. Contains null if packet rules data is unknown.
INTERFACE_TYPE	TYPE	VARCHAR(12) Nullable	The interface type: BROADCAST Broadcast capable. NONBROADCAST Non-broadcast capable. UNNUMBERED Unnumbered network. Contains null if this is an IPv6 connection.
NETWORK_FULL_NAME	NET_FNAME	VARCHAR(24) Nullable	The complete name of the network that this interface is a part of. Contains null if this is an IPv6 connection or if there is no network name.
INTERFACE_FULL_NAME	FNAME	VARCHAR(24) Nullable	The complete interface name. Contains null if this is an IPv6 connection or if there is no interface name.
ALIAS_NAME	ALIAS_NAME	VARGRAPHIC(50) CCSID 1200 Nullable	Name given to the interface to use as an alternate to the IP address. Contains null if there is no alias name.

Table 123. NETSTAT_INTERFACE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
INTERFACE_TEXT	LABEL	VARGRAPHIC(50) CCSID 1200 Nullable	Description of the interface. Contains null if there is no interface description.
DHCP_CREATED	DHPCPCRT	VARCHAR(3) Nullable	Specifies whether this interface was created using Dynamic Host Configuration Protocol (DHCP). NO This interface was not created using DHCP. YES This interface was created using DHCP. Contains null if this is an IPv6 connection.
DHCP_DYNAMIC_DNS_UPDATES	DHCPDYNDNS	VARCHAR(3) Nullable	Specifies whether dynamic updates to Domain Name System (DNS) tables are enabled or not. NO DNS updates are disabled. YES DNS updates are enabled. Contains null if this is an IPv6 connection or if interface was not created by DHCP.
DHCP_LEASE_EXPIRATION	DHCPLEXP	TIMESTAMP(0) Nullable	The timestamp when the DHCP lease will expire. Contains null if this is an IPv6 connection or if interface was not created by DHCP.
DHCP_LEASE_OBTAINED	DHCPLOBT	TIMESTAMP(0) Nullable	The timestamp when the DHCP lease was obtained or renewed. Contains null if interface was not created by DHCP.
DHCP_USE_UNIQUE_ID	DHCPUSEUID	VARCHAR(3) Nullable	Whether the DHCP unique identifier (DUID) is used as the client identification for the Dynamic Host Configuration Protocol (DHCP). NO The hardware (MAC) address is used for the client ID. YES The DHCP unique identifier is used for the client ID or this is an IPv6 connection. Contains null if interface was not created by DHCP.
DHCP_SERVER_UNIQUE_ID	DHCPSRVUID	VARCHAR(30) Nullable	Specifies the DHCP unique identifier (DUID) of the DHCP server from which the IP address was obtained. Contains null if this is an IPv4 connection or if interface was not created by DHCP.
DHCP_SERVER_ADDRESS	DHCPSRVADD	VARCHAR(15) Nullable	The Internet address, in dotted decimal notation, of the DHCP server from which the DHCP lease was obtained or renewed. Contains null if this is an IPv6 connection or if interface was not created by DHCP.
PREFERRED_INTERFACE_DEFAULT_ROUTE	PREFDFTRTE	VARCHAR(3) Nullable	This field describes whether the preferred proxy interfaces are based on the system's default route. NO The default route is not used to determine the preferred interface. YES The default route is used to determine the preferred interface. Contains null if this is an IPv6 connection.
PREFERRED_INTERFACE_LIST	PREFIFCLST	VARCHAR(159) Nullable	A list of up to 10 preferred interface internet addresses. Each internet address within the preferred interface list is given in dotted decimal notation. When there is more than one internet address, a single blank separates the addresses. Contains null if this is an IPv6 connection or if a preferred interface list is not being used.
PREFERRED_PHYSICAL_LINE_LIST	PREFLINLST	VARCHAR(159) Nullable	A list of up to 10 preferred physical line list entries. Each entry in the list is formatted as LINE_DESCRIPTION:VIRTUAL_LAN_ID. The line description can be up to 10 characters long. The virtual LAN ID can be up to 4 characters long. When there is more than one preferred physical line, a single blank separates entries. Contains null if this is an IPv4 connection.

Table 123. NETSTAT_INTERFACE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
ADDRESS_TYPE	ADDR_TYPE	VARCHAR(9) Nullable	The type of IPv6 address that is assigned to this network interface. ANYCAST An identifier for a set of interfaces (typically belonging to different nodes). A packet sent to an anycast address is delivered to one of the interfaces identified by that address (the "nearest" one, according to the routing protocols' measure of distance). MULTICAST An identifier for a set of interfaces (typically belonging to different nodes). A packet sent to a multicast address is delivered to all interfaces identified by that address. UNICAST An identifier for a single interface. A packet sent to a unicast address is delivered to the interface identified by that address. Contains null if this is an IPv4 connection.
ADDRESS_CLASS	ADDR_CLASS	VARCHAR(9) Nullable	The class of IPv6 address that is assigned to this network interface. PUBLIC The interface is a public one. TEMPORARY The interface is a temporary one used for privacy extensions. Contains null if this is an IPv4 connection.
ADDRESS_PREFERRED_LIFETIME	ADDPLIFE	BIGINT Nullable	The length of time that a "valid" address is preferred, in seconds. A negative value indicates that the address preferred lifetime expired that number of seconds ago. Contains null if this is an IPv4 connection or if this address has an infinite preferred lifetime.
ADDRESS_VALID_LIFETIME	ADDVLIFE	BIGINT Nullable	The length of time, in seconds, that an address remains in a "valid" state. A negative value indicates that the address valid lifetime expired that number of seconds ago. Contains null if this is an IPv4 connection or if this address has an infinite valid lifetime.
ADDRESS_PREFERRED_LIFETIME_EXPIRATION	ADDPFRLE	TIMESTAMP(0) Nullable	The timestamp when this address will no longer be in the preferred state. If the timestamp is in the future, the address is still preferred. If the timestamp is in the past, then this address is no longer preferred. Contains null if this is an IPv4 connection or if this address has an infinite preferred lifetime which never expires.
ADDRESS_VALID_LIFETIME_EXPIRATION	ADDVLDLE	TIMESTAMP(0) Nullable	The timestamp when this address will expire or did expire. If the timestamp is in the future, the address has not expired yet. If the timestamp is in the past, then this address has expired and is still being returned for a short period of time to indicate that the interface ceased to function because its valid lifetime expired. Contains null if this is an IPv4 connection or if this address has an infinite valid lifetime which never expires.
ON_LINK	ON_LINK	VARCHAR(3) Nullable	Whether or not this interface and all IPv6 addresses with the same prefix are on the same link. NO Addresses with the same prefix are not assumed to be on the same link. YES Addresses with the same prefix are assumed to be on the same link and directly reachable. Contains null if this is an IPv4 connection or if INTERNET_ADDRESS is *IP6SAC
PROXY_ARP_ENABLED	PRXARPENB	VARCHAR(3) Nullable	Indicates whether Proxy ARP is currently active for this interface. NO Proxy ARP not enabled. YES Proxy ARP enabled. Contains null if this is an IPv6 connection.

Table 123. NETSTAT_INTERFACE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
PROXY_ARP_ALLOWED	PRXARPALW	VARCHAR(3) Nullable	Indicates whether Proxy ARP has been configured to be allowed or not allowed. NO Proxy ARP not allowed. YES Proxy ARP allowed. Contains null if this is an IPv6 connection or if interface is not Opticonnect (*OPC) or Virtual Ethernet.
CURRENT_PROXY_AGENT_LINE	PRXAGT	VARCHAR(10) Nullable	Name of the communication line description that is used with the IPv6 interface for virtual IP address (VIPA) proxy Neighbor Discovery. Contains null if this is an IPv4 connection or if no association has been made between this interface and another physical interface.
CURRENT_PROXY_AGENT_LINE_VIRTUAL_LAN_ID	PRXAGTLAN	VARCHAR(4) Nullable	The virtual LAN to which the proxy agent line belongs according to IEEE standard 802.1Q. Can also contain the following special value: NONE There is no virtual LAN identifier associated with the current proxy agent line. Contains null if this is an IPv4 connection or if no association has been made between this interface and another physical interface.
LAST_CHANGE_TIMESTAMP	LASTCHG	TIMESTAMP(0) Nullable	The timestamp of the most recent change to this interface in the dynamic tables used by the protocol stack. Contains null if the interface has never been changed.

Example

Return information about all interfaces which are using Virtual Ethernet protocol..

```
SELECT * FROM QSYS2.NETSTAT_INTERFACE_INFO
WHERE INTERFACE_LINE_TYPE = 'VETH'
```

NETSTAT_JOB_INFO view

The NETSTAT_JOB_INFO view returns information about jobs using IPv4 and IPv6 network connections.

The values returned for the columns in the view are closely related to the values returned by the Retrieve Network Connection Data (QtocRtvNetCnnDta) API.

Authorization: None required.

The following table describes the columns in the view. The system name is NS_JOB. The schema is QSYS2.

Table 124. NETSTAT_JOB_INFO view

Column Name	System Column Name	Data Type	Description
CONNECTION_TYPE	CONN_TYPE	CHAR(4)	The type of connection. IPV4 The connection is an IPv4 connection. IPV6 The connection is an IPv6 connection.

Table 124. NETSTAT_JOB_INFO view (continued)

Column Name	System Column Name	Data Type	Description
REMOTE_ADDRESS	RMT_ADDR	VARCHAR(45)	The internet address of the remote host. For IPv4: <ul style="list-style-type: none"> The address is in IPv4 address format. A value of 0.0.0.0 indicates that either the system is waiting for a connection to open or that a UDP socket is being used. A value of 0 means that the connection is a listening or UDP socket so this field does not apply. For IPv6: <ul style="list-style-type: none"> The address is in IPv6 address format. A value of :: means that the connection is a listening socket so this field does not apply.
REMOTE_PORT	RMT_PORT	INTEGER	The remote host port number. A value of 0 means that the connection is a listening or UDP socket, so this field does not apply.
REMOTE_PORT_NAME	RMT_NAME	VARGRAPHIC(14) CCSID 1200 Nullable	The remote host well-known port name or the name from the service table entry. Contains null if there is no well-known port name.
LOCAL_ADDRESS	LOCAL_ADDR	VARCHAR(45)	The local address of this connection on this system. For IPv4: <ul style="list-style-type: none"> The address is in IPv4 address format. A value of 0.0.0.0 indicates that either the system is waiting for a connection to open or that a UDP socket is being used. For IPv6: <ul style="list-style-type: none"> The address is in IPv6 address format. A value of :: means the local application specified that any local internet address can be used.
LOCAL_PORT	LOCAL_PORT	INTEGER	The local system port number.
LOCAL_PORT_NAME	LOCAL_NAME	VARGRAPHIC(14) CCSID 1200 Nullable	The local system well-known port name or the name from the service table entry. Contains null if there is no well-known port name.
AUTHORIZATION_NAME	USER_NAME	VARCHAR(10) Nullable	The effective user profile of the thread for which information is being retrieved. This name may differ from the user portion of the job name. Contains null when SLIC_TASK_NAME is not null or if JOB_NAME is the special value *SIGNON.
JOB_NAME	JOB_NAME	VARCHAR(28) Nullable	The qualified job name. Can also contain the following special value: *SIGNON This connection is a telnet connection and the system is performing sign-on processing or is displaying a sign-on prompt on it. Contains null when SLIC_TASK_NAME is not null.
JOB_NAME_SHORT	JOB_NAME_S	VARCHAR(10) Nullable	The name of the job. Contains the null value when JOB_NAME is *SIGNON or SLIC_TASK_NAME is not null.
JOB_USER	JOB_USER	VARCHAR(10) Nullable	The user profile that started the job. Contains the null value when JOB_NAME is *SIGNON or SLIC_TASK_NAME is not null.
JOB_NUMBER	JOB_NUMBER	VARCHAR(6) Nullable	The job number of the job. Contains the null value when JOB_NAME is *SIGNON or SLIC_TASK_NAME is not null.
SLIC_TASK_NAME	SLIC_TASK	VARCHAR(16) Nullable	The task name as identified to the system. Contains null when JOB_NAME is not null.

Table 124. NETSTAT_JOB_INFO view (continued)

Column Name	System Column Name	Data Type	Description
INTERNAL_JOB_ID	JOB_ID	BINARY(16) Nullable	A value that can be used by system APIs to speed the process of locating the job on the system. Contains null if JOB_NAME is the special value *SIGNON or if SLIC_TASK_NAME is not null.
JOB_TYPE	JOB_TYPE	VARCHAR(11) Nullable	The type of job: AUTOSTART The job is an autostart job. BATCH The job is a batch job. INTERACTIVE The job is an interactive job. MONITOR The job is a subsystem monitor job. READER The job is a spooled reader job. SCPF The job is the SCPF system job. SYSTEM The job is a system job. WRITER The job is a spooled writer job. Contains null if JOB_NAME is the special value *SIGNON or if SLIC_TASK_NAME is not null.

Example

Return information about all jobs using IPv4 network connections.

```
SELECT * FROM QSYS2.NETSTAT_JOB_INFO
WHERE CONNECTION_TYPE = 'IPV4'
```

NETSTAT_ROUTE_INFO view

The NETSTAT_ROUTE_INFO view returns information about IPv4 and IPv6 routes.

The values returned for the columns in the view are closely related to the values returned by [List Network Routes API](#). Refer to the API for more detailed information.

Authorization: None required.

The following table describes the columns in the view. The system name is NS_ROUTE. The schema is QSYS2.

Table 125. NETSTAT_ROUTE_INFO view

Column Name	System Column Name	Data Type	Description
CONNECTION_TYPE	CONN_TYPE	CHAR(4)	The type of connection. IPV4 The connection is an IPv4 connection. IPV6 The connection is an IPv6 connection.
ROUTE_DESTINATION	ROUTE_DEST	VARCHAR(45)	The Internet Protocol address of the ultimate destination reached by this route. For IPv4: <ul style="list-style-type: none"> The address is in IPv4 address format. When used in combination with the subnet mask and the type of service values, the route destination identifies a route to a network or system. A value of 0.0.0.0 means that the route destination is the default route. For IPv6: <ul style="list-style-type: none"> The address is in IPv6 address format. When used in combination with the prefix length, the route destination identifies a route to a network or host.

Table 125. NETSTAT_ROUTE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SUBNET_MASK	SUBNET_MSK	VARCHAR(15) Nullable	The actual value of the subnet mask for the route destination in dotted-decimal notation. A value of 0.0.0.0 means no value is defined. Contains null if this is an IPv6 connection.
NEXT_HOP	NEXT_HOP	VARCHAR(45)	The internet address of the first system on the path from your system to the route destination. For IPv4: <ul style="list-style-type: none"> The address is in IPv4 address format. For IPv6: <ul style="list-style-type: none"> The address is in IPv6 address format. Can contain the following special value: <ul style="list-style-type: none"> *DIRECT This is the next hop value of a route that is automatically created.
PREFIX_LENGTH	PRE_LEN	INTEGER Nullable	The prefix length defines how many bits of the route destination IPv6 address are in the prefix. It specifies how many of the left-most bits of the address make up the prefix. The prefix length is used to generate network and host addresses. Contains null if this is an IPv4 connection.
ROUTE_STATUS	ROUTE_STS	VARCHAR(10) Nullable	The current state of the route. DOD This route is used for Point-to-Point (PPP) Dial-on-Demand. Currently, this Dial-on-Demand route is not available. The route will become available when a Dial-on-Demand session is initiated for the interface this route is associated with. For IPv4: <ul style="list-style-type: none"> YES The router specified by the next hop value for this interface is available for use. NO The router specified by the next hop value for this interface is not available for use. NO GATEWAY The router specified by the next hop value for this interface is not available for use, the router may be experiencing a problem. For IPv6: <ul style="list-style-type: none"> ACTIVE This route is currently active and is in the current route search path. INACTIVE This route is not in the route search path and is not being used. Contains null if the state is unknown.
ROUTE_MAXIMUM_TRANSMISSION_UNIT	ROUTE_MTU	VARCHAR(10)	The maximum transmission unit (MTU) value for this route in bytes. Can be either a number or one of the following special values: For IPv4: <ul style="list-style-type: none"> IFC The route is not currently active and the MTU was specified as *IFC. OTHER An Internet Protocol (IP) over SNA interface. For IPv6: <ul style="list-style-type: none"> *IP6LINMTU This route uses the MTU of the line it is bound to.

Table 125. NETSTAT_ROUTE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
CONFIGURED_ROUTE_ MAXIMUM_ TRANSMISSION_UNIT	CFG_RT_MTU	VARCHAR(10) Nullable	<p>A number representing the configured maximum transmission unit (MTU) value for this route, in bytes. Can be either a number or the following special value:</p> <p>*IP6LINMTU The route MTU was specified as *IP6LINMTU, the MTU value of the line to which this route is bound.</p> <p>Contains null if this is an IPv4 connection.</p>
ROUTE_TYPE	ROUTE_TYPE	VARCHAR(8) Nullable	<p>The type of route.</p> <p>DFTRROUTE A default route.</p> <p>DIRECT A route to a network or subnetwork to which this system has a direct physical connection.</p> <p>HOST A route to a specific remote host.</p> <p>NET An indirect route to a remote network.</p> <p>SUBNET An indirect route to a remote subnetwork. This option is only for IPv4 connections.</p> <p>Contains null if the type of route is unknown.</p>

Table 125. NETSTAT_ROUTE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
ROUTE_SOURCE	ROUTE_SRC	VARCHAR(18) Nullable	<p>Specifies how this route was added to the routing table.</p> <p>For IPv4:</p> <p>CFG The route was added using the configuration commands of the local system.</p> <p>ICMP The route was added with the Internet Control Message Protocol (ICMP) redirect mechanism.</p> <p>OTHER The route was added with a sockets input/output control (IOctl) or other mechanism.</p> <p>RIP The route was added by the Routing Information Protocol (RIP).</p> <p>SNMP The route was added by the Simple Network Management Protocol (SNMP).</p> <p>For IPv6:</p> <p>AUTOCONFIG This route was added because of an interface added by stateless autoconfiguration.</p> <p>BGP This route was added by the Border Gateway Protocol (BGP).</p> <p>CFGIFC The route was added because of a manually configured interface.</p> <p>CFG RTE The route was manually configured.</p> <p>IDRP This route was added by the Inter-Domain Routing Protocol (IDRP).</p> <p>IGRP This route was added by the Interior Gateway Routing Protocol (IGRP).</p> <p>OSPF The route was added by the Open Shortest Path First (OSPF) protocol.</p> <p>RA_PREFIX_INFO This route was added because of the presence of a Prefix Information Option on a Router Advertisement packet received by the system.</p> <p>RA_ROUTE_INFO This route was added because of the presence of a Route Information Option on a Router Advertisement packet received by the system.</p> <p>RA_ROUTER_LIFETIME This route was added because of the presence of a non-zero value in the Router Lifetime field in a Router Advertisement packet received by the system.</p> <p>REDIRECT This route was added by the ICMPv6 redirect mechanism.</p> <p>RIP The route was added by the Routing Information Protocol (RIP).</p> <p>ROUTING This route was determined to be necessary and added by the TCP/IP stack on this system.</p> <p>SNMP This route was added by the Simple Network Management Protocol (SNMP).</p> <p>Contains null if the route source is not known.</p>

Table 125. NETSTAT_ROUTE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SERVICE_TYPE	SRVC_TYPE	VARCHAR(9) Nullable	<p>The type of service that defines how the internet hosts and routers should make trade-offs between throughput, delay, reliability, and cost.</p> <p>MAXRLB A higher level of effort to ensure delivery is important for datagrams with the maximize reliability indication.</p> <p>MAXTHRPUT High data rate is important for datagrams with the maximize throughput indication.</p> <p>MINCOST Lower cost is important for datagrams with the minimize monetary cost indication.</p> <p>MINDELAY Prompt delivery is important for datagrams with the minimize delay indication.</p> <p>NORMAL Normal service is used for delivery of datagrams.</p> <p>OTHER An Internet Protocol (IP) over SNA interface.</p> <p>Contains null if this is an IPv6 connection.</p>
ROUTE_PROTOCOL	ROUTE_PTCL	VARCHAR(7) Nullable	<p>Specifies the protocol that was used to generate this route.</p> <p>BGP Border Gateway protocol.</p> <p>IDRP InterDomain Routing protocol.</p> <p>IGRP InterGateway Routing protocol.</p> <p>LOCAL Local configuration.</p> <p>NDISC Neighbor discovery.</p> <p>NETMGMT Network Management protocol.</p> <p>OSPF Open Shortest Path First protocol.</p> <p>OTHER None of the listed protocols.</p> <p>RIP Routing Information protocol.</p> <p>Contains null if this is an IPv4 connection.</p>
ROUTE_PREFERENCE	ROUTE_PREF	VARCHAR(6) Nullable	<p>The preference of this route during route selection.</p> <p>LOW This route has a low preference.</p> <p>MEDIUM This route has a medium preference.</p> <p>HIGH This route has a high preference.</p> <p>Contains null if this is an IPv4 connection.</p>
LOCAL_BINDING_TYPE	LOCALTYPE	VARCHAR(7) Nullable	<p>The type of line to which this route is bound.</p> <ul style="list-style-type: none"> • DYNAMIC • STATIC <p>Contains null if this is an IPv6 connection.</p>
LOCAL_BINDING_INTERFACE	LOCALIFC	VARCHAR(15) Nullable	<p>The IP interface to bind to this route.</p> <p>Contains null if this is an IPv6 connection.</p>

Table 125. NETSTAT_ROUTE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
LOCAL_BINDING_INTERFACE_STATUS	LOCALSTS	VARCHAR(12) Nullable	The current status of the logical interface.
			ACTIVE The interface has been started and is running.
			DOD This interface is being used for Point-to-Point (PPP) Dial-on-Demand.
			DUPLICATE Another host on the LAN responded to a packet destined for this logical interface.
			ENDING The operating system is processing the request to end this interface.
			FAILED The line description associated with this interface has entered the failed state.
			FAILED (TCP) An error was detected in the IBM TCP/IP Licensed Internal Code.
			INACTIVE The interface has not been started.
			RCYCNL A hardware failure has occurred and the line description associated with this interface is in the recovery canceled (RCYCNL) state.
			RCYPND An error with the physical line associated with this interface was detected by the system. The line description associated with this interface is in the recovery pending (RCYPND) state.
STARTING The operating system is processing the request to start this interface.			
			Contains null if this is an IPv6 connection.
LOCAL_BINDING_NETWORK_ADDRESS	LOCALADDR	VARCHAR(15) Nullable	The Internet address, in dotted decimal notation, of the IP network or subnetwork that the interface is attached to. Contains null if this is an IPv6 connection.
LOCAL_BINDING_SUBNET_MASK	LOCALMASK	VARCHAR(15) Nullable	The subnet mask for the network, subnet, and host address fields for the local binding network address, in dotted decimal notation, that defines the subnetwork for an interface. Contains null if this is an IPv6 connection.
LOCAL_BINDING_LINE_DESCRIPTION	LOCALLINE	VARCHAR(10)	The name of the communications line description or virtual line (L2TP) that identifies the network associated with an interface. Can contain the following special values: *LOOPBACK This is a loopback interface. Processing associated with the loopback interface does not extend to a physical line. *OPC This interface is attached to the optical bus (OptiConnect). *VIRTUALIP The virtual interface is a circuitless interface.
LOCAL_BINDING_LINE_STATUS	LOCALSTS	VARCHAR(8) Nullable	The current operational status of the communications line to which this route is bound. ACTIVE The line is operational. FAILED The desired state of the line is Active, but it is currently in the Inactive state. INACTIVE The line is not operational. Contains null if this is an IPv4 connection.

Table 125. NETSTAT_ROUTE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
LOCAL_BINDING_LINE_TYPE	LOCALLTYPE	VARCHAR(6)	<p>The type of line used by the interface. Only supported line types are listed here; obsolete values could be returned for inactive configurations.</p> <p>ASYNC Asynchronous communications protocol.</p> <p>ELAN Ethernet local area network protocol.</p> <p>L2TP Layer Two Tunneling protocol.</p> <p>PPP Point-to-Point protocol.</p> <p>PPPOE Point-to-Point over Ethernet protocol.</p> <p>VETH Virtual Ethernet protocol.</p> <p>Can also contain one of the following special values:</p> <p>ERROR A system error other than those for NOTFND was received while trying to determine the link type for an interface.</p> <p>NONE Line is not defined. This value is used for the following interfaces: *LOOPBACK, *VIRTUALIP, *OPC. There is no line type value for this interface.</p> <p>NOTFND Not found. The line description object for this interface cannot be found.</p>
LOCAL_BINDING_VIRTUAL_LAN_ID	LOCALLAN	VARCHAR(4)	<p>The virtual LAN to which this route is bound. Can also contain the following special value:</p> <p>NONE No virtual LAN identifier is associated with the binding line.</p>
ROUTE_PRECEDENCE	ROUTE_PRCD	INTEGER Nullable	<p>Priority of route. Values are 1 to 10, with the lowest priority being 1.</p> <p>Contains null if this is an IPv6 connection.</p>
ROUTE_TEXT	LABEL	VARGRAPHIC(50) CCSID(1200) Nullable	<p>Text description associated with the route.</p> <p>Contains null if there is no description.</p>
DUPLICATE	DUPLICATE	VARCHAR(6) Nullable	<p>Indicates whether this route is a duplicate of another route in the routing table or not, and also whether there are any routes which are duplicates of this route.</p> <p>NO This route is not a duplicate of another route but it does have duplicates.</p> <p>UNIQUE This route is not a duplicate of another route and it does not have any duplicates.</p> <p>YES This route is a duplicate of another route.</p> <p>Contains null if this is an IPv4 connection.</p>
EXPIRATION	EXPIRATION	TIMESTAMP(0) Nullable	<p>The timestamp when this route will expire or did expire. If the timestamp is in the future, the route has not expired yet. If the timestamp is in the past, then this route has expired and is still being returned for a short period of time to indicate that the route ceased to function because its lifetime expired.</p> <p>Contains null if this is an IPv4 connection or if the route will never expire.</p>
PPP_CONFIGURATION_PROFILE	PPPCFGPRF	VARCHAR(10) Nullable	<p>The name of the Point-to-Point Protocol (PPP) configuration profile associated with this route.</p> <p>Contains null if this is an IPv4 connection or if Point-to-Point Protocol is not being used with this route.</p>
PPP_AUTHENTICATION_USER_ID	PPPAUTUSR	VARCHAR(24) Nullable	<p>The Point-to-Point Protocol authentication user id associated with this route.</p> <p>Contains null if this is an IPv4 connection or if Point-to-Point Protocol is not being used with this route.</p>

Table 125. NETSTAT_ROUTE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
PPP_INTERNET_ADDRESS	PPPINTADD	VARCHAR(45) Nullable	The internet address, in IPv6 address format, to which this Point-to-Point route is bound. Contains null if this is an IPv4 connection or if Point-to-Point Protocol is not being used with this route.
PPP_DIAL_ON_DEMAND_PROFILE	PPPDODPRF	VARCHAR(10) Nullable	The name of the Dial-on-demand Remote Peer Enabled Point-to-Point profile associated with this route. Contains null if this is an IPv4 connection or if Point-to-Point Protocol is not being used with this route.
LAST_CHANGE_TIMESTAMP	LASTCHG	TIMESTAMP(0) Nullable	The timestamp of the most recent change to this route in the dynamic tables used by the protocol stack. Contains null if the interface has never been changed.

Example

Return information about all routes which are available for use.

```
SELECT * FROM QSYS2.NETSTAT_ROUTE_INFO
WHERE ROUTE_STATUS = 'YES' OR ROUTE_STATUS = 'ACTIVE'
```

NETWORK_ATTRIBUTE_INFO view

The NETWORK_ATTRIBUTE_INFO view returns a single row containing information about the network attributes of the system.

The information returned is similar to the detail available through the Display Network Attributes (DSPNETA) CL command, the Retrieve Network Attributes (RTVNETA) CL command, and the Retrieve Network Attributes (QWCRNETA) API.

Authorization: None required.

The following table describes the columns in the view. The system name is NET_ATTR. The schema is QSYS2.

Table 126. NETWORK_ATTRIBUTE_INFO view

Column Name	System Column Name	Data Type	Description
HOST_NAME	HOST_NAME	VARCHAR(8)	Name of the system where this information was generated. This is the name set by CHGNETA.
PENDING_HOST_NAME	PEND_HOST	VARCHAR(8) Nullable	The pending system name, if a change is pending. Contains the null value if no change is pending.
NETWORK_ID	NETWORK_ID	VARCHAR(8)	The local network ID assigned to the system.
CONTROL_POINT	CTL_POINT	VARCHAR(8)	The local control point name for the system.
LOCATION	LOCATION	VARCHAR(8)	The default local location name for the system.
MODE	MODE	VARCHAR(8) Nullable	The default mode name for the system. Contains the null value if there is no default mode.

Table 126. NETWORK_ATTRIBUTE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
APPN_NODE_TYPE	NODETYPE	VARCHAR(8)	<p>The advanced peer-to-peer networking (APPN) node type.</p> <p>*BEXNODE The node performs as a branch extender node. The node performs as an end node in the backbone APPN network, and performs as a network node server to end nodes within its local domain.</p> <p>*ENDNODE The node does not provide network services to other nodes, but may participate in the APPN network by using the services of an attached network server, or may operate in a peer environment similar to migration end nodes.</p> <p>*NETNODE The node provides intermediate routing, route selection services, and distributed directory services for local users and to end nodes and migration end nodes that it is serving.</p>
DATA_COMPRESSION	DTACPR	VARCHAR(10)	<p>Whether data compression is used when the system is an SNA end node. This value is used by mode descriptions that specify *NETATR for data compression.</p> <p>If data compression is requested by the remote system, the data compression levels used by the session are the lower of the requested levels and the configured levels.</p> <p>*ALLOW Data compression is allowed on the session by the local system if requested by a remote system. The local system does not request that compression be used.</p> <p>*NONE Data compression is not allowed on the session.</p> <p>*REQUEST Data compression is requested on the session by the local system. However, the request can be refused or changed to a lower compression level by the remote system. Data compression is allowed on the session if requested by the remote system.</p> <p>*REQUIRE Data compression is required on the session. If the remote system does not change the levels of compression to the local system's exact requested levels, the session is not established. The data compression levels that the local system requires are the specified levels.</p> <p>integer If either the receiving or sending link has a line speed equal to or less than this specified line speed, this value indicates the need for compression by requesting that the remote systems compress the session data. Otherwise, this value does not indicate to the remote systems that there is a need to compress the data. Values range from 1 through 2147483647 bits per second.</p>

Table 126. NETWORK_ATTRIBUTE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
INTERMEDIATE_DATA_COMPRESSION	DTACPRINM	VARCHAR(10)	<p>The level of data compression to request when the system is an SNA intermediate node.</p> <p>*NONE Does not indicate to the remote systems that there is a need to compress the data.</p> <p>*REQUEST Indicates the need for compression by requesting that the remote systems compress the session data.</p> <p>integer If either the receiving or sending link has a line speed equal to or less than this specified line speed, this value indicates the need for compression by requesting that the remote systems compress the session data. Otherwise, this value does not indicate to the remote systems that there is a need to compress the data. Values range from 1 through 2147483647 bits per second.</p>
MAXIMUM_SESSIONS	MAX_SSN	INTEGER Nullable	<p>The maximum number of advanced program-to-program communications (APPC) intermediate sessions for an advanced peer-to-peer networking (APPN) node type of *NETNODE or *BEXNODE.</p> <p>Contains the null value when APPN_NODE_TYPE is *ENDNODE.</p>
ROUTE_ADDITION_RESISTANCE	RESISTANCE	INTEGER Nullable	<p>The advanced peer-to-peer networking (APPN) route addition resistance for an APPN node type of *NETNODE or *BEXNODE.</p> <p>Contains the null value when APPN_NODE_TYPE is *ENDNODE.</p>
SERVER_NETWORK_ID_COUNT	SRV_NETCNT	INTEGER Nullable	<p>The number of network ID values in the SERVER_NETWORK_IDS column.</p> <p>Contains the null value when APPN_NODE_TYPE is not *ENDNODE.</p>
SERVER_NETWORK_IDS	SRV_NETIDS	VARCHAR(248) CCSID 1208 Nullable	<p>The advanced peer-to-peer networking (APPN) network node servers for an APPN node type of *ENDNODE or *BEXNODE.</p> <p>This list is returned as an array within a JSON object. The array can contain up to five elements and is identified by NET_IDS.</p> <p>Each entry in the JSON array contains two JSON objects:</p> <ul style="list-style-type: none"> An object with a name of "NET_ID" and a value of a network ID. An object with a name of "CTL_POINT" and a value of the corresponding control point. <p>The special value of *LCLNETID for a network ID. This indicates that the value of NETWORK_ID at the time the node server is referred to is be used.</p> <p>A special value of *ANY applies to the control point. This indicates that the first network node that offers services will become the network node server. Any network node with the same network ID as that specified for NETWORK_ID can be a potential network node server.</p> <p>Contains the null value when SERVER_NETWORK_ID_COUNT is 0 or APPN_NODE_TYPE is not *ENDNODE.</p>
SERVER_NETWORK_ID	SRV_NETID	VARCHAR(9) Nullable	<p>The server network ID for the first entry in the SERVER_NETWORK_IDS list. The special value of *LCLNETID indicates that the value of NETWORK_ID at the time the node server is referred to is be used.</p> <p>Contains the null value when SERVER_NETWORK_ID_COUNT is 0 or APPN_NODE_TYPE is not *ENDNODE.</p>

Table 126. NETWORK_ATTRIBUTE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SERVER_CONTROL_POINT	SRV_CTLPT	VARCHAR(8) Nullable	The server control point for the first entry in the SERVER_NETWORK_IDS list. A special value of *ANY indicates that the first network node that offers services will become the network node server. Any network node with the same network ID as that specified for NETWORK_ID can be a potential network node server. Contains the null value when SERVER_NETWORK_ID_COUNT is 0 or APPN_NODE_TYPE is not *ENDNODE.
ALERT_STATUS	ALERT_STS	VARCHAR(9)	Alert status controls the creation of local alerts. *OFF Alerts are not created by the system. *ON Alerts are created by a system for all changeable conditions except unattended conditions. *UNATTEND Alerts are created by the system for all alert conditions including those which have the alert indicator in the message description set to *UNATTEND.
ALERT_LOGGING	ALERT_LOG	VARCHAR(6)	Specifies which alerts are to be logged: *ALL Both locally created alerts and incoming alerts are logged. *LOCAL Only locally created alerts are logged. *NONE No alerts are logged. *RCV Only alerts received from other nodes are logged.
ALERT_PRIMARY_FOCAL_POINT	ALERT_PRIM	VARCHAR(4)	Whether the system is an alert primary focal point. *NO The system is not an alert primary focal point. *YES The system is defined to be an alert primary focal point and provides focal point services to all nodes in the network that are explicitly defined in the sphere of control.
ALERT_DEFAULT_FOCAL_POINT	ALERT_DFT	VARCHAR(4)	Whether the system is an alert default focal point. *NO The system is not an alert default focal point. *YES The system is defined to be an alert default focal point and provides focal point services to all nodes in the network that are not being serviced by another focal point.
ALERT_BACKUP_NETWORK_ID	ALERT_BNET	VARCHAR(8) Nullable	The network ID of the system that provides backup focal point services for alerts. These backup values define the system that provides alert focal point services if the local system is unavailable and ALERT_PRIMARY_FOCAL_POINT is *YES. The backup focal point is only used by systems in the primary sphere of control. Contains the null value if no backup focal point is defined.
ALERT_BACKUP_CONTROL_POINT	ALERT_BCTL	VARCHAR(8) Nullable	The control point name of the system that provides backup focal point services for alerts. Contains the null value if no backup focal point is defined.

Table 126. NETWORK_ATTRIBUTE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
ALERT_REQUEST_NETWORK_ID	ALERT_RQSD	VARCHAR(8) Nullable	The network ID of the system that is requested to provide focal point services for alerts. The focal point to request values define the name of the system that is requested to provide alert focal point services. Contains the null value if no backup focal point is defined.
ALERT_REQUEST_CONTROL_POINT	ALERT_RQSC	VARCHAR(8) Nullable	Specify the control point name of the system that is requested to provide focal point services for alerts. Contains the null value if no backup focal point is defined.
ALERT_CONTROLLER	ALERT_CTL	VARCHAR(10) Nullable	The name of the controller to be used for alerts in a system service control point - physical unit (SSCP-PU) session. This controller is ignored if the system has a focal point (in which case the node is in another system's sphere of control). Contains the null value if no alert controller is defined.
ALERT_HOLD_COUNT	ALERT_HOLD	INTEGER Nullable	The maximum number of alerts to be created before the alerts are sent over the system service control point - physical unit session. Alerts are held by the system until this number of alerts have been created. If the alert controller (ALERT_CONTROLLER) network attribute is being used to send alerts (SSCP-PU session), alerts will be sent automatically regardless of the ALERT_HOLD_COUNT network attribute when a switched connection is made for other reasons. Can contain the following special value: -2 Indicates *NOMAX. The alerts are held indefinitely. The alerts can be sent at a later time by changing the ALRHLCNT value on the CHGNETA CL command to a lower value. Contains the null value if no alert hold count is set.
ALERT_FILTER_LIBRARY	ALERT_FTRL	VARCHAR(10) Nullable	The name of the library that contains the filter object. Contains the null value if no alert filter is being used.
ALERT_FILTER	ALERT_FTR	VARCHAR(10) Nullable	The name of the filter object that is used by the alert manager when processing alerts. Contains the null value if no alert filter is being used.
MESSAGE_QUEUE_LIBRARY	MSGQ_LIB	VARCHAR(10)	The library where MESSAGE_QUEUE resides.
MESSAGE_QUEUE	MSGQ	VARCHAR(10)	The name of the message queue to which messages received through the SNA distribution services (SNADS) network are sent for: <ul style="list-style-type: none"> • Users who have no message queue specified in their user profile • Users whose message queue is not available
OUTPUT_QUEUE_LIBRARY	OUTQ_LIB	VARCHAR(10)	The library where OUTPUT_QUEUE resides.
OUTPUT_QUEUE	OUTQ	VARCHAR(10)	The name of the output queue to which spooled files received through the SNA distribution services (SNADS) network are sent for users whose output queue is not available.

Table 126. NETWORK_ATTRIBUTE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
JOB_ACTION	JOB_ACTION	VARCHAR(7)	<p>The action that is taken for any input stream received through the SNA distribution services (SNADS) network by the system.</p> <p>*FILE The input stream is filed in the queue of network files received for the user to whom it was sent. That user may then look at the input stream, end it, receive it, or submit it to a job queue.</p> <p>*REJECT The input stream is rejected by the system. This action allows users to secure their system from input streams received through the network.</p> <p>*SEARCH The table of network job entries is searched to determine the action to be taken for the input stream.</p>
MAXIMUM_HOPS	MAX_HOPS	INTEGER	<p>The maximum number of times in an SNA distribution services (SNADS) network that a distribution queue entry originating at this node may be received and routed on the path to its final destination. If this number is exceeded, the distribution queue entry is ended. When the distribution queue entry is ended, a feedback status is sent back to the sender if it was requested.</p>
DDM_REQUEST_ACCESS	DDM_RQS	VARCHAR(8)	<p>How the system processes distributed data management (DDM) and Distributed Relational Database Architecture (DRDA) requests from other systems.</p> <p>*OBJAUT All requests are allowed and controlled by the object authorization on the system.</p> <p>*REJECT The system does not allow DDM or DRDA requests from remote systems. This system can still use DDM or DRDA, however, to access files or SQL tables on remote systems.</p> <p>*PROGRAM The program identified in the DDM_REQUEST_LIBRARY and DDM_REQUEST_PROGRAM columns is used.</p>
DDM_REQUEST_LIBRARY	DDM_LIB	VARCHAR(10) Nullable	<p>The name of the library that contains DDM_REQUEST_PROGRAM.</p> <p>Contains the null value if DDM_REQUEST_ACCESS is not *PROGRAM.</p>
DDM_REQUEST_PROGRAM	DDM_PGM	VARCHAR(10) Nullable	<p>The name of a user-written validation program that is called each time a DDM request is made from a remote system. This program indicates to DDM whether the request should proceed or be ended. System security still applies.</p> <p>Contains the null value if DDM_REQUEST_ACCESS is not *PROGRAM.</p>

Table 126. NETWORK_ATTRIBUTE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
CLIENT_REQUEST_ACCESS	CLIENT_RQS	VARCHAR(8)	<p>The way in which the system processes client requests from other systems.</p> <p>*OBJAUT Normal object authorizations are checked for the client requests. For example, authorization to retrieve data from a database file for a transfer function request is checked.</p> <p>*REGFAC The registration facility is used to determine whether to call an exit program. If no exit program is defined for an exit point and this value is specified, *OBJAUT is used.</p> <p>*REJECT The system rejects every request from clients.</p> <p>*PROGRAM The program identified in the CLIENT_REQUEST_LIBRARY and CLIENT_REQUEST_PROGRAM columns is used.</p>
CLIENT_REQUEST_LIBRARY	CLIENT_LIB	VARCHAR(10) Nullable	<p>The name of the library that contains CLIENT_REQUEST_PROGRAM.</p> <p>Contains the null value if CLIENT_REQUEST_ACCESS is not *PROGRAM.</p>
CLIENT_REQUEST_PROGRAM	CLIENT_PGM	VARCHAR(10) Nullable	<p>The name of a user-written validation program that is called each time a server request comes from a client. The program is passed two parameters: the first is used by the program to indicate to the server application whether this client request should be handled; the second describes the client request (the name of the application and type request).</p> <p>Contains the null value if CLIENT_REQUEST_ACCESS is not *PROGRAM.</p>
NETWORK_SERVER_DOMAIN	NWS_DOMAIN	VARCHAR(8)	The LAN server domain associated with the file server.
ALLOW_VIRTUAL_APPN	VIRT_APPN	VARCHAR(4)	<p>Specifies whether APPC sessions and devices are allowed to use virtual APPN controllers.</p> <p>*NO The system does not allow APPC sessions or devices to use virtual APPN controllers. If sessions are using HPR transport tower support, they will use virtual APPN controllers regardless of this setting.</p> <p>*YES The system does allow APPC sessions or devices to use virtual APPN controllers.</p>
ALLOW_HPR_TRANSPORT_TOWER	HPR_TOWER	VARCHAR(4)	<p>The HPR transport tower support value is used for APPN session traffic.</p> <p>*NO The system does not allow HPR transport tower support to be used with APPN session traffic.</p> <p>*YES The system allows HPR transport tower support to be used with APPN session traffic.</p>
AUTOCREATE_APPC_DEVICE_LIMIT	APPC_LIMIT	INTEGER	The APPC device limit used for auto-creation of devices on virtual APPN controllers.
NETWORK_PRIORITY_TIMER	NET_TIMER	INTEGER Nullable	<p>The amount of time, in minutes, to allow for a path switch attempt of a Rapid Transport Protocol (RTP) connection that has network transmission priority.</p> <p>Contains the null value if no path switch is allowed.</p>
HIGH_PRIORITY_TIMER	HIGH_TIMER	INTEGER Nullable	<p>The amount of time, in minutes, to allow for a path switch attempt of an RTP connection that has high transmission priority.</p> <p>Contains the null value if no path switch is allowed.</p>

Table 126. NETWORK_ATTRIBUTE_INFO view (continued)

Column Name	System Column Name	Data Type	Description
MEDIUM_PRIORITY_TIMER	MED_TIMER	INTEGER Nullable	The amount of time, in minutes, to allow for a path switch attempt of an RTP connection that has medium transmission priority. Contains the null value if no path switch is allowed.
LOW_PRIORITY_TIMER	LOW_TIMER	INTEGER Nullable	The amount of time, in minutes, to allow for a path switch attempt of an RTP connection that has low transmission priority. Contains the null value if no path switch is allowed.
ALLOW_ADD_TO_CLUSTER	ADD_CLUST	VARCHAR(7)	Whether this system will allow another system to add it as a node in a cluster. *ANY Any other system can add this system as a node in a cluster. *NONE No other system can add this system as a node in a cluster. *RQSAUT Any other system can add this system as a node in a cluster only after the cluster add request has been authenticated.
MODEM_COUNTRY_OR_REGION_ID	MODEM_ID	CHAR(2) Nullable	The country or region identifier associated with a modem. This defines the country or region-specific default characteristics for modems that are internal to IBM i I/O adapters. This value must be configured correctly to ensure proper operation and, in some countries or regions, meet legal requirements. The adapter will fail the vary on of the line if the modem country or region ID is not set. Contains the null value if no country or region identifier has been defined.

Example

- Review the system network attributes.

```
SELECT * FROM QSYS2.NETWORK_ATTRIBUTE_INFO;
```

OBJECTCONNECT_INFO view

The OBJECTCONNECT_INFO view returns information about the ObjectConnect over IP server.

This view will only return data if Option 22 of the IBM i operating system is installed.

Authorization: None required.

The following table describes the columns in the view. The system name is OBJC_INFO. The schema is QSYS2.

Table 127. OBJECTCONNECT_INFO view

Column Name	System Column Name	Data Type	Description
STATE	STATE	VARCHAR(8)	The state of the ObjectConnect over IP server. ACTIVE The ObjectConnect over IP server is active. INACTIVE The ObjectConnect over IP server is not active.

Table 127. OBJECTCONNECT_INFO view (continued)

Column Name	System Column Name	Data Type	Description
AUTO_START	AUTO_START	VARCHAR(3)	Whether the ObjectConnect over IP server is started automatically. NO The ObjectConnect over IP server is not started automatically. YES The ObjectConnect over IP server is started automatically.
MINIMUM_JOBS	MIN_JOBS	INTEGER	The minimum number of server jobs.
MAXIMUM_JOBS	MAX_JOBS	INTEGER	The maximum number of server jobs.
INACTIVE_TIME	INACT_TIME	INTEGER	The length of time, in minutes, a server job keeps inactive before the server job ends.
SEND_BUFFER	SND_BUF	INTEGER	The size of the TCP send buffer, in bytes, that the data connection will use to send data over the network.
RECEIVE_BUFFER	RCV_BUF	INTEGER	The size of the TCP receive buffer, in bytes, that the data connection will use to receive data from the network.
SUBSYSTEM_DESCRIPTION_LIBRARY	SBSD_LIB	VARCHAR(10)	The library containing the subsystem description.
SUBSYSTEM_DESCRIPTION	SBSD	VARCHAR(10)	The subsystem in which the ObjectConnect servers run.
AUTHENTICATION_TYPE	AUTH_TYPE	VARCHAR(8)	The type of authentication that the ObjectConnect over IP server can use. ANY The ObjectConnect over IP server can use any of the supported authentication types to authenticate an incoming ObjectConnect connection request. KERBEROS The ObjectConnect over IP server can use Kerberos to authenticate an incoming ObjectConnect connection request. PASSWORD The ObjectConnect over IP server can use the user profile and password to authenticate an incoming ObjectConnect connection request.

Example

- List information about the ObjectConnect over IP server.

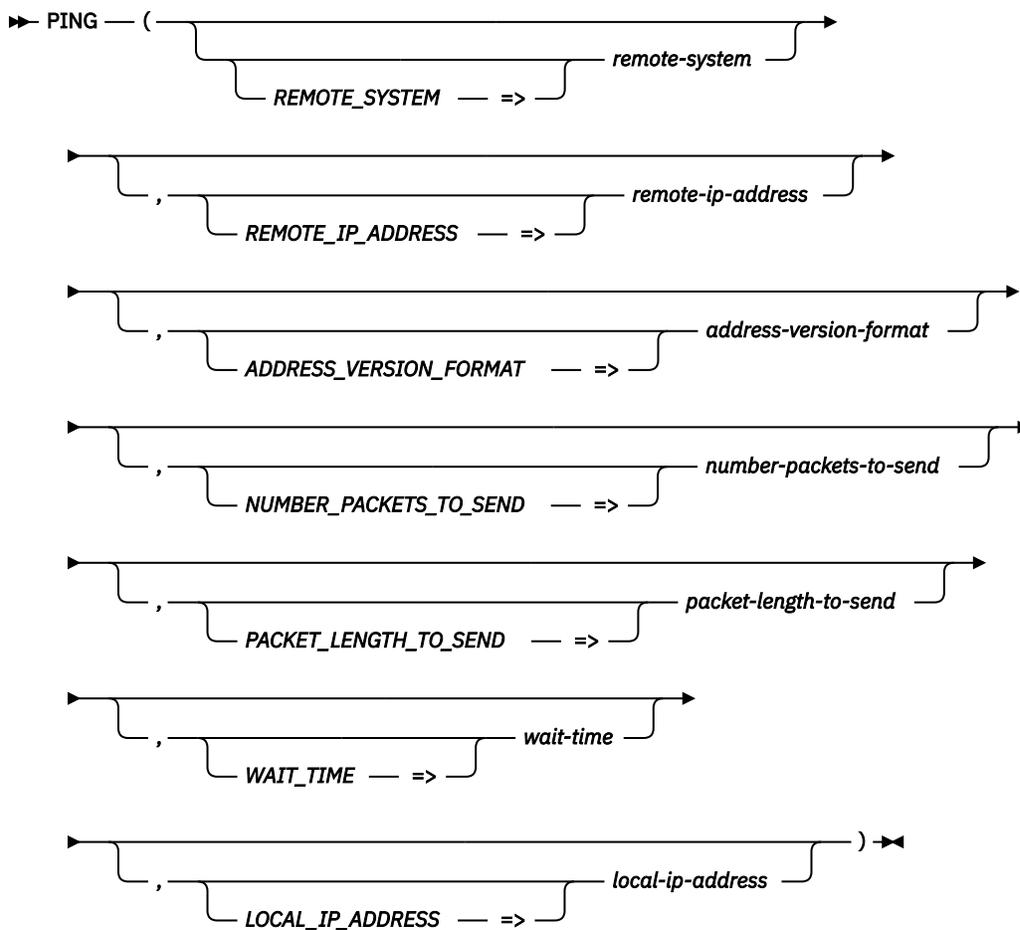

```
SELECT * FROM QSYS2.OBJECTCONNECT_INFO;
```

PING table function

The PING table function tests connectivity to a remote system.

This function is similar to the PING or Verify TCP/IP Connection (VFYTCPCNN) CL command.

Authorization: See Note below.

The schema is SYSTOOLS.

remote-system

A character string containing the name of the remote system with which the ping operation takes place. Can contain the following special value:

***INTNETADR** The *remote-ip-address* parameter identifies the remote system.

If this parameter is omitted, the default value is *INTNETADR and a value for *remote-ip-address* must be specified.

remote-ip-address

A character string that specifies the remote internet address. Either a valid IP Version 4 or IP Version 6 address is accepted.

If *remote-system* contains a value other than *INTNETADR, this parameter is ignored.

address-version-format

A character string that specifies how the host name specified for *remote-system* is to be resolved. It is also the address format to be used if *remote-ip-address* is specified.

***CALC** The host name resolution method will be determined based on the host name entered for *remote-system*. This is the default.

***IP4** Use the IP Version 4 host name resolution method.

***IP6** Use the IP Version 6 host name resolution method.

number-packets-to-send

An integer value that specifies the number of packets that are sent to the remote system. Valid values are 1 to 999. The default is 5.

packet-length-to-send

An integer value that specifies the packet length (in bytes) to be sent to the remote system. Valid values are 8 to 65500. The default is 256.

wait-time

An integer value that specifies the number of seconds to wait for the return (echo) packet before declaring a packet transfer a failure. Valid values are 1 to 120. The default is 1.

local-ip-address

A character string that specifies the local internet address of the interface that the outbound packets are to use. Either a valid IP Version 4 or IP Version 6 address is accepted. *ANY indicates that any interface's local internet address can be used. The default is *ANY.

The result of the function is a table containing one row with the format shown in the following table. All the columns are null capable.

Table 128. PING table function

Column Name	Data Type	Description
RESULT	VARCHAR(7)	The result of the ping request. FAILURE At least one packet did not respond or an error occurred with the command. SUCCESS All packets responded.
PERCENT_SUCCESSFUL	INTEGER	The percent of successful packet responses.
PACKETS_SENT	INTEGER	The total number of packets that were sent.
RESPONSES_RETURNED	INTEGER	The total number of responses received for the packets that were sent.
ROUND_TRIP_AVG	INTEGER	The average time, in milliseconds, for a response.
ROUND_TRIP_MIN	INTEGER	The shortest time, in milliseconds, for a response.
ROUND_TRIP_MAX	INTEGER	The longest time, in milliseconds, for a response.
REMOTE_HOST_NAME	VARCHAR(255)	The name of the host that was the target of the ping request.
REMOTE_IP_ADDRESS	VARCHAR(45)	The IP address for REMOTE_HOST_NAME.

Note

This function is provided in the SYSTOOLS schema as an example of how messages in a job log can be examined to gather status information. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

- Verify connectivity to a remote system by name.

```
SELECT * FROM TABLE(SYSTOOLS.PING('REMOTESYS'));
```

- Verify connectivity to a remote system by IP address.

```
SELECT * FROM TABLE(SYSTOOLS.PING(REMOTE_IP_ADDRESS => '9.1.2.3'));
```

RDB_ENTRY_INFO view

The RDB_ENTRY_INFO view returns information about relational database (RDB) directory entries.

The values returned for the columns in the view are similar to the values returned by the Display RDB Directory Entries (DSPRDBDIRE) CL command.

Authorization: None required.

The following table describes the columns in the view. The system name is RDB_INFO. The schema is QSYS2.

Table 129. RDB_ENTRY_INFO view

Column Name	System Column Name	Data Type	Description
RDB_NAME	RDB_NAME	VARCHAR(18)	The name of the relational database.
RDB_ALIAS	RDB_ALIAS	VARCHAR(18) Nullable	The RDB alias name. Contains the null value if no RDB alias is defined.
REMOTE_LOCATION_TYPE	RMT_TYPE	VARCHAR(4) Nullable	The remote location type. *IP The RDB is found using a host name or an internet address over a TCP/IP connection. *SNA The RDB is accessed using a Systems Network Architecture (SNA) address and protocol. Contains the null value if the value does not apply.
REMOTE_LOCATION	RMT_LOC	VARCHAR(254)	The remote location name of the system on which the RDB is located. remote-location-name The remote location name is in one of the following formats: <ul style="list-style-type: none"> • SNA remote location name (LU name). • SNA remote network identifier and remote location name separated by a period. • IPv4 address in dotted decimal form. • IPv6 address in colon hexadecimal form. • IP host domain name. *ARDPGM The RDB is accessed by using the Application Requester Driver (ARD) program. *LOCAL The system database on this system. LOOPBACK This value is an alias for the IP address of the host system. *MIRROR The RDB is accessed on the other system for a Db2 Mirror relationship.
TEXT_DESCRIPTION	TEXT	VARGRAPHIC(50) CCSID 1200 Nullable	The text description for this relational database entry. Contains the null value is there is no descriptive text.

Table 129. RDB_ENTRY_INFO view (continued)

Column Name	System Column Name	Data Type	Description
REMOTE_PORT_OR_SERVICE	RMT_PORT	VARCHAR(14) Nullable	The relational database entry port number or service name that is used at the remote location to communicate with the system on which the RDB is located. If *DRDA was specified, the Distributed Relational Database Architecture (DRDA) port is 446. Contains the null value if REMOTE_LOCATION_TYPE is not *IP.
PREFERRED_AUTHENTICATION	PREF_AUTH	VARCHAR(10) Nullable	The preferred authentication method on a connection request. *ENCUSRPWD Encrypted user ID and encrypted password. *KERBEROS Authentication occurs using Kerberos. *USRENCPWD User ID and encrypted password. *USRID User ID only. *USRIDPWD User ID and password. Contains the null value if REMOTE_LOCATION_TYPE is not *IP.
LOWER_AUTHENTICATION	LOWER_AUTH	VARCHAR(11) Nullable	Whether an authentication method lower than what was specified for the preferred method will be accepted during negotiation with the server. *ALWLOWER Allow negotiation of a lower authentication method. *NOALWLOWER Do not allow negotiation of a lower authentication method. Contains the null value if REMOTE_LOCATION_TYPE is not *IP.
ENCRYPTION_ALGORITHM	ENCRYPTION	VARCHAR(4) Nullable	The encryption algorithm to be used initially on the connection request. *AES Advanced Encryption Standard (AES) is to be used initially. *DES Data Encryption Standard (DES) is to be used initially. Contains the null value if the encryption algorithm does not apply.
SECURE_CONNECTION	SECURE	VARCHAR(5) Nullable	Whether Transport Layer Security (TLS) is to be used on a DDM/DRDA TCP/IP connection request. *NONE TLS is not used. *TLS TLS is used. Contains the null value if REMOTE_LOCATION_TYPE is not *IP.
APPC_DEVICE_DESCRIPTION	APPC_DEVD	VARCHAR(10) Nullable	The Advanced Program-to-Program Communications (APPC) device description on this system that is used with this RDB entry. Can contain the special value: *LOC If APPC is being used, the system determines which device description is used. Contains the null value if REMOTE_LOCATION_TYPE is not *SNA.

Table 129. RDB_ENTRY_INFO view (continued)

Column Name	System Column Name	Data Type	Description
LOCAL_LOCATION	LOCAL_LOC	VARCHAR(8) Nullable	<p>The local location name by which this system is identified to the system on which the RDB is located. Can contain one of the following special values:</p> <p>*LOC If APPC is being used, the system determines which local location name is used.</p> <p>*NETATR The LCLLOCNAME value specified in the system network attributes is used.</p> <p>Contains the null value if REMOTE_LOCATION_TYPE is not *SNA.</p>
REMOTE_NETWORK_ID	RMT_NETID	VARCHAR(8) Nullable	<p>The remote network identifier of the system on which the RDB is located. Can contain one of the following special values:</p> <p>*LOC If APPC is being used, the system determines which remote network identifier is used.</p> <p>*NETATR The remote network identifier specified in the network attributes is used.</p> <p>*NONE No remote network identifier is used.</p> <p>Contains the null value if REMOTE_LOCATION_TYPE is not *SNA.</p>
REMOTE_MODE	RMT_MODE	VARCHAR(8) Nullable	<p>The mode name to use with the remote location name to communicate with the system on which the RDB is located. Can contain one of the following special values:</p> <p>*NETATR The mode in the network attributes is used.</p> <p>BLANK A mode name of all blanks is used.</p> <p>Contains the null value if REMOTE_LOCATION_TYPE is not *SNA.</p>
TRANSACTION_PROGRAM	TRANS_PGM	VARCHAR(8) FOR BIT DATA Nullable	<p>The name of the transaction program to use with the RDB entry.</p> <p>transaction-program-name The transaction program name is in one of the following formats:</p> <ul style="list-style-type: none"> A 4-byte hexadecimal name. For example, X'07F6C4C2'. An 8-byte character name. The value *DRDA, which means the Distributed Relational Database Architecture (DRDA) transaction program name is used, X'07F6C4C2'. <p>Contains the null value if REMOTE_LOCATION_TYPE is not *SNA.</p>
ARD_LIBRARY	ARD_LIB	VARCHAR(10) Nullable	<p>The library containing the Application Requester Driver (ARD) program. Can contain the special values *LIBL or *CURLIB.</p> <p>Contains the null value if REMOTE_LOCATION is not *ARDPGM.</p>
ARD_PROGRAM	ARD_PGM	VARCHAR(10) Nullable	<p>The ARD program to be called to process SQL requests directed to the RDB.</p> <p>Contains the null value if REMOTE_LOCATION is not *ARDPGM.</p>

Example

- Find any RDBs that might be sending authentication data in the clear

```
SELECT * FROM QSYS2.RDB_ENTRY_INFO
WHERE PREFERRED_AUTHENTICATION IN ('*USRID', '*USRIDPWD', '*USRENCPWD');
```

REMOVE_TIME_SERVER procedure

The REMOVE_TIME_SERVER procedure removes a Network Time Protocol (NTP) server from the NTP configuration list.

The REMOVE_TIME_SERVER procedure requires 5770SS1 Option 33 - Portable Application Solutions Environment (PASE).

Authorization: The caller must have:

- *IOSYSCFG special authority, and
- *RW authority to /QIBM/UserData/OS400/TCPIP/NTP/ntp.conf

► REMOVE_TIME_SERVER — (— *time-server* —) ◄

TIME_SERVER — =>

The schema is QSYS2.

time-server A character or graphic string that identifies the DNS name of the NTP server to be removed from the configuration.

Example

- Remove time.domain.name.com as a preferred time server

```
CALL QSYS2.REMOVE_TIME_SERVER(TIME_SERVER =>'time.domain.name.com');
```

SERVER_SBS_CONFIGURATION view

The SERVER_SBS_CONFIGURATION view returns subsystem routing information for some IBM i servers. When a client attempts to use TCP/IP to form a connection to a server listed in this view, an attempt is made to attach to a prestart job in the subsystem configured for that server.

The information returned by this view is similar to the information shown by IBM Navigator for i in Network > Servers. For information about users who have alternate subsystem configurations for some IBM i servers, see “SERVER_SBS_ROUTING view” on page 594.

The QSYS2.SET_SERVER_SBS_ROUTING procedure can be used to modify entries shown in this view.

Authorization: None required.

The following table describes the columns in the view. The system name is SERVER_CFG. The schema is QSYS2.

Table 130. SERVER_SBS_CONFIGURATION view

Column Name	System Column Name	Data Type	Description
SERVER_NAME	SERVER	VARCHAR(10)	The server name for this entry.
SERVER_SEARCH_ORDER	SEARCH_ORD	INTEGER Nullable	The search order for selecting this subsystem routing entry. The order starts with one for each SERVER_NAME value. Contains the null value for the default entry for each server. This is the entry that will be selected if no other specific entry is selected.
SUBSYSTEM	SUBSYSTEM	VARCHAR(10)	The subsystem name that incoming connections for this server will be rerouted to when this entry is selected.

Table 130. SERVER_SBS_CONFIGURATION view (continued)

Column Name	System Column Name	Data Type	Description
ALLOW_ROLLOVER	ROLLOVER	VARCHAR(3)	Indicates how incoming connection requests are handled if the subsystem is not active. NO Incoming connections will be rejected. YES Incoming connections will be routed to a batch immediate job in the subsystem where the server daemon job is active.
IP_ADDRESS_TYPE	ADDR_TYPE	CHAR(4) Nullable	The type of IP address for IP_ADDRESS_START and IP_ADDRESS_END. IPV4 The addresses are IPv4 addresses. IPV6 The addresses are IPv6 addresses. Contains the null value if no IP addresses are used for defining this row.
IP_ADDRESS_START	IP_START	VARCHAR(45) Nullable	The IP address for alternate routing or the starting IP address for a range of IP addresses. Contains the null value if no IP addresses are used for defining this row.
IP_ADDRESS_END	IP_END	VARCHAR(45) Nullable	The ending IP address for a range of IP addresses. Contains the null value if this row is not for a range of IP addresses.
SUBNET_MASK	SUBNET	VARCHAR(15) Nullable	The actual value of the subnet mask in dotted-decimal notation. Contains the null value if IP_ADDRESS_START is null, there is no subnet mask, or this is an IPv6 address.
PREFIX_LENGTH	PREFIX	INTEGER Nullable	The prefix length defines how many of the left-most bits of the IPv6 address make up the prefix. Contains the null value if IP_ADDRESS_START is null or an IPv4 address.
TEXT_DESCRIPTION	TEXT	VARCHAR(50) Nullable	Descriptive text for this entry. Contains the null value if there is no descriptive text.

Example

List all the servers that have alternate subsystems defined.

```
SELECT * FROM QSYS2.SERVER_SBS_CONFIGURATION
ORDER BY SERVER_NAME, SERVER_SEARCH_ORDER;
```

SERVER_SBS_ROUTING view

The SERVER_SBS_ROUTING view returns information about the users who have alternate subsystem configurations for some IBM i servers. When a user profile listed in this view attempts to use TCP/IP to form a connection to the server, an attempt is made to use the alternate subsystem instead of the default subsystem for that server.

For subsystem routing information for some IBM i servers, see [“SERVER_SBS_CONFIGURATION view” on page 593](#).

The QSYS2.SET_SERVER_SBS_ROUTING procedure can be used to modify the values shown in this view.

Authorization: The caller must have *OBJOPR and *READ authority to the *USRPRF.

The following table describes the columns in the view. The system name is SRVR_RTG. The schema is QSYS2.

Table 131. SERVER_SBS_ROUTING view

Column Name	System Column Name	Data Type	Description
AUTHORIZATION_NAME	USER_NAME	VARCHAR(128)	The user profile that has an alternate subsystem configuration.
QRWTSRVR_SUBSYSTEM	DRDADDMSBS	VARCHAR(10) Nullable	The subsystem name that incoming DRDA or DDM connections will be rerouted to. Contains the null value when an alternate subsystem for this server has not been configured for this user.
QZDASOINIT_SUBSYSTEM	ZDASBS	VARCHAR(10) Nullable	The subsystem name that incoming database server connections will be rerouted to. Contains the null value when an alternate subsystem for this server has not been configured for this user.
QZRCSRVS_SUBSYSTEM	ZRCSBS	VARCHAR(10) Nullable	The subsystem name that incoming remote command server connections will be rerouted to. Contains the null value when an alternate subsystem for this server has not been configured for this user.
QZHQSSRV_SUBSYSTEM	ZHQBS	VARCHAR(10) Nullable	The subsystem name that incoming data queue server connections will be rerouted to. Contains the null value when an alternate subsystem for this server has not been configured for this user.
QZSCSRVS_SUBSYSTEM	ZSCSBS	VARCHAR(10) Nullable	The subsystem name that incoming central server connections will be rerouted to. Contains the null value when an alternate subsystem for this server has not been configured for this user.
QNPSERVS_SUBSYSTEM	NPSSBS	VARCHAR(10) Nullable	The subsystem name that incoming network print server connections will be rerouted to. Contains the null value when an alternate subsystem for this server has not been configured for this user.
QPWFSESRVSO_SUBSYSTEM	PWFSBS	VARCHAR(10) Nullable	The subsystem name that incoming file server connections will be rerouted to. Contains the null value when an alternate subsystem for this server has not been configured for this user.
QDBMSRVR_SUBSYSTEM	DBMSBS	VARCHAR(10) Nullable	The subsystem name that incoming database mirror connections will be rerouted to. Contains the null value when an alternate subsystem for this server has not been configured for this user.
QRWTSRVR_ROLLOVER	DRDA_RO	VARCHAR(3)	Indicates how incoming DRDA or DDM connection requests are handled if the specified subsystem cannot be used. NO Incoming connections will be rejected. YES Incoming connections will be routed to the default subsystem. If an alternate subsystem is not configured for this server, YES is the default.
QZDASOINIT_ROLLOVER	ZDA_RO	VARCHAR(3)	Indicates how incoming database server connection requests are handled if the specified subsystem cannot be used. NO Incoming connections will be rejected. YES Incoming connections will be routed to the default subsystem. If an alternate subsystem is not configured for this server, YES is the default.
QZRCSRVS_ROLLOVER	ZRC_RO	VARCHAR(3)	Indicates how incoming remote command connection requests are handled if the specified subsystem cannot be used. NO Incoming connections will be rejected. YES Incoming connections will be routed to the default subsystem. If an alternate subsystem is not configured for this server, YES is the default.

Table 131. SERVER_SBS_ROUTING view (continued)

Column Name	System Column Name	Data Type	Description
QZHQSSRV_ROLLOVER	ZHQ_RO	VARCHAR(3)	Indicates how incoming data queue server connection requests are handled if the specified subsystem cannot be used. NO Incoming connections will be rejected. YES Incoming connections will be routed to the default subsystem. If an alternate subsystem is not configured for this server, YES is the default.
QZSCSRVS_ROLLOVER	ZSC_RO	VARCHAR(3)	Indicates how incoming central server connection requests are handled if the specified subsystem cannot be used. NO Incoming connections will be rejected. YES Incoming connections will be routed to the default subsystem. If an alternate subsystem is not configured for this server, YES is the default.
QNPSERVS_ROLLOVER	NPS_RO	VARCHAR(3)	Indicates how incoming network print server connection requests are handled if the specified subsystem cannot be used. NO Incoming connections will be rejected. YES Incoming connections will be routed to the default subsystem. If an alternate subsystem is not configured for this server, YES is the default.
QPWFSEVS_ROLLOVER	PWF_RO	VARCHAR(3)	Indicates how incoming file server connection requests are handled if the specified subsystem cannot be used. NO Incoming connections will be rejected. YES Incoming connections will be routed to the default subsystem. If an alternate subsystem is not configured for this server, YES is the default.
QDBMSRVR_ROLLOVER	DBM_RO	VARCHAR(3)	Indicates how incoming database mirror connection requests are handled if the specified subsystem cannot be used. NO Incoming connections will be rejected. YES Incoming connections will be routed to the default subsystem. If an alternate subsystem is not configured for this server, YES is the default.

The following table shows the servers that can have alternate subsystem configurations.

Server Description	Server Name
Central server	QZSCSRVS
Database server	QZDASOINIT
Data queue server	QZHQSSRV
Db2 Mirror server	QDBMSRVR
DDM	QRWTSRVR
DRDA	QRWTSRVR
File server	QPWFSEVS
Network print server	QNPSERVS
Remote command server	QZRCSRVS

Example

Query subsystem routing information for all user profiles:

```
SELECT * FROM QSYS2.SERVER_SBS_ROUTING
```

SET_SERVER_SBS_ROUTING procedure

The SET_SERVER_SBS_ROUTING procedure provides the ability to configure a server to use an alternate subsystem. This can be for all users of the server, for a specific user profile, or by IP address.

This procedure allows an administrator to reposition certain connections to a server into an alternate, non-default, subsystem. When configured, new incoming TCP/IP server connections will use the alternate subsystem.

Connections to be re-routed can be defined three ways.

1. A server's default subsystem for all connections.
2. For an IP address or a range of IP addresses.
3. For a specific user profile. The user profile can be a group profile or a supplemental group profile. Some servers do not support routing by specific user profile; refer to [Table 133 on page 597](#) for details.

To select the subsystem for a connection, the routing logic first looks for an IP address routing entry for the server. If there is not one, it will route according to the defined default. The routing process will then immediately check for a configured entry for the specific user profile and attempt to route to its subsystem. For example, if a server is configured to route to a user-specified subsystem by incoming TCP/IP address as well as by user profile, the job will first attempt to route to the subsystem configured for that TCP/IP address and then immediately attempt to route to the subsystem configured for the connecting user profile. Understanding this order of processing is key to recognizing failures that may occur.

By default, all users for the following servers use the listed default subsystem:

Server Description	Server Name	Default subsystem	Supports routing by user	Supports routing by IP address
Central server	QZSCSRVS	QUSRWRK	Yes	Yes
Database server	QZDASOINIT	QUSRWRK	Yes	Yes
Data queue server	QZHQSSRV	QUSRWRK	Yes	Yes
Db2 Mirror server	QDBMSRVR	QUSRWRK	Yes	Yes
DDM	QRWTSRVR	QUSRWRK	Yes	Yes
DRDA	QRWTSRVR	QUSRWRK	Yes	Yes
File server	QPWFSEVS	QSERVER	Yes	Yes
IBM i NetServer	QZLSFILE	QSERVER	No	Yes
Network print server	QNPSEVS	QUSRWRK	Yes	Yes
Remote command server	QZRCSRVS	QUSRWRK	Yes	Yes
Sign-on server	QZSOSIGN	QUSRWRK	No	Yes

For more information on these servers see [DRDA and DDM overview](#) and [Host servers by function](#).

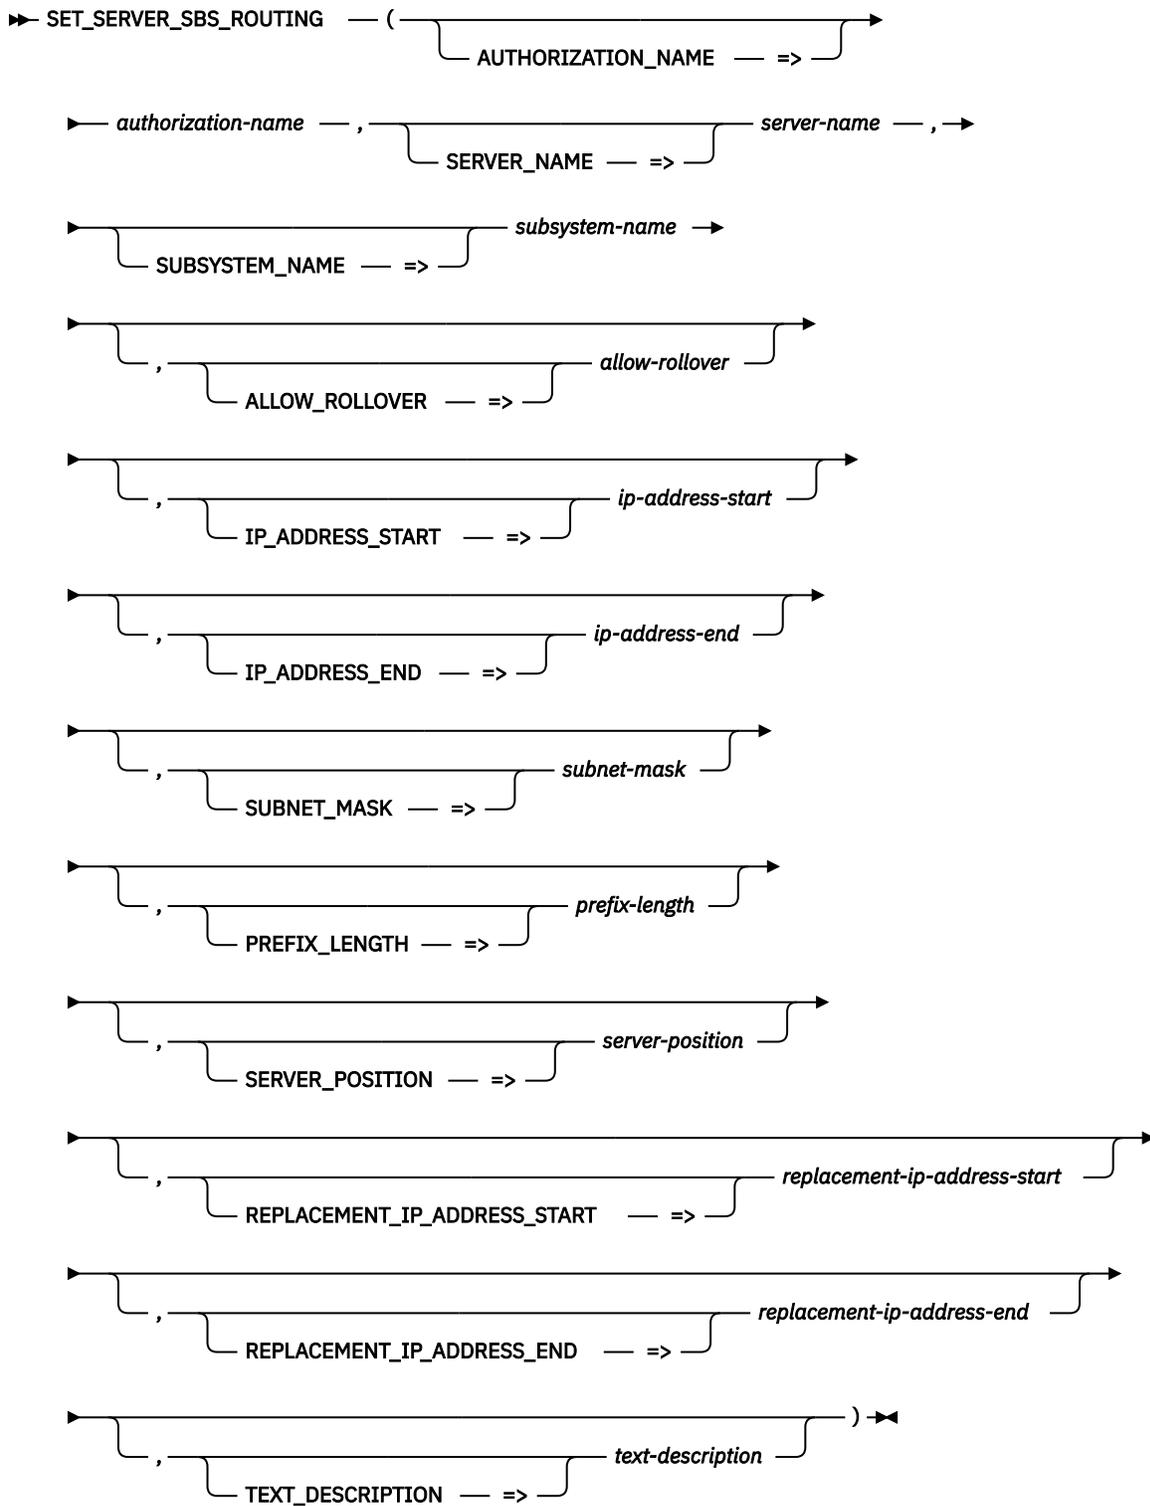

Routing information set by this procedure can be queried using the following views:

- For routing for a specific user, see [“SERVER_SBS_ROUTING view”](#) on page 594.

- For routing that applies to all users and IP addresses, see [“SERVER_SBS_CONFIGURATION view” on page 593](#).

Authorization:

- When *authorization-name* specifies a user profile, the caller must have:
 - *SECADM special authority, and
 - *OBJMGT and *USE authorities to the user profile.
- When *authorization-name* is *ALL, the caller must have *IOSYSCFG special authority.

The schema is QSYS2.

authorization-name

A character or graphic string expression that identifies an existing user or group profile name. Can contain the following special value:

- *ALL** This configuration applies to all users of the server unless a specific alternate subsystem is defined for the user. To route using an IP address, *ALL must be specified.

server-name A character or graphic string expression that identifies the name of the server job that will be rerouted to *subsystem-name* for all users or for *authorization-name* whenever a connection is initiated to this server job. Valid *server-name* values are:

- QDBMSRVR
- QNPSERVS
- QPWFSERVSO
- QRWTSRVR
- QZDASOINIT
- QZHQSSRV
- QZLSFILE
- QZRCSRVS
- QZSCSRVS
- QZSOSIGN

The special value of *ALL can be used to indicate all of the *server-name* values that support routing by user, listed in [Table 133 on page 597](#). *ALL is not allowed if *authorization-name* is *ALL.

subsystem-name A character or graphic string expression that identifies the name of the subsystem that will be used, instead of the default subsystem, whenever a connection is initiated to the specified server job. No validation is done on *subsystem-name* to make sure it is a valid and active subsystem.

If *subsystem-name* is the null value:

- When *authorization-name* is not *ALL, the configuration entry for the *server-name* for this *authorization-name* will be cleared. The default subsystem will revert to the system supplied default as shown in [Table 133 on page 597](#).
- When *authorization-name* is *ALL:
 - If *ip-address-start* is not specified, the configuration entry for the *server-name* will be removed, reverting incoming connections to use the default subsystem.
 - If *ip-address-start* is specified, the configuration entry identified by the *server-name* and the specified *ip-address-start* will be removed.

allow-rollover A character or graphic string expression that indicates the action to take if the specified subsystem is not active. Valid values are:

NO If the alternate subsystem cannot be used, the connection request will fail.

YES If the alternate subsystem cannot be used, the connection request will succeed by using a batch immediate job in the default subsystem.

If this parameter is not specified, the default is YES.

When routing for the server (*authorization-name* is *ALL), the following parameters are allowed:

ip-address-start A character or graphic string expression that identifies an IPv4 or IPv6 address for a single client.

- If *ip-address-end* is not specified, this is a specific IPv4 or IPv6 address.
- If *ip-address-end* is specified, this is the start value for a range of IPv4 or IPv6 addresses for a group of clients. When more than one range of addresses is defined for a server, the IP address ranges cannot overlap.

When *ip-address-start* is specified, either *subnet-mask* or *prefix-length* can be specified.

This parameter can only be specified when *authorization-name* is *ALL. If this parameter is not specified, the default is the null value, meaning that the connection will not be routed by IP address.

ip-address-end A character or graphic string expression that identifies the end value for a range of IPv4 or IPv6 addresses for a group of clients. This parameter can only be specified if *ip-address-start* is specified.

This parameter can only be specified when *authorization-name* is *ALL. If this parameter is not specified, the default is the null value.

subnet-mask A character or graphic string expression that identifies the IPv4 subnet mask.

This parameter can only be specified when *authorization-name* is *ALL. *subnet-mask* cannot be specified if *prefix-length* is specified.

prefix-length An integer value that defines how many bits of the IPv6 address are in the prefix.

When this parameter is specified with a non-zero value, the IP address parameters are treated as IPv6 addresses. It is required for an IPv6 address.

This parameter can only be specified when *authorization-name* is *ALL. *prefix-length* cannot be specified if *subnet-mask* is specified.

server-position An integer value that indicates the position for this entry for *server-name* in the list returned by the QSYS2.SERVER_SBS_CONFIGURATION view in the SERVER_SEARCH_ORDER column. This value represents the search order to be used when determining which entry to use for routing.

This entry will be added at the specified position in the list for *server-name*. An existing entry at this position and all later entries will have their search order position incremented by one. If this value is greater than the current number of entries for the server, this entry will be added to the end of the server's list.

This parameter can only be specified when *authorization-name* is *ALL. If this parameter is not specified, the default is the null value. This means that a new entry will be added to the end of the list, and a change to an existing IP address entry will remain in its current position.

replacement-ip-address-start A character or graphic string expression that identifies a replacement IPv4 or IPv6 address for the specified *ip-address-start* address. *ip-address-start* must already be configured for this server.

This parameter can only be specified when *authorization-name* is *ALL. If this parameter is not specified, the default is the null value.

replacement-ip-address-end A character or graphic string expression that identifies a replacement IPv4 or IPv6 address for the specified *ip-address-end* address. *ip-address-end* must already be configured for this server.

This parameter can only be specified when *authorization-name* is *ALL. If this parameter is not specified, the default is the null value.

text-description A character or graphic string expression describing this configuration.

This parameter can only be specified when *authorization-name* is *ALL. If this parameter is not specified, the default is the null value.

Notes

The prestart job entry must specify the *subsystem-name*.

When ALLOW_ROLLOVER is YES: if, for any reason, the alternate subsystem cannot be used to establish the connection, the connection will run in the default subsystem (or the last subsystem it was successfully routed to) as a batch immediate job. An example of this would be if the *authorization-name* does not have *USE authority to the subsystem description for *subsystem-name*.

If routing has been configured for a user profile, the user profile configuration will always be used, regardless of any group profile configuration or a subsystem configuration for *ALL. A group profile configuration will take precedence over any supplemental group profile configuration.

Examples

- Set new incoming DRDA and DDM TCP/IP server connections for user profile TIM to route to subsystem TIMSUBSYS.

```
CALL QSYS2.SET_SERVER_SBS_ROUTING('TIM', 'QRWTSRVR', 'TIMSUBSYS')
```

- Reset incoming DRDA and DDM TCP/IP server connections for user profile TIM back to the original default subsystem.

```
CALL QSYS2.SET_SERVER_SBS_ROUTING('TIM', 'QRWTSRVR', NULL)
```

- Configure group profile ADMIN to use an alternate subsystem for all of the servers supported by this procedure. Do not permit a connection request to rollover to use QUSRWRK.

```
CALL QSYS2.SET_SERVER_SBS_ROUTING('ADMIN', '*ALL', 'ADHOC SBS', 'NO')
```

- Set new incoming Database server TCP/IP connections for user profile BOB to route to subsystem BOBSUBSYS.

```
CALL QSYS2.SET_SERVER_SBS_ROUTING('BOB', 'QZDASOINIT', 'BOBSUBSYS')
```

- Construct a subsystem that will constrain the amount of system resources available to users who are known to execute expensive queries.

```
CRTSBS SBSD(QGPL/ADHOC SBS) POOLS((1 *BASE)) TEXT('Adhoc DRDA users SBS')
CRTCLS CLS(QGPL/ADHOC CLS) RUNPTY(55) TIMESLICE(100) TEXT('Adhoc DRDA users class')
ADDPJE SBSD(QGPL/ADHOC SBS) PGM(QSYS/QRWTSRVR) JOB(QGPL/QDFTSVR) CLS(QGPL/ADHOC CLS)
STRSBS SBSD(QGPL/ADHOC SBS)
CALL QSYS2.SET_SERVER_SBS_ROUTING('SLFUSER', 'QRWTSRVR', 'ADHOC SBS')
```

- Set all Db2 Mirror connections to run in subsystem QDBMWRK. This separates the jobs from the default QUSRWRK subsystem. Make sure the pool for the subsystem description has sufficient memory available.

```
CRTSBS SBSD(QSYS/QDBMWRK) POOLS((1 *BASE))
ADDPJE SBSD(QDBMWRK) PGM(QSYS/QDBMSRVR) USER(QUSER) STRJOBS(*YES) INLJOBS(50) THRESHOLD(20)
ADLJOBS(40) MAXJOBS(*NOMAX) JOB(*PGM) JOB(QSYS/QDBMSRVR) MAXUSE(*NOMAX) WAIT(*YES)
POOLID(1) CLS(QSYS/QSYSCLS20 *CALC *NONE *CALC)
STRSBS QSYS/QDBMWRK
CALL QSYS2.SET_SERVER_SBS_ROUTING('*ALL', 'QDBMSRVR', 'QDBMWRK')
```

- Define a complete block of IP addresses to be routed to subsystem NEWSBS for QZDASOINIT jobs. The range includes all addresses in the address block of 192.168.1.0-255

```
CALL QSYS2.SET_SERVER_SBS_ROUTING(AUTHORIZATION_NAME => '*ALL',
SERVER_NAME => 'QZDASOINIT',
IP_ADDRESS_START => '192.168.1.0',
SUBNET_MASK => '255.255.255.0',
SUBSYSTEM_NAME => 'NEWSBS')
```

- Define a range of IP addresses for QZDASOINIT jobs to be routed to a subsystem NEWSBS.

```
CALL QSYS2.SET_SERVER_SBS_ROUTING(AUTHORIZATION_NAME => '*ALL',
SERVER_NAME => 'QZDASOINIT',
IP_ADDRESS_START => '192.168.1.10',
```

```
IP_ADDRESS_END => '192.168.1.30',
SUBSYSTEM_NAME => 'NEWSBS')
```

- Change the range of IP addresses for QZDASOINIT jobs that are routed to a subsystem NEWSBS.

```
CALL QSYS2.SET_SERVER_SBS_ROUTING(AUTHORIZATION_NAME => '*ALL',
SERVER_NAME => 'QZDASOINIT',
IP_ADDRESS_START => '192.168.1.10',
IP_ADDRESS_END => '192.168.1.30',
REPLACEMENT_IP_ADDRESS_START => '192.168.1.10',
REPLACEMENT_IP_ADDRESS_END => '192.168.1.100',
SUBSYSTEM_NAME => 'NEWSBS')
```

- Remove a range of IP addresses for QZRCSRVS jobs.

```
CALL QSYS2.SET_SERVER_SBS_ROUTING(AUTHORIZATION_NAME => '*ALL',
SERVER_NAME => 'QZRCSRVS',
SUBSYSTEM_NAME => NULL,
IP_ADDRESS_START => '192.168.1.10',
IP_ADDRESS_END => '192.168.1.100')
```

- Add a new entry in the first position in the prioritized list of IP address routing entries for the QPWFSEVSO server.

```
CALL QSYS2.SET_SERVER_SBS_ROUTING(AUTHORIZATION_NAME => '*ALL',
SERVER_NAME => 'QPWFSEVSO',
SUBSYSTEM_NAME => 'SBS1',
IP_ADDRESS_START => '192.168.2.20',
SERVER_POSITION => 1,
TEXT_DESCRIPTION => 'Top rule for QPWFSEVSO')
```

Related information

[Use of prestart jobs](#)

TCPIP_INFO view

The TCPIP_INFO view contains TCP/IP information for the current host connection.

Authorization: None required.

The following table describes the columns in the view. The schema is QSYS2.

Table 134. TCPIP_INFO view

Column Name	System Column Name	Data Type	Description
COLLECTED_TIME	COLLE00001	TIMESTAMP Nullable	Timestamp indicating when this row of information was collected.
LOCAL_HOST_NAME	LOCAL00001	VARCHAR(255) Nullable	TCP/IP host name of the local system.
CLIENT_IP_ADDRESS_TYPE	CLIEN00001	VARCHAR(10) Nullable	TCP/IP address version of the client.
CLIENT_IP_ADDRESS	CLIEN00002	VARCHAR(45) Nullable	TCP/IP address of the client.
CLIENT_PORT_NUMBER	CLIEN00003	INTEGER Nullable	TCP/IP port of the client.
SERVER_IP_ADDRESS_TYPE	SERVE00001	VARCHAR(10) Nullable	TCP/IP address version of the server.
SERVER_IP_ADDRESS	SERVE00002	VARCHAR(45) Nullable	TCP/IP address of the server.
SERVER_PORT_NUMBER	SERVE00003	INTEGER Nullable	TCP/IP port number of the server.

Table 134. TCPIP_INFO view (continued)

Column Name	System Column Name	Data Type	Description
HOST_VERSION	HOST_00001	VARCHAR(10) Nullable	Operating system version.

Example

Return information about the current host connection.

```
SELECT * FROM QSYS2.TCPIP_INFO
```

TIME_PROTOCOL_INFO view

The TIME_PROTOCOL_INFO view returns information about Network Time Protocol (NTP) servers that are configured.

The TIME_PROTOCOL_INFO view requires 5770SS1 Option 33 - Portable Application Solutions Environment (PASE).

Authorization: The caller must have *IOSYSCFG special authority.

The following table describes the columns in the view. The system name is TIME_PROTO. The schema is QSYS2.

Table 135. TIME_PROTOCOL_INFO view

Column Name	System Column Name	Data Type	Description
TIME_SERVER	SERVER	VARCHAR(256)	The DNS domain name for the NTP server.
PREFERRED_INDICATOR	PREFERRED	VARCHAR(3)	Indicates whether this server is a preferred time source in the NTP client configuration NO This is not a preferred time server. YES This is a preferred time server.

Example

- List all the configured time protocol servers.

```
SELECT * FROM QSYS2.TIME_PROTOCOL_INFO;
```

Configuration Services

These services provide configuration information.

CONFIGURATION_STATUS view

The CONFIGURATION_STATUS view returns one row for each configuration description on the system.

The information returned is similar to the detail returned by the Retrieve Configuration Status (RTVCFGSTS) CL command.

Authorization: See Note below.

The following table describes the columns in the view. The system name is CONFIG_STS. The schema is SYSTOOLS.

Table 136. CONFIGURATION_STATUS view

Column Name	System Column Name	Data type	Description
OBJECT_NAME	NAME	VARCHAR(10)	The name of the configuration description.

Table 136. CONFIGURATION_STATUS view (continued)

Column Name	System Column Name	Data type	Description
OBJECT_TYPE	TYPE	VARCHAR(5)	The type of configuration description. *CTLD Controller description *DEVD Device description *LIND Line description *NWID Network interface description *NWSID Network interface description
OBJECT_ATTRIBUTE	ATTR	VARCHAR(10)	The object attribute of the configuration description.
STATUS	STATUS	INTEGER	The status value.
STATUS_DESCRIPTION	STATUS_D	VARCHAR(20)	The descriptive status value.
TEXT_DESCRIPTION	TEXT	VARCHAR(50) Nullable	The text description for the configuration object. Contains the null value if a description is not available.
CREATE_TIMESTAMP	CREATED	TIMESTAMP(0)	The timestamp when the configuration description was created.
LAST_USED_TIMESTAMP	LAST_USED	TIMESTAMP(0) Nullable	The timestamp when the configuration description was most recently used. Contains the null value if a value is not available or it has not been used.
CHANGE_TIMESTAMP	CHANGED	TIMESTAMP(0)	The timestamp when the configuration description was most recently changed.

Note

This function is provided in the SYSTOOLS schema as an example of how SQL can return information from a CL program. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

List the status of all controllers.

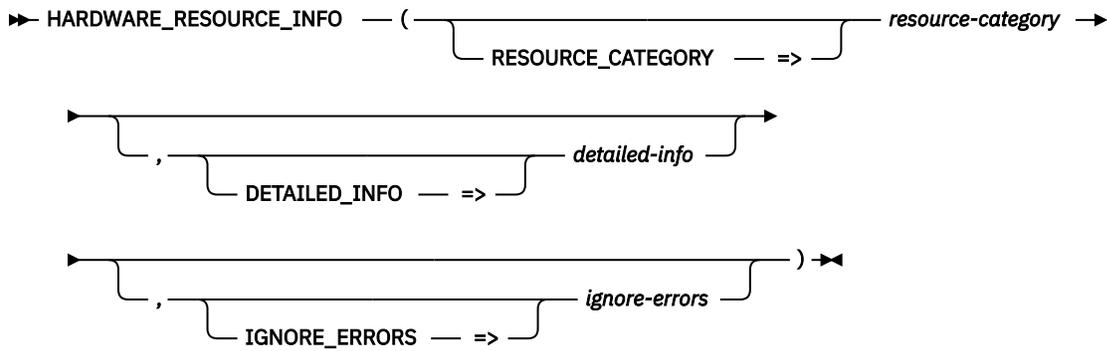

```
SELECT OBJECT_NAME, OBJECT_ATTRIBUTE, STATUS_DESCRIPTION, TEXT_DESCRIPTION
FROM SYSTOOLS.CONFIGURATION_STATUS
WHERE OBJECT_TYPE = '*CTLD';
```

HARDWARE_RESOURCE_INFO table function

The HARDWARE_RESOURCE_INFO table function returns information about configured hardware resources.

The information returned is similar to the detail available through the STRSST Hardware Service Manager interface and from the Retrieve Hardware Resource List (QGYRHRL, QgyRtvHdwRscList) and Retrieve Hardware Resource Information (QGYRHRI, QgyRtvHdwRscInfo) APIs.

Authorization: None required.

The schema is QSYS2.

resource-category A character or graphic string expression that identifies the category of resource information to be returned.

ADAPTER Coupled system adapter resources

ALL Information for all resource categories

COMM Communication resources

CRYPTO Cryptographic resources

OPTICAL Optical resources

PROCESSOR Processor resources

STORAGE Storage device resources, including tape and optical resources

TAPE Tape resources

WORKSTATION Local workstation resources

detailed-info A character or graphic string expression that indicates the type of information to be returned.

NO Only the basic information is returned for the resource. This is the information in the columns prior to the SERIAL_NUMBER column. This is the default.

YES All the information available for the resource is returned.

ignore-errors A character or graphic string expression that identifies what to do when an error is encountered.

NO An error is returned.

YES A warning is returned.
No row is returned when an error is encountered. This is the default.

The result of the function is a table containing multiple rows with the format shown in the following table. All the columns are nullable.

Table 137. HARDWARE_RESOURCE_INFO table function

Column Name	Data Type	Description
ID	INTEGER	A generated unique identifier for this row in the result set.
PARENT_ID	INTEGER	The ID of the parent to this resource. Contains the null value if this resource is not a child of another resource.

Table 137. *HARDWARE_RESOURCE_INFO* table function (continued)

Column Name	Data Type	Description
RESOURCE_CATEGORY	VARCHAR(11)	The hardware resource category of the resource for which information is returned. ADAPTER Coupled system adapter resources. COMM Communication resources. CRYPTO Cryptographic resources. OPTICAL Optical resources. PROCESSOR Processor resources. STORAGE Storage device resources. TAPE Tape resources. WORKSTATION Local workstation resources.
RESOURCE_NAME	VARCHAR(10)	The name of the resource.
STATUS	VARCHAR(12)	Whether the resource is operational. INOPERATIVE Resource is not operational. NOT DETECTED Presence of resource could not be detected. OPERATIONAL Resource is operational. Contains the null value if STATUS does not apply to this resource or could not be determined.
EXTENDED_STATUS	VARCHAR(14)	The extended hardware status of the resource. DEGRADED Resource is operational but performance is degraded. DISABLED Resource is currently disabled. ERROR Resource is operational but errors have been detected. FAILED Resource has failed. INOPERATIVE Resource is not operational. NO POWER Resource is powered off or no power is being supplied to it. NOT CONNECTED Resource is not connected. NOT INSTALLED Resource is not installed. OPERATIONAL Resource is operational. SOFTWARE ERROR Resource is failed due to a system software error. Contains the null value if STATUS does not apply to this resource or could not be determined.
DEVICE_TYPE	VARCHAR(4)	An identifier that represents the object type of this resource. For self-configuring tape devices, this represents the emulated device type number. A value of *TAP indicates that a self-configuring tape device is emulating a device type that contains characters outside the range of 0 to 9 and A to Z. Contains the null value if a value is not available.
DEVICE_MODEL	VARCHAR(3)	The model number of the resource. For self-configuring tape devices, this represents the emulated device model number. Contains the null value if a value is not available.
ADAPTER_SYSTEM	VARCHAR(8)	The system to which the coupled system adapter is connected. Contains the null value if a value is not available.
LAN_ADAPTER_ADDRESS	VARCHAR(12)	The network address of the LAN adapter resource. Contains the null value if a value is not available.

Table 137. *HARDWARE_RESOURCE_INFO* table function (continued)

Column Name	Data Type	Description
LINE_TYPE	VARCHAR(5)	The line type of the LAN resource. FDDI Fiber distributed data interface. TOKEN Token ring. Contains the null value if the resource has no line type.
TEXT_DESCRIPTION	VARCHAR(50)	The description of the resource. Contains the null value if there is no descriptive text.
MESSAGE_ID	CHAR(7)	The message from which TEXT_DESCRIPTION is obtained. This message is in the QCPFMSG message file in *LIBL. Contains the null value if there is no descriptive text.
RESOURCE_KIND	BINARY(24)	The resource kind field consists of 24 bytes of hexadecimal numbers. It can be divided into three 8-byte fields called Kind 1, Kind 2, and Kind 3. The system uses Kind 1, Kind 2, and Kind 3 to categorize the resource.
RESOURCE_KIND1	BINARY(8)	The value for Kind 1.
RESOURCE_KIND2	BINARY(8)	The value for Kind 2.
RESOURCE_KIND3	BINARY(8)	The value for Kind 3.
Non-null values can be returned for the following columns when DETAILED_INFO is YES		
SERIAL_NUMBER	VARCHAR(15)	The expanded unique number based on the manufacturing sequence for the resource.
SERIAL_NUMBER_SHORT	VARCHAR(10)	A unique number based on the manufacturing sequence for the resource.
PART_NUMBER	VARCHAR(12)	A manufacturing identifier that represents similar types of hardware. Contains the null value if the column does not apply to the resource.
BUS_NUMBER	INTEGER	A numerical representation of the path connection of the system processor to the card. Contains the null value if the column does not apply to the resource.
BOARD_NUMBER	INTEGER	A numerical representation of a section of the bus into which the card is plugged. Contains the null value if the column does not apply to the resource.
CARD_NUMBER	INTEGER	A numerical representation of the location of the card on the bus. Contains the null value if the column does not apply to the resource.
CARD_POSITION	VARCHAR(5)	The physical location where the device or feature is plugged into the bus. Contains the null value if the column does not apply to the resource.
FRAME_ID	VARCHAR(4)	The identifier of a frame resource. Contains the null value if the column does not apply to the resource.

Table 137. *HARDWARE_RESOURCE_INFO* table function

Column Name	Data Type	Description																
LOCATION_CODE	VARCHAR(79)	<p>The physical location of the hardware resource in the system.</p> <p>The location code field is a sequence of 0 or more location labels that when followed in order, lead to the resource location. This is the place someone could go to view, remove, or replace the piece of hardware. Location labels are etched, silk screened, or marked in other ways on hardware. The following location labels might be shown in the location code field (n represents a numerical or alphabetical identifier):</p> <table border="1"> <tbody> <tr> <td><i>Utttt.mmm.ssssss</i></td> <td>Unit location</td> </tr> <tr> <td><i>Pnn</i></td> <td>Planar location</td> </tr> <tr> <td><i>Cnn</i></td> <td>Card location</td> </tr> <tr> <td><i>Tnn</i></td> <td>Port location</td> </tr> <tr> <td><i>Dnn</i></td> <td>Device location</td> </tr> <tr> <td><i>Vnnn</i></td> <td>Virtual planar</td> </tr> <tr> <td><i>Wnnnnnnnnnnnnnnnn</i></td> <td>Worldwide port name</td> </tr> <tr> <td><i>Lnn</i></td> <td>Logical path location</td> </tr> </tbody> </table>	<i>Utttt.mmm.ssssss</i>	Unit location	<i>Pnn</i>	Planar location	<i>Cnn</i>	Card location	<i>Tnn</i>	Port location	<i>Dnn</i>	Device location	<i>Vnnn</i>	Virtual planar	<i>Wnnnnnnnnnnnnnnnn</i>	Worldwide port name	<i>Lnn</i>	Logical path location
<i>Utttt.mmm.ssssss</i>	Unit location																	
<i>Pnn</i>	Planar location																	
<i>Cnn</i>	Card location																	
<i>Tnn</i>	Port location																	
<i>Dnn</i>	Device location																	
<i>Vnnn</i>	Virtual planar																	
<i>Wnnnnnnnnnnnnnnnn</i>	Worldwide port name																	
<i>Lnn</i>	Logical path location																	

Table 137. HARDWARE_RESOURCE_INFO table function

Column Name	Data Type	Description																
LOCATION_CODE (continued)		<p>Following are the descriptions of the location labels:</p> <table border="1"> <tr> <td>Unit location</td> <td>Value of the unit enclosure identifier composed of uppercase alphabetic characters and digits. This value will often be composed of the machine type (tttt), model (mmm) and serial number (ssssss).</td> </tr> <tr> <td>Planar location</td> <td>Decimal value of the planar identifier within the unit.</td> </tr> <tr> <td>Card location</td> <td>The decimal value of the position of the card within the hardware package. This can be followed by additional card location labels that would identify the decimal value of additional card positions of the resource on the card.</td> </tr> <tr> <td>Port location</td> <td>The decimal value of the port location within the resource.</td> </tr> <tr> <td>Device location</td> <td>The decimal value of the position of the device within the hardware package.</td> </tr> <tr> <td>Virtual planar</td> <td>The decimal value of the position of the virtual planar resource within the hardware package.</td> </tr> <tr> <td>Worldwide port name</td> <td>The hexadecimal value of the worldwide port name of the resource within the hardware package. This value is usually present for fibre channel devices. It will be blank for fibre channel adapters. See the Retrieve Resource Information (QRZRSI) API and key value 169 for fibre channel adapters.</td> </tr> <tr> <td>Logical path location</td> <td>The decimal value of the logical path of the resource within the hardware package. This can be followed by additional logical path location labels that would identify the decimal value of additional logical path data of the resource on the hardware package.</td> </tr> </table> <p>This column is available only if the system supports the location code format and if the value applies for the resource. Otherwise the null value is returned.</p>	Unit location	Value of the unit enclosure identifier composed of uppercase alphabetic characters and digits. This value will often be composed of the machine type (tttt), model (mmm) and serial number (ssssss).	Planar location	Decimal value of the planar identifier within the unit.	Card location	The decimal value of the position of the card within the hardware package. This can be followed by additional card location labels that would identify the decimal value of additional card positions of the resource on the card.	Port location	The decimal value of the port location within the resource.	Device location	The decimal value of the position of the device within the hardware package.	Virtual planar	The decimal value of the position of the virtual planar resource within the hardware package.	Worldwide port name	The hexadecimal value of the worldwide port name of the resource within the hardware package. This value is usually present for fibre channel devices. It will be blank for fibre channel adapters. See the Retrieve Resource Information (QRZRSI) API and key value 169 for fibre channel adapters.	Logical path location	The decimal value of the logical path of the resource within the hardware package. This can be followed by additional logical path location labels that would identify the decimal value of additional logical path data of the resource on the hardware package.
Unit location	Value of the unit enclosure identifier composed of uppercase alphabetic characters and digits. This value will often be composed of the machine type (tttt), model (mmm) and serial number (ssssss).																	
Planar location	Decimal value of the planar identifier within the unit.																	
Card location	The decimal value of the position of the card within the hardware package. This can be followed by additional card location labels that would identify the decimal value of additional card positions of the resource on the card.																	
Port location	The decimal value of the port location within the resource.																	
Device location	The decimal value of the position of the device within the hardware package.																	
Virtual planar	The decimal value of the position of the virtual planar resource within the hardware package.																	
Worldwide port name	The hexadecimal value of the worldwide port name of the resource within the hardware package. This value is usually present for fibre channel devices. It will be blank for fibre channel adapters. See the Retrieve Resource Information (QRZRSI) API and key value 169 for fibre channel adapters.																	
Logical path location	The decimal value of the logical path of the resource within the hardware package. This can be followed by additional logical path location labels that would identify the decimal value of additional logical path data of the resource on the hardware package.																	
IO_BUS_ADDRESS	INTEGER	<p>The I/O bus address of the resource.</p> <p>Contains the null value if the column does not apply to the resource.</p>																
ADAPTER_ADDRESS	INTEGER	<p>The adapter address of the resource.</p> <p>Contains the null value if the column does not apply to the resource.</p>																
DEVICE_ADDRESS	INTEGER	<p>The device address of the resource.</p> <p>Contains the null value if the column does not apply to the resource.</p>																
DEVICE_POSITION	VARCHAR(5)	<p>The relative device position of the resource.</p> <p>Contains the null value if the column does not apply to the resource.</p>																
CONTROLLER_ADDRESS	INTEGER	<p>The controller address of the resource.</p> <p>Contains the null value if the column does not apply to the resource.</p>																

Table 137. *HARDWARE_RESOURCE_INFO* table function (continued)

Column Name	Data Type	Description
SYSTEM_PROCESSOR_FEATURE_CODE	CHAR(4)	The processor feature code level of the system. A value is returned for this column only if the RESOURCE_KIND3 value of the hardware resource indicates that the resource provides system information (X'0000000000080000'). Contains the null value if the column does not apply to the resource.
PROCESSOR_FEATURE_CODE	CHAR(4)	The processor feature, which corresponds to the processor capacity of the system. Contains the null value if the column does not apply to the resource.
INTERACTIVE_FEATURE_CODE	CHAR(4)	The interactive feature of the system. This feature defines the portion of the processor that can be used to perform interactive work. Contains the null value if the column does not apply to the resource.
SHARED_SESSION_NUMBER	INTEGER	The shared session number of the resource. Contains the null value if the column does not apply to the resource.
PORT_NUMBER	INTEGER	The port number of the resource. Contains the null value if the column does not apply to the resource.
LAN_SPEED	VARCHAR(12)	The LAN speed for communications ports. 4M 16M 4M AND 16M 25M 34M 45M 100M 155M 10M AND 100M 10M TO 1G 1G 10G 1G AND 10G 25G 40G 50G 56G 100G 1G TO 100G 1G TO 25G Contains the null value if the column does not apply to the resource.
LINK_AGGREGATION	VARCHAR(3)	Whether ports can be aggregated to compose an aggregate link. NO Link aggregation is not supported. YES Link aggregation is supported. Contains the null value if the column does not apply to the resource.
DEFAULT_MAC_ADDRESS	BINARY(6)	The default MAC address of a LAN port. Contains the null value if the column does not apply to the resource.

Example

- Return full information about tape resources.

```
SELECT * FROM TABLE (QSYS2.HARDWARE_RESOURCE_INFO(RESOURCE_CATEGORY => 'TAPE',
                                                    DETAILED_INFO => 'YES'));
```

HARDWARE_RESOURCE_INFO view

The HARDWARE_RESOURCE_INFO view returns information about configured hardware resources.

The information returned is similar to the detail available through the STRSST Hardware Service Manager interface and from the Retrieve Hardware Resource List (QGYRHRL, QgyRtvHdwRscList) and Retrieve Hardware Resource Information (QGYRHRI, QgyRtvHdwRscInfo) APIs.

Authorization: None required.

The following table describes the columns in the view. The system name is HW_INFO. The schema is QSYS2.

Table 138. HARDWARE_RESOURCE_INFO view

Column Name	System Column Name	Data Type	Description
ID	ID	INTEGER	A generated unique identifier for this row in the result set.
PARENT_ID	PARENT_ID	INTEGER Nullable	The ID of the parent to this resource. Contains the null value if this resource is not a child of another resource.
RESOURCE_CATEGORY	CATEGORY	VARCHAR(11)	The hardware resource category of the resource for which information is returned. ADAPTER Coupled system adapter resources. COMM Communication resources. CRYPTO Cryptographic resources. OPTICAL Optical resources. PROCESSOR Processor resources. STORAGE Storage device resources. TAPE Tape resources. WORKSTATION Local workstation resources.
RESOURCE_NAME	RESOURCE	VARCHAR(10)	The name of the resource.
STATUS	STATUS	VARCHAR(12) Nullable	Whether the resource is operational. INOPERATIVE Resource is not operational. NOT DETECTED Presence of resource could not be detected. OPERATIONAL Resource is operational. Contains the null value if STATUS does not apply to this resource or could not be determined.

Table 138. *HARDWARE_RESOURCE_INFO* view (continued)

Column Name	System Column Name	Data Type	Description
EXTENDED_STATUS	EXT_STATUS	VARCHAR(14) Nullable	<p>The extended hardware status of the resource.</p> <p>DEGRADED Resource is operational but performance is degraded.</p> <p>DISABLED Resource is currently disabled.</p> <p>ERROR Resource is operational but errors have been detected.</p> <p>FAILED Resource has failed.</p> <p>INOPERATIVE Resource is not operational.</p> <p>NO POWER Resource is powered off or no power is being supplied to it.</p> <p>NOT CONNECTED Resource is not connected.</p> <p>NOT INSTALLED Resource is not installed.</p> <p>OPERATIONAL Resource is operational.</p> <p>SOFTWARE ERROR Resource is failed due to a system software error.</p> <p>Contains the null value if STATUS does not apply to this resource or could not be determined.</p>
DEVICE_TYPE	DEV_TYPE	VARCHAR(4) Nullable	<p>An identifier that represents the object type of this resource. For self-configuring tape devices, this represents the emulated device type number.</p> <p>A value of *TAP indicates that a self-configuring tape device is emulating a device type that contains characters outside the range of 0 to 9 and A to Z.</p> <p>Contains the null value if a value is not available.</p>
DEVICE_MODEL	DEV_MODEL	VARCHAR(3) Nullable	<p>The model number of the resource. For self-configuring tape devices, this represents the emulated device model number.</p> <p>Contains the null value if a value is not available.</p>
ADAPTER_SYSTEM	ADAPT_SYS	VARCHAR(8) Nullable	<p>The system to which the coupled system adapter is connected.</p> <p>Contains the null value if a value is not available.</p>
LAN_ADAPTER_ADDRESS	LAN_ADAPT	VARCHAR(12) Nullable	<p>The network address of the LAN adapter resource.</p> <p>Contains the null value if a value is not available.</p>
LINE_TYPE	LINE_TYPE	VARCHAR(5) Nullable	<p>The line type of the LAN resource.</p> <p>FDDI Fiber distributed data interface.</p> <p>TOKEN Token ring.</p> <p>Contains the null value if the resource has no line type.</p>
TEXT_DESCRIPTION	TEXT	VARCHAR(50) Nullable	<p>The description of the resource.</p> <p>Contains the null value if there is no descriptive text.</p>
MESSAGE_ID	MESSAGE_ID	CHAR(7) Nullable	<p>The message from which TEXT_DESCRIPTION is obtained. This message is in the QCPFMSG message file in *LIBL.</p> <p>Contains the null value if there is no descriptive text.</p>
RESOURCE_KIND	KIND	BINARY(24)	<p>The resource kind field consists of 24 bytes of hexadecimal numbers. It can be divided into three 8-byte fields called Kind 1, Kind 2, and Kind 3. The system uses Kind 1, Kind 2, and Kind 3 to categorize the resource.</p>
RESOURCE_KIND1	KIND1	BINARY(8)	The value for Kind 1.
RESOURCE_KIND2	KIND2	BINARY(8)	The value for Kind 2.

Table 138. *HARDWARE_RESOURCE_INFO* view

Column Name	System Column Name	Data Type	Description
RESOURCE_KIND3	KIND3	BINARY(8)	The value for Kind 3.
SERIAL_NUMBER	SERIAL_NBR	VARCHAR(15)	The expanded unique number based on the manufacturing sequence for the resource.
SERIAL_NUMBER_SHORT	SHORT_SN	VARCHAR(10)	A unique number based on the manufacturing sequence for the resource.
PART_NUMBER	PART	VARCHAR(12) Nullable	A manufacturing identifier that represents similar types of hardware. Contains the null value if the column does not apply to the resource.
BUS_NUMBER	BUS_NBR	INTEGER Nullable	A numerical representation of the path connection of the system processor to the card. Contains the null value if the column does not apply to the resource.
BOARD_NUMBER	BOARD_NBR	INTEGER Nullable	A numerical representation of a section of the bus into which the card is plugged. Contains the null value if the column does not apply to the resource.
CARD_NUMBER	CARD_NBR	INTEGER Nullable	A numerical representation of the location of the card on the bus. Contains the null value if the column does not apply to the resource.
CARD_POSITION	CARD_POS	VARCHAR(5) Nullable	The physical location where the device or feature is plugged into the bus. Contains the null value if the column does not apply to the resource.
FRAME_ID	FRAME	VARCHAR(4) Nullable	The identifier of a frame resource. Contains the null value if the column does not apply to the resource.
LOCATION_CODE	LOC_CODE	VARCHAR(79) Nullable	The physical location of the hardware resource in the system. The location code field is a sequence of 0 or more location labels that when followed in order, lead to the resource location. This is the place someone could go to view, remove, or replace the piece of hardware. Location labels are etched, silk screened, or marked in other ways on hardware. The following location labels might be shown in the location code field (n represents a numerical or alphabetical identifier):

<i>Utttt.mmm.ssssss</i>	Unit location
<i>Pnn</i>	Planar location
<i>Cnn</i>	Card location
<i>Tnn</i>	Port location
<i>Dnn</i>	Device location
<i>Vnnn</i>	Virtual planar
<i>Wnnnnnnnnnnnnnnnn</i>	Worldwide port name
<i>Lnn</i>	Logical path location

Table 138. HARDWARE_RESOURCE_INFO view

See the Retrieve Resource Information (QRZRSI) API and key value 169 for fibre channel adapters.</td> </tr> <tr> <td>Logical path location</td> <td>The decimal value of the logical path of the resource within the hardware package. This can be followed by additional logical path location labels that would identify the decimal value of additional logical path data of the resource on the hardware package.</td> </tr> </table> <p>This column is available only if the system supports the location code format and if the value applies for the resource. Otherwise the null value is returned.</p>	Unit location	Value of the unit enclosure identifier composed of uppercase alphabetic characters and digits. This value will often be composed of the machine type (ttt), model (mmm) and serial number (ssssss).	Planar location	Decimal value of the planar identifier within the unit.	Card location	The decimal value of the position of the card within the hardware package. This can be followed by additional card location labels that would identify the decimal value of additional card positions of the resource on the card.	Port location	The decimal value of the port location within the resource.	Device location	The decimal value of the position of the device within the hardware package.	Virtual planar	The decimal value of the position of the virtual planar resource within the hardware package.	Worldwide port name	The hexadecimal value of the worldwide port name of the resource within the hardware package. This value is usually present for fibre channel devices. It will be blank for fibre channel adapters. See the Retrieve Resource Information (QRZRSI) API and key value 169 for fibre channel adapters.	Logical path location	The decimal value of the logical path of the resource within the hardware package. This can be followed by additional logical path location labels that would identify the decimal value of additional logical path data of the resource on the hardware package.
Unit location	Value of the unit enclosure identifier composed of uppercase alphabetic characters and digits. This value will often be composed of the machine type (ttt), model (mmm) and serial number (ssssss).																		
Planar location	Decimal value of the planar identifier within the unit.																		
Card location	The decimal value of the position of the card within the hardware package. This can be followed by additional card location labels that would identify the decimal value of additional card positions of the resource on the card.																		
Port location	The decimal value of the port location within the resource.																		
Device location	The decimal value of the position of the device within the hardware package.																		
Virtual planar	The decimal value of the position of the virtual planar resource within the hardware package.																		
Worldwide port name	The hexadecimal value of the worldwide port name of the resource within the hardware package. This value is usually present for fibre channel devices. It will be blank for fibre channel adapters. See the Retrieve Resource Information (QRZRSI) API and key value 169 for fibre channel adapters.																		
Logical path location	The decimal value of the logical path of the resource within the hardware package. This can be followed by additional logical path location labels that would identify the decimal value of additional logical path data of the resource on the hardware package.																		
IO_BUS_ADDRESS	IOBUS_ADDR	INTEGER Nullable	<p>The I/O bus address of the resource.</p> <p>Contains the null value if the column does not apply to the resource.</p>																

Table 138. *HARDWARE_RESOURCE_INFO* view (continued)

Column Name	System Column Name	Data Type	Description
ADAPTER_ADDRESS	ADAPT_ADDR	INTEGER Nullable	The adapter address of the resource. Contains the null value if the column does not apply to the resource.
DEVICE_ADDRESS	DEV_ADDR	INTEGER Nullable	The device address of the resource. Contains the null value if the column does not apply to the resource.
DEVICE_POSITION	DEVICE_POS	VARCHAR(5) Nullable	The relative device position of the resource. Contains the null value if the column does not apply to the resource.
CONTROLLER_ADDRESS	CON_ADDR	INTEGER Nullable	The controller address of the resource. Contains the null value if the column does not apply to the resource.
SYSTEM_PROCESSOR_FEATURE_CODE	SYSPROC_FC	CHAR(4) Nullable	The processor feature code level of the system. A value is returned for this column only if the RESOURCE_KIND3 value of the hardware resource indicates that the resource provides system information (X'0000000000080000'). Contains the null value if the column does not apply to the resource.
PROCESSOR_FEATURE_CODE	PROC_FC	CHAR(4) Nullable	The processor feature, which corresponds to the processor capacity of the system. Contains the null value if the column does not apply to the resource.
INTERACTIVE_FEATURE_CODE	INTER_FC	CHAR(4) Nullable	The interactive feature of the system. This feature defines the portion of the processor that can be used to perform interactive work. Contains the null value if the column does not apply to the resource.
SHARED_SESSION_NUMBER	SHARED_SES	INTEGER Nullable	The shared session number of the resource. Contains the null value if the column does not apply to the resource.
PORT_NUMBER	PORT	INTEGER Nullable	The port number of the resource. Contains the null value if the column does not apply to the resource.

Table 138. *HARDWARE_RESOURCE_INFO* view (continued)

Column Name	System Column Name	Data Type	Description
LAN_SPEED	LAN_SPEED	VARCHAR(12) Nullable	The LAN speed for communications ports. 4M 16M 4M AND 16M 25M 34M 45M 100M 155M 10M AND 100M 10M TO 1G 1G 10G 1G AND 10G 25G 40G 50G 56G 100G 1G TO 100G 1G TO 25G Contains the null value if the column does not apply to the resource.
LINK_AGGREGATION	LINK_AGGR	VARCHAR(3) Nullable	Whether ports can be aggregated to compose an aggregate link. NO Link aggregation is not supported. YES Link aggregation is supported. Contains the null value if the column does not apply to the resource.
DEFAULT_MAC_ADDRESS	MAC_ADDR	BINARY(6) Nullable	The default MAC address of a LAN port. Contains the null value if the column does not apply to the resource.

Examples

- List all resources that are not operational.

```
SELECT RESOURCE_NAME, STATUS, EXTENDED_STATUS FROM QSYS2.HARDWARE_RESOURCE_INFO
WHERE STATUS <> 'OPERATIONAL';
```

- Return a list of all resources and their children. For each parent device (those with a PARENT_ID value that is null), it recursively finds all the children that are under the parent. In addition to some basic resource information and the ID values for the parent and child, the query returns the nesting depth of the each row and a list of all the device numbers that form the path to that row.

```
SELECT TEXT_DESCRIPTION, RESOURCE_CATEGORY, RESOURCE_NAME, ID, PARENT_ID AS PART_OF,
       LEVEL, SYS_CONNECT_BY_PATH (VARCHAR(ID), ' ') AS RESOURCE_PATH
FROM QSYS2.HARDWARE_RESOURCE_INFO
START WITH ID IN (SELECT ID FROM QSYS2.HARDWARE_RESOURCE_INFO WHERE PARENT_ID IS NULL)
CONNECT BY PRIOR ID = PARENT_ID;
```

SERVICE_TOOLS_SERVER_INFO view

The SERVICE_TOOLS_SERVER_INFO view returns one row containing the service tools server configuration information.

The information is similar to what can be changed with the Configure Service Tools Server LAN Adapter through the Start System Service Tools (STRSST) and DST interfaces.

Authorization: The caller must have *IOSYSCFG special authority and must be linked to a service tools user ID with the service tool server privilege Display/Alter/Dump.

The following table describes the columns in the view. The system name is STS_INFO. The schema is QSYS2.

Table 139. SERVICE_TOOLS_SERVER_INFO view

Column Name	System Column Name	Data Type	Description
SERVER_ENABLED	ENABLED	VARCHAR(3)	Whether the service tools server is enabled. NO The server is disabled. YES The server is enabled.
SERVER_START_ON_IPL	START_IPL	VARCHAR(3)	Whether the service tools server is configured to start on an IPL. NO The server will not be started on an IPL. YES The server will be started on an IPL.
RESOURCE_NAME	RESOURCE	VARCHAR(10)	The resource name of the communication device used by the service tools server.
SERVER_NAME	SERVER	VARCHAR(12) Nullable	The name assigned to the service tools server as seen from the network. Contains the null value if a name is not assigned for the server.
TYPE	TYPE	VARCHAR(4)	The type of adapter.
SERIAL_NUMBER	SERIAL	VARCHAR(10)	The serial number of the adapter.
IP_VERSION	IP_VERSION	CHAR(4)	The service tools server active IP versions. BOTH Both IPv4 and IPv6 addresses are active for the service tools server. IPV4 Only the IPv4 address is active for the service tools server. IPV6 Only the IPv6 address is active for the service tools server.
IPV4_ADDRESS	IPV4	VARCHAR(15) Nullable	The IPv4 address of the service tools server. Contains the null value if IPv4 is not configured for the server.
GATEWAY_ADDRESS	GATEWAY	VARCHAR(15) Nullable	The IPv4 gateway server internet address used for the connection. Contains the null value if a gateway address is not configured for the server.
SUBNET_MASK	SUBNET	VARCHAR(15) Nullable	The subnet mask in dotted-decimal notation for the IPv4 interface. Contains the null value if a subnet mask is not configured for the server or if GATEWAY_ADDRESS is null.
IPV6_ADDRESS	IPV6	VARCHAR(45) Nullable	The IPv6 address, in colon-separated hexadecimal notation, of the service tools server. Contains the null value if IPv6 is not configured for the server.
VIRTUAL_LAN_ID	LAN_ID	INTEGER Nullable	The virtual LAN ID associated with the IPv6 interface. Contains the null value if IPv6 is not configured for the server.

Table 139. SERVICE_TOOLS_SERVER_INFO view (continued)

Column Name	System Column Name	Data Type	Description
INTERFACE_ID	INTERFACE	CHAR(16)	The IPv6 interface ID. This value is used to generate stateless auto-configured IPv6 addresses.
DUPLEX	DUPLEX	VARCHAR(4)	<p>The duplex setting for the service tools server. This specifies whether the hardware can send and receive data simultaneously.</p> <p>AUTO The duplex value will be determined by the hardware using auto-negotiation.</p> <p>FULL The line communicates using full duplex mode. This means that one cable is dedicated to send data and another cable is dedicated to receive data.</p> <p>HALF The line communicates using half duplex mode. This means that the hardware must alternate between sending data and receiving data.</p>
NETWORK_SPEED	SPEED	VARCHAR(4)	<p>The network line speed in bits per second (bps).</p> <p>AUTO The line speed value will be determined by the hardware using auto-negotiation.</p> <p>10 The network speed is 10 million bits per second. This is only used for Ethernet adapter.</p> <p>100 The network speed is 100 million bits per second. This is only used for Ethernet adapter.</p> <p>1000 The network speed is 1 giga bits per second. This is only used for Ethernet adapter.</p> <p>10G The network speed is 10 giga bits per second. This is only used for Ethernet adapter.</p> <p>25G The network speed is 25 giga bits per second. This is only used for Ethernet adapter.</p> <p>100G The network speed is 100 giga bits per second. This is only used for Ethernet adapter.</p>

Example

- Show information about the service tools server configuration.

```
SELECT * FROM QSYS2.SERVICE_TOOLS_SERVER_INFO;
```

IFS Services

These services provide information about the integrated file system.

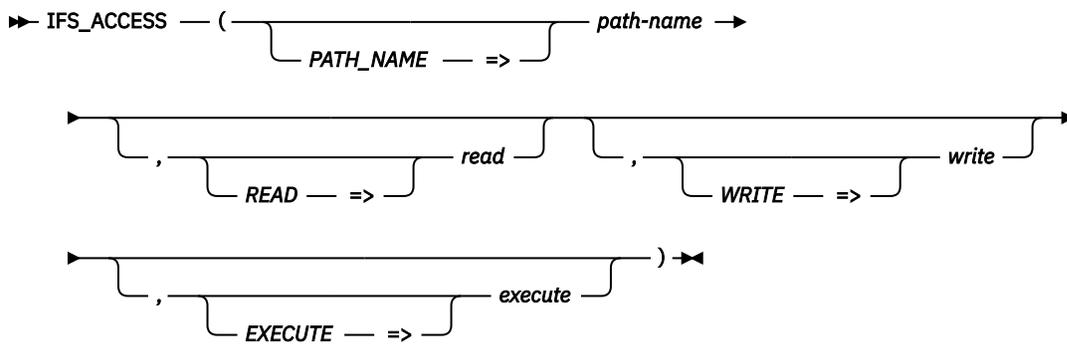

IFS_ACCESS scalar function

The IFS_ACCESS scalar function determines whether a file can be accessed in a particular manner.

This function uses the [access\(\)](#)--Determine File Accessibility API. When checking whether a job has appropriate permissions, the API looks at the real user ID (UID) and group ID (GID), not the effective IDs. Adopted authority is not used.

The function requires that Option 13 (System Openness Includes) of the IBM i operating system is installed.

Authorization: See Note below.

The schema is SYSTOOLS.

path-name A character string containing the path of the file to be checked.

read Test whether the file can be accessed for reading.

NO Do not check for read access. This is the default.

YES Check for read access.

write Test whether the file can be accessed for writing.

NO Do not check for write access. This is the default.

YES Check for write access.

execute Test whether the file can be accessed for execution.

NO Do not check for execute access. This is the default.

YES Check for execute access.

The result of the function is an integer. If the access is allowed, the function returns a value of 0. If the access returns an error, the function returns the `errno` value from the API.

Note

This function is provided in the SYSTOOLS schema as an example of how to embed a C language interface in an SQL scalar function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

Determine whether the invoker of the function has read access to `/usr/reportdata.txt`.

```
VALUES SYSTOOLS.IFS_ACCESS(PATH_NAME => '/usr/reportdata.txt',
                           READ => 'YES');
```

COMPARE_IFS table function

The COMPARE_IFS table function returns differences between the specified integrated file system (IFS) objects. This can be a single object or a subtree of objects starting from a specified directory.

Either a name compare or a full attribute compare can be requested. When comparing attributes, one row is returned for each attribute that is different between a pair of objects. The attributes are a subset of the values returned by the QSYS2.IFS_OBJECT_STATISTICS and QSYS2.IFS_OBJECT_PRIVILEGES table functions.

If no differences are found for any objects, no rows are returned.

The integrated file system supports many file systems. Only those objects in the root (/) and QOpenSys file systems can be compared. Other file systems are not supported. The specified *start-path-name1* and *start-path-name2* must be in a supported file system or an error will occur.

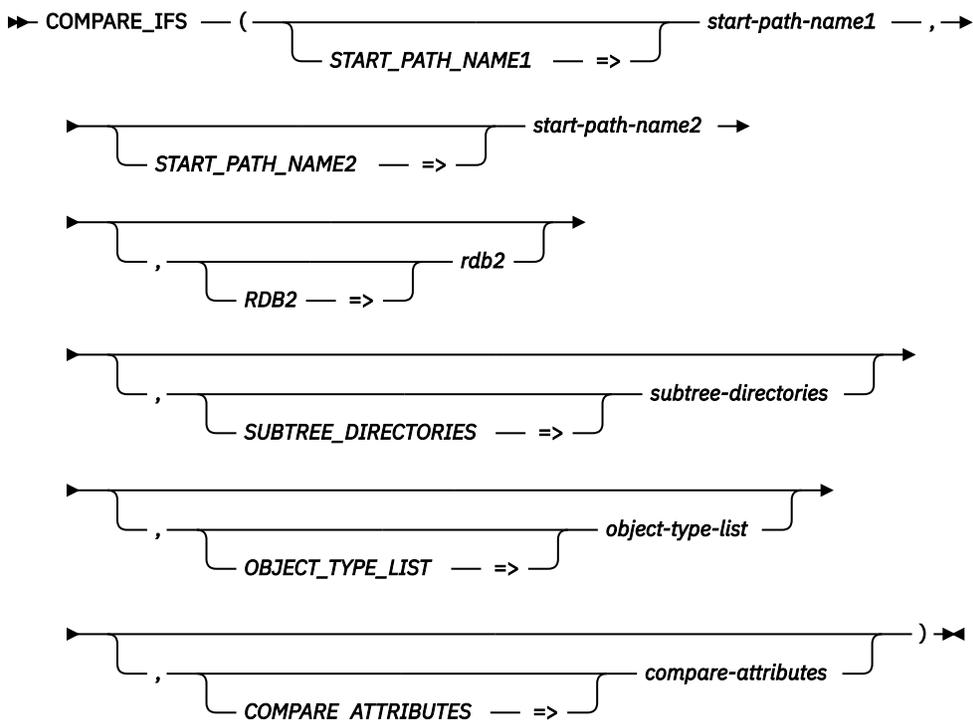

Independent auxiliary storage pool (IASP) objects are supported. *start-path-name1* and *start-path-name2* can be within an IASP.

Authorization: The caller must have:

- For each directory included in the path name used to start the compare, *X
- For each directory processed recursively, *RX and *OBJMGT
- For each object compared, *OBJMGT

The caller must have *ALLOBJ or *AUDIT special authority to compare the object auditing attributes for objects and directories. If the caller does not have this authority, a difference in these values will not be reported.

Any object for which the caller has no authority will be treated as though it does not exist.

The schema is QSYS2.

start-path-name1 An expression that returns a path name for the first object of the comparison. A relative path name is relative to the current directory. If an absolute path name is not specified, the current working directory is used in combination with the relative path name to resolve to the object. The object must exist on the current server.

If *start-path-name1* identifies an object, the single object is compared with the object provided by *start-path-name2*. If *start-path-name1* identifies a directory, the directory and all objects included in the *object-type-list* within the directory are compared with the directory provided by *start-path-name2*. When comparing directories, the *subtree-directories* parameter determines whether the compare will process subdirectories.

start-path-name2 An expression that returns a path name for the second object of the comparison. A relative path name is relative to the current directory. If an absolute path name is not specified, the current working directory on *rdb2* is used in combination with the relative path name to resolve to the object. The object must exist on the server implicitly or explicitly identified by *rdb2*.

rdb2 A character or graphic string expression that identifies the relational database where *start-path-name2* exists.
If this parameter is omitted, *start-path-name2* must exist on the current server.

subtree-directories An expression that indicates whether all subdirectories are recursively compared. This parameter only applies when comparing directories. Otherwise, the value is ignored.

NO The objects in the directory identified by *start-path-name1* are compared to the objects in the directory identified by *start-path-name2*.

YES All objects in all subdirectories for the directory identified by *start-path-name1* are compared to the corresponding objects in *start-path-name2*. This is the default.

object-type-list A list of one or more object types to be included in the compare. One or more blanks separate multiple values. The default is *ALL, indicating all object types are compared. Supported values are all of the root (/) and QOpenSys file system object types (*CHRSF, *DIR, *FIFO, *SOCKET, *STMF, *SYMLNK) and the following special values:

***ALL** Compare all root (/) and QOpenSys file system object types. These are *CHRSF, *DIR, *FIFO, *SOCKET, *STMF, and *SYMLNK.

***ALLSAV** Compare all root (/) and QOpenSys file system object types which can be saved using the Save (SAV) command. These are *CHRSF, *DIR, *FIFO, *STMF, and *SYMLNK.

compare-attributes A string expression that indicates which attributes are compared for an object.

NAMES Only the object names are compared. A row is returned for any name that is not found in both directories. This option is only allowed when comparing directories.

YES The attributes are compared for an object. A row is returned for each difference found.

If this parameter is omitted and *start-path-name1* and *start-path-name2* are directories, NAMES is the used as the default. Otherwise, YES is used.

The attributes compared for an object vary based upon the object type. Not all attributes are eligible to be compared.

The result of the function is a table containing rows with the format shown in the following table. All columns are nullable.

Table 140. COMPARE_IFS table function

Column Name	Data Type	Description
PATH_NAME1	DBCLOB(16M) CCSID 1200	The full path name of the first object for the compare.
PATH_NAME2	DBCLOB(16M) CCSID 1200	The full path name of the second object for the compare.

Table 140. COMPARE_IFS table function (continued)

Column Name	Data Type	Description
ATTRIBUTE_NAME	VARGRAPHIC(512) CCSID 1200	The name of an object attribute that is not identical.
VALUE1	VARGRAPHIC(2048) CCSID 1200	The attribute value for the first object.
VALUE2	VARGRAPHIC(2048) CCSID 1200	The attribute value for the second object.

Examples

- Compare the attributes for all objects in two subtrees. Do not look within any subdirectories.

```
SELECT * FROM TABLE(QSYS2.COMPARE_IFS(
    START_PATH_NAME1 => '/usr',
    START_PATH_NAME2 => '/usrbackup',
    SUBTREE_DIRECTORIES => 'NO',
    COMPARE_ATTRIBUTES => 'YES'
));
```

- Compare the names for all objects in two subtrees. Compare recursively through the entire set of subdirectories.

```
SELECT * FROM TABLE(QSYS2.COMPARE_IFS(
    START_PATH_NAME1 => '/usr/files.dir',
    START_PATH_NAME2 => '/usrbackup/files.dir',
    SUBTREE_DIRECTORIES => 'YES',
    COMPARE_ATTRIBUTES => 'NAMES'
));
```

- Compare the attributes for all stream file objects recursively.

```
SELECT * FROM TABLE(QSYS2.COMPARE_IFS(
    START_PATH_NAME1 => '/usr/files.dir',
    START_PATH_NAME2 => '/usrbackup/files.dir',
    OBJECT_TYPE_LIST => '*STMF',
    SUBTREE_DIRECTORIES => 'YES',
    COMPARE_ATTRIBUTES => 'YES'
));
```

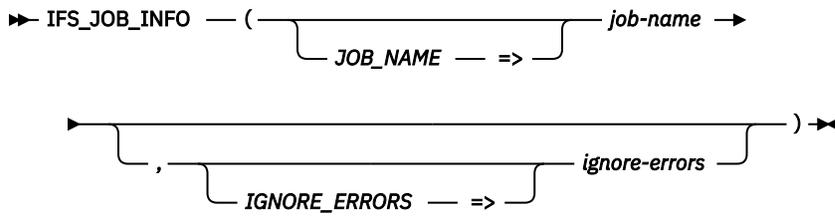

IFS_JOB_INFO table function

The IFS_JOB_INFO table function returns a table that contains information about integrated file system references for a job.

This information is similar to what is returned by the Retrieve Referenced Objects (QPOLRRO) API.

The list of objects returned may be incomplete for objects residing in file systems other than the root (/), QOpenSys, and user-defined file systems. Objects in some of the other file systems can be locked with interfaces that do not use the integrated file system. Therefore, objects referenced by a job will only have references that were obtained as part of an integrated file system operation, or an operation that causes an integrated file system operation to occur.

Authorization: The caller must be running with the same user profile as the job being retrieved or have *JOBCTL special authority.

job-name An expression that returns the qualified job name whose reference information is to be returned. Can contain the following special value:

- * Return information for the current job.

ignore-errors A character or graphic string expression that identifies what to do when an error is encountered.

NO An error is returned.

YES A warning is returned.

No row is returned when an error is encountered. This is the default.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 141. IFS_JOB_INFO table function

Column Name	Data Type	Description
PATH_NAME	DBCLOB(16M) CCSID 1200	The path name of an integrated file system object that is referenced by the job. Contains the null value if the object is not linked to a path. This can occur in the root (/) file system, the QOpenSys file system, or a user-defined file system. Can also contain the null value if the object is in a remote file system or the optical file system (QOPT).
FILE_SYSTEM_TYPE	VARCHAR(15)	The file system for the object. NFS The Network File System (NFS). QDLS The Document Library Services (QDLS) file system. QFILSVR400 The QFileSvr.400 file system. QNTC The Windows NT® Server file system. QOPENSYS The QOpenSys file system. QOPT The optical file system (QOPT). QSYS The QSYS.LIB file system. QSYSIASP An independent ASP QSYS.LIB file system. ROOT The root (/) file system UDFS A user-defined file system. UDFS MANAGEMENT A file system that manages the block special files (*BLKSF) for the user-defined file systems.
FILE_IDENTIFIER_NUMBER	BIGINT	The file identifier number of the object. This number uniquely identifies the object with a file system. The file identifier number, generation identifier, and file system identifier used together uniquely identify the object on the system.
GENERATION_IDENTIFIER	BIGINT	The generation identifier associated with the object. The file identifier number, generation identifier, and file system identifier used together uniquely identify the object on the system.

Table 141. IFS_JOB_INFO table function (continued)

Column Name	Data Type	Description
FILE_SYSTEM_IDENTIFIER	BIGINT	The file system ID to which the object belongs. This number uniquely identifies the file system to which the object belongs. The file identifier number, generation identifier, and file system identifier used together uniquely identify the object on the system.
FILE_IDENTIFIER	BINARY(16)	An identifier associated with the referred to object.
REFERENCE_COUNT	INTEGER	Current number of references on the object for the specified job.
RO_SHARE_R_COUNT	INTEGER	Number of read only accesses for the job where the sharing mode allows sharing with read and execute access intents only.
RO_SHARE_W_COUNT	INTEGER	Number of read only accesses for the job where the sharing mode allows sharing with write access intents only.
RO_SHARE_RW_COUNT	INTEGER	Number of read only accesses for the job where the sharing mode allows sharing with read, execute, and write access intents.
RO_SHARE_NONE_COUNT	INTEGER	Number of read only accesses for the job where the sharing mode allows sharing with no other access intents.
WO_SHARE_R_COUNT	INTEGER	Number of write only accesses for the job where the sharing mode allows sharing with read and execute access intents only.
WO_SHARE_W_COUNT	INTEGER	Number of write only accesses for the job where the sharing mode allows sharing with write access intents only.
WO_SHARE_RW_COUNT	INTEGER	Number of write only accesses for the job where the sharing mode allows sharing with read, execute, and write access intents.
WO_SHARE_NONE_COUNT	INTEGER	Number of write only accesses for the job where the sharing mode allows sharing with no other access intents.
RW_SHARE_R_COUNT	INTEGER	Number of read and write accesses for the job where the sharing mode allows sharing with read and execute access intents only.
RW_SHARE_W_COUNT	INTEGER	Number of read and write accesses for the job where the sharing mode allows sharing with write access intents only.
RW_SHARE_RW_COUNT	INTEGER	Number of read and write accesses for the job where the sharing mode allows sharing with read, execute, and write access intents.
RW_SHARE_NONE_COUNT	INTEGER	Number of read and write accesses for the job where the sharing mode allows sharing with no other access intents.
XO_SHARE_R_COUNT	INTEGER	Number of execute only accesses for the job where the sharing mode allows sharing with read and execute access intents only.
XO_SHARE_W_COUNT	INTEGER	Number of execute only accesses for the job where the sharing mode allows sharing with write access intents only.
XO_SHARE_RW_COUNT	INTEGER	Number of execute only accesses for the job where the sharing mode allows sharing with read, execute, and write access intents.
XO_SHARE_NONE_COUNT	INTEGER	Number of execute only accesses for the job where the sharing mode allows sharing with no other access intents.
XR_SHARE_R_COUNT	INTEGER	Number of execute and read accesses for the job where the sharing mode allows sharing with read and execute access intents only.
XR_SHARE_W_COUNT	INTEGER	Number of execute and read accesses for the job where the sharing mode allows sharing with write access intents only.
XR_SHARE_RW_COUNT	INTEGER	Number of execute and read accesses for the job where the sharing mode allows sharing with read, execute, and write access intents.
XR_SHARE_NONE_COUNT	INTEGER	Number of execute and read accesses for the job where the sharing mode allows sharing with no other access intents.
CURRENT_DIRECTORY	VARCHAR(3)	The object is a directory that is being used as the current directory of the job. NO The object is not a directory that is being used as the current directory of the job. YES The object is the current directory of the job.

Table 141. IFS_JOB_INFO table function (continued)

Column Name	Data Type	Description
ROOT_DIRECTORY	VARCHAR(3)	The object is a directory that is being used as the root directory of the job. NO The object is not a directory that is being used as the root directory of the job. YES The object is the root directory of the job.
ATTRIBUTE_LOCK	VARCHAR(3)	Indicates whether attribute changes are prevented. NO Attribute changes are not prevented. YES Attribute changes are prevented.
SAVE_LOCK	VARCHAR(3)	Indicates whether the object is being referenced by an object save operation. NO Object is not being referenced by an object save operation. YES Object is being referenced by an object save operation.
INTERNAL_SAVE_LOCK	VARCHAR(3)	Indicates whether the object is being referenced internally during a save operation on a different object. NO The object is not being referenced internally during a save operation on a different object. YES The object is being referenced internally during a save operation on a different object.
LINK_CHANGES_LOCK	VARCHAR(3)	Indicates whether changes to links in the directory are prevented. NO Changes to links in the directory are not prevented. YES Changes to links in the directory are prevented.
CHECKED_OUT	VARCHAR(3)	Indicates whether the object is currently checked out. NO The object is not checked out. YES The object is checked out.
CHECKED_OUT_USER_NAME	VARCHAR(10)	The name of the user who has the object checked out. Contains the null value if CHECKED_OUT is NO.
FILE_SERVER_REFERENCE	VARCHAR(3)	The File Server is holding a generic reference on the object on behalf of a client. NO The File Server is not holding a generic reference on the object on behalf of a client. YES The File Server is holding a generic reference on the object on behalf of a client.
FILE_SERVER_WORKING_DIRECTORY	VARCHAR(3)	The object is a directory, and the File Server is holding a working directory reference on it on behalf of a client. NO The object is not a directory or the File Server is not holding a working directory reference on it on behalf of a client. YES The object is a directory, and the File Server is holding a working directory reference on it on behalf of a client.
NFS_SERVER_REFERENCE	VARCHAR(3)	The Network File System (NFS) Version 4 server job is holding a generic reference on the object on behalf of a client. NO The NFS server job is not holding a generic reference on the object on behalf of a client. YES The NFS server job is holding a generic reference on the object on behalf of a client.

Example

- List all the integrated file system references for the current job.

```
SELECT * FROM TABLE(QSYS2.IFS_JOB_INFO(JOB_NAME => '*'));
```

IFS_OBJECT_LOCK_INFO table function

The IFS_OBJECT_LOCK_INFO table function returns a result table that contains a row for each job that is known to be holding a reference, or lock, on the object.

This information is similar to what is returned by the Retrieve Object References (QPOLROR) API.

The list of object usages may be incomplete for objects residing in file systems other than the root (/), QOpenSys, and user-defined file systems. Objects in some of the other file systems can be locked with interfaces that do not use the integrated file system. Therefore, rows are only returned for references that were obtained as part of an integrated file system operation, or an operation that cause the integrated file system operation to occur.

Authorization: The caller must have:

- Execute (*X) data authority to each directory preceding the object whose references are to be obtained, and
- Read (*R) data authority to the object whose references are to be obtained.

```

>> IFS_OBJECT_LOCK_INFO ( ( path-name )
                          PATH_NAME =>
, ( ignore-errors )
  IGNORE_ERRORS =>
)

```

path-name An expression that defines the path name to the object whose reference information is to be returned. If the last element of the path is a symbolic link, the reference information will be for the symbolic link itself. If an absolute path name is not specified, the current working directory is used in combination with the relative path name to resolve to the object.

ignore-errors A character or graphic string expression that identifies what to do when an error is encountered.

NO An error is returned.

YES A warning is returned.

No row is returned when an error is encountered. This is the default.

The result of the function is a table containing multiple rows with the format shown in the following table. All the columns are nullable.

Table 142. IFS_OBJECT_LOCK_INFO table function

Column Name	Data Type	Description
PATH_NAME	DBCLOB(16M) CCSID 1200	The full path name of the object.
JOB_NAME	VARCHAR(28)	The qualified job name holding the reference.
RO_COUNT	INTEGER	Total number of read only access references for this job.
WO_COUNT	INTEGER	Total number of write only access references for this job.
RW_COUNT	INTEGER	Total number of read and write access references for this job.
XO_COUNT	INTEGER	Total number of execute only access references for this job.
SHARE_R_COUNT	INTEGER	Total number of references for this job where the sharing mode allows sharing with read and execute access intents only.

Table 142. IFS_OBJECT_LOCK_INFO table function (continued)

Column Name	Data Type	Description
SHARE_W_COUNT	INTEGER	Total number of references for this job where the sharing mode allows sharing with write access intents only.
SHARE_RW_COUNT	INTEGER	Total number of references for this job where the sharing mode allows sharing with read, execute, and write access intents.
SHARE_NONE_COUNT	INTEGER	Total number of references for this job where the sharing mode allows sharing with no other access intents.
ATTRIBUTE_LOCK	VARCHAR(3)	Indicates whether attribute changes are prevented for this job. NO Attribute changes are not prevented. YES Attribute changes are prevented.
SAVE_LOCK	VARCHAR(3)	Indicates whether the object is being referenced by an object save operation by this job. NO Object is not being referenced by an object save operation. YES Object is being referenced by an object save operation.
INTERNAL_SAVE_LOCK	VARCHAR(3)	Indicates whether the object is being referenced internally during a save operation on a different object by this job. NO The object is not being referenced internally during a save operation on a different object. YES The object is being referenced internally during a save operation on a different object.
LINK_CHANGES_LOCK	VARCHAR(3)	Indicates whether changes to links in the directory are prevented for this job. NO Changes to links in the directory are not prevented. YES Changes to links in the directory are prevented.
CHECKED_OUT	VARCHAR(3)	Indicates whether the object is currently checked out by this job. NO The object is not checked out. YES The object is checked out.
CHECKED_OUT_USER_NAME	VARCHAR(10)	The name of the user who has the object checked out. Contains the null value if CHECKED_OUT is NO.
RO_SHARE_R_COUNT	INTEGER	Number of read only accesses for the job where the sharing mode allows sharing with read and execute access intents only.
RO_SHARE_W_COUNT	INTEGER	Number of read only accesses for the job where the sharing mode allows sharing with write access intents only.
RO_SHARE_RW_COUNT	INTEGER	Number of read only accesses for the job where the sharing mode allows sharing with read, execute, and write access intents.
RO_SHARE_NONE_COUNT	INTEGER	Number of read only accesses for the job where the sharing mode allows sharing with no other access intents.
WO_SHARE_R_COUNT	INTEGER	Number of write only accesses for the job where the sharing mode allows sharing with read and execute access intents only.
WO_SHARE_W_COUNT	INTEGER	Number of write only accesses for the job where the sharing mode allows sharing with write access intents only.
WO_SHARE_RW_COUNT	INTEGER	Number of write only accesses for the job where the sharing mode allows sharing with read, execute, and write access intents.
WO_SHARE_NONE_COUNT	INTEGER	Number of write only accesses for the job where the sharing mode allows sharing with no other access intents.
RW_SHARE_R_COUNT	INTEGER	Number of read and write accesses for the job where the sharing mode allows sharing with read and execute access intents only.
RW_SHARE_W_COUNT	INTEGER	Number of read and write accesses for the job where the sharing mode allows sharing with write access intents only.
RW_SHARE_RW_COUNT	INTEGER	Number of read and write accesses for the job where the sharing mode allows sharing with read, execute, and write access intents.

Table 142. IFS_OBJECT_LOCK_INFO table function (continued)

Column Name	Data Type	Description
RW_SHARE_NONE_COUNT	INTEGER	Number of read and write accesses for the job where the sharing mode allows sharing with no other access intents.
XO_SHARE_R_COUNT	INTEGER	Number of execute only accesses for the job where the sharing mode allows sharing with read and execute access intents only.
XO_SHARE_W_COUNT	INTEGER	Number of execute only accesses for the job where the sharing mode allows sharing with write access intents only.
XO_SHARE_RW_COUNT	INTEGER	Number of execute only accesses for the job where the sharing mode allows sharing with read, execute, and write access intents.
XO_SHARE_NONE_COUNT	INTEGER	Number of execute only accesses for the job where the sharing mode allows sharing with no other access intents.
XR_SHARE_R_COUNT	INTEGER	Number of execute and read accesses for the job where the sharing mode allows sharing with read and execute access intents only.
XR_SHARE_W_COUNT	INTEGER	Number of execute and read accesses for the job where the sharing mode allows sharing with write access intents only.
XR_SHARE_RW_COUNT	INTEGER	Number of execute and read accesses for the job where the sharing mode allows sharing with read, execute, and write access intents.
XR_SHARE_NONE_COUNT	INTEGER	Number of execute and read accesses for the job where the sharing mode allows sharing with no other access intents.
CURRENT_DIRECTORY	VARCHAR(3)	Indicates whether the object is a directory that is being used as the current directory of the job. NO The object is not a directory that is being used as the current directory of the job. YES The object is a directory that is being used as the current directory of the job.
ROOT_DIRECTORY	VARCHAR(3)	Indicates whether the object is a directory that is being used as the root directory of the job. NO The object is not a directory that is being used as the root directory of the job. YES The object is a directory that is being used as the root directory of the job.
FILE_SERVER_REFERENCE	VARCHAR(3)	Indicates whether the File Server is holding a generic reference on the object on behalf of a client for this job. NO The File Server is not holding a generic reference on the object on behalf of a client. YES The File Server is holding a generic reference on the object on behalf of a client.
FILE_SERVER_WORKING_DIRECTORY	VARCHAR(3)	Indicates whether the object is a directory, and the File Server is holding a working directory reference on it on behalf of a client for this job. NO The object is not a directory or the File Server is not holding a working directory reference on it on behalf of a client. YES The object is a directory, and the File Server is holding a working directory reference on it on behalf of a client.
NFS_SERVER_REFERENCE	VARCHAR(3)	Indicates whether the Network File System (NFS) Version 4 server job is holding a generic reference on the object on behalf of a client for this job. NO The NFS server job is not holding a generic reference on the object on behalf of a client. YES The NFS server job is holding a generic reference on the object on behalf of a client.

Table 142. IFS_OBJECT_LOCK_INFO table function (continued)

Column Name	Data Type	Description
NETSERVER_SESSION	CLOB(1M)	<p>This column contains a list of NetServer sessions, with each entry formatted as follows:</p> <ol style="list-style-type: none"> 1. 20 characters containing the session ID number 2. 10 character user name 3. 15 character workstation name 4. 45 character workstation address 5. 1 semicolon (;) <p>Contains the null value if there are no NetServer sessions.</p>

Example

- List all the jobs that have a lock on /usr/test1

```
SELECT * FROM TABLE(QSYS2.IFS_OBJECT_LOCK_INFO(PATH_NAME => '/usr/test1'))
```

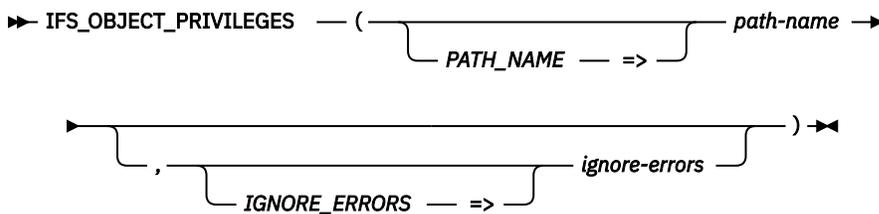

IFS_OBJECT_PRIVILEGES table function

The IFS_OBJECT_PRIVILEGES table function returns a row for every user authorized to the object identified by the path name, along with their associated object and data authorities.

This information is similar to the information available through the Display Authority (DSPAUT) CL command and the Qp0lGetAttr()--Get Attributes API.

Authorization: The caller must have:

- For objects not in the QSYS.LIB file system:
 - For each directory included in the path name prior to the object name, *X
 - For the object, *OBJMGT
- For objects in the QSYS.LIB file system:
 - For each directory included in the path name prior to the object name, *X
 - For a *MBR object, *RX and *OBJMGT
 - For all other object types, *OBJMGT

path-name An expression that returns the path name identifying the object. A relative path name is relative to the current directory. If an absolute path name is not specified, the current working directory is used in combination with the relative path name to resolve to the object. If the last element of the path is a symbolic link, the privilege information will be for the symbolic link itself.

ignore-errors A character or graphic string expression that identifies what to do when an error is encountered.

NO An error is returned.

YES A warning is returned.

No row is returned when an error is encountered. This is the default.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 143. IFS_OBJECT_PRIVILEGES table function

Column Name	Data Type	Description
PATH_NAME	DBCLOB(16M) CCSID 1200	The full path name of the object.
OBJECT_TYPE	VARCHAR(8)	The type of the object.
OWNER	VARCHAR(10)	The user profile that owns the object. Contains the null value if no owner is available.
PRIMARY_GROUP	VARCHAR(10)	The name of the user profile that is the primary group of the object. Can contain the following special value: *NOUSRPRF This special value is used by the Network File System to indicate that there is no user profile on the local server on the IBM i with a group ID (GID) matching the GID of the remote object. Contains the null value if the object has no primary group.
AUTHORIZATION_LIST	VARCHAR(10)	The name of the authorization list if the object is secured by an authorization list. Contains the null value if the object is not secured by an authorization list.
AUTHORIZATION_NAME	VARCHAR(10)	User profile name for this row. Can contain the following special values: *NOUSRPRF The authorities of either the owner or the primary group of the object for which the profile name could not be determined. This value is used by the Network File System only. It indicates that the user ID (UID) or the group ID (GID) for the remote object does not match any profile on the local server on the IBM i with that UID or GID. *PUBLIC This row contains the public authority for the object.
DATA_AUTHORITY	VARCHAR(12)	The operation, use, or access that AUTHORIZATION_NAME has to the object. Contains one of the following special values: *AUTL The public authority specified in the authorization list used by this object is used. *EXCLUDE All operations on the object are prohibited. *NONE The user does not have any data authorities. *R Allows access to the object attributes. *RW Allows access to the object attributes and allows the object to be changed. The user cannot use the object. *RWX Allows all operations on the object except those that are limited to the owner or controlled by the object rights. *RX Allows access to the object attributes and use of the object. The user cannot change the object. *W Allows the object to be changed. *WX Allows use of the object and allows the object to be changed. The user cannot access the object attributes. *X Allows the use of the object. USER DEFINED The specific data authorities do not match any of the predefined authority levels.
OBJECT_OPERATIONAL	VARCHAR(3)	Indicates the object operational authority for AUTHORIZATION_NAME. NO The user does not have this authority. YES The user has this authority.
OBJECT_MANAGEMENT	VARCHAR(3)	The object management authority for AUTHORIZATION_NAME. NO The user does not have this authority. YES The user has this authority.

Table 143. IFS_OBJECT_PRIVILEGES table function (continued)

Column Name	Data Type	Description
OBJECT_EXISTENCE	VARCHAR(3)	The object existence authority for AUTHORIZATION_NAME.
		NO The user does not have this authority.
		YES The user has this authority.
OBJECT_ALTER	VARCHAR(3)	The object alter authority for AUTHORIZATION_NAME.
		NO The user does not have this authority.
		YES The user has this authority.
OBJECT_REFERENCE	VARCHAR(3)	The object reference authority for AUTHORIZATION_NAME.
		NO The user does not have this authority.
		YES The user has this authority.
DATA_READ	VARCHAR(3)	The data read authority for AUTHORIZATION_NAME.
		NO The user does not have this authority.
		YES The user has this authority.
DATA_ADD	VARCHAR(3)	The data add authority for AUTHORIZATION_NAME.
		NO The user does not have this authority.
		YES The user has this authority.
DATA_UPDATE	VARCHAR(3)	The data update authority for AUTHORIZATION_NAME.
		NO The user does not have this authority.
		YES The user has this authority.
DATA_DELETE	VARCHAR(3)	The data delete authority for AUTHORIZATION_NAME.
		NO The user does not have this authority.
		YES The user has this authority.
DATA_EXECUTE	VARCHAR(3)	The data execute authority for AUTHORIZATION_NAME.
		NO The user does not have this authority.
		YES The user has this authority.

Example

- List all the authorities for all objects in the /usr directory.

```
WITH OBJS AS (SELECT PATH_NAME
              FROM TABLE (QSYS2.IFS_OBJECT_STATISTICS(START_PATH_NAME => '/usr'))
              SELECT * FROM OBJS, TABLE(QSYS2.IFS_OBJECT_PRIVILEGES(PATH_NAME));
```

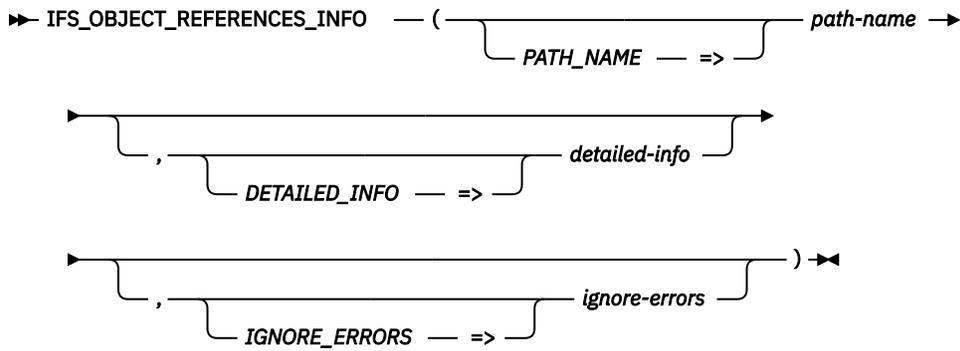

IFS_OBJECT_REFERENCES_INFO table function

The IFS_OBJECT_REFERENCES_INFO table function returns a single row result table that contains information about integrated file system references on an object.

This information is similar to what is returned by the Retrieve Object References (QPOLROR) API. The information may not be complete for objects residing in file systems other than the root (/), QOpenSys, and user-defined file systems.

Authorization: The caller must have:

- Execute (*X) data authority to each directory preceding the object whose references are to be obtained, and
- Read (*R) data authority to the object whose references are to be obtained.

path-name An expression that defines the path name to the object whose reference information is to be returned. If the last element of the path is a symbolic link, the reference information will be for the symbolic link itself. If an absolute path name is not specified, the current working directory is used in combination with the relative path name to resolve to the object.

detailed-info A character or graphic string expression that indicates the type of information to be returned.

NO Only basic information is returned. Values for columns through the CHECKED_OUT_USER_NAME are returned; NULL is returned for the remaining columns. This is the default.

YES Values are returned for all columns.

ignore-errors A character or graphic string expression that identifies what to do when an error is encountered.

NO An error is returned.

YES A warning is returned.

No row is returned when an error is encountered. This is the default.

The result of the function is a table containing a single row with the format shown in the following table. All the columns are nullable.

Table 144. IFS_OBJECT_REFERENCES_INFO table function

Column Name	Data Type	Description
PATH_NAME	DBCLOB(16M) CCSID 1200	The full path name of the object.
REFERENCE_COUNT	INTEGER	Current number of references on the object. This may be 0 even though IN_USE has a value of YES.
IN_USE	VARCHAR(3)	Whether the object is currently in use. NO The object is not in use and all of the reference type fields are 0. YES The object is in use. At least one of the reference type fields is greater than 0. This condition may occur even if REFERENCE_COUNT is 0.
RO_COUNT	INTEGER	Total number of read only access references.
WO_COUNT	INTEGER	Total number of write only access references.
RW_COUNT	INTEGER	Total number of read and write access references.
XO_COUNT	INTEGER	Total number of execute only access references.
SHARE_R_COUNT	INTEGER	Total number of references where the sharing mode allows sharing with read and execute access intents only.

Table 144. IFS_OBJECT_REFERENCES_INFO table function (continued)

Column Name	Data Type	Description
SHARE_W_COUNT	INTEGER	Total number of references where the sharing mode allows sharing with write access intents only.
SHARE_RW_COUNT	INTEGER	Total number of references where the sharing mode allows sharing with read, execute, and write access intents.
SHARE_NONE_COUNT	INTEGER	Total number of references where the sharing mode allows sharing with no other access intents.
ATTRIBUTE_LOCK	VARCHAR(3)	Indicates whether attribute changes are prevented. NO Attribute changes are not prevented. YES Attribute changes are prevented.
SAVE_LOCK	VARCHAR(3)	Indicates whether the object is being referenced by an object save operation. NO Object is not being referenced by an object save operation. YES Object is being referenced by an object save operation.
INTERNAL_SAVE_LOCK	VARCHAR(3)	Indicates whether the object is being referenced internally during a save operation on a different object. NO The object is not being referenced internally during a save operation on a different object. YES The object is being referenced internally during a save operation on a different object.
LINK_CHANGES_LOCK	VARCHAR(3)	Indicates whether changes to links in the directory are prevented. NO Changes to links in the directory are not prevented. YES Changes to links in the directory are prevented.
CHECKED_OUT	VARCHAR(3)	Indicates whether the object is currently checked out. NO The object is not checked out. YES The object is checked out.
CHECKED_OUT_USER_NAME	VARCHAR(10)	The name of the user who has the object checked out. Contains the null value if CHECKED_OUT is NO.
Values are returned for the following columns when the DETAILED_INFO parameter is YES. They will contain the null value if DETAILED_INFO is NO.		
RO_SHARE_R_COUNT	INTEGER	Total number of read only access references. The sharing mode allows sharing with read and execute access intents only.
RO_SHARE_W_COUNT	INTEGER	Total number of read only access references. The sharing mode allows sharing with write access intents only.
RO_SHARE_RW_COUNT	INTEGER	Total number of read only access references. The sharing mode allows sharing with read, execute, and write access intents.
RO_SHARE_NONE_COUNT	INTEGER	Total number of read only access references. The sharing mode allows sharing with no other access intents.
WO_SHARE_R_COUNT	INTEGER	Total number of write only access references. The sharing mode allows sharing with read and execute access intents only.
WO_SHARE_W_COUNT	INTEGER	Total number of write only access references. The sharing mode allows sharing with write access intents only.
WO_SHARE_RW_COUNT	INTEGER	Total number of write only access references. The sharing mode allows sharing with read, execute, and write access intents.
WO_SHARE_NONE_COUNT	INTEGER	Total number of write only access references. The sharing mode allows sharing with no other access intents.
RW_SHARE_R_COUNT	INTEGER	Total number of read and write access references. The sharing mode allows sharing with read and execute access intents only.
RW_SHARE_W_COUNT	INTEGER	Total number of read and write access references. The sharing mode allows sharing with write access intents only.

Table 144. IFS_OBJECT_REFERENCES_INFO table function (continued)

Column Name	Data Type	Description
RW_SHARE_RW_COUNT	INTEGER	Total number of read and write access references. The sharing mode allows sharing with read, execute, and write access intents.
RW_SHARE_NONE_COUNT	INTEGER	Total number of read and write access references. The sharing mode allows sharing with no other access intents.
XO_SHARE_R_COUNT	INTEGER	Total number of execute only access references. The sharing mode allows sharing with read and execute access intents only.
XO_SHARE_W_COUNT	INTEGER	Total number of execute only access references. The sharing mode allows sharing with write access intents only.
XO_SHARE_RW_COUNT	INTEGER	Total number of execute only access references. The sharing mode allows sharing with read, execute, and write access intents.
XO_SHARE_NONE_COUNT	INTEGER	Total number of execute only access references. The sharing mode allows sharing with no other access intents.
XR_SHARE_R_COUNT	INTEGER	Total number of execute and read access references. The sharing mode allows sharing with read and execute access intents only.
XR_SHARE_W_COUNT	INTEGER	Total number of execute and read access references. The sharing mode allows sharing with write access intents only.
XR_SHARE_RW_COUNT	INTEGER	Total number of execute and read access references. The sharing mode allows sharing with read, execute, and write access intents.
XR_SHARE_NONE_COUNT	INTEGER	Total number of execute and read access references. The sharing mode allows sharing with no other access intents.
CURRENT_DIRECTORY_COUNT	INTEGER	Total number of jobs where the object is a directory that is being used as the current directory of the job.
ROOT_DIRECTORY_COUNT	INTEGER	Total number of jobs where the object is a directory that is being used as the root directory of the job.
FILE_SERVER_REFERENCE_COUNT	INTEGER	Total number of jobs where the File Server is holding a generic reference on the object on behalf of a client.
FILE_SERVER_WORKING_DIRECTORY_COUNT	INTEGER	Total number of jobs where the object is a directory, and the File Server is holding a working directory reference on it on behalf of a client.
NFS_SERVER_REFERENCE_COUNT	INTEGER	Total number of jobs where the Network File System (NFS) Version 4 server job is holding a generic reference on the object on behalf of a client.

Example

- Determine how /usr/test is currently being used.

```
SELECT * FROM TABLE (QSYS2.IFS_OBJECT_REFERENCES_INFO(PATH_NAME => '/usr/test'));
```

IFS_OBJECT_STATISTICS table function

The IFS_OBJECT_STATISTICS table function returns a table of objects contained in the starting path name or accessible from the starting path name.

This information is similar to what is returned by the Retrieve Directory Information (RTVDIRINF) command or the QpOIGetAttr()--Get Attributes API.

No rows are returned for remote file system objects. This means that for the QNTC file system, only a row for /QNTC is returned. For the Network File System (NFS) and QFileSvr.400 file systems, no rows are returned.

Some file systems, including QDLS, are not threadsafe. Accessing information from these file systems might not return some rows. If this happens, an error or warning is returned based on the IGNORE_ERRORS parameter setting. See the Usage Notes on this page for the list of threadsafe file systems: [access\(\)--Determine File Accessibility](#).

Authorization: The caller must have:

For file systems other than QDLS and QSYS:

- For each directory included in the path name used to start the search, *X
- For each directory processed recursively, *RX and *OBJMGT
- For each object returned, *OBJMGT

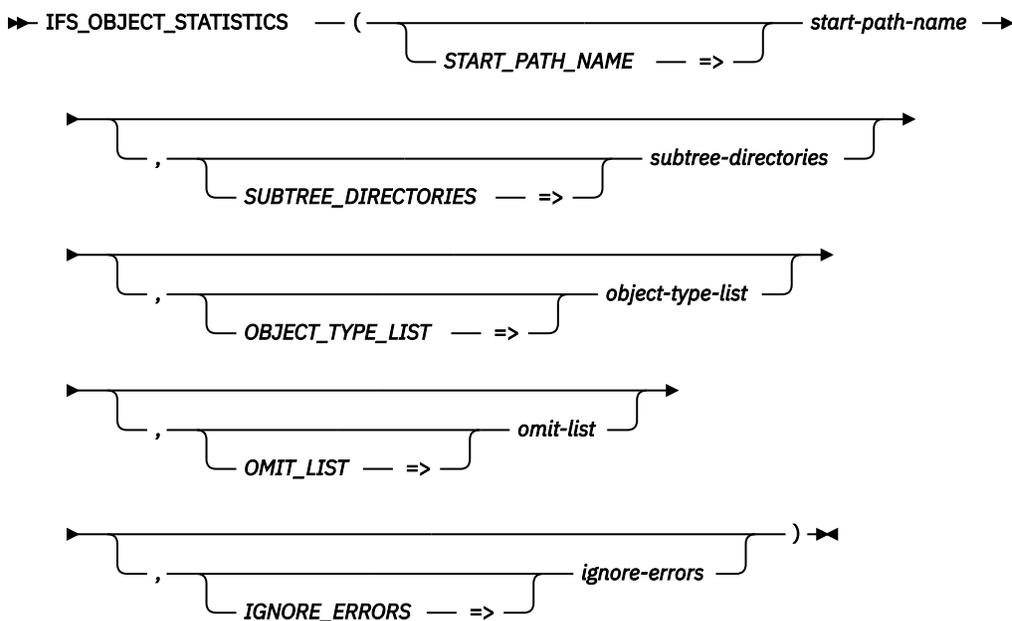

For the QDLS file system:

- For each directory included in the path name, except for QDLS, used to start the search, *X
- For every object being returned or processed recursively, *RWX and *OBJEXIST *OBJMGT *OBJALTER *OBJREF

For the QSYS file system:

- For the library or object included in the path name used to start the search, *USE
- For each library or object processed recursively by the service, *USE and *OBJMGT
- For each object returned, *OBJMGT

To return values for OBJECT_AUDIT and OBJECT_AUDIT_CREATE, the caller must have *ALLOBJ or *AUDIT special authority.

start-path-name An expression that returns a path name for starting the search. A relative path name is relative to the current directory. If an absolute path name is not specified, the current working directory is used in combination with the relative path name to resolve to the object.

subtree-directories An expression that indicates whether all subdirectories should be recursively processed or not.

NO Only objects in the directory identified by *start-path-name* are processed.

YES All subdirectories for the directory identified by *start-path-name* are processed. This is the default.

object-type-list A list of one or more object types that should be returned. One or more blanks separate multiple values. The default is the empty string, indicating all objects are returned. Values include all the standard system object types, for example *PGM or *STMF, and the following special values:

- *ALLDIR** Select all directory object types. This includes *LIB, *DIR, *FLR, *FILE, and *DDIR object types.
- *ALLSTMF** Select all stream file object types. This includes *MBR, *DOC, *STMF, *DSTMF, and *USRSPC object types.
- *MBR** Select all database file member types.
- *NOQDLS** Exclude all QDLS file system object types.
- *NOQOPT** Exclude all QOPT and QNTC file system object types.
- *NOQSYS** Exclude all QSYS.LIB object types. This includes all objects in the QSYS.LIB file system and all independent ASP QSYS.LIB file systems which are available when the function is invoked.

omit-list

A character string containing one or more path names to exclude from processing. All objects and sub directories accessed from this path are excluded as well. The default is the empty string, indicating no path names are excluded from processing.

The root path ('/') must not be included in the list. If more than one path is provided, the values are separated by one or more blanks. If a blank exists in a path name, the path name must be enclosed in either apostrophes (') or quotes(""). When delimiting a path name and there is an apostrophe or quote (matching the enclosing character) in the path name, the embedded character needs to be doubled. For example, the following are valid path strings.

- One path name. No delimiter needed:
/dir1/dir2/content
- Two path names. No delimiter needed:
/dir1/content /dir1/dir3
- Blank in path name, path delimited with apostrophes:
'dir1/content string'
- Two path names. Blank and apostrophe in first path. First path name is delimited with apostrophes and the apostrophe in the name is doubled. Second path is does not need to be delimited:
'dir1/dir2/my file"s content' /dir4/test'123
- Two path names. Blank and apostrophe in first path. First path name is delimited with quotes. Second path is delimited even though not required:
"/dir1/dir2/my file's content" "/dir4/test'123"

ignore-errors

A character or graphic string expression that identifies what to do when an error is encountered.

- NO** An error is returned.
- YES** A warning is returned.
- No row is returned when an error is encountered. This is the default.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 145. IFS_OBJECT_STATISTICS table function

Column Name	Data Type	Description
PATH_NAME	DBCLOB(16M) CCSID 1200	The path name of an integrated file system object.

Table 145. IFS_OBJECT_STATISTICS table function (continued)

Column Name	Data Type	Description
OBJECT_TYPE	VARCHAR(10)	The object type.
SYMBOLIC_LINK	DBCLOB(16M) CCSID 1200	The symbolic link for this object. Contains the null value if OBJECT_TYPE is not *SYMLNK.
ASP_NUMBER	INTEGER	The auxiliary storage pool (ASP) in which the object is stored. 1 indicates the system ASP. Contains the null value if the object does not reside on this IBM i.
TEXT_DESCRIPTION	VARGRAPHIC(50) CCSID 1200	The text string associated with the object. Contains the null value if there is no text string.
FILE_IDENTIFIER_NUMBER	BIGINT	The file identifier number of the object. This number uniquely identifies the object with a file system. The file identifier number, generation identifier, and file system identifier used together uniquely identify the object on the system.
GENERATION_IDENTIFIER	BIGINT	The generation identifier associated with the object. The file identifier number, generation identifier, and file system identifier used together uniquely identify the object on the system.
FILE_SYSTEM_IDENTIFIER	BIGINT	The file system ID to which the object belongs. This number uniquely identifies the file system to which the object belongs. The file identifier number, generation identifier, and file system identifier used together uniquely identify the object on the system.
FILE_IDENTIFIER	BINARY(16)	An identifier associated with the referred to object.
FILE_ACCESS	BINARY(4)	Bit string containing information including the file type and file mode
CREATE_TIMESTAMP	TIMESTAMP(0)	The time the object was created.
ACCESS_TIMESTAMP	TIMESTAMP(0)	The time that the object's data was last accessed. Contains the null value if the object has never been accessed.
DATA_CHANGE_TIMESTAMP	TIMESTAMP(0)	The time that the object's data was last changed. Contains the null value if the object's data has never been changed.
OBJECT_CHANGE_TIMESTAMP	TIMESTAMP(0)	The time that the object's data or attributes were last changed. Contains the null value if the object's data or attributes have never been changed.
LAST_USED_TIMESTAMP	TIMESTAMP(0)	The date the object was last used. Contains the null value if the object has never been used or if usage data is not maintained for the IBM i type or the file system to which an object belongs.
DAYS_USED_COUNT	INTEGER	The number of days an object has been used. Usage has different meanings according to the specific file system and according to the individual object types supported within a file system. Usage can indicate the opening or closing of a file or can refer to adding links, renaming, restoring, or checking out an object. This count is incremented once each day that an object is used and can be reset.
LAST_RESET_TIMESTAMP	TIMESTAMP(0)	The timestamp when the days used count was last reset to zero. Contains the null value if the days used count has never been reset.
ALLOCATED_SIZE	BIGINT	The number of bytes that have been allocated for this object.
DATA_SIZE	BIGINT	The size, in bytes, of the data in this object. This size does not include object headers or the size of extended attributes associated with the object.
CCSID	INTEGER	The CCSID of the data and extended attributes of the object. Contains the null value if there is no CCSID.
CODE_PAGE	INTEGER	The code page derived from the coded character set identifier (CCSID) used for the data in the file or the extended attributes of the directory. Contains the null value if there is more than one code page or if the CCSID is not a supported CCSID.
EXTENDED_ATTRIBUTE_COUNT	BIGINT	Number of extended attributes associated with this object.
CRITICAL_EXTENDED_ATTRIBUTE_COUNT	BIGINT	Number of critical extended attributes associated with this object.

Table 145. IFS_OBJECT_STATISTICS table function (continued)

Column Name	Data Type	Description
EXTENDED_ATTRIBUTE_SIZE	BIGINT	The total number of extended attribute bytes.
HARD_LINK_COUNT	INTEGER	The number of hard links to the object.
OBJECT_READ_ONLY	VARCHAR(3)	Whether the object can be written to or deleted, have its extended attributes changed or deleted, or have its size changed. NO The object can be changed. YES The object can only be read.
OBJECT_HIDDEN	VARCHAR(3)	Whether the object can be displayed using an ordinary directory listing. NO The object is not hidden. YES The object is hidden.
TEMPORARY_OBJECT	VARCHAR(3)	Whether the object is a temporary object. NO The object is a permanent object. YES The object is a temporary object.
SYSTEM_FILE	VARCHAR(3)	Whether the object is a system file and is excluded from normal directory searches. NO The object is not a system file. YES The object is a system file.
SYSTEM_USAGE	VARCHAR(6)	Whether the file has a special use by the system. NONE The file is a generic stream file. NWSSTG The file is a network server storage space. VRTVOL The file is a virtual volume. Examples include tape and optical virtual volumes. Contains the null value if OBJECT_TYPE is not *STMF.
DEVICE_SPECIAL_FILE	BIGINT	It the object is a device special file, the real device it represents. Contains the null value if this is not a device special file.
OBJECT_OWNER	VARCHAR(10)	The name of the user profile that is the owner of the object. Can contain the following special value: *NOUSRPRF This special value is used by the Network File System to indicate that there is no user profile on the local server on the IBM i with a user ID (UID) matching the UID of the remote object. Contains the null value if there is no owner.
USER_ID_NUMBER	BIGINT	User ID (UID) number of the owner of the object. Contains the null value if there is no owner.
PRIMARY_GROUP	VARCHAR(10)	The name of the user profile that is the primary group of the object. Can contain the following special value: *NOUSRPRF This special value is used by the Network File System to indicate that there is no user profile on the local server on the IBM i with a group ID (GID) matching the GID of the remote object. Contains the null value if the object has no primary group.
GROUP_ID_NUMBER	BIGINT	Group ID (GID) number of the user profile that is the primary group of the object. Contains the null value if the object has no primary group.
AUTHORIZATION_LIST	VARCHAR(10)	The name of the authorization list that is used to secure the named object. Contains the null value if no authorization list is used in determining authority to the object.

Table 145. IFS_OBJECT_STATISTICS table function (continued)

Column Name	Data Type	Description
SET_EFFECTIVE_USER_ID	VARCHAR(3)	<p>Set effective user ID (UID) at execution time.</p> <p>NO The user ID (UID) is not set at execution time.</p> <p>YES The object owner is the effective user ID (UID) at execution time.</p>
SET_EFFECTIVE_GROUP_ID	VARCHAR(3)	<p>Set effective group ID (GID) at execution time.</p> <p>NO If the object is a file, the group ID (GID) is not set at execution time. If the object is a directory in the "root" (/), QOpenSys, or user-defined file systems, the group ID (GID) of objects created in the directory is set to the effective GID of the thread creating the object. This value cannot be set for other file systems.</p> <p>YES If the object is a file, the group ID (GID) is set at execution time. If the object is a directory, the group ID (GID) of objects created in the directory is set to the GID of the parent directory.</p>
AUTHORITY_COLLECTION_VALUE	VARCHAR(10)	<p>Specifies the authority collection value used for the object when authority collection for objects is active.</p> <p>*NONE No authority information will be collected for this object when authority collection for objects is active. A value of *NONE will be returned if the object type is not supported by authority collection.</p> <p>*OBJINF Authority information will be collected for this object when authority collection for objects is active. The authority checking information is collected for each unique instance of the object level information associated with the authority check.</p>
OBJECT_AUDIT	VARCHAR(7)	<p>The auditing value associated with the object.</p> <p>*ALL Audit all access to this object by all users on the system. All access is defined as a read or change operation.</p> <p>*CHANGE Audit all change access to this object by all users on the system.</p> <p>*NONE No auditing occurs for this object when it is read or changed regardless of the user who is accessing the object.</p> <p>*USRPRF Audit this object only if the current user is being audited. The current user is tested to determine if auditing should be done for this object. The user profile can specify if only change access is audited or if both read and change accesses are audited for this object.</p> <p>Contains the null value if the user is not allowed to retrieve the current auditing value.</p>
OBJECT_AUDIT_CREATE	VARCHAR(7)	<p>The create object auditing value associated with the directory. This is the auditing value given to any objects created in the directory.</p> <p>*ALL Audit all access to this object by all users on the system. All access is defined as a read or change operation.</p> <p>*CHANGE Audit all change access to this object by all users on the system.</p> <p>*NONE No auditing occurs for this object when it is read or changed regardless of the user who is accessing the object.</p> <p>*SYSVAL The object auditing value for the objects created in the directory is determined by the system auditing value (QCRTOBJAUD).</p> <p>*USRPRF Audit this object only if the current user is being audited. The current user is tested to determine if auditing should be done for this object. The user profile can specify if only change access is audited or if both read and change accesses are audited for this object. The OBJAUD parameter of the Change User Auditing (CHGUSRAUD) command is used to change the auditing for a specific user.</p> <p>Contains the null value if the user is not allowed to retrieve the current create object auditing value.</p>

Table 145. IFS_OBJECT_STATISTICS table function (continued)

Column Name	Data Type	Description
JOURNALED	VARCHAR(3)	<p>Current journaling status of the object.</p> <p>NO The object is not currently being journaled.</p> <p>YES The object is currently being journaled.</p>
JOURNAL_LIBRARY	VARCHAR(10)	<p>The name of the library containing the journal currently being used .</p> <p>Contains the null value if the object is not journaled.</p>
JOURNAL_NAME	VARCHAR(10)	<p>The name of the journal currently being used.</p> <p>Contains the null value if the object is not journaled.</p>
JOURNAL_BEFORE_IMAGE	VARCHAR(3)	<p>Indicates whether the image of the object before a change is journaled when journaling is active.</p> <p>NO The image of the object before a change is not journaled.</p> <p>YES The image of the object before a change is journaled.</p> <p>Contains the null value if the object has never been journaled.</p>
JOURNAL_AFTER_IMAGE	VARCHAR(3)	<p>Indicates whether the image of the object after a change is journaled when journaling is active.</p> <p>NO The image of the object after a change is not journaled.</p> <p>YES The image of the object after a change is journaled.</p> <p>Contains the null value if the object has never been journaled.</p>
JOURNAL_IDENTIFIER	VARCHAR(10)	<p>The journal identifier (JID) for this object.</p> <p>Contains the null value if the object has never been journaled.</p>
JOURNAL_START_TIMESTAMP	TIMESTAMP(0)	<p>The timestamp when the object had most recently had journaling started for it.</p> <p>Contains the null value if the object has never been journaled.</p>
JOURNAL_OPTIONAL_ENTRIES	VARCHAR(3)	<p>When journaling is active, entries that are considered optional are journaled. The list of optional journal entries varies for each object type. See Integrated file system for information regarding these optional entries for various objects.</p> <p>NO Optional entries for this object are not journaled.</p> <p>YES Optional entries for this object are journaled.</p> <p>Contains the null value if the object has never been journaled.</p>
JOURNAL_SUBTREE	VARCHAR(3)	<p>Indicates whether this object is a directory or library with inherit journal semantics.</p> <p>NO This object does not use inherit journal semantics.</p> <p>YES If this object is a directory, new objects created or linked within this directory will inherit the journal options and state from this directory.</p> <p>If this object is a library, new objects created or linked within this library will inherit the journal options and state from this library according to the journal inherit rules for this library.</p> <p>Contains the null value if the object has never been journaled.</p>

Table 145. IFS_OBJECT_STATISTICS table function (continued)

Column Name	Data Type	Description
PARTIAL_TRANSACTION	CHAR(1)	<p>Indicates whether the object contains a partial transaction:</p> <p>N The object does not contain a partial transaction.</p> <p>R A rollback abnormally ended prior to completion. It is recommended that the object be restored as it can not be used. As a last resort, the Change Journal Object (CHGJRNOBJ) command can be used to allow the object to be used. Doing this, however, may leave the object in an inconsistent state.</p> <p>Y The object was saved while active with a partial transaction. A subsequent restore of the object contains the partial transaction. The user should apply changes from the journal to complete the transaction.</p> <p>Contains the null value if the object has never been journaled.</p>
APPLY_STARTING_RECEIVER_LIBRARY	VARCHAR(10)	<p>The name of the library that contains the journal receiver. Contains the null value if the object has never been journaled.</p>
APPLY_STARTING_RECEIVER	VARCHAR(10)	<p>The oldest journal receiver needed to successfully Apply Journaled Changes (APYJRNCHG). If PARTIAL_TRANSACTION has a value of Y, the journal receiver contains the journal entries representing the start of the partial transaction. Otherwise; the journal receiver contains the journal entries representing the start-of-the-save operation.</p> <p>Contains the null value if PARTIAL_TRANSACTION has a value of R. Also contains the null value if the object has never been journaled.</p>
APPLY_STARTING_RECEIVER_ASP	VARCHAR(10)	<p>The name of the ASP for the library that contains the starting journal receiver. Can contain the special value *SYSBAS. Contains the null value if the object has never been journaled.</p>
OBJECT_SIGNED	VARCHAR(3)	<p>Whether an object has a digital signature.</p> <p>NO The object does not have a digital signature.</p> <p>YES The object does have a digital signature.</p> <p>Contains the null value if OBJECT_TYPE is not *STMF.</p>
SYSTEM_TRUSTED_SOURCE	VARCHAR(3)	<p>Whether the object was signed by a source that is trusted by the system.</p> <p>NO None of the signatures came from a source that is trusted by the system.</p> <p>YES The object was signed by a source that is trusted by the system. If the object has multiple signatures, at least one of the signatures came from a source that is trusted by the system.</p> <p>Contains the null value if OBJECT_TYPE is not *STMF or if OBJECT_SIGNED is NO.</p>
MULTIPLE_SIGNATURES	VARCHAR(3)	<p>Whether an object has more than one digital signature.</p> <p>NO The object has only one digital signature.</p> <p>YES The object has more than one digital signature. If SYSTEM_TRUSTED_SOURCE is YES, at least one of the signatures is from a source trusted by the system.</p> <p>Contains the null value if OBJECT_TYPE is not *STMF or if OBJECT_SIGNED is NO.</p>
OBJECT_DOMAIN	VARCHAR(7)	<p>The domain of the object.</p> <p>*SYSTEM The object exists in system domain.</p> <p>*USER The object exists in user domain.</p>
BLOCK_SIZE	INTEGER	The block size of the object.

Table 145. IFS_OBJECT_STATISTICS table function (continued)

Column Name	Data Type	Description
AUX_STORAGE_ALLOCATION	VARCHAR(8)	<p>Determines how auxiliary storage is allocated by the system for the specified object.</p> <p>DYNAMIC The system will dynamically determine the optimal auxiliary storage allocation for the object, balancing space used versus disk I/O operations.</p> <p>MINIMIZE The auxiliary storage will be allocated to minimize the space used by the object. That is, as additional auxiliary storage is required, it will be allocated in small sized extents to accommodate the current space requirement. Accessing an object composed of many small extents may increase the number of disk I/O operations for that object.</p> <p>NORMAL The auxiliary storage will be allocated normally. That is, as additional auxiliary storage is required, it will be allocated in logically sized extents to accommodate the current space requirement, and anticipated future requirements, while minimizing the number of disk I/O operations.</p> <p>Contains the null value if OBJECT_TYPE is not *STMF.</p>
AUX_STORAGE_OVERFLOW	VARCHAR(3)	<p>Whether the object has overflowed the auxiliary storage pool it resides in.</p> <p>NO The auxiliary storage pool is not overflowed.</p> <p>YES The auxiliary storage pool is overflowed.</p>
MAIN_STORAGE_ALLOCATION	VARCHAR(8)	<p>Determines how main storage is allocated by the system for the specified object.</p> <p>DYNAMIC The system will dynamically determine the optimal main storage allocation for the object depending on other system activity and main storage contention. That is, when there is little main storage contention, as much storage as possible will be allocated and used to minimize the number of disk I/O operations. When there is significant main storage contention, less main storage will be allocated and used to minimize the main storage contention.</p> <p>MINIMIZE The main storage will be allocated to minimize the space used by the object. That is, as little main storage as possible will be allocated and used. This minimizes main storage usage while increasing the number of disk I/O operations since less information is cached in main storage.</p> <p>NORMAL The main storage will be allocated normally. That is, as much main storage as possible will be allocated and used. This minimizes the number of disk I/O operations since the information is cached in main storage.</p> <p>Contains the null value if OBJECT_TYPE is not *STMF.</p>
STORAGE_FREED	VARCHAR(3)	<p>Whether the object's data has been moved offline, freeing its online storage.</p> <p>NO The object's data is not offline.</p> <p>YES The object's data is offline.</p>
STORED_LOCAL	VARCHAR(3)	<p>Indicates whether an object is stored locally or stored on a remote system. The decision of whether a file is local or remote varies according to the respective file system rules. Objects in file systems that do not carry either a local or remote indicator are treated as remote.</p> <p>NO The object's data is on a remote system.</p> <p>YES The object's data is stored locally.</p>
VIRTUAL_DISK_STORAGE	VARCHAR(3)	<p>Whether the object is the storage which was allocated for Integrated xSeries servers to use as virtual disk drives for the xSeries servers.</p> <p>NO Object is not virtual disk storage.</p> <p>YES Object is virtual disk storage.</p> <p>Contains the null value if OBJECT_TYPE is not *STMF.</p>

Table 145. IFS_OBJECT_STATISTICS table function (continued)

Column Name	Data Type	Description
DIRECTORY_FORMAT	CHAR(6)	<p>The format of the specified directory object.</p> <p>*TYPE1 The directory has the original directory format. The Convert Directory (CVTDIR) command may be used to convert from the *TYPE1 format to the *TYPE2 format.</p> <p>*TYPE2 The directory is optimized for performance, size, and reliability compared to directories having the *TYPE1 format.</p> <p>Contains the null value if OBJECT_TYPE is not *DIR.</p>
STREAM_FILE_FORMAT	CHAR(6)	<p>The format of the stream file.</p> <p>*TYPE1 The object has the same format as *STMF objects created on releases prior to V4R4. It has a minimum object size of 4096 bytes and a maximum object size of approximately 128 gigabytes.</p> <p>*TYPE2 This format was introduced in V4R4. It has a minimum object size of 4096 bytes and a maximum object size of approximately one terabyte in the "root" (/), QOpenSys and user-defined file systems. Otherwise, the maximum is approximately 256 gigabytes.</p> <p>Contains the null value if OBJECT_TYPE is not *STMF.</p>
UDFS_FILE_FORMAT	CHAR(6)	<p>The default file format of stream files (*STMF) created in the user-defined file system.</p> <p>*TYPE1 The stream file (*STMF) has the same format as *STMFs created on releases prior to V4R4. It has a minimum object size of 4096 bytes and a maximum object size of approximately 128 gigabytes.</p> <p>*TYPE2 This format was introduced in V4R4. It has a minimum object size of 4096 bytes and a maximum object size of approximately one terabyte in the "root" (/), QOpenSys and user-defined file systems. Otherwise, the maximum is approximately 256 gigabytes.</p> <p>Contains the null value if OBJECT_TYPE is not *STMF.</p>
UDFS_PREFERRED_STORAGE	CHAR(3)	<p>The preferred storage media for the objects in the UDFS.</p> <p>ANY No storage media is preferred. Storage will be allocated from any available storage media.</p> <p>SSD Solid state drive storage media is preferred. Storage should be allocated from solid state drive storage media, if available.</p> <p>Contains the null value if the preferred storage media is not known.</p>
UDFS_TEMPORARY_OBJECT	VARCHAR(3)	<p>Whether the objects in the UDFS are temporary objects.</p> <p>NO The objects in the UDFS are permanent objects.</p> <p>YES The objects in the UDFS are temporary objects.</p>
CASE_SENSITIVE_FILE_SYSTEM	VARCHAR(3)	<p>The case sensitivity of the file system that contains this object.</p> <p>NO The file system is not case sensitive.</p> <p>YES The file system is case sensitive.</p>
RESTRICT_RENAME_AND_UNLINK	VARCHAR(3)	<p>Restricted renames and unlinks for objects within a directory. Objects can be linked into a directory that has this attribute set on, but cannot be renamed or unlinked from it unless one or more of the following are true for the user performing the operation:</p> <ul style="list-style-type: none"> • The user is the owner of the object. • The user is the owner of the directory. • The user has *ALLOBJ special authority. <p>NO No additional restrictions for rename and unlink operations.</p> <p>YES Additional restrictions for rename and unlink operations.</p>

Table 145. IFS_OBJECT_STATISTICS table function (continued)

Column Name	Data Type	Description
PC_ARCHIVE	VARCHAR(3)	<p>Whether the object has changed since the last time it was saved on the PC.</p> <p>NO The object has not changed.</p> <p>YES The object has changed.</p>
SYSTEM_ARCHIVE	VARCHAR(3)	<p>Whether the object has changed and needs to be saved on the IBM i. The value will be YES when an object's change time is updated, and set to NO when the object has been saved.</p> <p>NO The object has not changed and does not need to be saved.</p> <p>YES The object has changed and needs to be saved.</p>
ALLOW_SAVE	VARCHAR(3)	<p>Whether the object can be saved or not.</p> <p>NO This object will not be saved when using the Save Object (SAV) command or the QsrSave() API.</p> <p>Additionally, if this object is a directory, none of the objects in the directory's subtree will be saved unless they were explicitly specified as an object to be saved.</p> <p>YES This object will be saved when using the Save Object (SAV) command or the QsrSave() API.</p>
SYSTEM_RESTRICT_SAVE	VARCHAR(3)	<p>Whether the system prevents the object from being saved.</p> <p>NO The system does not prevent the object from being saved.</p> <p>YES The system has determined that the object cannot be saved because of system restrictions.</p>
INHERIT_ALLOW_CHECKPOINT_WRITER	VARCHAR(3)	<p>Whether new objects created within a directory should inherit the save-while-active checkpoint processing options of its parent.</p> <p>NO New directory objects created within this directory will have the QPOL_ATTR_INHERIT_ALWCKPWRT attribute set to NO.</p> <p>New objects created within this directory will have the QPOL_ATTR_ALWCKPWRT attribute set to QPOL_NOT_ALWCKPWRT.</p> <p>YES New directory objects created within this directory will have the QPOL_ATTR_INHERIT_ALWCKPWRT attribute set to YES.</p> <p>New objects created within this directory will have the QPOL_ATTR_ALWCKPWRT attribute set to QPOL_ALWCKPWRT.</p>
ALLOW_WRITE_DURING_SAVE	VARCHAR(3)	<p>If the object is a stream file, indicates whether the stream file can be shared with readers and writers during save-while-active checkpoint processing. If the object is a directory, indicates whether links can be added, removed, or renamed in the directory during a save-while-active operation.</p> <p>NO If the object is a stream file, it can be shared with readers only during save-while-active checkpoint processing. If the object is a directory, links can not be added, removed, or renamed in the directory during a save-while-active operation.</p> <p>YES If the object is a stream file, it can be shared with readers and writers during save-while-active checkpoint processing. If the object is a directory, links can be added, removed, or renamed in the directory during a save-while-active operation.</p> <p>Contains the null value if OBJECT_TYPE is not *STMF or *DIR.</p>

Table 145. IFS_OBJECT_STATISTICS table function (continued)

Column Name	Data Type	Description
EXIT_PROGRAM_SCAN	VARCHAR(11)	<p>Whether the object will be scanned when exit programs are registered with any of the integrated file system scan-related exit points.</p> <p>CHANGE ONLY The object will be scanned according to the rules described in the scan-related exit programs only if the object has been modified since the last time the object was scanned. It will not be scanned if the scanning software has been updated. This attribute only takes effect if the Scan file systems control (QSCANFCTL) system value has *USEOCOATR specified. Otherwise, it will be treated the same as YES.</p> <p>NO The object will not be scanned according to the rules described in the scan-related exit programs.</p> <p>YES The object will be scanned according to the rules described in the scan-related exit programs if the object has been modified or if the scanning software has been updated since the last time the object was scanned.</p> <p>Contains the null value if OBJECT_TYPE is not *STMF.</p>
EXIT_PROGRAM_SCAN_DIRECTORY	VARCHAR(11)	<p>Whether the objects created in a directory will be scanned when exit programs are registered with any of the integrated file system scan-related exit points.</p> <p>CHANGE ONLY After an object is created in the directory, the object will be scanned according to the rules described in the scan-related exit programs only if the object has been modified since the last time the object was scanned. It will not be scanned if the scanning software has been updated. This attribute only takes effect if the Scan file systems control (QSCANFCTL) system value has *USEOCOATR specified. Otherwise, it will be treated the same as YES.</p> <p>NO After an object is created in the directory, the object will not be scanned according to the rules described in the scan-related exit programs.</p> <p>YES After an object is created in the directory, the object will be scanned according to the rules described in the scan-related exit programs if the object has been modified or if the scanning software has been updated since the last time the object was scanned.</p> <p>Contains the null value if OBJECT_TYPE is not *DIR.</p>
SCAN_STATUS	VARCHAR(12)	<p>The scan status associated with this object.</p> <p>FAILURE The object has been scanned by a scan-related exit program, and at the time of that last scan request, the object failed the scan and the operation did not complete. Once an object has been marked as a failure, it will not be scanned again until the object's scan signature is different than the global scan key signature or independent ASP group scan key signature as appropriate. Therefore, subsequent requests to work with the object will fail with a scan failure indication if that access meets the criteria for when an object is to be scanned.</p> <p>NOT REQUIRED The object does not require any scanning because the object is marked to not be scanned.</p> <p>PENDING The object is in a file system that has not completely converted to the *TYPE2 directory format, and therefore will not be scanned until the file system is completely converted.</p> <p>REQUIRED A scan is required for the object either because it has not yet been scanned by the scan-related exit programs, or because the object data or CCSID has been modified since it was last scanned.</p> <p>SUCCESS The object has been scanned by a scan-related exit program, and at the time of that last scan request, the object did not fail the scan.</p>

Table 145. IFS_OBJECT_STATISTICS table function (continued)

Column Name	Data Type	Description
CCSID_SCAN	INTEGER	A CCSID value that the object has been scanned in if it was previously scanned in a CCSID. If SCAN_STATUS is SUCCESS, the object was successfully scanned in this CCSID. If SCAN_STATUS is FAILURE, the object failed the scan in this CCSID. Contains the null value if no CCSID applies.
CCSID_SCAN_SUCCESS	INTEGER	If SCAN_STATUS is SUCCESS, the object was successfully scanned in this CCSID. Contains the null value if the SCAN_STATUS is FAILURE or if CCSID_SCAN is the null value.
SCAN_SIGNATURES_DIFFERENT	VARCHAR(3)	When an object is in an independent ASP group, the object scan signature is compared to the associated independent ASP group scan signature. When an object is not in an independent ASP group, the object scan signature is compared to the global scan signature value. NO The compared signatures are not different. YES The compared signatures are different.
BINARY_SCAN	VARCHAR(3)	The object was scanned in binary mode when it was previously scanned. NO The object was not scanned in binary mode. YES The object was scanned in binary mode.
CHECKED_OUT	VARCHAR(3)	Whether the object is checked out. NO The object is not checked out. YES The object is checked out.
CHECKED_OUT_TIMESTAMP	TIMESTAMP(0)	The time the object was checked out. Contains the null value if the object is not checked out.
CHECKED_OUT_USER	VARCHAR(10)	The user who has the object checked out. Contains the null value if the object is not checked out.

Example

- List basic information for all the objects in directory /usr.

```
SELECT PATH_NAME, OBJECT_TYPE, DATA_SIZE, OBJECT_OWNER
FROM TABLE (QSYS2.IFS_OBJECT_STATISTICS(START_PATH_NAME => '/usr',
SUBTREE_DIRECTORIES => 'NO'));
```

- List basic information for all the objects in /usr, processing all subdirectories as well.

```
SELECT PATH_NAME, OBJECT_TYPE, DATA_SIZE, OBJECT_OWNER
FROM TABLE (QSYS2.IFS_OBJECT_STATISTICS(START_PATH_NAME => '/usr',
SUBTREE_DIRECTORIES => 'YES'));
```

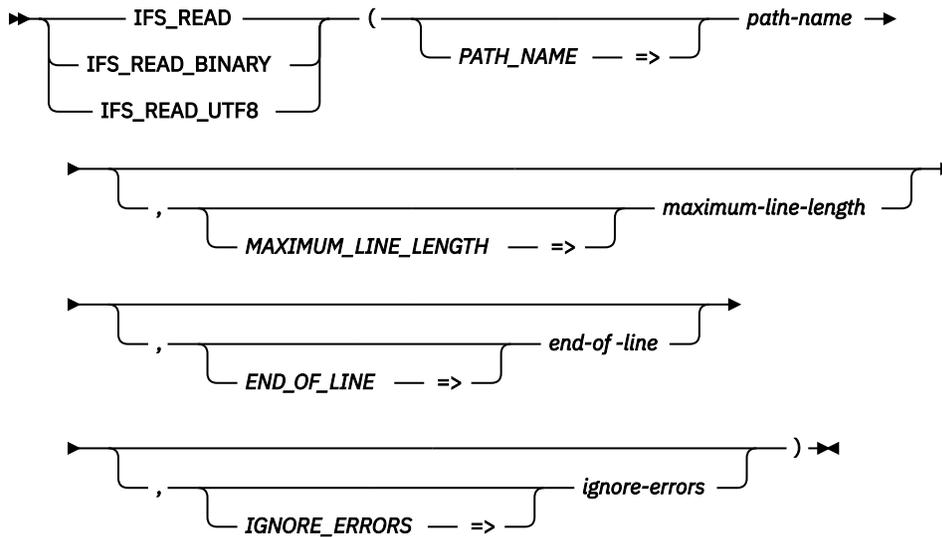

IFS_READ, IFS_READ_BINARY, and IFS_READ_UTF8 table functions

The IFS_READ, IFS_READ_BINARY, and IFS_READ_UTF8 table functions read an integrated file system stream file identified by *path-name*. The file's data is returned as character, binary, or UTF-8 data. It can be returned as one string of data, or it can be broken into multiple lines using a specified length or end of line characters.

Authorization: The caller must have:

- For objects not in the QSYS.LIB file system:
 - Execute (*X) data authority to each directory preceding the stream file being read and
 - Read (*R) data authority to the stream file
- For objects in the QSYS.LIB file system:

- Execute (*X) data authority to each directory preceding the object being read and
 - For a *SAVF object, Read, Write, and Execute (*RWX) data authority to the object
 - For all other object types, Read (*R) data authority to the object

The schema is QSYS2.

- path-name** An expression that returns the path name identifying the stream file to read. A relative path name is relative to the current directory. If an absolute path name is not specified, the current working directory is used in combination with the relative path name to resolve to the object. If the object is not a stream file, an error is issued.
- maximum-line-length** An integer value that specifies the maximum number of characters returned for each line. It must be greater than 0. The default is 2 gigabytes.
 If *end-of-line* is NONE or if no end of line sequence is found in the stream file, the number of characters returned for each line will be limited to this value.
 If an end of line sequence is encountered before this length is reached, the line will end at that point. The next line returned will start with the character directly after the end of line sequence.
- end-of-line** A character or graphic string that specifies the end of line characters to be recognized in the stream file. Each occurrence of an end of line sequence determines a line which is returned. The end of line character sequence is not returned with the line. When using IFS_READ_BINARY, end of line characters are never processed, so this parameter must have a value of NONE.
 The carriage-return character is always X'0D'. Based on the CCSID of the stream file being read, the line feed character is X'25' for an EBCDIC CCSID and X'0A' for ASCII and UTF-8 CCSIDs.
- ANY** Any of the four end of line sequences indicate the end of a line. This is the default for IFS_READ and IFS_READ_UTF8.
- CR** A carriage return indicates the end of a line.
- CRLF** A carriage return and line feed indicate the end of a line.
- LF** A line feed indicates the end of a line.
- LFCR** A line feed and carriage return indicate the end of a line.
- NONE** No end of line characters are recognized. *maximum-line-length* determines the number of characters to be returned. This is the default for IFS_READ_BINARY.

ignore-errors A character or graphic string expression that identifies what to do when an error is encountered.

NO An error is returned.

YES A warning is returned.

No row is returned when an error is encountered. This is the default.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 146. IFS_READ table function

Column Name	Data Type	Description
LINE_NUMBER	INTEGER	Relative position of this line in the stream file.
LINE	For IFS_READ: CLOB(2G) For IFS_READ_BINARY: BLOB(2G) For IFS_READ_UTF8: CLOB(2G) CCSID 1208	The data for this line. <ul style="list-style-type: none"> For IFS_READ, the data from the stream file will be returned in the job CCSID. For IFS_READ_BINARY, the data from the stream file will be returned exactly as it is stored without conversion. For IFS_READ_UTF8, the data from the stream file will be returned in CCSID 1208.

Example

- Read the data from stream file /usr/file1. Break lines when a carriage return/line feed sequence is encountered. The result will be in the job's CCSID.

```
SELECT * FROM TABLE(QSYS2.IFS_READ(PATH_NAME => '/usr/file1',
                                   END_OF_LINE => 'CRLF'));
```

- Read the data from stream file /usr/file2. If the file size is less than 2 gigabytes, the result will be a single row containing the entire file. If the file size is greater than 2 gigabytes, multiple rows will be returned.

```
SELECT * FROM TABLE(QSYS2.IFS_READ_BINARY(PATH_NAME => '/usr/file2'));
```

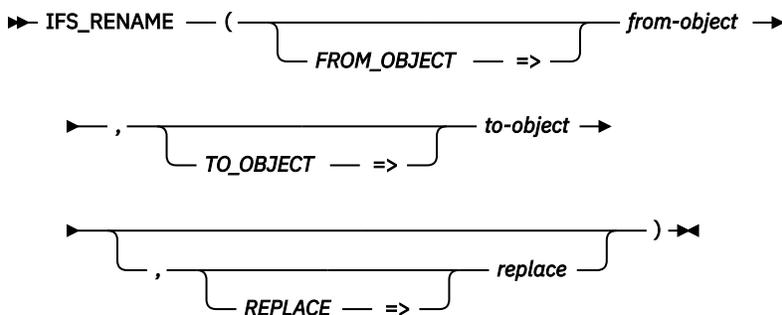

IFS_RENAME scalar function

The IFS_RENAME scalar function renames either a file or a directory in the integrated file system.

The function requires that Option 13 (System Openness Includes) of the IBM i operating system is installed.

This function uses the [Qp0IRenameUnlink\(\)--Rename File or Directory, Unlink "new" If It Exists](#) and [Qp0IRenameKeep\(\)--Rename File or Directory, Keep "new" If It Exists](#) APIs to rename the object. Refer to the APIs for more detailed information.

Authorization: See Note below.

Note

This function is provided in the SYSTOOLS schema as an example of how to embed a C language interface in an SQL scalar function. Similar to other Db2 for i provided tools within SYSTOOLS, the SQL source can be extracted and used as a model for building similar helper functions, or to create a customized version within a user-specified schema.

Services provided in SYSTOOLS have authorization requirements that are determined by the interfaces used to implement the service. To understand the authority requirements, extract the SQL for the service and examine the implementation.

Example

Unlink file /usr/reportdata.txt.

```
VALUES SYSTOOLS.IFS_UNLINK(PATH_NAME => '/usr/reportdata.txt');
```

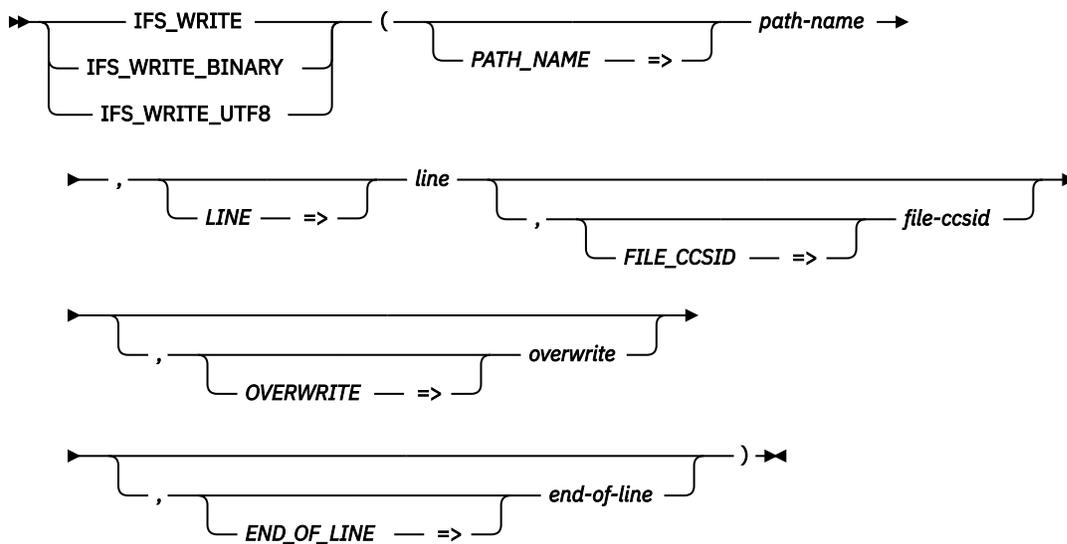

IFS_WRITE, IFS_WRITE_BINARY, and IFS_WRITE_UTF8 procedures

The IFS_WRITE, IFS_WRITE_BINARY, and IFS_WRITE_UTF8 procedures write data to an integrated file system stream file. The data can be written as character, binary, or UTF-8 data. Data can be either replaced or appended for an existing file, or a new file can be created.

Up to 2 gigabytes of data can be written by one call to this procedure. It can contain embedded end of line characters, or the procedure can append end of line characters to the input data.

Authorization: The caller must have:

- For objects not in the QSYS.LIB file system when the stream file exists and is not being replaced:
 - Execute (*X) data authority to each directory preceding the stream file being written and
 - Write (*W) data authority to the stream file
- For objects not in the QSYS.LIB file system when the stream file does not exist or is being replaced:
 - Execute (*X) data authority to each directory preceding the stream file being written and
 - Write and Execute (*WX) authority to the parent directory of the stream file
- For objects in the QSYS.LIB file system when the object exists and is not being replaced:
 - Execute (*X) data authority to each directory preceding the object being written and
 - For a *SAVF object, Read, Write, and Execute (*RWX) data authority to the object
 - For all other object types, Write (*W) data authority to the object
- For objects in the QSYS.LIB file system when the object does not exist or is being replaced:
 - Execute (*X) data authority to each directory preceding the object being written and
 - For a *SAVF object, Read and Execute and Add (*RX and *ADD) data authority to the parent directory of the object
 - For a physical file member, Add (*ADD) data authority to the parent directory of the object
 - For all other object types, *OBJMGT or *OBJALTER authority to the parent directory of the object

The schema is QSYS2.

path-name A character or graphic string that defines the path name for the file to be written. If an absolute path name is not specified, the current working directory is used in combination with the relative path name to resolve to the object.

If *path-name* identifies an existing object, the object must be a stream file. Otherwise, a stream file will be created.

When a stream file is created, the default authority for the parent directory is used.

line A character or graphic string containing the data to be written to the stream file at *path-name*. It can be up to 2 gigabytes long.

- For IFS_WRITE, *line* is a character string in the job CCSID. If the stream file is not in the job CCSID, *line* will be converted to the stream file's CCSID as it is written.
- For IFS_WRITE_BINARY, *line* is a binary string. The data will not be converted when writing to the stream file.
- For IFS_WRITE_UTF8, *line* is a UTF-8 string. If the stream file is not UTF-8, *line* will be converted to the stream file's CCSID as it is written.

file-ccsid An integer value that specifies the CCSID to be used when creating a new stream file. This parameter is ignored when appending to an existing file.

If this parameter is not specified, the default is 1208 for IFS_WRITE_UTF8 and 0 for IFS_WRITE and IFS_WRITE_BINARY.

When *file-ccsid* is 0, the job CCSID is used when creating a new stream file.

overwrite A character or graphic string that specifies whether the write operation appends to the stream file, replaces the stream file, or fails when a stream file with the specified name already exists.

APPEND The data in *line* is added to the end of the existing stream file. If the stream file does not exist, it is created. This is the default.

NONE The write operation fails if the stream file exists.

REPLACE The data in *line* replaces the existing stream file if it exists. An existing stream file is deleted and a new stream file is created. The CCSID of the stream file might change. If the stream file does not exist, it is created.

end-of-line

A character or graphic string that specifies the end of line characters to write to the stream file after *line* is written. When using IFS_WRITE_BINARY, end of line characters are never appended, so this parameter must have a value of NONE.

The carriage-return character is always X'0D'. Based on the CCSID of the stream file being written, the line feed character is X'25' for an EBCDIC CCSID and X'0A' for ASCII and UTF-8 CCSIDs.

- CR** A carriage return is appended.
- CRLF** A carriage return and line feed are appended. This is the default for IFS_WRITE and IFS_WRITE_UTF8.
- LF** A line feed is appended.
- LFCR** A line feed and carriage return are appended.
- NONE** No end of line characters are appended. This is the default for IFS_WRITE_BINARY.

Examples

- Create a stream file which contains a list of all of the libraries on the system, one per line. The file is created in job CCSID.

```
BEGIN
-- Make sure output file is empty to start
CALL QSYS2.IFS_WRITE(PATH_NAME => '/tmp/library_names',
                    LINE => '',
                    OVERWRITE => 'REPLACE',
                    END_OF_LINE => 'NONE');

-- Add lines to the output file
FOR SELECT OBJNAME AS LIBNAME FROM TABLE(QSYS2.OBJECT_STATISTICS('*ALLSIMPLE', 'LIB')) DO
    CALL QSYS2.IFS_WRITE(PATH_NAME => '/tmp/library_names',
                        LINE => LIBNAME);
END FOR;
END;
```

The QSYS2.IFS_READ table function can be used to read the contents of the generated stream file.

```
SELECT * FROM TABLE(QSYS2.IFS_READ('/tmp/library_names'));
```

- Create a UTF-8 (CCSID 1208) stream file which contains a UTF-8 Byte Order Mark (BOM) and the string 'Hello'.

```
CALL QSYS2.IFS_WRITE_BINARY(PATH_NAME => '/usr/utf8file',
                            LINE => BLOB(X'EFBBBF48656C6C6F'),
                            FILE_CCSID => 1208,
                            OVERWRITE => 'REPLACE'
                            );
```

SERVER_SHARE_INFO view

The SERVER_SHARE_INFO view returns information about IBM i NetServer shares.

This information is similar to what is returned by the List Server Information (QZLSLSTI) and Open List of Server Information (QZLSOLST) APIs.

Authorization: None required.

The following table describes the columns in the view. The system name is SHARE_INFO. The schema is QSYS2.

Table 147. SERVER_SHARE_INFO view

Column Name	System Column Name	Data Type	Description
SERVER_SHARE_NAME	SHARE	VARCHAR(12)	The network name of the resource.
SHARE_TYPE	SHARE_TYPE	VARCHAR(5)	The type of share. FILE This is a file share PRINT This is a print share
TEXT_DESCRIPTION	TEXT	VARCHAR(50) Nullable	An optional comment about the shared resource or computer. Contains the null value if there is no text description.
ENCRYPTION_REQUIRED	ENCRYPTION	VARCHAR(3)	Whether the server requires access to the share to use encryption. NO Access to the share does not require encryption YES Access to the share can only be made from an SMB 3 or newer client with encryption enabled. Unencrypted access to this share is denied.
The following columns can contain values when SHARE_TYPE is FILE. They will contain the null value when SHARE_TYPE is PRINT.			
PATH_NAME	PATH_NAME	DBCLOB(16M) CCSID 1200 Nullable	The file share path in the integrated file system. Contains the null value when SHARE_TYPE is PRINT.
PERMISSIONS	PERMISSION	VARCHAR(3) Nullable	Permissions to be applied against the file for sharing. *R Read only *RW Read/write Contains the null value when SHARE_TYPE is PRINT.
MAXIMUM_CONNECTIONS	MAX_CONN	INTEGER Nullable	The maximum number of concurrent connections that the shared file resource can accommodate. Contains the null value if the number is unlimited or SHARE_TYPE is PRINT.
CURRENT_CONNECTIONS	CUR_CONN	INTEGER Nullable	The number of connections that are currently made to the resource. Contains the null value if the value could not be returned or SHARE_TYPE is PRINT.
TEXT_CONVERSION_ENABLED	TEXT_CONV	VARCHAR(5) Nullable	Whether the server enables text file data conversion for this file share. MIXED Text conversion enabled and mixed data is allowed NO Text conversion not enabled YES Text conversion enabled Contains the null value when SHARE_TYPE is PRINT.
TEXT_CONVERSION_CCSID	TEXT_CCSID	INTEGER Nullable	The CCSID that is used for text file data conversion. If the value is 0, no CCSID was specified so the IBM i NetServer's default CCSID will be used. Contains the null value if TEXT_CONVERSION_ENABLED is NO or when SHARE_TYPE is PRINT.

Table 147. SERVER_SHARE_INFO view (continued)

Column Name	System Column Name	Data Type	Description												
FILE_EXTENSION_COUNT	EXT_COUNT	INTEGER Nullable	The number of file extension entries returned in FILE_EXTENSIONS. Contains the null value when SHARE_TYPE is PRINT.												
FILE_EXTENSIONS	EXTENSIONS	VARBINARY(5000) Nullable	A string containing a list of file extensions. The format of each entry is a 2 byte integer length followed by that number of characters followed by a single blank. If there are more file extensions than what fit in this column, the last file extension in the list will have a length of 3 with a value of +++ to indicate the list was truncated. Examples of extensions are: <table border="0"> <tr> <td style="padding-right: 20px;">*</td> <td>The server will convert all files.</td> </tr> <tr> <td>.</td> <td>The server will convert all files without an extension.</td> </tr> <tr> <td>.TXT, .TXT</td> <td>The server will convert all files ending with .TXT (that is, a.TXT, a.b.c.TXT).</td> </tr> <tr> <td>..TXT, ...TXT,TXT</td> <td>Extensions with more than one leading period will have no effect on the server. No translation will be done.</td> </tr> <tr> <td>T*T</td> <td>The server will convert all files ending with an extension that substitutes any number of characters for the * wild card (that is, a.T123T, b.TXT, c.TEST).</td> </tr> <tr> <td>T?T</td> <td>The server will convert all files ending with an extension that substitutes any one character for the ? wild card (that is, a.T1T, b.TXT).</td> </tr> </table> Contains the null value when SHARE_TYPE is PRINT.	*	The server will convert all files.	.	The server will convert all files without an extension.	.TXT, .TXT	The server will convert all files ending with .TXT (that is, a.TXT, a.b.c.TXT).	..TXT, ...TXT,TXT	Extensions with more than one leading period will have no effect on the server. No translation will be done.	T*T	The server will convert all files ending with an extension that substitutes any number of characters for the * wild card (that is, a.T123T, b.TXT, c.TEST).	T?T	The server will convert all files ending with an extension that substitutes any one character for the ? wild card (that is, a.T1T, b.TXT).
*	The server will convert all files.														
.	The server will convert all files without an extension.														
.TXT, .TXT	The server will convert all files ending with .TXT (that is, a.TXT, a.b.c.TXT).														
..TXT, ...TXT,TXT	Extensions with more than one leading period will have no effect on the server. No translation will be done.														
T*T	The server will convert all files ending with an extension that substitutes any number of characters for the * wild card (that is, a.T123T, b.TXT, c.TEST).														
T?T	The server will convert all files ending with an extension that substitutes any one character for the ? wild card (that is, a.T1T, b.TXT).														
The following columns can contain values when SHARE_TYPE is PRINT. They will contain the null value when SHARE_TYPE is FILE.															
SPOOLED_FILE_TYPE	SPOOL_TYPE	VARCHAR(9) Nullable	The type of spooled files that will be created using this print share. <table border="0"> <tr> <td style="padding-right: 20px;">AFP</td> <td>Advanced Function Presentation</td> </tr> <tr> <td>AUTOSENSE</td> <td>Automatic type sensing</td> </tr> <tr> <td>SCS</td> <td>Simplified Character Set</td> </tr> <tr> <td>USERASCII</td> <td>User ASCII</td> </tr> </table> Contains the null value when SHARE_TYPE is FILE.	AFP	Advanced Function Presentation	AUTOSENSE	Automatic type sensing	SCS	Simplified Character Set	USERASCII	User ASCII				
AFP	Advanced Function Presentation														
AUTOSENSE	Automatic type sensing														
SCS	Simplified Character Set														
USERASCII	User ASCII														
OUTPUT_QUEUE_LIBRARY	OUTQLIB	VARCHAR(10) Nullable	The library containing the output queue. Contains the null value when SHARE_TYPE is FILE.												
OUTPUT_QUEUE	OUTQ	VARCHAR(10) Nullable	The name of the output queue. Contains the null value when SHARE_TYPE is FILE.												

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 148. JVM_INFO table function

Column Name	Data Type	Description
JOB_NAME	VARCHAR(28)	The qualified job name for the active JVM.
JOB_NAME_SHORT	VARCHAR(10)	The name of the job for the active JVM.
JOB_USER	VARCHAR(10)	The user profile that started the job for the active JVM.
JOB_NUMBER	VARCHAR(6)	The job number of the job for the active JVM.
PROCESS_ID	INTEGER	The process identifier used by the kernel to uniquely identify the process.
START_TIME	TIMESTAMP	The current time when the JVM was started.
INITIAL_THREAD_TASKCOUNT	BIGINT	The taskcount or TDE number of the JVM's initial thread. The taskcount or TDE number is a unique identifier assigned to each job, thread, and task running in the system.
JAVA_THREAD_COUNT	BIGINT	The current number of java threads within the JVM job.
TOTAL_GC_TIME	BIGINT	Total time spent performing garbage collection tasks in milliseconds.
GC_CYCLE_NUMBER	INTEGER	The current or last garbage collection cycle performed.
GC_POLICY_NAME	VARGRAPHIC(16) CCSID 1200	The name of the garbage collection policy in use.
JAVA_HOME	VARGRAPHIC(1024) CCSID 1200	The java.home environment variable value in effect for this JVM. This value indicates the JDK that is used when running a Java application. The location of the Java tools and utilities is in one of two directories, either <JAVA_HOME>/jre/bin or <JAVA_HOME>/bin, where <JAVA_HOME> is the value of the JAVA_HOME environment variable. For example, if JAVA_HOME is set to /QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit, indicating that IBM Technology for Java 6 32-bit is to be used, then the Java tools and utilities directories would be: /QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit/bin /QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit/jre/bin
USER_DIRECTORY	VARGRAPHIC(1024) CCSID 1200	The user working directory for the JVM. This also indicates the location where diagnostic detail will be dumped for the JVM.
NUM_CURRENT_PROPERTIES	INTEGER	Total number of Java system properties currently present.
INITIAL_HEAP_SIZE	BIGINT	The initial heap size available to the JVM code, in kilobytes.
CURRENT_HEAP_SIZE	BIGINT	The amount of memory, in kilobytes, currently allocated for heap space.
IN_USE_HEAP_SIZE	BIGINT	The amount of memory, in kilobytes, currently in use by the heap.
MAX_HEAP_SIZE	BIGINT	The maximum heap size available to the JVM code, in kilobytes.
MALLOC_MEMORY_SIZE	BIGINT	The amount of memory, in kilobytes, that has been allocated with malloc().
INTERNAL_MEMORY_SIZE	BIGINT	The amount of memory, in kilobytes, that the JVM is using for internal operations.
JIT_MEMORY_SIZE	BIGINT	The size of the memory space, in kilobytes, that is used by the JIT (Just in Time) compiler.
SHARED_CLASS_SIZE	BIGINT	The amount of memory, in kilobytes, that the JVM is using for shared classes.
BIT_MODE	INTEGER	The Java version of this job. 32 32 bit Java job 64 64 bit Java job

Example

- Show information for all JVMs on the system. Do not wait longer than 10 seconds for the results of any individual JVM to be returned.

```
SELECT * FROM TABLE(QSYS2.JVM_INFO(WAIT_TIME => 10));
```

JVM_INFO view

The JVM_INFO view returns information about active Java Virtual Machine (JVM) jobs.

The information returned is similar to the detail available through the Work with JVM Jobs (WRKJVMJOB) CL command.

Authorization: The caller must have *JOBCTL special authority to see values for columns other than the job name columns and PROCESS_ID.

The following table describes the columns in the view. The schema is QSYS2.

Table 149. JVM_INFO view

Column Name	System Column Name	Data Type	Description
JOB_NAME	JOB_NAME	VARCHAR(28)	The qualified job name for the active JVM.
JOB_NAME_SHORT	JOB_NAME_S	VARCHAR(10)	The name of the job for the active JVM.
JOB_USER	JOB_USER	VARCHAR(10)	The user profile that started the job for the active JVM.
JOB_NUMBER	JOB_NUMBER	VARCHAR(6)	The job number of the job for the active JVM.
PROCESS_ID	PROCESS_ID	INTEGER	The process identifier used by the kernel to uniquely identify the process.
START_TIME	START_TIME	TIMESTAMP	The current time when the JVM was started.
INITIAL_THREAD_TASKCOUNT	INITTHDNUM	BIGINT	The taskcount or TDE number of the JVM's initial thread. The taskcount or TDE number is a unique identifier assigned to each job, thread, and task running in the system.
JAVA_THREAD_COUNT	JAVATHDNUM	BIGINT	The current number of java threads within the JVM job.
TOTAL_GC_TIME	ACCUMTIME	BIGINT	Total time spent performing garbage collection tasks in milliseconds.
GC_CYCLE_NUMBER	GCCYCLE	INTEGER	The current or last garbage collection cycle performed.
GC_POLICY_NAME	GCPOLICY	VARGRAPHIC(16) CCSID 1200	The name of the garbage collection policy in use.
JAVA_HOME	JAVA_HOME	VARGRAPHIC(102 4) CCSID 1200	The java.home environment variable value in effect for this JVM. This value indicates the JDK that is used when running a Java application. The location of the Java tools and utilities is in one of two directories, either <JAVA_HOME>/jre/bin or <JAVA_HOME>/bin, where <JAVA_HOME> is the value of the JAVA_HOME environment variable. For example, if JAVA_HOME is set to /QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit, indicating that IBM Technology for Java 6 32-bit is to be used, then the Java tools and utilities directories would be: /QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit/bin /QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit/jre/bin
USER_DIRECTORY	USER_DIR	VARGRAPHIC(102 4) CCSID 1200	The user working directory for the JVM. This also indicates the location where diagnostic detail will be dumped for the JVM.
NUM_CURRENT_PROPERTIES	NUMPROP	INTEGER	Total number of Java system properties currently present.
INITIAL_HEAP_SIZE	INITHEAP	BIGINT	The initial heap size available to the JVM code, in kilobytes.
CURRENT_HEAP_SIZE	CURHEAP	BIGINT	The amount of memory, in kilobytes, currently allocated for heap space.
IN_USE_HEAP_SIZE	INUSEHEAP	BIGINT	The amount of memory, in kilobytes, currently in use by the heap.
MAX_HEAP_SIZE	MAXHEAP	BIGINT	The maximum heap size available to the JVM code, in kilobytes.
MALLOC_MEMORY_SIZE	MALLOCSIZE	BIGINT	The amount of memory, in kilobytes, that has been allocated with malloc().
INTERNAL_MEMORY_SIZE	INTMEM	BIGINT	The amount of memory, in kilobytes, that the JVM is using for internal operations.
JIT_MEMORY_SIZE	JITSIZE	BIGINT	The size of the memory space, in kilobytes, that is used by the JIT (Just in Time) compiler.

Table 149. JVM_INFO view (continued)

Column Name	System Column Name	Data Type	Description
SHARED_CLASS_SIZE	SHARED_SIZE	BIGINT	The amount of memory, in kilobytes, that the JVM is using for shared classes.
BIT_MODE	BIT_MODE	INTEGER	The Java version of this job. <div style="display: flex; justify-content: space-between;"> 32 32 bit Java job </div> <div style="display: flex; justify-content: space-between;"> 64 64 bit Java job </div>

Example

Examine the active JVM jobs, ordered by top heap space consumption.

```
SELECT * FROM QSYS2.JVM_INFO
ORDER BY CURRENT_HEAP_SIZE DESC
```

SET_JVM procedure

The SET_JVM procedure can be used to manage specific JVM jobs.

This actions provided by this Db2 for i procedure can also be accomplished interactively using the Work with JVM Jobs (WRKJVMJOB) command.

Authorization: None required.

➤ SET_JVM — (— *job_name* — , — *action* —) ➤

The schema is QSYS2.

job_name A character or graphic string expression that identifies the qualified job name of the job to change.

action A character or graphic string expression that specifies that action to perform. Supported actions are:

GC_ENABLE_VERBOSE	Enable verbose garbage collection detail.
GC_DISABLE_VERBOSE	Disable verbose garbage collection detail.
GENERATE_HEAP_DUMP	Generates information about the JVM's heap. Generates a dump of all the heap space allocations which have not yet been freed.
GENERATE_SYSTEM_DUMP	Generates system detail for the JVM. Generates a binary format raw memory image of the job that was running when the dump was initiated.
GENERATE_JAVA_DUMP	Generates Java detail for the JVM. Generates multiple files that contain diagnostic information for the JVM and the Java applications running within the JVM.

Example

- Change a specific web admin JVM to provide verbose garbage collection details:

```
CALL QSYS2.SET_JVM('121376/QWEBADMIN/ADMIN4', 'GC_ENABLE_VERBOSE') ;
```

Journal Services

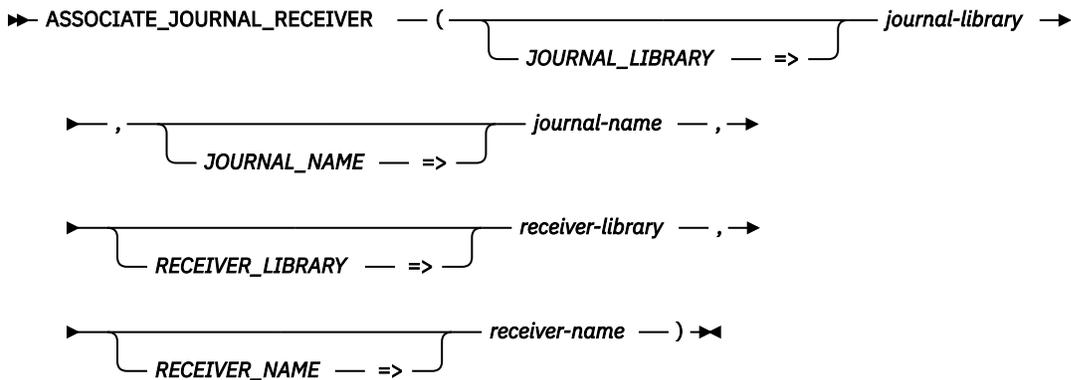

These services provide information about audit journals and data journals.

ASSOCIATE_JOURNAL_RECEIVER table function

The ASSOCIATE_JOURNAL_RECEIVER table function associates one or more journal receivers with a journal if the journal receiver was originally associated with the journal.

Authorization: The user must have:

- *EXECUTE authority to the library containing the journal receiver
- *OBJMGT authority to the journal receiver
- *EXECUTE authority to the library containing the journal
- *OBJMGT and *OBJOPR authority to the journal

The schema is QSYS2.

journal-library A character or graphic string expression that identifies the library that contains *journal-name*. Can contain the special values *LIBL or *CURLIB.

journal-name A character or graphic string expression that identifies the name of the journal.

receiver-library A character or graphic string expression that identifies the name of the library containing *receiver-name*. Can contain the special values *LIBL or *CURLIB.

receiver-name A character or graphic string expression that identifies the name of the journal receiver. A generic name can be specified to select specific journal receivers. If the last character in the name is an asterisk, the name is a generic name. For example, to select all journal receivers that start with 'JR', specify a *receiver-name* value of 'JR*'.
The special value of *ALL can be used to select all journal receivers in *receiver-library*. *ALL is not allowed if *receiver-library* is *LIBL.

The result of the function is a table containing rows with the format shown in the following table. All columns are nullable.

Table 150. ASSOCIATE_JOURNAL_RECEIVER table function

Column name	Data type	Description
JOURNAL_LIBRARY	VARCHAR(10)	The library containing the journal that the journal receiver attempted to associate with.
JOURNAL_NAME	VARCHAR(10)	The journal that the journal receiver attempted to associate with.
RECEIVER_LIBRARY	VARCHAR(10)	The library containing the journal receiver.
RECEIVER_NAME	VARCHAR(10)	The journal receiver.

Table 150. ASSOCIATE_JOURNAL_RECEIVER table function (continued)

Column name	Data type	Description
RESULT	VARCHAR(7)	Result type. FAILURE The operation did not complete. SUCCESS The operation completed successfully. WARNING The operation completed but a warning was issued.
RESULT_DETAIL	VARGRAPHIC(100) CCSID 1200	Descriptive text that corresponds to RESULT.

Table 150. ASSOCIATE_JOURNAL_RECEIVER table function (continued)

Column name	Data type	Description
RETURN_CODE	INTEGER	<p>The return code that corresponds to the result.</p> <ul style="list-style-type: none"> 0 The specified journal receiver was successfully associated with the specified journal. 1 The specified journal receiver was already associated with the specified journal. 2 The specified journal receiver could not be associated with the specified journal because the journal receiver was already associated with a different journal. 3 The specified journal receiver could not be associated with the specified journal because the journal receiver was never associated with that journal or could not be associated with that journal in a remote journal network. 4 The specified journal receiver could not be associated with the specified journal because the journal receiver's library could not be found. 5 The specified journal receiver could not be associated with the specified journal because the journal receiver could not be found. 6 The specified journal receiver could not be associated with the specified journal because the journal's library could not be found. 7 The specified journal receiver could not be associated with the specified journal because the journal could not be found. 8 The specified journal receiver could not be associated with the specified journal because the journal receiver could not be locked. 9 The specified journal receiver could not be associated with the specified journal because the journal could not be locked. 10 The specified journal receiver could not be associated with the specified journal because the user is not authorized to the journal receiver's library. 11 The specified journal receiver could not be associated with the specified journal because the user is not authorized to the journal receiver. 12 The specified journal receiver could not be associated with the specified journal because the user is not authorized to the journal's library. 13 The specified journal receiver could not be associated with the specified journal because the user is not authorized to the journal. 14 The specified journal receiver could not be associated with the specified journal because the journal receiver is damaged. 15 The specified journal receiver could not be associated with the specified journal because the journal is damaged. 16 The specified journal receiver could not be associated with the specified journal because the journal receiver and journal are not both in the system or user auxiliary storage pools (ASPs) or the journal receiver and journal are in different independent auxiliary storage pool (IASP) groups.

Example

Re-establish the association of journal APPLIB/APPJRN with journal receiver RCVRLIB/RCV001.

```
SELECT *
FROM TABLE(QSYS2.ASSOCIATE_JOURNAL_RECEIVER('APPLIB', 'APPJRN', 'RCVRLIB', 'RCV001'));
```

AUDIT_JOURNAL_DATA_MART_INFO view

The AUDIT_JOURNAL_DATA_MART_INFO view contains information about the AUDIT_JOURNAL_XX data mart tables that are populated and updated using the MANAGE_AUDIT_JOURNAL_DATA_MART procedure.

Authorization: The caller must have *AUDIT special authority.

The following table describes the columns in the view. There is one row of information for each audit journal entry type that has been requested for each library. The system name is AJ_DMART. The schema is QSYS2.

Table 151. AUDIT_JOURNAL_DATA_MART_INFO view

Column Name	System Column Name	Data Type	Description
DATA_MART_LIBRARY	LIBRARY	VARCHAR(10)	The library containing the data mart table.
DATA_MART_TABLE	TABLE	CHAR(16)	The name of the data mart table.
DATA_MART_SYSTEM_TABLE_NAME	SYS_TABLE	CHAR(5)	The system name of the data mart table.
JOURNAL_ENTRY_TYPE	ENTRY	CHAR(2)	The journal entry type contained within the data mart table.
DATA_MART_FILTER	FILTER	VARCHAR(1000) Nullable	The string of predicates that is applied to limit the rows included in this data mart table. Contains the null value if no filter is defined for this data mart.
AUDIT_JOURNAL_STARTING_TIMESTAMP	AJ_START	TIMESTAMP	The STARTING_TIMESTAMP parameter value for the most recent call to the MANAGE_AUDIT_JOURNAL_DATA_MART procedure for this JOURNAL_ENTRY_TYPE and DATA_MART_LIBRARY.
AUDIT_JOURNAL_ENDING_TIMESTAMP	AJ_END	TIMESTAMP	The ENDING_TIMESTAMP parameter value for the most recent call to the MANAGE_AUDIT_JOURNAL_DATA_MART procedure for this JOURNAL_ENTRY_TYPE and DATA_MART_LIBRARY.
BUILD_START	B_START	TIMESTAMP	The timestamp of the most recent call to the MANAGE_AUDIT_JOURNAL_DATA_MART procedure for this JOURNAL_ENTRY_TYPE and DATA_MART_LIBRARY.
BUILD_END	B_END	TIMESTAMP Nullable	The timestamp of when the most recent call to the MANAGE_AUDIT_JOURNAL_DATA_MART procedure finished for this JOURNAL_ENTRY_TYPE and DATA_MART_LIBRARY. Contains the null value if the MANAGE_AUDIT_JOURNAL_DATA_MART procedure is running or if a failure occurred during the call.
BUILD_JOB	BUILD_JOB	VARCHAR(28)	The qualified job name that most recently called the MANAGE_AUDIT_JOURNAL_DATA_MART procedure for this JOURNAL_ENTRY_TYPE and DATA_MART_LIBRARY.

Table 151. AUDIT_JOURNAL_DATA_MART_INFO view (continued)

Column Name	System Column Name	Data Type	Description
FAILURE_DETAIL	FAILURE	VARCHAR(300) Nullable	The failure information for the most recent call to the MANAGE_AUDIT_JOURNAL_DATA_MART procedure for this JOURNAL_ENTRY_TYPE and DATA_MART_LIBRARY. Contains the null value if no failure occurred.

Examples

- Check for failures after calling the MANAGE_AUDIT_JOURNAL_DATA_MART procedure for the PW journal entry in the library DMARTLIB.

```
SELECT DATA_MART_LIBRARY, DATA_MART_TABLE, JOURNAL_ENTRY_TYPE, BUILD_END, FAILURE_DETAIL
FROM QSYS2.AUDIT_JOURNAL_DATA_MART_INFO
WHERE JOURNAL_ENTRY_TYPE = 'PW' AND DATA_MART_LIBRARY = 'DMARTLIB'
AND FAILURE_DETAIL IS NOT NULL;
```

Audit journal entry services

These table functions provide detailed information for audit journal entries.

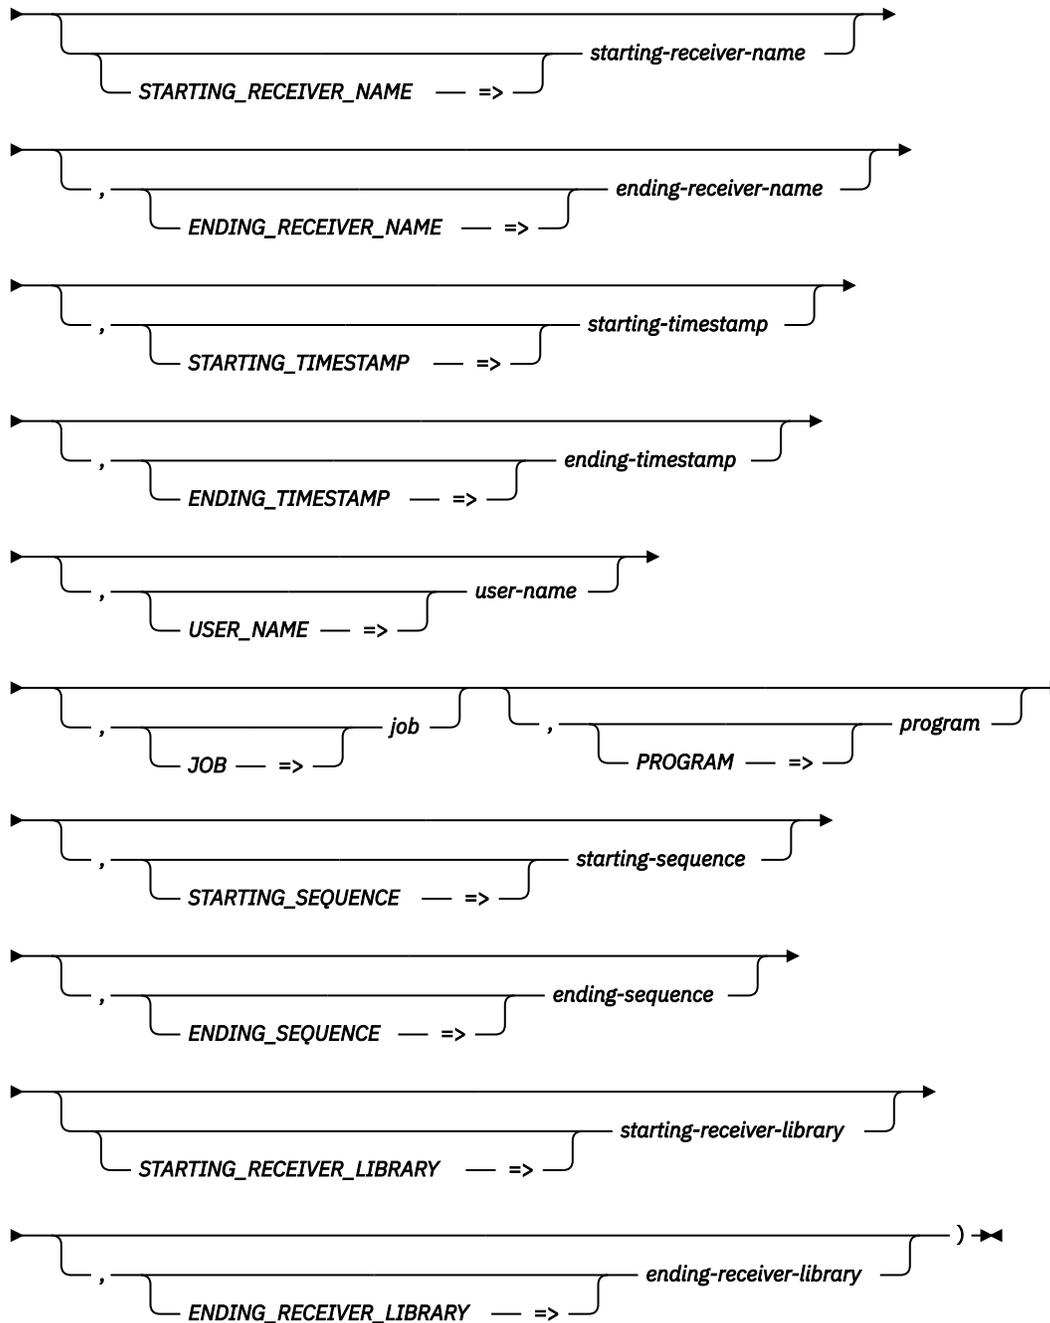

AUDIT JOURNAL table function common information

Each of the AUDIT_JOURNAL_xx table functions returns information from the audit journal specific to an individual entry type. The invocation of every function and the first set of columns returned by the function are identical. This common information is described in this section.

Authorization: The caller must have:

- *USE authority to the audit journal and to all requested journal receivers, and
- *OBJEXIST authority to the audit journal

►► AUDIT_JOURNAL_xx — (→

The schema is SYSTOOLS.

The function name, identified as AUDIT_JOURNAL_xx in the syntax diagram, represents any of the audit journal functions. For example, to invoke the AUDIT_JOURNAL_PW function, replace the xx with PW.

starting-receiver-name A character or graphic string expression that identifies the name of the starting journal receiver. The special values *CURRENT, *CURCHAIN, *CURAVLCHN, and *CURSEQCHN are supported. Otherwise, *starting-receiver-name* must identify a valid journal receiver.

If no journal receiver is specified, *CURAVLCHN is used.

ending-receiver-name A character or graphic string expression that identifies the name of the ending journal receiver. The special value *CURRENT is supported. Otherwise, *ending-receiver-name* must identify a valid journal receiver.

	If <i>ending-receiver-name</i> is not specified, *CURRENT is used.
starting-timestamp	A timestamp value that specifies the starting timestamp to use ¹ . A value cannot be specified for both <i>starting-timestamp</i> and <i>starting-sequence</i> . If no starting timestamp is specified, CURRENT DATE - 1 DAY is used.
ending-timestamp	A timestamp value that specifies the ending timestamp to use ¹ . A value cannot be specified for both <i>ending-timestamp</i> and <i>ending-sequence</i> . If no ending timestamp is specified, CURRENT TIMESTAMP is used.
user-name	A character or graphic string expression that identifies the user profile name for the current user of the job. If <i>user-name</i> is not specified, *ALL is used.
job	A character or graphic string expression that identifies the name of a job. Two forms of a job name are supported: <ol style="list-style-type: none"> 1. A fully qualified job name in the form <i>job-number/job-user/job-name</i>. 2. The first 10 characters are the job name, the second 10 characters are the user name, and the last 6 characters are the job number. If <i>job</i> is not specified, *ALL is used.
program	A character or graphic string expression that identifies the name of a program. If <i>program</i> is not specified, *ALL is used.
starting-sequence	A decimal expression that identifies the starting sequence number to use. This is the value shown in the SEQUENCE_NUMBER column in the QSYS2.DISPLAY_JOURNAL results. If the <i>starting-sequence</i> value is not found in the receiver range, an error is returned. A value cannot be specified for both <i>starting-timestamp</i> and <i>starting-sequence</i> . If no starting sequence is specified, *FIRST is used.
ending-sequence	A decimal expression that identifies the ending sequence number to use. If the <i>ending-sequence</i> value is not found in the receiver range, an error is returned. A value cannot be specified for both <i>ending-timestamp</i> and <i>ending-sequence</i> . If no ending sequence is specified, *LAST is used. When <i>ending-sequence</i> is used, the query results will end when the first ending sequence value is encountered. If the journal has had its sequence numbers reset, <i>ending-sequence</i> will only return results through the first match of <i>ending-sequence</i> .
starting-receiver-library	A character or graphic string expression that identifies the library that contains <i>starting-receiver-name</i> .
ending-receiver-library	A character or graphic string expression that identifies the library that contains <i>ending-receiver-name</i> .

The special values supported for the function arguments are the same as for the Display Journal (DSPJRN) CL command.

¹ The accuracy of the entry timestamp stored in journal receivers is only accurate to 16 microseconds. Hence, a value passed as a starting-timestamp and ending-timestamp will be truncated such that the actual timestamps being searched for may be from 0 to 15 microseconds less than the specified value.

The first set of columns returned by each of the audit journal functions are information from the audit journal entry's common header. They have the format shown in the following table. All the columns are nullable.

Table 152. Common columns returned from the audit journal entry header

Column Name	Data Type	Description
ENTRY_TIMESTAMP	TIMESTAMP	The system date and time when the journal entry was added to the journal receiver.
SEQUENCE_NUMBER	DECIMAL(21,0)	A number assigned by the system to each journal entry.
USER_NAME	VARCHAR(10)	The name of the effective user profile under which the thread was running when the entry was created. Contains *NONE if the effective user profile is not available.
QUALIFIED_JOB_NAME	VARCHAR(28)	The qualified job name that added the entry. Contains the null value if the system job is running in a task rather than a process.
JOB_NAME	VARCHAR(10)	The name of the job that added the entry.
JOB_USER	VARCHAR(10)	The user profile that started the job. Contains the null value if the system job is running in a task rather than a process.
JOB_NUMBER	VARCHAR(6)	The job number of the job that added the entry. Contains the null value if the system job is running in a task rather than a process.
THREAD	BIGINT	Identifies the thread within the process that added the journal entry. Contains the null value if the system job is running in a task rather than a process.
PROGRAM_LIBRARY	VARCHAR(10)	The name of the library that contains PROGRAM_NAME. Contains *NONE if PROGRAM_NAME returns *NONE.
PROGRAM_NAME	VARCHAR(10)	The name of the program that caused the journal entry to be added. This can also be the name of a service program or the partial name of a class file used in a compiled Java program. If an application program or CL program did not cause the entry, contains the name of a system-supplied program such as QCMD. Contains *NONE if one of the following conditions is true: <ul style="list-style-type: none"> The program name does not apply to this entry type. The program name was not available.
PROGRAM_LIBRARY_ASP_DEVICE	VARCHAR(10)	The name of the ASP device that contains PROGRAM_NAME.
PROGRAM_LIBRARY_ASP_NUMBER	INTEGER	The number for the auxiliary storage pool that contains PROGRAM_NAME. 1 indicates the system ASP.
REMOTE_PORT	INTEGER	The port number of the remote address associated with this journal entry. Contains the null value if a remote port is not available.
REMOTE_ADDRESS	VARCHAR(46)	The remote address associated with the journal entry in IPv4 or IPv6 format. Contains the null value if a remote address is not available.
SYSTEM_NAME	VARCHAR(8)	The name of the system on which the entry is being retrieved.
SYSTEM_SEQUENCE_NUMBER	DECIMAL(21,0)	The system sequence number which indicates the relative sequence of when this journal entry was deposited into the journal.
RECEIVER_LIBRARY	VARCHAR(10)	The name of the library containing RECEIVER_NAME.
RECEIVER_NAME	VARCHAR(10)	The name of the receiver holding the journal entry.
RECEIVER_ASP_DEVICE	VARCHAR(10)	The name of the ASP device containing RECEIVER_NAME.
RECEIVER_ASP_NUMBER	INTEGER	The number for the auxiliary storage pool containing RECEIVER_NAME. 1 indicates the system ASP.
ARM_NUMBER	INTEGER	The number of the disk arm that contains the journal entry.

AUDIT_JOURNAL_AD table function

The AUDIT_JOURNAL_AD table function returns rows from the audit journal that contain information from the AD (Auditing Change) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 153. AUDIT_JOURNAL_AD table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the AD audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. D CHGDLOAUD command O CHGOBJAUD or CHGAUD command S The scan attribute was changed using CHGATR command or the QpOlSetAttr API, or when the object was created. U CHGUSRAUD command
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
OBJECT_AUDIT	VARCHAR(10)	The current object audit value. Contains the null value if ENTRY_TYPE is S.
PREV_OBJECT_AUDIT	VARCHAR(10)	The previous object audit value. Contains the null value if ENTRY_TYPE is S.
SCAN_ATTRIBUTE	VARCHAR(10)	The scan attribute value. Contains the null value if ENTRY_TYPE is not S.
LIBRARY_NAME	VARCHAR(10)	Name of the library for the object. Contains the null value if there is no library name.
OBJECT_NAME	VARCHAR(10)	Name of the object for which auditing was changed. Contains the null value if there is no object name.
OBJECT_TYPE	VARCHAR(7)	The type of object. Contains the null value if there is no object type.
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the object resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs. Contains the null value if there is no ASP information.
OBJECT_ASP_NUMBER	INTEGER	The number of the ASP device. 1 indicates the system ASP. Contains the null value if there is no ASP information.
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The path name of the object. Contains the null value if the path name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PATH_NAME_INDICATOR	VARCHAR(3)	Path name indicator: NO The PATH_NAME column does not contain an absolute path name for the object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name. YES The PATH_NAME column contains the absolute path name for the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.

Table 153. AUDIT_JOURNAL_AD table function (continued)

Column Name	Data Type	Description
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the object identified in the PATH_NAME column. Contains the null value when PATH_NAME_INDICATOR is YES, or if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	The name of the object. Contains the null value if the object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
OBJECT_FILE_ID	BINARY(16)	The file ID of the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PARENT_FILE_ID	BINARY(16)	The file ID of the parent directory. Contains the null value if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
DLO_NAME	VARCHAR(12)	The name of the folder or document. Contains the null value if there is no name or if ENTRY_TYPE is not D.
FOLDER_PATH	VARCHAR(63)	The path of the folder. Contains the null value if there is no folder path or if ENTRY_TYPE is not D.
CHGUSRAUD_AUTFAIL	VARCHAR(3)	Write an audit record when this user has an authorization failure. NO Do not write an audit record when this user has an authorization failure. YES Write an audit record when this user has an authorization failure. Contains the null value if ENTRY_TYPE is not U.
CHGUSRAUD_CMD	VARCHAR(3)	Audit commands for this user. NO Do not audit commands for this user. YES Audit commands for this user. Contains the null value if ENTRY_TYPE is not U.
CHGUSRAUD_CREATE	VARCHAR(3)	Write an audit record when this user creates an object. NO Do not write an audit record. YES Write an audit record. Contains the null value if ENTRY_TYPE is not U.
CHGUSRAUD_DELETE	VARCHAR(3)	Write an audit record when this user deletes an object. NO Do not write an audit record. YES Write an audit record. Contains the null value if ENTRY_TYPE is not U.
CHGUSRAUD_JOBBAS	VARCHAR(3)	Write an audit record when this user performs a job base function. NO Do not write an audit record. YES Write an audit record. Contains the null value if ENTRY_TYPE is not U.

Table 153. AUDIT_JOURNAL_AD table function (continued)

Column Name	Data Type	Description
CHGUSRAUD_JOBCHGUSR	VARCHAR(3)	<p>Write an audit record when this user changes a thread's active user profile or its group file.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>
CHGUSRAUD_JOBDTA	VARCHAR(3)	<p>Write an audit record when this user changes a job.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>
CHGUSRAUD_NETBAS	VARCHAR(3)	<p>Write an audit record when this user performs network base functions.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>
CHGUSRAUD_NETCLU	VARCHAR(3)	<p>Write an audit record when this user performs cluster or cluster resource group functions.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>
CHGUSRAUD_NETCMN	VARCHAR(3)	<p>Write an audit record when this user performs network communications functions.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>
CHGUSRAUD_NETFAIL	VARCHAR(3)	<p>Write an audit record when this user has a network failure.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>
CHGUSRAUD_NETSCK	VARCHAR(3)	<p>Write an audit record when this user performs sockets tasks.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>
CHGUSRAUD_NETSECURE	VARCHAR(3)	<p>Write an audit record when this user establishes a secure connection.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>
CHGUSRAUD_NETUDP	VARCHAR(3)	<p>Write an audit record for UDP inbound and outbound traffic for this user.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>

Table 153. AUDIT_JOURNAL_AD table function (continued)

Column Name	Data Type	Description
CHGUSRAUD_OBJMGT	VARCHAR(3)	<p>Write an audit record when this user moves or renames an object.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>
CHGUSRAUD_OFCSRV	VARCHAR(3)	<p>Write an audit record when this user performs office functions.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>
CHGUSRAUD_OPTICAL	VARCHAR(3)	<p>Write an audit record when this user accesses optical devices.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>
CHGUSRAUD_PGMADP	VARCHAR(3)	<p>Write an audit record when this user obtains authority through adopted authority.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>
CHGUSRAUD_PGMFAIL	VARCHAR(3)	<p>Write an audit record when this user has a program failure.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>
CHGUSRAUD_PRTDTA	VARCHAR(3)	<p>Write an audit record when this user performs a print function with parameter SPOOL(*NO).</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>
CHGUSRAUD_SAVRST	VARCHAR(3)	<p>Write an audit record when this user saves or restores objects.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>
CHGUSRAUD_SECCFG	VARCHAR(3)	<p>Write an audit record when this user performs security configuration.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>
CHGUSRAUD_SECDIRSRV	VARCHAR(3)	<p>Write an audit record when this user makes changes or updates using directory service functions.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>

Table 153. AUDIT_JOURNAL_AD table function (continued)

Column Name	Data Type	Description
CHGUSRAUD_SECIPC	VARCHAR(3)	<p>Write an audit record when this user makes changes to interprocess communications.</p> <p>NO Do not write an audit record.</p> <p>YES Write an audit record.</p> <p>Contains the null value if ENTRY_TYPE is not U.</p>

Example

- List objects in APPLIB that had auditing changes made with the CHGOBJAUD CL command yesterday and today.

```
SELECT LIBRARY_NAME, OBJECT_NAME, OBJECT_TYPE , OBJECT_AUDIT
FROM TABLE (
    SYSTOOLS.AUDIT_JOURNAL_AD (STARTING_TIMESTAMP => CURRENT DATE - 1 DAY)
)
WHERE ENTRY_TYPE = '0' AND LIBRARY_NAME = 'APPLIB';
```

AUDIT_JOURNAL_AF table function

The AUDIT_JOURNAL_AF table function returns rows from the audit journal that contain information from the AF (Authority Failure) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 154. AUDIT_JOURNAL_AF table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the AF audit journal entry.		
VIOLATION_TYPE	CHAR(1)	The type of authority violation. A Not authorized to object B Restricted instruction C Validation failure. See VALIDATION_ERROR_ACTION for additional details. D Use of unsupported interface, object domain failure E Hardware storage protection error, program constant space violation H Scan exit program action. See VALIDATION_ERROR_ACTION for additional details. I System Java inheritance not allowed J Submit job profile error K Special authority violation N Profile token not a regenerable token O Optical Object Authority Failure P Profile swap error R Hardware protection error S Default sign-on attempt T Not authorized to TCP/IP port U User permission request not valid V Profile token not valid for generating new profile token W Profile token not valid for swap X System violation. See OPERATION_VIOLATION_CODE for additional details. Y Not authorized to the current JUID field during a clear JUID operation. Z Not authorized to the current JUID field during a set JUID operation.
VIOLATION_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the violation type.

Table 154. AUDIT_JOURNAL_AF table function (continued)

Column Name	Data Type	Description
VALIDATION_ERROR_ACTION	CHAR(1)	<p>Action taken after validation error detected, set when VIOLATION_TYPE is C or H.</p> <p>A The translation of the object was not attempted or it failed. The QALWBJRST system value setting allowed the object to be restored. The user doing the restore did not have *ALLOBJ special authority and the system security level is set to 10, 20, or 30. Therefore, all authorities to the object were retained.</p> <p>B The translation of the object was not attempted or it failed. The QALWBJRST system value setting allowed the object to be restored. The user doing the restore did not have *ALLOBJ special authority and the system security level is set to 40 or above. Therefore, all authorities to the object were revoked.</p> <p>C The translation of the object was successful. The translated copy was restored on the system.</p> <p>D The translation of the object was not attempted or it failed. The QALWBJRST system value setting allowed the object to be restored. The user doing the restore had *ALLOBJ special authority. Therefore, all authorities to the object were retained.</p> <p>E System install time error detected.</p> <p>F The object was not restored because the signature is not IBM i format.</p> <p>G Unsigned system or inherit state object found when checking system.</p> <p>H Unsigned user state object found when checking system.</p> <p>I Mismatch between object and its signature found when checking system.</p> <p>J IBM certificate not found when checking system.</p> <p>K Invalid signature format found when checking system.</p> <p>M Scan exit program modified the object that was scanned.</p> <p>X Scan exit program wanted object marked as having a scan failure.</p> <p>Contains the null value if VIOLATION_TYPE is not C or H.</p>
VALIDATION_ERROR_ACTION_DETAIL	VARCHAR(200)	<p>Descriptive text that corresponds to the violation error action.</p> <p>Contains the null value if VIOLATION_TYPE is not C or H.</p>
OPERATION_VIOLATION_CODE	CHAR(3)	<p>The type of operation violation that occurred, set when VIOLATION_TYPE is X.</p> <p>AAC Not authorized to use SST Advanced Analysis Command.</p> <p>HCA Service tool user profile not authorized to perform hardware configuration operation (QYHCHCOP).</p> <p>LIC LIC indicates that a Licensed Internal Code fix was not applied because of a signature violation.</p> <p>SFA Not authorized to activate the environment attribute for system file access.</p> <p>CMD An attempt was made to use a command that has been disabled by a system administrator.</p> <p>Contains the null value if the VIOLATION_TYPE is not X.</p>
OBJECT_LIBRARY	VARCHAR(10)	<p>The name of the library containing the object.</p> <p>When VIOLATION_TYPE is K, contains the name of the program's library or the command's library that detected the error.</p> <p>Contains the null value if there is no library name.</p>

Table 154. AUDIT_JOURNAL_AF table function (continued)

Column Name	Data Type	Description
OBJECT_NAME	VARCHAR(10)	The name of the object. When VIOLATION_TYPE is K, contains the name of the command or program that detected the error. If the command has several alternative names, the command name in the audit record might not match the specific command name used but will be one of the equivalent alternatives. A special value of *INSTR indicates that a machine instruction detected the error. When OBJECT_TYPE is *LIC, contains a Licensed Internal Code replacement unit (RU) name. Contains the null value if there is no object name.
OBJECT_TYPE	VARCHAR(7)	The type of the object. When VIOLATION_TYPE is K, contains the object type of the command or program that detected the error. When VIOLATION_TYPE is G, contains the name of the *SRVPGM that contained the exit that detected the error. Contains the null value if there is no object type.
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the object resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs.
OBJECT_ASP_NUMBER	INTEGER	The number of the ASP device. 1 indicates the system ASP.
FIELD_NAME	VARCHAR(10)	The system name of the column. Contains the null value if the authority is not related to a column or the column name is not available.
TCPIP_PORT	INTEGER	The TCP/IP port the user is not authorized to use, when VIOLATION_TYPE is T. Contains the null value if VIOLATION_TYPE is not T.
API_NAME	VARCHAR(20)	The full API name of the API or exit point name that detected the error, when VIOLATION_TYPE is K. Contains the null value when the VIOLATION_TYPE is not K or if there is no API or exit point information.
PTF_NUMBER	CHAR(7)	The PTF number that failed to apply because of a signature violation when the VIOLATION_TYPE is X and OPERATION_VIOLATION_CODE is LIC. Contains the null value if VIOLATION_TYPE is not X with an OPERATION_VIOLATION_CODE of LIC.
AAC_NAME	VARCHAR(30)	The Advanced Analysis Command name, when the VIOLATION_TYPE is X and the OPERATION_VIOLATION_CODE is AAC. Contains the null value if VIOLATION_TYPE is not X with an OPERATION_VIOLATION_CODE of AAC.
USER_PROFILE_NAME	VARCHAR(10)	The name of the user that caused the authority failure. Contains the null value if the user name is not available.
WORKSTATION_NAME	VARCHAR(10)	The name of the workstation or workstation type. Contains the null value if the workstation name is not available.
PROGRAM_INSTRUCTION	INTEGER	The instruction number of the program. Contains the null value if the instruction number is not available.
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The path name of the object. Contains the null value if the object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PATH_NAME_INDICATOR	VARCHAR(3)	Path name indicator. NO The PATH_NAME column does not contain an absolute path name for the object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name. YES The PATH_NAME column contains complete absolute path name for the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.

Table 154. AUDIT_JOURNAL_AF table function (continued)

Column Name	Data Type	Description
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the object identified in the PATH_NAME column. Contains the null value when PATH_NAME_INDICATOR is YES, or if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	The name of the object. Contains the null value if the object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
OBJECT_FILE_ID	BINARY(16)	The file ID of the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PARENT_FILE_ID	BINARY(16)	The file ID of the parent directory. Contains the null value if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
OFFICE_USER	VARCHAR(10)	The name of the office user. Contains the null value if there is no office user.
OFFICE_ON_BEHALF_OF_USER	VARCHAR(10)	User working on behalf of another user. Contains the null value if the user name is not available.
DLO_NAME	VARCHAR(12)	The name of the document library object. Contains the null value if there is no document library object.
FOLDER_PATH	VARCHAR(63)	The path of the folder. Contains the null value if there is no folder path.

Example

- Find any authority failures for integrated file system objects in the past 24 hours.

```
SELECT * FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_AF(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 1 DAY
  )
) WHERE PATH_NAME IS NOT NULL;
```

- Determine the number of 'Not authorized to object' authority failures for user BOB in the last week.

```
SELECT COUNT(*) FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_AF(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 7 DAYS,
    USER_NAME => 'BOB'
  )
) WHERE VIOLATION_TYPE = 'A';
```

AUDIT_JOURNAL_AP table function

The AUDIT_JOURNAL_AP table function returns rows from the audit journal that contain information from the AP (Adopted Authority) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 155. AUDIT_JOURNAL_AP table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the AP audit journal entry.		

Table 155. AUDIT_JOURNAL_AP table function (continued)

Column Name	Data Type	Description
ENTRY_TYPE	CHAR(1)	The type of entry. A Adopted authority used during program activation E End S Start
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
OBJECT_LIBRARY	VARCHAR(10)	The name of the library containing the program, service program, or SQL package.
OBJECT_NAME	VARCHAR(10)	The name of the program, service program, or SQL package.
OBJECT_TYPE	VARCHAR(7)	The type of the object.
OBJECT_OWNER	VARCHAR(10)	The name of the user profile whose authority is adopted.
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the object resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs.
OBJECT_ASP_NUMBER	INTEGER	The number of the ASP device. 1 indicates the system ASP.
OBJECT_FILE_ID	BINARY(16)	The file ID of the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.

Example

- Find any programs that used adopted authority today.

```
SELECT OBJECT_LIBRARY, OBJECT_NAME, OBJECT_TYPE, OBJECT_OWNER FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_AP(
    STARTING_TIMESTAMP => CURRENT DATE
  )
);
```

AUDIT_JOURNAL_AU table function

The AUDIT_JOURNAL_AU table function returns rows from the audit journal that contain information from the AU (Attribute Changes) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 156. AUDIT_JOURNAL_AU table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the AU audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. A EIM association E EIM configuration attributes
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.

Table 156. AUDIT_JOURNAL_AU table function (continued)

Column Name	Data Type	Description
ACTION	VARCHAR(6)	The action that was performed. When ENTRY_TYPE is A: ADD Add association REMOVE Remove association When ENTRY_TYPE is E: CHANGE Attributes changed
ACTION_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the action.
ATTRIBUTE_NAME	VARCHAR(100)	The name of the changed attribute. Contains the null value if ENTRY_TYPE is A.
ATTRIBUTE_VALUE	VARGRAPHIC(2000) CCSID 1200	The value of the attribute. Contains the null value if ENTRY_TYPE is A.
PREV_ATTRIBUTE_VALUE	VARGRAPHIC(2000) CCSID 1200	The previous value of the attribute. Contains the null value if ENTRY_TYPE is A.
ASSOCIATION_TYPE	VARCHAR(17)	The association type that was added or removed: <ul style="list-style-type: none"> • ADMINISTRATIVE • ALL • TARGET • SOURCE AND TARGET • SOURCE Contains the null value if ENTRY_TYPE is E.
REGISTRY_USER_NAME	VARCHAR(100)	The registry user name. Contains the null value if ENTRY_TYPE is E.
IDENTIFIER_DISTINGUISHED_NAME	VARGRAPHIC(1000) CCSID 1200	The identifier distinguished name. Contains the null value if ENTRY_TYPE is E.
REGISTRY_DISTINGUISHED_NAME	VARGRAPHIC(1000) CCSID 1200	The registry distinguished name. Contains the null value if ENTRY_TYPE is E.

Example

- List the EIM configuration attributes that were changed in the last two months.

```
SELECT * FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_AU(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 2 MONTHS
  )
)
WHERE ENTRY_TYPE = 'E' AND ACTION = 'CHANGE';
```

AUDIT_JOURNAL_AX table function

The AUDIT_JOURNAL_AX table function returns rows from the audit journal that contain information from the AX (Row and Column Access Control) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 157. AUDIT_JOURNAL_AX table function

Column Name	Data Type	Description
<p>The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the AX audit journal entry.</p>		
ENTRY_TYPE	CHAR(1)	<p>The type of entry.</p> <p>M Column mask</p> <p>P Row permission</p> <p>T Table</p>
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
OPERATION_TYPE	VARCHAR(8)	<p>The type of operation.</p> <p>ALTER Alter</p> <p>CREATE Create</p> <p>DROP Drop</p> <p>INTERNAL Internal use only</p>
LIBRARY_NAME	VARCHAR(10)	The name or the library where the file is stored.
FILE_NAME	VARCHAR(10)	The system name of the base table that the permission or mask is associated with or the table being altered.
MASK_NAME	VARCHAR(128)	<p>The column mask name.</p> <p>Contains the null value if ENTRY_TYPE is not M.</p>
COLUMN_NAME	VARCHAR(10)	<p>The name of the column to which the mask applies.</p> <p>Contains the null value if ENTRY_TYPE is not M or OPERATION_TYPE is not CREATE.</p>
PERMISSION_NAME	VARCHAR(128)	<p>The row permission name.</p> <p>Contains the null value if ENTRY_TYPE is not P.</p>
ENABLED	VARCHAR(3)	<p>The row permission or column mask state.</p> <p>NO The row permission or column mask is set to disabled.</p> <p>YES The row permission or column mask is set to enabled.</p> <p>Contains the null value if ENTRY_TYPE is not M or P or OPERATION_TYPE is not CREATE or ALTER.</p>
ROW_ACCESS_CONTROL	VARCHAR(10)	<p>The row access control state.</p> <p>ACTIVATE Row access control is set to activate.</p> <p>DEACTIVATE Row access control is set to deactivate.</p> <p>Contains the null value if ENTRY_TYPE is not T or OPERATION_TYPE is not ALTER, or the value was not changed.</p>
COLUMN_ACCESS_CONTROL	VARCHAR(10)	<p>The column access control state.</p> <p>ACTIVATE Column access control is set to activate.</p> <p>DEACTIVATE Column access control is set to deactivate.</p> <p>Contains the null value if ENTRY_TYPE is not T or OPERATION_TYPE is not ALTER, or the value was not changed.</p>
PREV_ENABLED	VARCHAR(3)	<p>The previous row permission or column mask state.</p> <p>NO The row permission or column mask is set to disabled.</p> <p>YES The row permission or column mask is set to enabled.</p> <p>Contains the null value if ENTRY_TYPE is not M or P or OPERATION_TYPE is not ALTER.</p>

Table 157. AUDIT_JOURNAL_AX table function (continued)

Column Name	Data Type	Description
PREV_ROW_ACCESS_CONTROL	VARCHAR(10)	The previous row access control state. ACTIVATE Row access control is set to activate. DEACTIVATE Row access control is set to deactivate. Contains the null value if ENTRY_TYPE is not T or OPERATION_TYPE is not ALTER, or the value was not changed.
PREV_COLUMN_ACCESS_CONTROL	VARCHAR(10)	The previous column access control state. ACTIVATE Column access control is set to activate. DEACTIVATE Column access control is set to deactivate. Contains the null value if ENTRY_TYPE is not T or OPERATION_TYPE is not ALTER, or the value was not changed.
SQL_STATEMENT_TEXT	VARGRAPHIC(5000) CCSID 1200	The SQL statement text for the CREATE MASK or CREATE PERMISSION statement. Contains the null value if ENTRY_TYPE is not M or P or OPERATION_TYPE is not CREATE.
STATEMENT_TRUNCATED	VARCHAR(3)	Whether SQL_STATEMENT_TEXT is truncated. NO SQL_STATEMENT contains the complete statement text. YES SQL_STATEMENT contains truncated statement text. Contains the null value if ENTRY_TYPE is not M or P or OPERATION_TYPE is not CREATE.
ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the object resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs. Contains the null value if there is no ASP information.
ASP_NUMBER	INTEGER	The number of the ASP device. 1 indicates the system ASP. Contains the null value if there is no ASP information.

Example

- List any changes to active row or column access control for the last week. These are operations performed by an ALTER TABLE statement with an ACTIVATE or DEACTIVATE option.

```
SELECT LIBRARY_NAME, FILE_NAME, ROW_ACCESS_CONTROL, COLUMN_ACCESS_CONTROL,
       PREV_ROW_ACCESS_CONTROL, PREV_COLUMN_ACCESS_CONTROL
FROM TABLE (
    SYSTOOLS.AUDIT_JOURNAL_AX (STARTING_TIMESTAMP => CURRENT DATE - 7 DAYS)
)
WHERE ENTRY_TYPE = 'T';
```

AUDIT_JOURNAL_CA table function

The AUDIT_JOURNAL_CA table function returns rows from the audit journal that contain information from the CA (Authority Changes) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in “AUDIT JOURNAL table function common information” on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 158. AUDIT_JOURNAL_CA table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the CA audit journal entry.		

Table 158. AUDIT_JOURNAL_CA table function (continued)

Column Name	Data Type	Description								
OBJECT_LIBRARY	VARCHAR(10)	The name of the library containing the object. Contains the null value if there is no library name.								
OBJECT_NAME	VARCHAR(10)	The name of the object. Contains the null value if there is no object name.								
OBJECT_TYPE	VARCHAR(7)	The type of the object. Contains the null value if there is no object type.								
OBJECT_ATTRIBUTE	VARCHAR(10)	The attribute for the object type. Contains the null value if there is no object attribute.								
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which OBJECT_NAME resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs.								
OBJECT_ASP_NUMBER	INTEGER	The number of the auxiliary storage pool to which storage for OBJECT_NAME is allocated. 1 indicates the system ASP.								
FIELD_NAME	VARCHAR(10)	The system name of the column. Contains the null value if the authority is not related to a column or the column name is not available.								
COMMAND_TYPE	VARCHAR(9)	The type of command used. <table border="0"> <tr> <td>GRANT</td> <td>Grant</td> </tr> <tr> <td>GRTUSRAUT</td> <td>GRTUSRAUT operation</td> </tr> <tr> <td>REPLACE</td> <td>Grant with replace</td> </tr> <tr> <td>REVOKE</td> <td>Revoke</td> </tr> </table>	GRANT	Grant	GRTUSRAUT	GRTUSRAUT operation	REPLACE	Grant with replace	REVOKE	Revoke
GRANT	Grant									
GRTUSRAUT	GRTUSRAUT operation									
REPLACE	Grant with replace									
REVOKE	Revoke									
USER_PROFILE_NAME	VARCHAR(10)	The name of the user profile whose authority is being granted or revoked. Contains the null value if a user profile is not being changed.								
AUTHORIZATION_LIST_MANAGEMENT	VARCHAR(3)	Indicates whether authorization list management (*AUTLMGT) authority is granted or revoked. <table border="0"> <tr> <td>NO</td> <td>The authority is not changed.</td> </tr> <tr> <td>YES</td> <td>The authority might have changed.</td> </tr> </table>	NO	The authority is not changed.	YES	The authority might have changed.				
NO	The authority is not changed.									
YES	The authority might have changed.									
OBJECT_EXCLUDE	VARCHAR(3)	Indicates whether exclude (*EXCLUDE) authority is granted or revoked. <table border="0"> <tr> <td>NO</td> <td>The authority is not changed.</td> </tr> <tr> <td>YES</td> <td>The authority might have changed.</td> </tr> </table>	NO	The authority is not changed.	YES	The authority might have changed.				
NO	The authority is not changed.									
YES	The authority might have changed.									
OBJECT_OPERATIONAL	VARCHAR(3)	Indicates whether object operational (*OBJOPR) authority is granted or revoked. <table border="0"> <tr> <td>NO</td> <td>The authority is not changed.</td> </tr> <tr> <td>YES</td> <td>The authority might have changed.</td> </tr> </table>	NO	The authority is not changed.	YES	The authority might have changed.				
NO	The authority is not changed.									
YES	The authority might have changed.									
OBJECT_MANAGEMENT	VARCHAR(3)	Indicates whether object management (*OBJMGT) authority is granted or revoked. <table border="0"> <tr> <td>NO</td> <td>The authority is not changed.</td> </tr> <tr> <td>YES</td> <td>The authority might have changed.</td> </tr> </table>	NO	The authority is not changed.	YES	The authority might have changed.				
NO	The authority is not changed.									
YES	The authority might have changed.									
OBJECT_EXISTENCE	VARCHAR(3)	Indicates whether object existence (*OBJEXIST) authority is granted or revoked. <table border="0"> <tr> <td>NO</td> <td>The authority is not changed.</td> </tr> <tr> <td>YES</td> <td>The authority might have changed.</td> </tr> </table>	NO	The authority is not changed.	YES	The authority might have changed.				
NO	The authority is not changed.									
YES	The authority might have changed.									
OBJECT_ALTER	VARCHAR(3)	Indicates whether object alter (*OBJALTER) authority is granted or revoked. <table border="0"> <tr> <td>NO</td> <td>The authority is not changed.</td> </tr> <tr> <td>YES</td> <td>The authority might have changed.</td> </tr> </table>	NO	The authority is not changed.	YES	The authority might have changed.				
NO	The authority is not changed.									
YES	The authority might have changed.									

Table 158. AUDIT_JOURNAL_CA table function (continued)

Column Name	Data Type	Description
OBJECT_REFERENCE	VARCHAR(3)	Indicates whether object reference (*OBJREF) authority is granted or revoked. NO The authority is not changed. YES The authority might have changed.
DATA_READ	VARCHAR(3)	Indicates whether data read (*READ) authority is granted or revoked. NO The authority is not changed. YES The authority might have changed.
DATA_ADD	VARCHAR(3)	Indicates whether data add (*ADD) authority is granted or revoked. NO The authority is not changed. YES The authority might have changed.
DATA_UPDATE	VARCHAR(3)	Indicates whether data update (*UPD) authority is granted or revoked. NO The authority is not changed. YES The authority might have changed.
DATA_DELETE	VARCHAR(3)	Indicates whether data delete (*DLT) authority is granted or revoked. NO The authority is not changed. YES The authority might have changed.
DATA_EXECUTE	VARCHAR(3)	Indicates whether data execute (*EXECUTE) authority is granted or revoked. NO The authority is not changed. YES The authority might have changed.
PREV_AUTHORIZATION_LIST_MANAGEMENT	VARCHAR(3)	Indicates whether the user previously had authorization list management (*AUTLMGT) authority. NO The user did not have this authority. YES The user had this authority. Contains the null value if the AUTHORIZATION_LIST_MANAGEMENT column is NO.
PREV_OBJECT_EXCLUDE	VARCHAR(3)	Indicates whether the user previously had exclude (*EXCLUDE) authority. NO The user did not have this authority. YES The user had this authority. Contains the null value if the OBJECT_EXCLUDE column is NO.
PREV_OBJECT_OPERATIONAL	VARCHAR(3)	Indicates whether the user previously had object operational (*OBJOPR) authority. NO The user did not have this authority. YES The user had this authority. Contains the null value if the OBJECT_OPERATIONAL column is NO.
PREV_OBJECT_MANAGEMENT	VARCHAR(3)	Indicates whether the user previously had object management (*OBJMGT) authority. NO The user did not have this authority. YES The user had this authority. Contains the null value if the OBJECT_MANAGEMENT column is NO.

Table 158. AUDIT_JOURNAL_CA table function (continued)

Column Name	Data Type	Description
PREV_OBJECT_EXISTENCE	VARCHAR(3)	<p>Indicates whether the user previously had object existence (*OBJEXIST) authority.</p> <p>NO The user did not have this authority.</p> <p>YES The user had this authority.</p> <p>Contains the null value if the OBJECT_EXISTENCE column is NO.</p>
PREV_OBJECT_ALTER	VARCHAR(3)	<p>Indicates whether the user previously had object alter (*OBJALTER) authority.</p> <p>NO The user did not have this authority.</p> <p>YES The user had this authority.</p> <p>Contains the null value if the OBJECT_ALTER column is NO.</p>
PREV_OBJECT_REFERENCE	VARCHAR(3)	<p>Indicates whether the user previously had object reference (*OBJREF) authority.</p> <p>NO The user did not have this authority.</p> <p>YES The user had this authority.</p> <p>Contains the null value if the OBJECT_REFERENCE column is NO.</p>
PREV_DATA_READ	VARCHAR(3)	<p>Indicates whether the user previously had data read (*READ) authority.</p> <p>NO The user did not have this authority.</p> <p>YES The user had this authority.</p> <p>Contains the null value if the DATA_READ column is NO.</p>
PREV_DATA_ADD	VARCHAR(3)	<p>Indicates whether the user previously had data add (*ADD) authority.</p> <p>NO The user did not have this authority.</p> <p>YES The user had this authority.</p> <p>Contains the null value if the DATA_ADD column is NO.</p>
PREV_DATA_UPDATE	VARCHAR(3)	<p>Indicates whether the user previously had data update (*UPD) authority.</p> <p>NO The user did not have this authority.</p> <p>YES The user had this authority.</p> <p>Contains the null value if the DATA_UPDATE column is NO.</p>
PREV_DATA_DELETE	VARCHAR(3)	<p>Indicates whether the user previously had data delete (*DLT) authority.</p> <p>NO The user did not have this authority.</p> <p>YES The user had this authority.</p> <p>Contains the null value if the DATA_DELETE column is NO.</p>
PREV_DATA_EXECUTE	VARCHAR(3)	<p>Indicates whether the user previously had data execute (*EXECUTE) authority.</p> <p>NO The user did not have this authority.</p> <p>YES The user had this authority.</p> <p>Contains the null value if the DATA_EXECUTE column is NO.</p>
AUTHORIZATION_LIST	VARCHAR(10)	<p>The name of the authorization list that is being modified.</p> <p>Contains the null value if an authorization list is not being changed.</p>
AUTHORIZATION_LIST_PUBLIC	VARCHAR(3)	<p>Indicates whether authorization list (*AUTL public authority) authority has been granted or revoked.</p> <p>NO The authority is not changed.</p> <p>YES The authority might have changed.</p>
PREV_AUTHORIZATION_LIST	VARCHAR(10)	<p>The name of the previous authorization list.</p> <p>Contains the null value if an authorization list is not being changed.</p>

Table 158. AUDIT_JOURNAL_CA table function (continued)

Column Name	Data Type	Description
PREV_AUTHORIZATION_LIST_PUBLIC	VARCHAR(3)	Indicates whether the user previously had authorization list (*AUTL public authority) authority. NO The user did not have this authority. YES The user had this authority. Contains the null value if the AUTHORIZATION_LIST_PUBLIC column is NO.
PERSONAL_STATUS_CHANGED	VARCHAR(3)	The personal status changed. NO The status did not changed. YES The status changed.
ACCESS_CODE_CHANGED	VARCHAR(6)	Whether the access code changed. ADD The access code was added. REMOVE The access code was removed. Contains the null value if the access code was not changed.
ACCESS_CODE	VARCHAR(4)	Access code. Contains the null value if the access code was not changed.
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The path name of the object. Contains the null value if the object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PATH_NAME_INDICATOR	VARCHAR(3)	Path name indicator. NO The PATH_NAME column does not contain an absolute path name for the object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name. YES The PATH_NAME column contains complete absolute path name for the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the object identified in the PATH_NAME column. Contains the null value when PATH_NAME_INDICATOR is YES, or if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	The name of the object. Contains the null value if the object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
OBJECT_FILE_ID	BINARY(16)	The file ID of the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PARENT_FILE_ID	BINARY(16)	The file ID of the parent directory. Contains the null value if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
OFFICE_USER	VARCHAR(10)	The name of the office user. Contains the null value if there is no office user.
OFFICE_ON_BEHALF_OF_USER	VARCHAR(10)	User working on behalf of another user. Contains the null value if the user name is not available.
DLO_NAME	VARCHAR(12)	The name of the document library object. Contains the null value if there is no document library object.
FOLDER_PATH	VARCHAR(63)	The path of the folder. Contains the null value if there is no folder path.

Example

- List any files in APPLIB1 that had the ability to change data granted to them in the last week.

```
SELECT OBJECT_NAME, USER_PROFILE_NAME FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_CA(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 7 DAYS)
)
WHERE COMMAND_TYPE = 'GRANT' AND
  OBJECT_LIBRARY = 'APPLIB1' AND
  OBJECT_TYPE = '*FILE' AND
  (DATA_ADD = 'YES' OR DATA_UPDATE = 'YES' OR DATA_DELETE = 'YES');
```

AUDIT_JOURNAL_CD table function

The AUDIT_JOURNAL_CD table function returns rows from the audit journal that contain information from the CD (Command String) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in “AUDIT JOURNAL table function common information” on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 159. AUDIT_JOURNAL_CD table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the CD audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. <ul style="list-style-type: none"> C Command run L OCL statement O Operator control command P S/36 procedure S Command run after command substitution took place U Utility control statement X Proxy command
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
OBJECT_LIBRARY	VARCHAR(10)	The name of the library where the object is stored.
OBJECT_NAME	VARCHAR(10)	The name of the object.
OBJECT_TYPE	VARCHAR(7)	The type of object.
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the object resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs.
OBJECT_ASP_NUMBER	INTEGER	The number of the ASP device. 1 indicates the system ASP.
WHERE_RUN	CHAR(1)	Where the CL command was run. <ul style="list-style-type: none"> B In a batch job but not for any of the reason listed under Y, R, or E. Typical case would be that the CL command was run using STRDBRDR or SBMDBJOB command or was specified on the CMD parameter of the SBMJOB command. E The command string was passed as a parameter to one of the Command Analyzer APIs: QCMDEXC, QCAPCMD, or QCAEXEC N Interactively from a command line or by choosing a menu option that runs a CL command R From a REXX procedure Y From a compiled OPM CL program or an ILE CL program
WHERE_RUN_DETAIL	VARCHAR(200)	Descriptive text that corresponds to where the CL command was run.

Table 159. AUDIT_JOURNAL_CD table function (continued)

Column Name	Data Type	Description
COMMAND_STRING	VARCHAR(6000)	The command that was run, with parameters. Contains the null value if no command was run.

Example

- List any change commands that were run this week.

```
SELECT *
FROM TABLE (
  SYSTOOLS.AUDIT_JOURNAL_CD (STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 7 DAYS)
)
WHERE ENTRY_TYPE = 'C' AND
      OBJECT_LIBRARY = 'QSYS' AND
      OBJECT_NAME LIKE 'CHG%' ;
```

AUDIT_JOURNAL_CO table function

The AUDIT_JOURNAL_CO table function returns rows from the audit journal that contain information from the CO (Create Object) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 160. AUDIT_JOURNAL_CO table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the CO audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. N Create of new object R Replacement of existing object
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
OBJECT_LIBRARY	VARCHAR(10)	The name of the library containing the object. Contains the null value if there is no library name.
OBJECT_NAME	VARCHAR(10)	The name of the object. Contains the null value if there is no object name.
OBJECT_TYPE	VARCHAR(7)	The type of the object. Contains the null value if there is no object type.
OBJECT_ATTRIBUTE	VARCHAR(10)	The attribute for the object type. Contains the null value if there is no object attribute.
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the object resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs.
OBJECT_ASP_NUMBER	INTEGER	The number of the ASP device. 1 indicates the system ASP.
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The path name of the object. Contains the null value if the path name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.

Table 160. AUDIT_JOURNAL_CO table function (continued)

Column Name	Data Type	Description
PATH_NAME_INDICATOR	VARCHAR(3)	<p>Path name indicator.</p> <p>NO The PATH_NAME column does not contain an absolute path name for the object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name.</p> <p>YES The PATH_NAME column contains complete absolute path name for the object.</p> <p>Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	<p>When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the object identified in the PATH_NAME column.</p> <p>Contains the null value when PATH_NAME_INDICATOR is YES, or if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	<p>The name of the object.</p> <p>Contains the null value if the object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
OBJECT_FILE_ID	BINARY(16)	<p>The file ID of the object.</p> <p>Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
PARENT_FILE_ID	BINARY(16)	<p>The file ID of the parent directory.</p> <p>Contains the null value if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
OFFICE_USER	VARCHAR(10)	<p>The name of the office user.</p> <p>Contains the null value if there is no office user.</p>
OFFICE_ON_BEHALF_OF_USER	VARCHAR(10)	<p>User working on behalf of another user.</p> <p>Contains the null value if the user name is not available.</p>
DLO_NAME	VARCHAR(12)	<p>The name of the document library object.</p> <p>Contains the null value if there is no document library object.</p>
FOLDER_PATH	VARCHAR(63)	<p>The path of the folder.</p> <p>Contains the null value if there is no folder path.</p>

Example

- Find the objects created in APPLIB in the last 2 months.

```
SELECT OBJECT_LIBRARY, OBJECT_NAME, OBJECT_TYPE FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_CO(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 2 MONTHS
  )
) WHERE OBJECT_LIBRARY = 'APPLIB';
```

AUDIT_JOURNAL_CP table function

The AUDIT_JOURNAL_CP table function returns rows from the audit journal that contain information from the CP (User Profile Changes) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 161. AUDIT_JOURNAL_CP table function

Column Name	Data Type	Description
<p>The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the CP audit journal entry.</p>		
ENTRY_TYPE	CHAR(1)	The type of entry. A Change to a user profile
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
USER_PROFILE	VARCHAR(10)	The user profile that was changed.
COMMAND_TYPE	CHAR(3)	The type of command used. CHG Change User Profile (CHGUSRPRF) or Change Expiration Scd Entry (CHGEXPSCDE) commands CRT Create User Profile (CRTUSRPRF) command DST QSECOFR password reset using DST RPA Reset Profile Attributes (QSYRESPA) API RST Restore User Profile (RSTUSRPRF) command SQL QSYS2/SET_SERVER_SBS_ROUTING() Db2® for i procedure
STATUS	VARCHAR(9)	User profile status. *DISABLED The user profile cannot be used *ENABLED The user profile is valid Contains the null value if the value was not changed.
PASSWORD_CHANGED	VARCHAR(3)	Whether the password changed. YES Password changed Contains the null value if the value was not changed.
NO_PASSWORD_INDICATOR	VARCHAR(3)	Whether the password is *NONE. YES Password is *NONE Contains the null value if the value was not changed.
PASSWORD_EXPIRED	VARCHAR(4)	Whether the password is expired. *NO Password is not expired *YES Password is expired Contains the null value if the value was not changed.
LOCAL_PASSWORD_MANAGEMENT	VARCHAR(4)	Specifies whether the user profile password should be managed locally. *NO The password is not managed on the local system. *YES The password is managed on the local system. Contains the null value if the value was not changed.
PASSWORD_CONFORMANCE	VARCHAR(8)	Indicates whether the new password conforms to the password composition rules. *EXITPGM Checked but does not conform because of an exit program response. *NOCHECK Not checked; password was changed. *NONE Not checked; *NONE was specified for the new password. *PASSED Checked and conforms. *SYSVAL Checked but does not conform because of a system value based rule. Contains the null value if PASSWORD_CHANGED is not YES.

Table 161. AUDIT_JOURNAL_CP table function (continued)

Column Name	Data Type	Description
BLOCK_PASSWORD_CHANGE	VARCHAR(7)	<p>Specifies the value that the block password change has been changed to.</p> <p>1-99 Blocked hours.</p> <p>*NONE No block period.</p> <p>*SYSVAL The system value QPWDCHGBLK is used.</p> <p>Contains the null value if the value was not changed.</p>
PASSWORD_EXPIRATION_INTERVAL	VARCHAR(7)	<p>Specifies the value that the password expiration interval has been changed to.</p> <p>1-366 The size of the expiration interval in days.</p> <p>*NOMAX No expiration interval.</p> <p>*SYSVAL The system value QPWDEXPITV is used.</p> <p>Contains the null value if the value was not changed.</p>
USER_EXPIRATION_DATE	VARCHAR(10)	<p>Specifies the date when the user profile expires. The user profile is automatically disabled or deleted on this date. Can contain the special value *NONE to indicate the user profile does not expire.</p> <p>Contains the null value if the value was not changed.</p>
USER_EXPIRATION_ACTION	CHAR(3)	<p>The action performed on the profile when it expires. This value is always DSB when using the CRTUSRPRF and CHGUSRPRF commands. When using the CHGEXPSCDE command, this value is one of the following values.</p> <p>DLT The profile is deleted when it expires.</p> <p>DSB The profile is disabled when it expires.</p> <p>Contains the null value if the value was not changed.</p>
OWNED_OBJECT_OPTION	VARCHAR(7)	<p>The type of operation performed on the objects owned by the expiring profile. The owned object option value is specified on the OWNBOBJOPT parameter of the CHGEXPSCDE ACTION(*DELETE) command.</p> <p>*CHGOWN The owned objects for the user profile have ownership transferred to the new owner user profile. The user profile is deleted if the transfer of all owned objects is successful.</p> <p>*DLT The owned objects for the user profile are deleted. The user profile is deleted if the deletion of all owned objects is successful.</p> <p>*NODLT The owned objects for the user profile are not changed, and the user profile is not deleted if the user owns any objects.</p> <p>Contains the null value if USER_EXPIRATION_ACTION is not DLT or if the value was not changed.</p>
OWNED_OBJECT_OPTION_NEW_OWNER	VARCHAR(10)	<p>The profile that will own all of the objects owned by the expiring profile.</p> <p>Contains the null value if OWNED_OBJECT_OPTION is not *CHGOWN or if the value was not changed.</p>
PRIMARY_GROUP_OPTION	VARCHAR(7)	<p>The type of operation performed on the objects that have the expiring user profile as their primary group. The primary group option value is specified on the PGPOPT parameter of the CHGEXPSCDE ACTION(*DELETE) command.</p> <p>*CHGPGP The objects the user profile is the primary group for are transferred to the new primary group user profile. The user profile is deleted if the transfer of all objects is successful.</p> <p>*NOCHG The objects the user profile is the primary group for do not change, and the user profile is not deleted if the user is the primary group for any objects.</p> <p>Contains the null value if USER_EXPIRATION_ACTION is not DLT or if the value was not changed.</p>

Table 161. AUDIT_JOURNAL_CP table function (continued)

Column Name	Data Type	Description
NEW_PRIMARY_GROUP	VARCHAR(10)	<p>The profile that will become the new primary group of the objects for which the expiring profile is the primary group. Can contain the following special value:</p> <p>*NONE All of the objects for which the expiring user is the primary group will no longer have a primary group.</p> <p>Contains the null value when PRIMARY_GROUP_OPTION is not *CHGPGP or if the value was not changed.</p>
NEW_PRIMARY_GROUP_AUTHORITY	VARCHAR(8)	<p>The authority the new primary group has to the object.</p> <p>*ALL The new primary group has *ALL authority to the object.</p> <p>*CHANGE The new primary group has *CHANGE authority to the object.</p> <p>*EXCLUDE The new primary group has *EXCLUDE authority to the object.</p> <p>*OLDPGP The new primary group has the same authority to the object as the old primary group.</p> <p>*PRIVATE The new primary group has the same authority to the object as its private authority to the object was.</p> <p>*USE The new primary group has *USE authority to the object.</p> <p>Contains the null value when PRIMARY_GROUP_OPTION is not *CHGPGP or NEW_PRIMARY_GROUP is *NONE or if the value was not changed.</p>
USER_CLASS_NAME	VARCHAR(7)	<p>The user class of the user.</p> <p>*PGMR Programmer</p> <p>*SECADM Security administrator</p> <p>*SECOFR Security officer</p> <p>*SYSOPR System operator</p> <p>*USER User</p> <p>Contains the null value if the value was not changed.</p>
SPECIAL_AUTHORITIES	VARCHAR(72)	<p>Current list of special authorities. This is a single string containing the list of special authorities separated by one blank.</p> <p>Contains the null value if the value was not changed.</p>
ALLOBJ	VARCHAR(3)	<p>Current *ALLOBJ special authority</p> <p>YES Profile has *ALLOBJ special authority</p> <p>Contains the null value if the value was not changed.</p>
JOBCTL	VARCHAR(3)	<p>Current *JOBCTL special authority</p> <p>YES Profile has *JOBCTL special authority</p> <p>Contains the null value if the value was not changed.</p>
SAVSYS	VARCHAR(3)	<p>Current *SAVSYS special authority</p> <p>YES Profile has *SAVSYS special authority</p> <p>Contains the null value if the value was not changed.</p>
SECADM	VARCHAR(3)	<p>Current *SECADM special authority</p> <p>YES Profile has *SECADM special authority</p> <p>Contains the null value if the value was not changed.</p>
SPLCTL	VARCHAR(3)	<p>Current *SPLCTL special authority</p> <p>YES Profile has *SPLCTL special authority</p> <p>Contains the null value if the value was not changed.</p>

Table 161. AUDIT_JOURNAL_CP table function (continued)

Column Name	Data Type	Description
SERVICE	VARCHAR(3)	Current *SERVICE special authority YES Profile has *SERVICE special authority Contains the null value if the value was not changed.
AUDIT	VARCHAR(3)	Current *AUDIT special authority YES Profile has *AUDIT special authority Contains the null value if the value was not changed.
IOSYSCFG	VARCHAR(3)	Current *IOSYSCFG special authority YES Profile has *IOSYSCFG special authority Contains the null value if the value was not changed.
PREVIOUS_SPECIAL_AUTHORITIES	VARCHAR(72)	Previous list of special authorities. This is a single string containing the list of special authorities separated by one blank. Contains the null value if the value was not changed.
PREVIOUS_ALLOBJ	VARCHAR(3)	Previous *ALLOBJ special authority YES Profile had *ALLOBJ special authority Contains the null value if the value was not changed.
PREVIOUS_JOBCTL	VARCHAR(3)	Previous *JOBCTL special authority YES Profile had *JOBCTL special authority Contains the null value if the value was not changed.
PREVIOUS_SAVSYS	VARCHAR(3)	Previous *SAVSYS special authority YES Profile had *SAVSYS special authority Contains the null value if the value was not changed.
PREVIOUS_SECADM	VARCHAR(3)	Previous *SECADM special authority YES Profile had *SECADM special authority Contains the null value if the value was not changed.
PREVIOUS_SPLCTL	VARCHAR(3)	Previous *SPLCTL special authority YES Profile had *SPLCTL special authority Contains the null value if the value was not changed.
PREVIOUS_SERVICE	VARCHAR(3)	Previous *SERVICE special authority YES Profile had *SERVICE special authority Contains the null value if the value was not changed.
PREVIOUS_AUDIT	VARCHAR(3)	Previous *AUDIT special authority YES Profile had *AUDIT special authority Contains the null value if the value was not changed.
PREVIOUS_IOSYSCFG	VARCHAR(3)	Previous *IOSYSCFG special authority YES Profile had *IOSYSCFG special authority Contains the null value if the value was not changed.
GROUP_PROFILE_NAME	VARCHAR(10)	The user's group profile. Can contain the special value *NONE to indicate the user is not a member of any group profiles. Contains the null value if the value was not changed.

Table 161. AUDIT_JOURNAL_CP table function (continued)

Column Name	Data Type	Description
GROUP_OWNER	VARCHAR(7)	<p>Owner of objects created as a member of a group profile.</p> <p>*GRPPRF The user's group profile becomes the owner</p> <p>*USRPRF The user's user profile becomes the owner</p> <p>Contains the null value if the value was not changed.</p>
GROUP_AUTHORITY	VARCHAR(8)	<p>The authority the user's group profile has to objects the user creates.</p> <p>*ALL ALL authority</p> <p>*CHANGE CHANGE authority</p> <p>*EXCLUDE The group is denied access</p> <p>*NONE No authority is granted to the group profile</p> <p>*USE USE authority</p> <p>Contains the null value if the value was not changed.</p>
GROUP_AUTHORITY_TYPE	VARCHAR(8)	<p>The value of the group authority type parameter.</p> <p>*PGP The group becomes the object's primary group and is given the authority specified in GROUP_AUTHORITY.</p> <p>*PRIVATE The authority defined in the GROUP_AUTHORITY is assigned as private authority to the group profile.</p> <p>Contains the null value if the value was not changed.</p>
SUPPLEMENTAL_GROUP_LIST	VARCHAR(150)	<p>The names of up to 15 supplemental group profiles for the user. Can contain the special value *NONE to indicate the user has no supplemental groups. Each entry except for the last one is padded with blanks to fill 10 characters.</p> <p>Contains the null value if the value was not changed.</p>
INITIAL_PROGRAM_LIBRARY	VARCHAR(10)	<p>The library where the initial program is found. Can contain the special value *LIBL.</p> <p>Contains the null value if INITIAL_PROGRAM is *NONE or if the value was not changed.</p>
INITIAL_PROGRAM	VARCHAR(10)	<p>The user's initial program. Can contain the special value *NONE to indicate the user has no initial program.</p> <p>Contains the null value if the value was not changed.</p>
INITIAL_MENU_LIBRARY	VARCHAR(10)	<p>The library where the initial menu is found. Can contain the special value *LIBL.</p> <p>Contains the null value if INITIAL_MENU is *SIGNOFF or if the value was not changed.</p>
INITIAL_MENU	VARCHAR(10)	<p>The user's initial menu. Can contain the special value *SIGNOFF to indicate the user is limited to running the initial program specified for this profile.</p> <p>Contains the null value if the value was not changed.</p>
CURRENT_LIBRARY_NAME	VARCHAR(10)	<p>The user's current library. Can contain the special value *CRTDFT to indicate the user has no current library.</p> <p>Contains the null value if the value was not changed.</p>
HOME_DIRECTORY	VARGRAPHIC(5000) CCSID 1200	<p>Path name of the home directory or the following special value:</p> <p>*USRPRF The home directory assigned to the user will be /home/USRPRF, where USRPRF is the name of the user profile.</p> <p>Contains the null value if the value was not changed.</p>

Table 161. AUDIT_JOURNAL_CP table function (continued)

Column Name	Data Type	Description
LOCALE_PATH_NAME	VARGRAPHIC(5000) CCSID 1200	<p>Path name of the locale or one of the following special values:</p> <ul style="list-style-type: none"> *C The C locale path name is assigned to this user. *NONE No locale path name is assigned to this user. *POSIX The POSIX locale path name is assigned to this user. *SYSVAL The system value, QLOCALE, is used to determine the locale path name to be assigned to this user. <p>Contains the null value if the value was not changed.</p>
LIMIT_CAPABILITIES	VARCHAR(8)	<p>The value of limited capabilities parameter.</p> <ul style="list-style-type: none"> *NO No limitations. *PARTIAL The user can change the initial menu, but cannot change the initial program, current library, or attention key handling program. The user can run commands from command lines. *YES The user cannot change the initial program, initial menu, current library, and attention key handling programs. The user cannot run commands from command lines. <p>Contains the null value if the value was not changed.</p>
ASSISTANCE_LEVEL	VARCHAR(9)	<p>The user interface that will be used.</p> <ul style="list-style-type: none"> *ADVANCED The expert system interface is used. *BASIC The Operational Assistant user interface is used. *INTERMED The system interface is used. *SYSVAL The system value, QASTLVL, is used to determine the user interface that will be used. <p>Contains the null value if the value was not changed.</p>
USER_OPTIONS	VARCHAR(70)	<p>The level of help information detail to be shown and the default function of the Page Up and Page Down keys. This column can contain up to seven values, each ten characters long.</p> <ul style="list-style-type: none"> *CLKWD Parameter keywords are shown instead of the possible parameter values when a control language (CL) command is prompted. *EXPERT More detailed information is shown when the user is performing display and edit options to define or change the system. *HLPFULL Help text is shown on a full display rather than in a window. *NONE Detailed information is not shown. *NOSTMSG Status messages are not displayed when sent to the user. *PRTMSG A message is sent to this user's message queue when a spooled file for this user is printed or held by the printer writer. *ROLLKEY The actions of the Page Up and Page Down keys are reversed. *STMSG Status messages are displayed when sent to the user. <p>Contains the null value if the value was not changed.</p>
SPECIAL_ENVIRONMENT	VARCHAR(7)	<p>The special environment in which the user operates after signing on.</p> <ul style="list-style-type: none"> *NONE The user operates in the IBM i system environment after signing on the system. *S36 The user operates in the System/36 environment after signing on the system. *SYSVAL The system value, QSPCENV, is used to determine the system environment in which the user operates after signing on the system. <p>Contains the null value if the value was not changed.</p>

Table 161. AUDIT_JOURNAL_CP table function (continued)

Column Name	Data Type	Description
DISPLAY_SIGNON_INFORMATION	VARCHAR(7)	<p>Indicates if the sign-on information display is shown.</p> <p>*NO The sign-on information display is not shown.</p> <p>*SYSVAL The system value, QDSPSGNINF, is used to determine whether the sign-on information display is shown.</p> <p>*YES The sign-on information display is shown.</p> <p>Contains the null value if the value was not changed.</p>
LIMIT_DEVICE_SESSIONS	VARCHAR(7)	<p>The number of device sessions allowed for a user is limited.</p> <p>0 The user is not limited to a specific number of device sessions. This value has the same meaning as *NO.</p> <p>1 The user is limited to a single device session. This value has the same meaning as *YES.</p> <p>2-9 The user is limited to the specified number of device sessions.</p> <p>*NO The user is not limited to a specific number of device sessions.</p> <p>*SYSVAL The system value, QLMTDEVSSN, is used to determine whether the user is limited to a specific number of device sessions.</p> <p>*YES The user is limited to a single device session.</p> <p>Contains the null value if the value was not changed.</p>
KEYBOARD_BUFFERING	VARCHAR(10)	<p>The keyboard buffering value to be used when a job is initialized for this user profile.</p> <p>*NO The type-ahead feature and attention key buffering option are not active.</p> <p>*SYSVAL The system value, QKBDBUF, is used to determine the keyboard buffering value.</p> <p>*TYPEAHEAD The type-ahead feature is active, but the attention key buffering option is not.</p> <p>*YES The type-ahead feature and attention key buffering option are active.</p> <p>Contains the null value if the value was not changed.</p>
MAXIMUM_ALLOWED_STORAGE	BIGINT	<p>The amount of auxiliary storage (in kilobytes) assigned to store permanent objects owned by this user profile in the system auxiliary storage pool (ASP) and on all the basic ASPs combined. In addition, this value also controls the maximum amount of auxiliary storage that can be used to store permanent objects owned by this user profile on each Independent ASP (IASP). A value of -1 indicates *NOMAX.</p> <p>Contains the null value if the value was not changed.</p>
PRIORITY_LIMIT	INTEGER	<p>The value of the priority limit parameter. Values are 0 to 9.</p> <p>Contains the null value if the value was not changed.</p>
JOB_DESCRIPTION_LIBRARY	VARCHAR(10)	<p>The library where the job description is found. Can contain the special value *LIBL.</p> <p>Contains the null value if the value was not changed.</p>
JOB_DESCRIPTION	VARCHAR(10)	<p>The job description used for jobs that start through subsystem work station entries whose job description parameter values indicate the user JOBD(*USRPRF).</p> <p>Contains the null value if the value was not changed.</p>
ALTERNATE_SUBSYSTEM_NAME	VARCHAR(10)	<p>The alternative subsystem that will be used for this user, instead of the default subsystem, whenever a connection is initiated to the server job specified in ALTERNATE_SERVER_JOB_NAME.</p> <p>Contains the null value when COMMAND_TYPE is not SQL or if the value was not changed.</p>

Table 161. AUDIT_JOURNAL_CP table function (continued)

Column Name	Data Type	Description
ALTERNATE_SERVER_JOB_NAME	VARCHAR(10)	<p>When a connection to this server is initiated for this user it will be routed to the subsystem specified in the ALTERNATIVE_SUBSYSTEM_NAME column. Can contain the special value *ALL.</p> <p>To understand the Server Job Name mapping to server names and the default subsystem use, see Server table.</p> <p>Contains the null value when COMMAND_TYPE is not SQL or if the value was not changed.</p>
ACCOUNTING_CODE	VARCHAR(15)	<p>The accounting code that is associated with this user profile or the following special value:</p> <p>*BLANK An accounting code of 15 blanks is assigned to this user profile.</p> <p>Contains the null value if the value was not changed.</p>
MESSAGE_QUEUE_LIBRARY	VARCHAR(10)	<p>The library where the message queue is found. Can contain the special value *LIBL.</p> <p>Contains the null value if the value was not changed.</p>
MESSAGE_QUEUE	VARCHAR(10)	<p>The message queue to which messages are sent or the following special value:</p> <p>*USRPRF A message queue with the same name as the user profile is used as the message queue for this user. The message queue is located in the QUSRSYS library.</p> <p>Contains the null value if the value was not changed.</p>
MESSAGE_QUEUE_DELIVERY_METHOD	VARCHAR(7)	<p>How messages sent to the message queue for this user are to be delivered.</p> <p>*BREAK The job to which the message queue is assigned is interrupted when a message arrives at the message queue.</p> <p>*DFT The default reply to the inquiry message is sent.</p> <p>*HOLD The messages are held in the message queue until they are requested by the user or program.</p> <p>*NOTIFY The job to which the message queue is assigned is notified when a message arrives at the message queue.</p> <p>Contains the null value if the value was not changed.</p>
MESSAGE_QUEUE_SEVERITY	INTEGER	<p>The lowest severity code that a message can have and still be delivered to a user in break or notify mode. This is a value from 0 to 99.</p> <p>Contains the null value if the value was not changed.</p>
PRINT_DEVICE	VARCHAR(10)	<p>The default printer device for this user or one of the following special values:</p> <p>*SYSVAL The system value, QPRTDEV, is used to determine the printer device.</p> <p>*WRKSTN The printer assigned to the user's work station is used.</p> <p>Contains the null value if the value was not changed.</p>
OUTPUT_QUEUE_LIBRARY	VARCHAR(10)	<p>The library where the output queue is found. Can contain the special value *LIBL.</p> <p>Contains the null value if the value was not changed.</p>
OUTPUT_QUEUE	VARCHAR(10)	<p>The output queue to be used by this user profile or one of the following special values:</p> <p>*DEV The output queue associated with the printer specified for the Printer Device is used.</p> <p>*WRKSTN The output queue assigned to the user's work station is used.</p> <p>Contains the null value if the value was not changed.</p>
ATTENTION_KEY_HANDLING_PROGRAM_LIBRARY	VARCHAR(10)	<p>The library where the ATTN program is found. Can contain the special value *LIBL.</p> <p>Contains the null value if the value was not changed.</p>

Table 161. AUDIT_JOURNAL_CP table function (continued)

Column Name	Data Type	Description
ATTENTION_KEY_HANDLING_PROGRAM	VARCHAR(10)	<p>The program to be used as the Attention (ATTN) key handling program for this user or one of the following special values:</p> <p>*ASSIST The Operational Assistant ATTN key handling program, QEZMAIN, is used.</p> <p>*NONE No ATTN key handling program is used by this user.</p> <p>*SYSVAL The system value, QATNPGM, is used to determine the ATTN key handling program.</p> <p>Contains the null value if the value was not changed.</p>
SORT_SEQUENCE_TABLE_LIBRARY	VARCHAR(10)	<p>The library where the sort sequence table is found. Can contain the special value *LIBL.</p> <p>Contains the null value if the value was not changed.</p>
SORT_SEQUENCE_TABLE	VARCHAR(10)	<p>The sort sequence table to be used for string comparisons for this user profile or one of the following special values:</p> <p>*HEX A sort sequence table is not used. The hexadecimal values of the characters are used to determine the sort sequence.</p> <p>*LANGIDSHR A shared-weight sort table is used.</p> <p>*LANGIDUNQ A unique-weight sort table is used.</p> <p>*SYSVAL The system value, QSRTSEQ, is used to determine the sort sequence table.</p> <p>Contains the null value if the value was not changed.</p>
LANGUAGE_ID	VARCHAR(7)	<p>The language identifier to be used for this user profile or the following special value:</p> <p>*SYSVAL The system value, QLANGID, is used to determine the language identifier.</p> <p>Contains the null value if the value was not changed.</p>
COUNTRY_OR_REGION_ID	VARCHAR(7)	<p>The country or region identifier to be used for this user profile or the following special value:</p> <p>*SYSVAL The system value, QCNTYID, is used to determine the country or region ID.</p> <p>Contains the null value if the value was not changed.</p>
CCSID	VARCHAR(7)	<p>The coded character set identifier (CCSID) to be used for this user profile.</p> <p>*SYSVAL The system value, QCCSID, is used to determine the CCSID.</p> <p>Contains the null value if the value was not changed.</p>
CHARACTER_IDENTIFIER_CONTROL	VARCHAR(9)	<p>The character identifier control (CHRIDCTL) for the job.</p> <p>*DEVD Performs the same function as it does on the CHRID parameter for display files, printer files, and panel groups.</p> <p>*JOBCCSID Performs the same function as it does on the CHRID parameter for display files, printer files, and panel groups.</p> <p>*SYSVAL The system value, QCHRIDCTL, is used to determine the CHRIDCTL for the job.</p> <p>Contains the null value if the value was not changed.</p>

Table 161. AUDIT_JOURNAL_CP table function (continued)

Column Name	Data Type	Description
LOCALE_JOB_ATTRIBUTES	VARCHAR(60)	<p>The job attributes that are to be taken from the locale when the job is initiated. This column can contain up to six values, each ten characters long.</p> <p>*CCSID The coded character set identifier from the locale is used.</p> <p>*DATFMT The date format from the locale is used.</p> <p>*DATSEP The date separator from the locale is used.</p> <p>*DECfmt The decimal format from the locale is used.</p> <p>*NONE No job attributes are taken from the locale.</p> <p>*SRTSEQ The sort sequence from the locale is used.</p> <p>*SYSVAL The system value, QSETJOBATR, is used to determine which job attributes are taken from the locale.</p> <p>*TIMSEP The time separator from the locale is used.</p> <p>Contains the null value if the value was not changed.</p>
DOCUMENT_PASSWORD_CHANGED	VARCHAR(3)	<p>Indicates if the document password has been changed.</p> <p>YES Document password changed.</p> <p>Contains the null value if the value was not changed.</p>
DOCUMENT_PASSWORD_NONE	VARCHAR(3)	<p>Indicates if the document password is *NONE.</p> <p>YES Document password is *NONE.</p> <p>Contains the null value if the value was not changed.</p>
EIM_ID	VARCHAR(128)	<p>Enterprise Identity Mapping (EIM) identifier name or the following special value:</p> <p>*USRPRF The EIM identifier is the same name as the user profile.</p> <p>Contains the null value if no EIM values were changed.</p>
EIM_ASSOCIATION_TYPE	VARCHAR(7)	<p>EIM association type.</p> <p>*ADMIN Administrative association.</p> <p>*ALL All association types.</p> <p>*SOURCE Source association.</p> <p>*TARGET Target association.</p> <p>*TGTSRC Target and source associations.</p> <p>Contains the null value if no EIM values were changed.</p>
EIM_ASSOCIATION_ACTION	VARCHAR(8)	<p>EIM association action.</p> <p>*ADD Add an association.</p> <p>*REMOVE Remove an association.</p> <p>*REPLACE Associations of the specified type will be removed from all EIM identifiers that have an association for this user profile and local EIM registry. A new association will be added to the specified EIM identifier.</p> <p>Contains the null value if no EIM values were changed.</p>
CREATE_EIM_ID	VARCHAR(11)	<p>Indicates whether the EIM identifier should be created if it does not exist.</p> <p>*CRTEIMID EIM identifier gets created if it does not exist.</p> <p>*NOCRTEIMID EIM identifier does not get created.</p> <p>Contains the null value if no EIM values were changed.</p>
USER_ID_NUMBER	VARCHAR(10)	<p>The UID for the user. Can contain the special value *GEN to indicate the uid number is generated for the user.</p> <p>Contains the null value if the value was not changed.</p>

Table 161. AUDIT_JOURNAL_CP table function (continued)

Column Name	Data Type	Description
GROUP_ID_NUMBER	VARCHAR(10)	The GID for the user. Can contain the special values *GEN to indicate the gid number is generated for the user or *NONE to indicate the user profile does not have a group profile. Contains the null value if the value was not changed.

Example

- List any user profiles that were created in the last 6 months.

```
SELECT USER_PROFILE FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_CP(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 6 MONTHS
  )
)
WHERE COMMAND_TYPE = 'CRT';
```

AUDIT_JOURNAL_DO table function

The AUDIT_JOURNAL_DO table function returns rows from the audit journal that contain information from the DO (Delete Operation) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 162. AUDIT_JOURNAL_DO table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the DO audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. A Object was deleted (not under commitment control) C A pending object delete was committed D A pending object create was rolled back P The object delete is pending (the delete was performed under commitment control) R A pending object delete was rolled back
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
OBJECT_LIBRARY	VARCHAR(10)	The name of the library containing the object. Contains the null value if there is no library name.
OBJECT_NAME	VARCHAR(10)	The name of the object. Contains the null value if there is no object name.
OBJECT_TYPE	VARCHAR(7)	The type of the object. Contains the null value if there is no object type.
OBJECT_ATTRIBUTE	VARCHAR(10)	The attribute for the object type. Contains the null value if there is no object attribute.
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the object resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs.
OBJECT_ASP_NUMBER	INTEGER	The number of the ASP device. 1 indicates the system ASP.
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The path name of the object. Contains the null value if the object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.

Table 162. AUDIT_JOURNAL_DO table function (continued)

Column Name	Data Type	Description
PATH_NAME_INDICATOR	VARCHAR(3)	<p>Path name indicator.</p> <p>NO The PATH_NAME column does not contain an absolute path name for the object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name.</p> <p>YES The PATH_NAME column contains complete absolute path name for the object.</p> <p>Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	<p>When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the object identified in the PATH_NAME column.</p> <p>Contains the null value when PATH_NAME_INDICATOR is YES, or if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	<p>The name of the object.</p> <p>Contains the null value if the object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
OBJECT_FILE_ID	BINARY(16)	<p>The file ID of the object.</p> <p>Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
PARENT_FILE_ID	BINARY(16)	<p>The file ID of the parent directory.</p> <p>Contains the null value if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
OFFICE_USER	VARCHAR(10)	<p>The name of the office user.</p> <p>Contains the null value if there is no office user.</p>
OFFICE_ON_BEHALF_OF_USER	VARCHAR(10)	<p>User working on behalf of another user.</p> <p>Contains the null value if the user name is not available.</p>
DLO_NAME	VARCHAR(12)	<p>The name of the document library object.</p> <p>Contains the null value if there is no document library object.</p>
FOLDER_PATH	VARCHAR(63)	<p>The path of the folder.</p> <p>Contains the null value if there is no folder path.</p>

Example

- List any *FILE objects that were deleted this week. Return the user profile in effect when the delete occurred.

```
SELECT OBJECT_LIBRARY, OBJECT_NAME, USER_NAME FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_DO(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 7 DAYS
  )
) WHERE OBJECT_TYPE = '*FILE';
```

AUDIT_JOURNAL_DS table function

The AUDIT_JOURNAL_DS table function returns rows from the audit journal that contain information from the DS (Service Tools User ID and Attribute Changes) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information” on page 664](#).

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 163. AUDIT_JOURNAL_DS table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the DS audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. A Reset of a service tools user ID password using the Change IBM Service Tools Pwd (CHGDSTPWD) command. C Change to a service tools user ID using the Change Service Tools User ID (QSYCHGDS) API. D Delete of a service tools user ID using the Delete Service Tools User ID (DLTSSTUSR) command. H Change to a service tools user ID using the Change Service Tools User ID (CHGSSTUSR) command. P Change to a service tools user ID password using the Change Service Tools User ID (QSYCHGDS) API. R Create of a service tools user ID using the Create Service Tools User ID (CRTSSTUSR) command. S Change to the service tools security attributes using the Change SST Security Attributes (CHGSSTSECA) command.
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
SST_USERID	VARCHAR(10)	The name of the service tools user ID that requested the action. Contains the null value when ENTRY_TYPE is A.
SST_USERID_MODIFIED	VARCHAR(10)	The service tools user ID being created, changed, renamed, or deleted. When ENTRY_TYPE is C or P, it can contain one of the following special values. *BASIC *FULL *SECURITY *SERVICE Contains the null value when ENTRY_TYPE is not C, D, H, P, or R.
SST_USERID_NEW	VARCHAR(10)	The new service tools user ID when a user ID is renamed. Contains the null value when ENTRY_TYPE is not C.
SET_PASSWORD_EXPIRED	VARCHAR(3)	Set password to expired. NO Password is not set to expired YES Password is set to expired Contains the null value when ENTRY_TYPE is not H or R.
USERID_STATUS	VARCHAR(9)	Status of the user ID. *DISABLED *ENABLED Contains the null value when ENTRY_TYPE is not H or R, or if ENTRY_TYPE is H but no status is available.
PREV_USERID_STATUS	VARCHAR(9)	Previous status of the user ID. *DISABLED *ENABLED Contains the null value when ENTRY_TYPE is not H or R, or if ENTRY_TYPE is H but no status is available.
LINKED_PROFILE	VARCHAR(10)	The user profile that is linked to the service tools user ID. Contains the null value when ENTRY_TYPE is not H or R, or there is no linked user profile.

Table 163. AUDIT_JOURNAL_DS table function (continued)

Column Name	Data Type	Description
PREV_LINKED_PROFILE	VARCHAR(10)	The user profile that was previously linked to the service tools user ID. Contains the null value when ENTRY_TYPE is not H, or no user profile was previously linked.
ALLOW_SECURITY_SYSVAL_CHANGE	VARCHAR(3)	Allow changes to security related system values. NO Do not allow changes YES Allow changes Contains the null value when this security attribute did not change or when ENTRY_TYPE is not S.
PREV_ALLOW_SECURITY_SYSVAL_CHANGE	VARCHAR(3)	Previous value of allow changes to security related system values. NO Do not allow changes YES Allow changes Contains the null value when this security attribute did not change or when ENTRY_TYPE is not S.
PASSWORD_LEVEL	INTEGER	System Service Tools (SST) password level. The service tools password rules are similar to the values that are specified in the Password Rules (QPWDRULES) system value. Contains the null value when this value did not change or when ENTRY_TYPE is not S.
PASSWORD_LIMIT_USERID	VARCHAR(3)	Limit SST user profile name. NO The password can contain the upper case profile name. YES The password must not contain the upper case profile name. Contains the null value when this value did not change or when ENTRY_TYPE is not S.
PASSWORD_CHANGE_BLOCK	INTEGER	After a password change, the number of hours during which the password is blocked from being changed again. 0 There is no restriction on how frequently a user can change a password. Contains the null value when this value did not change or when ENTRY_TYPE is not S.
PASSWORD_MINIMUM_LENGTH	INTEGER	Minimum password length. Contains the null value when this value did not change or when ENTRY_TYPE is not S.
PASSWORD_MAXIMUM_LENGTH	INTEGER	Maximum password length. Contains the null value when this value did not change or when ENTRY_TYPE is not S.
PASSWORD_REQUIRE_GROUPS	VARCHAR(3)	The password must contain characters from at least three of the four types of characters: Uppercase letters, lowercase letters, digits, and special characters. NO The password is not required to contain characters from multiple groups. YES The password must contain characters from at least three of the four groups. Contains the null value when this value did not change or when ENTRY_TYPE is not S.
PASSWORD_LIMIT_ADJACENT	VARCHAR(3)	Limit adjacent characters. NO The password has no limit for adjacent (consecutive) characters. YES The password may not contain two or more adjacent characters. Contains the null value when this value did not change or when ENTRY_TYPE is not S.

Table 163. AUDIT_JOURNAL_DS table function (continued)

Column Name	Data Type	Description
PASSWORD_LIMIT_REPEAT	VARCHAR(3)	<p>Limit repeating characters.</p> <p>NO The password can contain multiple occurrences of the same character.</p> <p>YES The password may not contain two or more occurrences of the same character.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PASSWORD_LIMIT_POSITIONS	VARCHAR(3)	<p>Limit characters in the same position.</p> <p>NO Characters can be used in the same position as in the previous password.</p> <p>YES The same character may not be used in the same position as in the previous password.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PASSWORD_REQUIRE_DIGIT	INTEGER	<p>The minimum number of digit characters that must occur in the password.</p> <p>0 No digits are required.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PASSWORD_MAXIMUM_DIGITS	VARCHAR(6)	<p>The maximum number of digit characters that may occur in the password.</p> <p>*NOMAX Any number of digits are allowed in the password.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PASSWORD_LIMIT_DIGITS	VARCHAR(3)	<p>Limit adjacent digits.</p> <p>NO The password has no limit for adjacent (consecutive) digits.</p> <p>YES The password must not contain two or more adjacent (consecutive) digits.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PASSWORD_LIMIT_DIGIT_FIRST	VARCHAR(3)	<p>Limit digit in first position.</p> <p>NO The first character of the password can be a digit.</p> <p>YES The first character of the password must not be a digit.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PASSWORD_LIMIT_DIGIT_LAST	VARCHAR(3)	<p>Limit digit in last position.</p> <p>NO The last character of the password can be a digit.</p> <p>YES The last character of the password must not be a digit.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PASSWORD_REQUIRE_LETTER	INTEGER	<p>The minimum number of letter characters that must occur in the password.</p> <p>0 No letters are required.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PASSWORD_MAXIMUM_LETTERS	VARCHAR(6)	<p>The maximum number of letter characters that may occur in the password.</p> <p>*NOMAX Any number of letters are allowed in a password.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>

Table 163. AUDIT_JOURNAL_DS table function (continued)

Column Name	Data Type	Description
PASSWORD_LIMIT_LETTERS	VARCHAR(3)	<p>Limit adjacent letters.</p> <p>NO The password has no limit for adjacent (consecutive) letters.</p> <p>YES The password must not contain two or more adjacent (consecutive) letters.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PASSWORD_LIMIT_LETTER_FIRST	VARCHAR(3)	<p>Limit letter in first position.</p> <p>NO The first character of the password can be a letter.</p> <p>YES The first character of the password must not be a letter.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PASSWORD_LIMIT_LETTER_LAST	VARCHAR(3)	<p>Limit letter in last position.</p> <p>NO The last character of the password can be a letter.</p> <p>YES The last character of the password must not be a letter.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PASSWORD_REQUIRE_MIXED_CASE	INTEGER	<p>The password must contain at least the specified number of uppercase and lowercase letters.</p> <p>0 Mixed case letters are not required in a password.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PASSWORD_REQUIRE_SPECIAL	INTEGER	<p>The minimum number of special characters that must occur in the password.</p> <p>0 No special characters are required.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PASSWORD_MAXIMUM_SPECIAL	VARCHAR(6)	<p>The maximum number of special characters that may occur in the password.</p> <p>*NOMAX Any number of special characters are allowed in a password.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PASSWORD_LIMIT_SPECIAL	VARCHAR(3)	<p>Limit adjacent special characters.</p> <p>NO The password has no limit for adjacent (consecutive) special characters.</p> <p>YES The password must not contain two or more adjacent (consecutive) special characters.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PASSWORD_LIMIT_SPECIAL_FIRST	VARCHAR(3)	<p>Limit special character in first position.</p> <p>NO The first character of the password can be a special character.</p> <p>YES The first character of the password must not be a special character.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PASSWORD_LIMIT_SPECIAL_LAST	VARCHAR(3)	<p>Limit special character in last position.</p> <p>NO The last character of the password can be a special character.</p> <p>YES The last character of the password must not be a special character.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>

Table 163. AUDIT_JOURNAL_DS table function (continued)

Column Name	Data Type	Description
PREV_PASSWORD_LEVEL	INTEGER	Previous System Service Tools password level. Contains the null value when this value did not change or when ENTRY_TYPE is not S.
PREV_PASSWORD_LIMIT_USERID	VARCHAR(3)	The previous value for limit SST user profile name. NO The password can contain the upper case profile name. YES The password must not contain the upper case profile name. Contains the null value when this value did not change or when ENTRY_TYPE is not S.
PREV_PASSWORD_CHANGE_BLOCK	INTEGER	The previous value for the number of hours during which the password is blocked from being changed a second time. 0 There is no restriction on how frequently a user can change a password. Contains the null value when this value did not change or when ENTRY_TYPE is not S.
PREV_PASSWORD_MINIMUM_LENGTH	INTEGER	The previous value for minimum password length. Contains the null value when this value did not change or when ENTRY_TYPE is not S.
PREV_PASSWORD_MAXIMUM_LENGTH	INTEGER	The previous value for maximum password length. Contains the null value when this value did not change or when ENTRY_TYPE is not S.
PREV_PASSWORD_REQUIRE_GROUPS	VARCHAR(3)	The previous value for password must contain characters from at least three of the four types of characters: Uppercase letters, lowercase letters, digits, and special characters. NO The password is not required to contain characters from multiple groups. YES The password must contain characters from at least three of the four groups. Contains the null value when this value did not change or when ENTRY_TYPE is not S.
PREV_PASSWORD_LIMIT_ADJACENT	VARCHAR(3)	The previous value for limit adjacent characters. NO The password has no limit for adjacent (consecutive) characters. YES The password may not contain two or more adjacent (consecutive) characters. Contains the null value when this value did not change or when ENTRY_TYPE is not S.
PREV_PASSWORD_LIMIT_REPEAT	VARCHAR(3)	The previous value for limit repeating characters. NO The password can contain multiple occurrences of the same character. YES The password may not contain two or more occurrences of the same character. Contains the null value when this value did not change or when ENTRY_TYPE is not S.
PREV_PASSWORD_LIMIT_POSITIONS	VARCHAR(3)	The previous value for limit characters in the same position. NO Characters can be used in the same position as in the previous password. YES The same character may not be used in the same position as in the previous password. Contains the null value when this value did not change or when ENTRY_TYPE is not S.

Table 163. AUDIT_JOURNAL_DS table function (continued)

Column Name	Data Type	Description
PREV_PASSWORD_REQUIRE_DIGIT	INTEGER	<p>The previous value for the minimum number of digit characters that must occur in the password.</p> <p>0 No digits are required.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PREV_PASSWORD_MAXIMUM_DIGITS	VARCHAR(6)	<p>The previous value for the maximum number of digit characters that may occur in the password.</p> <p>*NOMAX Any number of digits are allowed in the password.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PREV_PASSWORD_LIMIT_DIGITS	VARCHAR(3)	<p>The previous value for limit adjacent digits.</p> <p>NO The password has no limit for adjacent (consecutive) digits.</p> <p>YES The password must not contain two or more adjacent (consecutive) digits.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PREV_PASSWORD_LIMIT_DIGIT_FIRST	VARCHAR(3)	<p>The previous value for limit digit in first position.</p> <p>NO The first character of the password can be a digit.</p> <p>YES The first character of the password must not be a digit.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PREV_PASSWORD_LIMIT_DIGIT_LAST	VARCHAR(3)	<p>The previous value for limit digit in last position.</p> <p>NO The last character of the password can be a digit.</p> <p>YES The last character of the password must not be a digit.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PREV_PASSWORD_REQUIRE_LETTER	INTEGER	<p>The previous value for the minimum number of letter characters that must occur in the password.</p> <p>0 No letters are required.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PREV_PASSWORD_MAXIMUM_LETTERS	VARCHAR(6)	<p>The previous value for the maximum number of letter characters that may occur in the password.</p> <p>*NOMAX Any number of letters are allowed in a password.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PREV_PASSWORD_LIMIT_LETTERS	VARCHAR(3)	<p>The previous value for limit adjacent letters.</p> <p>NO The password has no limit for adjacent (consecutive) letters.</p> <p>YES The password must not contain two or more adjacent (consecutive) letters.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PREV_PASSWORD_LIMIT_LETTER_FIRST	VARCHAR(3)	<p>The previous value for limit letter in first position.</p> <p>NO The first character of the password can be a letter.</p> <p>YES The first character of the password must not be a letter.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>

Table 163. AUDIT_JOURNAL_DS table function (continued)

Column Name	Data Type	Description
PREV_PASSWORD_LIMIT_LETTER_LAST	VARCHAR(3)	<p>The previous value for limit letter in last position.</p> <p>NO The last character of the password can be a letter.</p> <p>YES The last character of the password must not be a letter.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PREV_PASSWORD_REQUIRE_MIXED_CASE	INTEGER	<p>The previous value for the password must contain at least the specified number of uppercase and lowercase letters.</p> <p>0 Mixed case letters are not required in a password.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PREV_PASSWORD_REQUIRE_SPECIAL	INTEGER	<p>The previous value for the minimum number of special characters that must occur in the password.</p> <p>0 No special characters are required.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PREV_PASSWORD_MAXIMUM_SPECIAL	VARCHAR(6)	<p>The previous value for the maximum number of special characters that may occur in the password.</p> <p>*NOMAX Any number of special characters are allowed in a password.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PREV_PASSWORD_LIMIT_SPECIAL	VARCHAR(3)	<p>The previous value for limit adjacent special characters.</p> <p>NO The password has no limit for adjacent (consecutive) special characters.</p> <p>YES The password must not contain two or more adjacent (consecutive) special characters.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PREV_PASSWORD_LIMIT_SPECIAL_FIRST	VARCHAR(3)	<p>The previous value for limit special character in first position.</p> <p>NO The first character of the password can be a special character.</p> <p>YES The first character of the password must not be a special character.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
PREV_PASSWORD_LIMIT_SPECIAL_LAST	VARCHAR(3)	<p>The previous value for limit special character in last position.</p> <p>NO The last character of the password can be a special character.</p> <p>YES The last character of the password must not be a special character.</p> <p>Contains the null value when this value did not change or when ENTRY_TYPE is not S.</p>
DISK_OPERATIONS	VARCHAR(3)	<p>Current privilege to perform disk operator service functions.</p> <p>NO Service tools user ID does not have the privilege</p> <p>YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H or R, or it is H and the privilege is not changing.</p>
DISK_ADMIN	VARCHAR(3)	<p>Current privilege to perform disk unit administrator service functions.</p> <p>NO Service tools user ID does not have the privilege</p> <p>YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H or R, or it is H and the privilege is not changing.</p>

Table 163. AUDIT_JOURNAL_DS table function (continued)

Column Name	Data Type	Description
DISK_READ_ONLY	VARCHAR(3)	<p>Current privilege to perform disk read only service functions.</p> <p>NO Service tools user ID does not have the privilege YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H or R, or it is H and the privilege is not changing.</p>
SYSTEM_PARTITION_OPERATIONS	VARCHAR(3)	<p>Current privilege to perform system partition operator service functions.</p> <p>NO Service tools user ID does not have the privilege YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H or R, or it is H and the privilege is not changing.</p>
SYSTEM_PARTITION_ADMIN	VARCHAR(3)	<p>Current privilege to perform system partition administrator service functions.</p> <p>NO Service tools user ID does not have the privilege YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H or R, or it is H and the privilege is not changing.</p>
PARTITION_REMOTE_PANEL_KEY	VARCHAR(3)	<p>Current privilege to change a panel key for the specified partition where it is secured.</p> <p>NO Service tools user ID does not have the privilege YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H or R, or it is H and the privilege is not changing.</p>
OPERATOR_PANEL_FUNCTIONS	VARCHAR(3)	<p>Current privilege to use the operator panel functions.</p> <p>NO Service tools user ID does not have the privilege YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H or R, or it is H and the privilege is not changing.</p>
IPL	VARCHAR(3)	<p>Current privilege to perform an IPL.</p> <p>NO Service tools user ID does not have the privilege YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H or R, or it is H and the privilege is not changing.</p>
INSTALL	VARCHAR(3)	<p>Current privilege to perform a system install.</p> <p>NO Service tools user ID does not have the privilege YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H or R, or it is H and the privilege is not changing.</p>
PDC	VARCHAR(3)	<p>Current privilege to perform Performance Data Collector (PDC) service functions.</p> <p>NO Service tools user ID does not have the privilege YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H or R, or it is H and the privilege is not changing.</p>

PREV_REMOTE_SERVICE_SUPPORT	VARCHAR(3)	<p>Previous privilege to configure and connect to the system using the Remote Service Support interface.</p> <p>NO Service tools user ID does not have the privilege YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H, or it is H and the privilege is not changing.</p>
PREV_SERVICE_TOOLS_SECURITY	VARCHAR(3)	<p>Previous privilege to work with and change Licensed Internal Code (LIC) security values.</p> <p>NO Service tools user ID does not have the privilege YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H, or it is H and the privilege is not changing.</p>
PREV_SERVICE_TOOLS_SAVE_RESTORE	VARCHAR(3)	<p>Previous privilege to perform save and restore service security functions.</p> <p>NO Service tools user ID does not have the privilege YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H, or it is H and the privilege is not changing.</p>
PREV_DEBUG	VARCHAR(3)	<p>Previous privilege to use the service debug tools.</p> <p>NO Service tools user ID does not have the privilege YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H, or it is H and the privilege is not changing.</p>
PREV_SYSTEM_CAPACITY_OPERATIONS	VARCHAR(3)	<p>Previous privilege to perform system capacity operations service functions.</p> <p>NO Service tools user ID does not have the privilege YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H, or it is H and the privilege is not changing.</p>
PREV_SYSTEM_CAPACITY_ADMIN	VARCHAR(3)	<p>Previous privilege to perform system capacity administration service functions.</p> <p>NO Service tools user ID does not have the privilege YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H, or it is H and the privilege is not changing.</p>

Table 163. AUDIT_JOURNAL_DS table function (continued)

Column Name	Data Type	Description
PREV_SYSTEM_SECURITY	VARCHAR(3)	<p>Previous privilege to perform security service functions and to work with security lock down values.</p> <p>NO Service tools user ID does not have the privilege</p> <p>YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H, or it is H and the privilege is not changing.</p>
PREV_SST	VARCHAR(3)	<p>Previous privilege to sign-on and work with SST.</p> <p>NO Service tools user ID does not have the privilege</p> <p>YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H, or it is H and the privilege is not changing.</p>
PREV_TAKE_OVER_CONSOLE	VARCHAR(3)	<p>Previous privilege for a LAN console user to take over the console from another LAN console user.</p> <p>NO Service tools user ID does not have the privilege</p> <p>YES Service tools user ID has the privilege</p> <p>Contains the null value when ENTRY_TYPE is not H, or it is H and the privilege is not changing.</p>

Example

- List SST users that were created or deleted in the last month

```
SELECT *
FROM TABLE (
    SYSTOOLS.AUDIT_JOURNAL_DS (STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 1 MONTH)
)
WHERE ENTRY_TYPE IN ('D', 'R');
```

AUDIT_JOURNAL_EV table function

The AUDIT_JOURNAL_EV table function returns rows from the audit journal that contain information from the EV (Environment Variable) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 164. AUDIT_JOURNAL_EV table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the EV audit journal entry.		
ENTRY_TYPE	CHAR(1)	<p>The type of entry.</p> <p>A Add</p> <p>C Change</p> <p>D Delete</p> <p>I Initialize environment variable space</p>
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
ENVIRONMENT_VARIABLE_NAME	VARGRAPHIC(1000) CCSID 1200	<p>The name of the environment variable.</p> <p>Contains the null value when ENTRY_TYPE is I.</p>

Table 164. AUDIT_JOURNAL_EV table function (continued)

Column Name	Data Type	Description
NAME_TRUNCATED	VARCHAR(3)	Indicates whether ENVIRONMENT_VARIABLE_NAME is truncated. NO Environment variable name is not truncated. YES Environment variable name is truncated. Contains the null value when ENVIRONMENT_VARIABLE_NAME is null.
ENVIRONMENT_VARIABLE_VALUE	VARGRAPHIC(1000) CCSID 1200	The value of the environment variable. Contains the null value when no environment variable value is available.
VALUE_TRUNCATED	VARCHAR(3)	Indicates whether ENVIRONMENT_VARIABLE_VALUE is truncated. NO Environment variable value is not truncated. YES Environment variable value is truncated. Contains the null value when ENVIRONMENT_VARIABLE_VALUE is null.

Example

- List any environment variables that have been changed in the last month.

```
SELECT *
  FROM TABLE (
    SYSTOOLS.AUDIT_JOURNAL_EV (STARTING_TIMESTAMP => CURRENT DATE - 1 MONTH))
 WHERE ENTRY_TYPE = 'C';
```

AUDIT_JOURNAL_GR table function

The AUDIT_JOURNAL_GR table function returns rows from the audit journal that contain information from the GR (Generic Record) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 165. AUDIT_JOURNAL_GR table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the GR audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. A Exit program added D Exit program removed F Function registration operations O ObjectConnect operations R Exit program replaced
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
ACTION	CHAR(2)	The action performed. ZC Change ZR Read When ENTRY_TYPE is O: SV Save RS Restore

Table 165. AUDIT_JOURNAL_GR table function (continued)

Column Name	Data Type	Description
ACTION_DETAIL	VARCHAR(200)	Descriptive text that describes the action.
EXIT_POINT_NAME	VARCHAR(20)	When ENTRY_TYPE is A, D, or R, the exit point name. Contains the null value when ENTRY_TYPE is F, or O.
EXIT_POINT_FORMAT	CHAR(8)	When ENTRY_TYPE is A, D, or R, the exit point format name associated with the exit point Contains the null value when ENTRY_TYPE is F, or O.
EXIT_PROGRAM_NUMBER	INTEGER	When ENTRY_TYPE is A, D, or R, the exit program number associated with the exit program. Contains the null value when ENTRY_TYPE is F, or O.
EXIT_PROGRAM_LIBRARY	VARCHAR(10)	When ENTRY_TYPE is A, D, or R, the library in which EXIT_PROGRAM resides. Contains the null value when ENTRY_TYPE is F, or O.
EXIT_PROGRAM	VARCHAR(10)	When ENTRY_TYPE is A, D, or R, the name of the exit program.. Contains the null value when ENTRY_TYPE is F, or O.
USER_PROFILE_NAME	VARCHAR(10)	User profile name When ENTRY_TYPE is F, contains the name of the user the function registration operation was performed against. When a REGISTER or REREGISTER operation is being performed that includes the default usage, contains *DEFAULT. When ENTRY_TYPE is O, contains the name of the user performing the ObjectConnect operation. Contains the null value when ENTRY_TYPE is A, D, or R, or if a user profile name does not apply to the entry.
FUNCTION_REGISTRATION_OPERATION	VARCHAR(13)	When ENTRY_TYPE is F, contains the description of the function registration operation that was performed. The possible values are: CHANGE USAGE Function usage information has been changed, such as which user profiles are allowed to use a function. CHECK USAGE Function usage information was checked for a user and determined the user is allowed to use the specified function. DEREGISTER Function and all associated usage information has been removed from the registration facility. REGISTER Function has been registered with the registration facility. REREGISTER Function has been updated and replaced within the registration facility. USAGE FAILURE Function usage information was checked for a user and determined the user is not allowed to use the specified function. Contains the null value when ENTRY_TYPE is not F.
FUNCTION_NAME	VARCHAR(30)	When ENTRY_TYPE is F, contains the name of the function that was operated on. Contains the null value when ENTRY_TYPE is not F.
USAGE_SETTING	VARCHAR(7)	When ENTRY_TYPE is F, contains the usage value for the user specified in USER_PROFILE_NAME. If USER_PROFILE_NAME is *DEFAULT, this is the default usage. ALLOWED The user is allowed to use the function. DENIED The user is not allowed to use the function. REMOVED The user's previous setting is removed. UNKNOWN The user did not previously have a usage value. Contains the null value when ENTRY_TYPE is not F or if no value is available.

Table 165. AUDIT_JOURNAL_GR table function (continued)

Column Name	Data Type	Description
PREVIOUS_USAGE	VARCHAR(7)	<p>When ENTRY_TYPE is F, contains the previous usage value for a user. If USER_PROFILE_NAME is *DEFAULT, this is the previous default usage.</p> <p>ALLOWED The user is allowed to use the function.</p> <p>DENIED The user is not allowed to use the function.</p> <p>REMOVED The user's previous setting is removed.</p> <p>UNKNOWN The user did not previously have a usage value.</p> <p>Contains the null value when ENTRY_TYPE is not F or if no value is available.</p>
FUNCTION_ALLOBJ	VARCHAR(8)	<p>When ENTRY_TYPE is F and FUNCTION_REGISTRATION_OPERATION is REGISTER or REREGISTER, contains the setting that indicates whether all object (*ALLOBJ) special authority may be used to give a user access to the function.</p> <p>NOT USED For a user with *ALLOBJ special authority to use the function, the usage information specified for the function must indicate that the user is allowed to use the function</p> <p>USED A user with *ALLOBJ special authority is always allowed to use the function.</p> <p>Contains the null value when ENTRY_TYPE is not F or if no value is available.</p>
PREVIOUS_ALLOBJ	VARCHAR(8)	<p>When ENTRY_TYPE is F and FUNCTION_REGISTRATION_OPERATION is REREGISTER, contains the previous setting that indicates whether all object (*ALLOBJ) special authority may be used to give a user access to the function.</p> <p>NOT USED For a user with *ALLOBJ special authority to use the function, the usage information specified for the function must indicate that the user is allowed to use the function</p> <p>USED A user with *ALLOBJ special authority is always allowed to use the function.</p> <p>Contains the null value when ENTRY_TYPE is not F or if no value is available.</p>
OBJECTCONNECT_COMMAND	VARCHAR(9)	<p>When ENTRY_TYPE is O, contains the ObjectConnect CL command.</p> <p>SAVRST Save/Restore Integrated File System Object</p> <p>SAVRSTCFG Save/Restore Configuration</p> <p>SAVRSTCHG Save/Restore Changed Object</p> <p>SAVRSTDLO Save/Restore Document Library Object</p> <p>SAVRSTLIB Save/Restore Library</p> <p>SAVRSTOBJ Save/Restore Object</p> <p>Contains the null value when ENTRY_TYPE is not O.</p>
SAVE_SYSTEM	VARCHAR(15)	<p>When ENTRY_TYPE is O and ACTION is RS, contains the name of the system on which the objects are saved.</p> <p>When ENTRY_TYPE is O and ACTION is SV, contains the name of the system on which the objects are restored.</p> <p>If ObjectConnect uses *DB2MIRROR for the connection type, the NRG name is returned.</p> <p>Contains the null value when ENTRY_TYPE is not O.</p>
SAVE_ASP	VARCHAR(10)	<p>When ENTRY_TYPE is O and OBJECTCONNECT_COMMAND is SAVRST, SAVRSTCHG, SAVRSTLIB, or SAVRSTOBJ, the ASP device name. Can contain one of the following special values:</p> <ul style="list-style-type: none"> • * • *ALLAVL • *ANY • *CURASPGRP • *SYSBAS • 1-32 <p>Contains the null value when ENTRY_TYPE is not O or there is no ASP device.</p>

Table 165. AUDIT_JOURNAL_GR table function (continued)

Column Name	Data Type	Description
SAVE_LIBRARY	VARCHAR(10)	When ENTRY_TYPE is O and OBJECTCONNECT_COMMAND is SAVRST, SAVRSTCHG, SAVRSTLIB, or SAVRSTOBJ, the library name is set when processing objects from the QSYS file system. It is the name of the saved library or the library from which the objects were saved. Contains the null value when ENTRY_TYPE is not O or there is no saved library.
RESTORE_ASP_DEVICE	VARCHAR(10)	When ENTRY_TYPE is O and OBJECTCONNECT_COMMAND is SAVRST, SAVRSTCHG, SAVRSTLIB, or SAVRSTOBJ, the ASP device name. Can contain the following special value: • *SAVASPDEV Contains the null value when ENTRY_TYPE is not O or RESTORE_ASP_NUMBER is set.
RESTORE_ASP_NUMBER	VARCHAR(10)	When ENTRY_TYPE is O and OBJECTCONNECT_COMMAND is SAVRST, SAVRSTCHG, SAVRSTLIB, or SAVRSTOBJ, the ASP number, 1-32. Can contain the following special value: • *SAVASP Contains the null value when ENTRY_TYPE is not O or RESTORE_ASP_DEVICE is set.
RESTORE_LIBRARY	VARCHAR(10)	When ENTRY_TYPE is O and OBJECTCONNECT_COMMAND is SAVRST, SAVRSTCHG, SAVRSTLIB, or SAVRSTOBJ, the library name is set when processing objects from the QSYS file system otherwise it is blank. It is the name of the restored library or the library to which the objects were restored. Contains the null value when ENTRY_TYPE is not O or there is no restore library name.
OBJECTCONNECT_UUID	VARCHAR(16)	When ENTRY_TYPE is O, contains the Universal Unique Identifier (UUID) of the ObjectConnect operation. Contains the null value when ENTRY_TYPE is not O.
RESTORE_USER	VARCHAR(10)	When ENTRY_TYPE is O and ACTION is SV, contains the name of the user under which the restore will be performed. Can contain the following special values: *CURRENT *KERBEROS *NONE Contains the null value when ENTRY_TYPE is not O with an ACTION of SV.

Example

- List any changes to function usage definitions from the last two weeks

```
SELECT *
  FROM TABLE (
    SYSTOOLS.AUDIT_JOURNAL_GR (STARTING_TIMESTAMP => CURRENT DATE - 14 DAYS))
 WHERE ENTRY_TYPE = 'F' AND
        FUNCTION_REGISTRATION_OPERATION = 'CHANGE USAGE';
```

AUDIT_JOURNAL_IM table function

The AUDIT_JOURNAL_IM table function returns rows from the audit journal that contain information from the IM (Intrusion Monitor) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 166. AUDIT_JOURNAL_IM table function

Column Name	Data Type	Description
<p>The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the IM audit journal entry.</p>		
ENTRY_TYPE	CHAR(1)	The type of entry. P Potential intrusion event detected
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
EVENT_TIMESTAMP	TIMESTAMP	The date and time that the event was detected.
EVENT_LOCAL_ADDRESS_FAMILY	CHAR(4)	The type of local address associated with the detected event. IPV4 The address is in IPv4 format. IPV6 The address is in IPv6 format. Contains the null value when a value is not available.
EVENT_LOCAL_ADDRESS	VARCHAR(45)	Local IP address associated with the detected event. Contains the null value when a value is not available.
EVENT_LOCAL_PORT	INTEGER	Local port number associated with the detected event. Contains the null value when a value is not available.
EVENT_REMOTE_ADDRESS_FAMILY	CHAR(4)	The type of remote address associated with the detected event. IPV4 The address is in IPv4 format. IPV6 The address is in IPv6 format. Contains the null value when a value is not available.
EVENT_REMOTE_ADDRESS	VARCHAR(45)	Remote IP address associated with the detected event. Contains the null value when a value is not available.
EVENT_REMOTE_PORT	INTEGER	Remote port number associated with the detected event. Contains the null value when a value is not available.
PROBE_TYPE	VARCHAR(6)	The type of probe used to detect the potential intrusion. ATTACK Attack event OPEN Intrusion Detection System (IDS) state change SCANE Scan event SCANG Scan global event TR-SSL Traffic regulation event (System TLS) TR-TCP Traffic regulation event (TCP) TR-UDP Traffic regulation event (UDP) XATTAC Possible extrusion attack XSCAN Outbound scan XTRTCP Outbound traffic regulation event (TCP) XTRUDP Outbound traffic regulation event (UDP)
PROBE_TYPE_DETAIL	VARCHAR(200)	Descriptive text for the probe type.
EVENT_CORRELATOR	VARCHAR(4)	Identifier for this specific intrusion event. This identifier can be used to correlate this audit record with other intrusion detection information.

Table 166. AUDIT_JOURNAL_IM table function (continued)

Column Name	Data Type	Description		
EVENT_ATTACK_TYPE	VARCHAR(8)	The type of potential intrusion that was detected.		
		ACKSTORM TCP ACK Storm		
		ADRPOISN Address Poisoning		
		FLOOD Flood		
		FRAGGLE Fraggle		
		ICMPRED ICMP Redirect		
		IPFRAG IP Fragment		
		MALFPKT Malformed Packet		
		OUTRAW Outbound Raw		
		PERPECH Perpetual Echo		
		PNGDEATH Ping of Death		
		RESTOPT Restricted IP Options		
		RESTPROT Restricted IP Protocol		
		SMURF Smurf		
		Contains the null value when PROBE_TYPE is not ATTACK or XATTAC.		
EVENT_ATTACK_TYPE_DETAIL	VARCHAR(200)	Descriptive text for the type of potential intrusion.		
		Contains the null value when PROBE_TYPE is not ATTACK or XATTAC.		
PROTOCOL	VARCHAR(6)	Protocol. Recognized protocol values and their protocol numbers are:		
		ICMP 1		
		ICMPV6 58		
		IGMP 2		
		OSPF 89		
		TCP 6		
		UDP 17		
				If the protocol is not one of these well-known values, the integer representation of the protocol is returned.
				Contains the null value when a value is not available.
		CONDITION_NUMBER	INTEGER	Condition number from IDS policy file.
Contains the null value when a value is not available.				
THROTTLING_ACTIVE	VARCHAR(3)	Throttling status at the time the event was flagged.		
		NO Throttling is not active.		
		YES Throttling is active.		
DISCARDED_PACKETS	INTEGER	Number of discarded packets when throttled.		
		Contains the null value when THROTTLING_ACTIVE is NO.		
TARGET_TCPIP_STACK	VARCHAR(10)	The type of TCP/IP stack that was targeted.		
		PRODUCTION Production Stack		
		SERVICE Service Stack		
SUSPECTED_PACKET	VARBINARY(1000)	The first 1000 bytes of the IP packet associated with the detected event. Contains the null value when PROBE_TYPE is TR-SSL or when a value is not available.		
FAILING_HANDSHAKE_LOCATION	VARCHAR(6)	The processing location that detected the failed handshake.		
		Contains the null value when PROBE_TYPE is not TR-SSL or when a value is not available.		

Table 166. AUDIT_JOURNAL_IM table function (continued)

Column Name	Data Type	Description
FAILING_HANDSHAKE_ERROR	VARCHAR(40)	The error returned on the failing handshake. Contains the null value when PROBE_TYPE is not TR-SSL or when a value is not available.
DETECTION_POINT_ID	VARCHAR(4)	A unique identifier for the processing location that detected the intrusion event. This value is intended for use by service personnel.

Example

- List all intrusion events for this week.

```
SELECT * FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_IM(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 7 DAYS
  )
);
```

AUDIT_JOURNAL_JS table function

The AUDIT_JOURNAL_JS table function returns rows from the audit journal that contain information from the JS (Job Change) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 167. AUDIT_JOURNAL_JS table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the JS audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. A ENDJOBABN command B Submit C Change E End H Hold I Disconnect J The current job is attempting to interrupt another job K The current job is about to be interrupted L The interruption of the current job has completed M Change profile or group profile N ENDJOB command P Attach prestart or batch immediate job Q Change query attributes R Release S Start T Change profile or group profile using a profile token U CHGUSRTRC V Virtual device changed by QWSACCD5 API
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.

Table 167. AUDIT_JOURNAL_JS table function (continued)

Column Name	Data Type	Description
JOB_TYPE	VARCHAR(3)	<p>The job type. This value is based on the values of the JOB_TYPE_BASIC and JOB_SUBTYPE columns.</p> <p>ASJ Autostart</p> <p>BCH Batch</p> <p>BCI Batch Immediate</p> <p>EVK Started by a procedure start request</p> <p>INT Interactive</p> <p>M36 Advanced 36 server job</p> <p>MRT Multiple requester terminal</p> <p>PDJ Print driver job</p> <p>PJ Prestart job</p> <p>RDR Spool reader</p> <p>SBS Subsystem monitor</p> <p>SYS System</p> <p>WTR Spool writer</p> <p>Contains the null value if no value is available.</p>
JOB_TYPE_BASIC	CHAR(1)	<p>The type of job.</p> <p>A Autostart</p> <p>B Batch</p> <p>I Interactive</p> <p>M Subsystem monitor</p> <p>R Reader</p> <p>S System</p> <p>W Writer</p> <p>X SCPF</p> <p>Contains the null value if no value is available.</p>
JOB_SUBTYPE	CHAR(1)	<p>The subtype of the job.</p> <p>D Batch immediate</p> <p>E Procedure start request</p> <p>J Prestart</p> <p>P Print device driver</p> <p>Q Query</p> <p>T MRT</p> <p>U Alternate spool user</p> <p>Contains the null value if there is no subtype for the job.</p>
TARGET_QUALIFIED_JOB_NAME	VARCHAR(28)	The qualified job name of the job that is being operated on.
TARGET_JOB_NAME	VARCHAR(10)	The name of the job that is being operated on.
TARGET_JOB_USER	VARCHAR(10)	The user profile that of the job that is being operated on.
TARGET_JOB_NUMBER	VARCHAR(6)	The job number of the job that is being operated on.
DEVICE_NAME	VARCHAR(10)	<p>The name of the device.</p> <p>Contains the null value if no value is available.</p>

Table 167. AUDIT_JOURNAL_JS table function (continued)

Column Name	Data Type	Description
EFFECTIVE_USER_PROFILE	VARCHAR(10)	The name of the effective user profile for the thread. When this audit record is generated because one job performs an operation on another job this column contains data from the initial thread of the job that is being operated on. In all other cases, the column contains data from the thread that performed the operation. Contains the null value if no value is available.
EFFECTIVE_GROUP_PROFILE	VARCHAR(10)	The name of the effective group profile for the thread. When this audit record is generated because one job performs an operation on another job, this column contains data from the initial thread of the job that is being operated on. In all other cases, the column contains data from the thread that performed the operation. Contains the null value if no value is available.
SUPPLEMENTAL_GROUP_PROFILES	VARCHAR(150)	The names of the supplemental group profiles for the thread. When this audit record is generated because one job performs an operation on another job, this column contains data from the initial thread of the job that is being operated on. In all other cases, the column contains data from the thread that performed the operation. Contains the null value if no value is available.
REAL_USER_PROFILE	VARCHAR(10)	The name of the real (initial) user profile for the thread. Contains the null value if no value is available.
SAVED_USER_PROFILE	VARCHAR(10)	The name of the saved user profile for the thread. Contains the null value if no value is available.
REAL_GROUP_PROFILE	VARCHAR(10)	The name of the real (initial) group profile for the thread. Contains the null value if no value is available.
SAVED_GROUP_PROFILE	VARCHAR(10)	The name of the saved group profile for the thread. Contains the null value if no value is available.
REAL_USER_CHANGED	VARCHAR(3)	The real user profile was changed. NO The real user profile was not changed. YES The real user profile was changed. Contains the null value when ENTRY_TYPE is not M or T.
EFFECTIVE_USER_CHANGED	VARCHAR(3)	The effective user profile was changed. NO The effective user profile was not changed. YES The effective user profile was changed. Contains the null value when ENTRY_TYPE is not M or T.
SAVED_USER_CHANGED	VARCHAR(3)	The saved user profile was changed. NO The saved user profile was not changed. YES The saved user profile was changed. Contains the null value when ENTRY_TYPE is not M or T.
REAL_GROUP_CHANGED	VARCHAR(3)	The real group profile was changed. NO The real group profile was not changed. YES The real group profile was changed. Contains the null value when ENTRY_TYPE is not M or T.
EFFECTIVE_GROUP_CHANGED	VARCHAR(3)	The effective group profile was changed. NO The effective group profile was not changed. YES The effective group profile was changed. Contains the null value when ENTRY_TYPE is not M or T.

Table 167. AUDIT_JOURNAL_JS table function (continued)

Column Name	Data Type	Description
SAVED_GROUP_CHANGED	VARCHAR(3)	The saved group profile was changed. NO The saved group profile was not changed. YES The saved group profile was changed. Contains the null value when ENTRY_TYPE is not M or T.
SUPPLEMENTAL_GROUPS_CHANGED	VARCHAR(3)	The supplemental group profiles were changed. NO The supplemental group profiles were not changed. YES The supplemental group profiles were changed. Contains the null value when ENTRY_TYPE is not M or T.
JOB_DESCRIPTION_LIBRARY	VARCHAR(10)	The name of the library for the job description. Contains the null value if no value is available.
JOB_DESCRIPTION	VARCHAR(10)	The name of the job description for the job. Contains the null value if no value is available.
JOB_DESCRIPTION_ASP_NAME	VARCHAR(10)	ASP name for JOB_DESCRIPTION_LIBRARY. Contains the null value if no value is available.
JOB_DESCRIPTION_ASP_NUMBER	INTEGER	ASP number for JOB_DESCRIPTION_LIBRARY. 1 indicates the system ASP. Contains the null value if no value is available.
JOB_QUEUE_LIBRARY	VARCHAR(10)	The name of the library for the job queue. Contains the null value if no value is available.
JOB_QUEUE_NAME	VARCHAR(10)	The name of the job queue for the job. Contains the null value if no value is available.
JOB_QUEUE_ASP_NAME	VARCHAR(10)	ASP name for JOB_QUEUE_LIBRARY. Contains the null value if no value is available.
JOB_QUEUE_ASP_NUMBER	INTEGER	ASP number of JOB_QUEUE_LIBRARY. Contains the null value if no value is available.
OUTPUT_QUEUE_LIBRARY	VARCHAR(10)	The name of the library for the output queue. Contains the null value if no value is available.
OUTPUT_QUEUE_NAME	VARCHAR(10)	The name of the output queue for the job. Contains the null value if no value is available.
PRINTER_DEVICE	VARCHAR(10)	The name of the printer device for the job. Contains the null value if no value is available.
TIME_ZONE_DESCRIPTION_NAME	VARCHAR(10)	The timezone description name. Contains the null value if no value is available.
THREAD_ASP_NAME	VARCHAR(10)	The ASP group for the current thread. Contains the null value if no value is available.
LIBRARY_LIST_COUNT	INTEGER	The number of libraries in LIBRARY_LIST.
LIBRARY_LIST	VARCHAR(2680)	The library list for the job. The list is an array of entries, each ten characters long. When this audit record is generated because one job performs an operation on another job, this column contains data from the initial thread of the job that is being operated on. In all other cases, the column contains data from the thread that performed the operation. Contains the null value when LIBRARY_LIST_COUNT is 0.

Table 167. AUDIT_JOURNAL_JS table function (continued)

Column Name	Data Type	Description
JOB_USER_IDENTITY_DESCRIPTION	VARCHAR(5)	Describes the meaning of JOB_USER_IDENTITY. CLEAR The clear JUID API was called. JOB_USER_IDENTITY contains the new value. JOB JOB_USER_IDENTITY contains the value for the JOB. SET The set JUID API was called. JOB_USER_IDENTITY contains the new value.
JOB_USER_IDENTITY	VARCHAR(10)	The job user identity value. Contains the null value if no value is available.
WORKLOAD_GROUP	VARCHAR(10)	The name of the workload group associated with the job. Contains the null value when ENTRY_TYPE is not C, E, or S.
EXIT_QUALIFIED_JOB_NAME	VARCHAR(28)	<ul style="list-style-type: none"> When ENTRY_TYPE is J, the qualified job name of the job that was interrupted by the current job. When ENTRY_TYPE is K or L, the qualified job name of the job that requested the interruption of the current job. Contains the null value when ENTRY_TYPE is not J, K, or L.
EXIT_JOB_NAME	VARCHAR(10)	<ul style="list-style-type: none"> When ENTRY_TYPE is J, the name of the job that was interrupted by the current job. When ENTRY_TYPE is K or L, the name of the job that requested the interruption of the current job. Contains the null value when ENTRY_TYPE is not J, K, or L.
EXIT_JOB_USER	VARCHAR(10)	<ul style="list-style-type: none"> When ENTRY_TYPE is J, the user of the job that was interrupted by the current job. When ENTRY_TYPE is K or L, the user of the job that requested the interruption of the current job. Contains the null value when ENTRY_TYPE is not J, K, or L.
EXIT_JOB_NUMBER	VARCHAR(6)	<ul style="list-style-type: none"> When ENTRY_TYPE is J, the job number of the job that was interrupted by the current job. When ENTRY_TYPE is K or L, the number of the job that requested the interruption of the current job. Contains the null value when ENTRY_TYPE is not J, K, or L.
EXIT_PROGRAM_LIBRARY	VARCHAR(10)	The library name of the exit program used to interrupt the job. Contains the null value when ENTRY_TYPE is not J, K, or L.
EXIT_PROGRAM	VARCHAR(10)	The exit program used to interrupt the job. Contains the null value when ENTRY_TYPE is not J, K, or L.

Example

- List jobs that were ended today with the ENDJOB or ENDJOBABN CL commands.

```
SELECT *
FROM TABLE (
  SYSTOOLS.AUDIT_JOURNAL_JS (STARTING_TIMESTAMP => CURRENT DATE)
)
WHERE ENTRY_TYPE IN ('A', 'N');
```

AUDIT_JOURNAL_LD table function

The AUDIT_JOURNAL_LD table function returns rows from the audit journal that contain information from the LD (Link, Unlink, Search Directory) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 168. AUDIT_JOURNAL_LD table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the LD audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. K Search directory L Link directory U Unlink directory
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The path name of the object. Contains the null value if the path name is not available.
PATH_NAME_INDICATOR	VARCHAR(3)	Path name indicator. NO The PATH_NAME column does not contain an absolute path name for the object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name. YES The PATH_NAME column contains complete absolute path name for the object. Contains the null value if the path name is not available.
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the object identified in the PATH_NAME column. Contains the null value if the path name is not available, or the PATH_NAME_INDICATOR is YES, or the file ID is not available.
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	The name of the object.
OBJECT_FILE_ID	BINARY(16)	The file ID of the object.
PARENT_FILE_ID	BINARY(16)	The file ID of the parent directory. Contains the null value if the file ID is not available.
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the object resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs.
OBJECT_ASP_NUMBER	INTEGER	The number of the auxiliary storage pool to which storage for the object is allocated. 1 indicates the system ASP.

Example

- List directories that have been searched in the last week.

```
SELECT PATH_NAME FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_LD(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 7 DAYS)
)
WHERE ENTRY_TYPE = 'K';
```

AUDIT_JOURNAL_M0 table function

The AUDIT_JOURNAL_M0 table function returns rows from the audit journal that contain information from the M0 (Db2 Mirror Setup Tools) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 169. AUDIT_JOURNAL_M0 table function

Column Name	Data Type	Description
<p>The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the M0 audit journal entry.</p>		
ENTRY_TYPE	CHAR(1)	The type of entry. A Db2 Mirror setup tools
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
ACTION	VARCHAR(15)	The action performed. CHECKSYSBASE Verify the cloning of SYSBASE and the configuration of the setup copy node has completed successfully. CONFIGFILE Manipulate the JSON configuration files. FLASHCOPY Perform the flash copy process on the storage. IASPCOPY Perform the entire automated DB IASP clone process. POSTIASP Perform the post-IASP copy steps. POWEROFF Power [®] off the setup source or copy node using the HMC poweroff operation. PRECHECK Perform validation and checking to ensure the whole cloning process will complete successfully. PREIASP Perform the pre-IASP copy steps. REMOTECOPY Perform the remote copy process on the storage. START Begin the entire SYSBASE cloning process. STARTWARMCLONE Start Db2 Mirror tracking and flush main memory on the setup source node.
ACTION_TYPE	VARCHAR(10)	The type of action being performed. When ACTION is START or IASPCOPY: COLD WARM When ACTION is CONFIGFILE: NEW RESTORE SAVE UPDATE When ACTION is POWEROFF: CONTROL HMC IMMED Contains the null value if there is no action type.
ACTION_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the action. Contains the null value if ACTION_TYPE is null.

Table 169. AUDIT_JOURNAL_M0 table function (continued)

Column Name	Data Type	Description
ACTION_STATUS	VARCHAR(12)	<p>Status of the action. This column can return a value when ACTION has a value of START, CHECKSYSBASE, POWEROFF, PRECHECK, FLASHCOPY, REMOTECOPY, and IASPCOPY. For these ACTION values, two audit entries will be sent: one when the action starts and another when the action ends. When the audit entry is for the start of the action, this column contains STARTED. When the audit entry is for the end of the action, this column contains the status of the action.</p> <p>COMPLETED The action was successful</p> <p>STARTED The action has started</p> <p>UNSUCCESSFUL The action was not successful</p> <p>Contains the null value if there is no status.</p>
IASP_NAME	VARCHAR(10)	<p>The name of the auxiliary storage pool (ASP). A value of *SYSBAS indicates the system ASP and all basic user ASPs.</p> <p>Contains the null value if ACTION is not IASPCOPY, PREIASP, or POSTIASP.</p>
SETUP_SOURCE_NODE	VARCHAR(8)	The partition name of the Db2 Mirror setup source node.
SETUP_COPY_NODE	VARCHAR(8)	The partition name of the Db2 Mirror setup copy node.
SETUP_SOURCE_STORAGE	VARCHAR(256)	<p>The IP address or host and domain name of the setup source storage system.</p> <p>Contains the null value if ACTION is not START, PRECHECK, FLASHCOPY, REMOTECOPY, or IASPCOPY.</p>
SETUP_COPY_STORAGE	VARCHAR(256)	<p>The IP address or host and domain name of the setup copy storage system.</p> <p>Contains the null value if ACTION is not START, PRECHECK, FLASHCOPY, REMOTECOPY, or IASPCOPY.</p>

Example

- List any Db2 Mirror set up actions that were unsuccessful from the last week.

```
SELECT ENTRY_TIMESTAMP, IASP_NAME, ACTION, ACTION_TYPE, ACTION_DETAIL
FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_M0(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 7 DAYS
  )
)
WHERE ACTION_STATUS = 'UNSUCCESSFUL';
```

AUDIT_JOURNAL_M6 table function

The AUDIT_JOURNAL_M6 table function returns rows from the audit journal that contain information from the M6 (Db2 Mirror Communication Services) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 170. AUDIT_JOURNAL_M6 table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the M6 audit journal entry.		
ENTRY_TYPE	CHAR(1)	<p>The type of Network Redundancy Group (NRG) entry.</p> <p>A Add NRG</p> <p>C Change NRG</p> <p>R Remove NRG</p>

Table 170. AUDIT_JOURNAL_M6 table function (continued)

Column Name	Data Type	Description
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
NRG_NAME	VARCHAR(15)	The name associated with the NRG.
NRG_TYPE	VARCHAR(12)	Type of NRG. UNSPECIFIED Unspecified DB2 MIRROR Db2 Mirror USER DEFINED User defined Contains the null value if ENTRY_TYPE is R.
TEXT_DESCRIPTION	VARCHAR(50)	Text description. Contains the null value if there is no text description or if ENTRY_TYPE is R.
LOAD_BALANCE_LINK_COUNT	INTEGER	Load balance link count. Contains the null value if ENTRY_TYPE is R.
LINK_COUNT	INTEGER	Number of links configured in the group. This indicates the number of sets of link information columns, with a suffix of _n, that contain values. The information for links greater than LINK_COUNT will contain the null value. Contains the null value if ENTRY_TYPE is R. All the link information columns will contain the null value.
ADDRESS_SPACE_TYPE_1	CHAR(4)	The address family of the first link. IPV4 Internet Protocol Version 4 IPV6 Internet Protocol Version 6
SOURCE_ADDRESS_1	VARCHAR(45)	The local IP address for the first link.
LINE_DESCRIPTION_1	VARCHAR(10)	The local line description for the first link.
VIRTUAL_LAN_ID_1	INTEGER	The local VLAN ID for the first link.
TARGET_ADDRESS_1	VARCHAR(45)	The remote IP address for the first link.
LINK_TYPE_1	CHAR(2)	The link type of the first link. V1 RoCE v1 V2 RoCE v2
LINK_PRIORITY_1	INTEGER	The priority of the first link.
ADDRESS_SPACE_TYPE_2	CHAR(4)	The address family of the second link. IPV4 Internet Protocol Version 4 IPV6 Internet Protocol Version 6
SOURCE_ADDRESS_2	VARCHAR(45)	The local IP address for the second link.
LINE_DESCRIPTION_2	VARCHAR(10)	The local line description for the second link.
VIRTUAL_LAN_ID_2	INTEGER	The local VLAN ID for the second link.
TARGET_ADDRESS_2	VARCHAR(45)	The remote IP address for the second link.
LINK_TYPE_2	CHAR(2)	The link type of the second link. V1 RoCE v1 V2 RoCE v2
LINK_PRIORITY_2	INTEGER	The priority of the second link.
ADDRESS_SPACE_TYPE_3	CHAR(4)	The address family of the third link. IPV4 Internet Protocol Version 4 IPV6 Internet Protocol Version 6
SOURCE_ADDRESS_3	VARCHAR(45)	The local IP address for the third link.
LINE_DESCRIPTION_3	VARCHAR(10)	The local line description for the third link.

Table 170. AUDIT_JOURNAL_M6 table function (continued)

Column Name	Data Type	Description
VIRTUAL_LAN_ID_3	INTEGER	The local VLAN ID for the third link.
TARGET_ADDRESS_3	VARCHAR(45)	The remote IP address for the third link.
LINK_TYPE_3	CHAR(2)	The link type of the third link. V1 RoCE v1 V2 RoCE v2
LINK_PRIORITY_3	INTEGER	The priority of the third link.
ADDRESS_SPACE_TYPE_4	CHAR(4)	The address family of the fourth link. IPV4 Internet Protocol Version 4 IPV6 Internet Protocol Version 6
SOURCE_ADDRESS_4	VARCHAR(45)	The local IP address for the fourth link.
LINE_DESCRIPTION_4	VARCHAR(10)	The local line description for the fourth link.
VIRTUAL_LAN_ID_4	INTEGER	The local VLAN ID for the fourth link.
TARGET_ADDRESS_4	VARCHAR(45)	The remote IP address for the fourth link.
LINK_TYPE_4	CHAR(2)	The link type of the fourth link. V1 RoCE v1 V2 RoCE v2
LINK_PRIORITY_4	INTEGER	The priority of the fourth link.
ADDRESS_SPACE_TYPE_5	CHAR(4)	The address family of the fifth link. IPV4 Internet Protocol Version 4 IPV6 Internet Protocol Version 6
SOURCE_ADDRESS_5	VARCHAR(45)	The local IP address for the fifth link.
LINE_DESCRIPTION_5	VARCHAR(10)	The local line description for the fifth link.
VIRTUAL_LAN_ID_5	INTEGER	The local VLAN ID for the fifth link.
TARGET_ADDRESS_5	VARCHAR(45)	The remote IP address for the fifth link.
LINK_TYPE_5	CHAR(2)	The link type of the fifth link. V1 RoCE v1 V2 RoCE v2
LINK_PRIORITY_5	INTEGER	The priority of the fifth link.
ADDRESS_SPACE_TYPE_6	CHAR(4)	The address family of the sixth link. IPV4 Internet Protocol Version 4 IPV6 Internet Protocol Version 6
SOURCE_ADDRESS_6	VARCHAR(45)	The local IP address for the sixth link.
LINE_DESCRIPTION_6	VARCHAR(10)	The local line description for the sixth link.
VIRTUAL_LAN_ID_6	INTEGER	The local VLAN ID for the sixth link.
TARGET_ADDRESS_6	VARCHAR(45)	The remote IP address for the sixth link.
LINK_TYPE_6	CHAR(2)	The link type of the sixth link. V1 RoCE v1 V2 RoCE v2
LINK_PRIORITY_6	INTEGER	The priority of the sixth link.

Table 170. AUDIT_JOURNAL_M6 table function (continued)

Column Name	Data Type	Description
ADDRESS_SPACE_TYPE_7	CHAR(4)	The address family of the seventh link. IPV4 Internet Protocol Version 4 IPV6 Internet Protocol Version 6
SOURCE_ADDRESS_7	VARCHAR(45)	The local IP address for the seventh link.
LINE_DESCRIPTION_7	VARCHAR(10)	The local line description for the seventh link.
VIRTUAL_LAN_ID_7	INTEGER	The local VLAN ID for the seventh link.
TARGET_ADDRESS_7	VARCHAR(45)	The remote IP address for the seventh link.
LINK_TYPE_7	CHAR(2)	The link type of the seventh link. V1 RoCE v1 V2 RoCE v2
LINK_PRIORITY_7	INTEGER	The priority of the seventh link.
ADDRESS_SPACE_TYPE_8	CHAR(4)	The address family of the eighth link. IPV4 Internet Protocol Version 4 IPV6 Internet Protocol Version 6
SOURCE_ADDRESS_8	VARCHAR(45)	The local IP address for the eighth link.
LINE_DESCRIPTION_8	VARCHAR(10)	The local line description for the eighth link.
VIRTUAL_LAN_ID_8	INTEGER	The local VLAN ID for the eighth link.
TARGET_ADDRESS_8	VARCHAR(45)	The remote IP address for the eighth link.
LINK_TYPE_8	CHAR(2)	The link type of the eighth link. V1 RoCE v1 V2 RoCE v2
LINK_PRIORITY_8	INTEGER	The priority of the eighth link.
ADDRESS_SPACE_TYPE_9	CHAR(4)	The address family of the ninth link. IPV4 Internet Protocol Version 4 IPV6 Internet Protocol Version 6
SOURCE_ADDRESS_9	VARCHAR(45)	The local IP address for the ninth link.
LINE_DESCRIPTION_9	VARCHAR(10)	The local line description for the ninth link.
VIRTUAL_LAN_ID_9	INTEGER	The local VLAN ID for the ninth link.
TARGET_ADDRESS_9	VARCHAR(45)	The remote IP address for the ninth link.
LINK_TYPE_9	CHAR(2)	The link type of the ninth link. V1 RoCE v1 V2 RoCE v2
LINK_PRIORITY_9	INTEGER	The priority of the ninth link.
ADDRESS_SPACE_TYPE_10	CHAR(4)	The address family of the tenth link. IPV4 Internet Protocol Version 4 IPV6 Internet Protocol Version 6
SOURCE_ADDRESS_10	VARCHAR(45)	The local IP address for the tenth link.
LINE_DESCRIPTION_10	VARCHAR(10)	The local line description for the tenth link.
VIRTUAL_LAN_ID_10	INTEGER	The local VLAN ID for the tenth link.
TARGET_ADDRESS_10	VARCHAR(45)	The remote IP address for the tenth link.

Example

- List NRG configuration changes from the last month

```
SELECT * FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_M6(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 1 MONTH
  )
)
WHERE ENTRY_TYPE = 'C';
```

AUDIT_JOURNAL_M7 table function

The AUDIT_JOURNAL_M7 table function returns rows from the audit journal that contain information from the M7 (Db2 Mirror Replication Services) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 171. AUDIT_JOURNAL_M7 table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the M7 audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. <ul style="list-style-type: none"> A Add active replication criteria rule D Duplicate replication criteria rules (a rename library was performed) P Activate pending replication criteria rules R Remove active replication criteria rule S Resynchronization of eligible objects U User deferred or deleted entries in the Object Tracking List (OTL) using the QSYS2.CHANGE_RESYNC_ENTRIES procedure V Generic versioning
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
ACTION	VARCHAR(7)	When ENTRY_TYPE is A, P, R, S, or U the type of resynchronization action to performed: <ul style="list-style-type: none"> INITIAL Initial synchronization of newly replicated objects. RECLONE Resynchronization of actively replicating objects. RESUME Resynchronization of objects that are on the OTL because the node was previously blocked. When ENTRY_TYPE is V: <ul style="list-style-type: none"> ADD Register (add) an applied version information entry for a specific feature or function in the Mirror Version List (MVL). APPLY Apply pending version information entries. REMOVE Unregister (remove) an applied version information entry from the Mirror Version List (MVL). REFRESH Refresh the version information entries in Mirror Version List by running user specified version handlers. Contains the null value if ENTRY_TYPE is D.
ACTION_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the action. Contains the null value if ACTION is null.
RULE_IDENTIFIER	BIGINT	Identifier for this replication criteria rule. Contains the null value if ENTRY_TYPE is not A, D, or R.
INCLUSION_STATE	VARCHAR(10)	The inclusion state of the replication criteria rule. <ul style="list-style-type: none"> DEFINITION Objects that best match this replication criteria rule are replicated. Only the definition of the object is replicated. EXCLUDE Objects that best match this replication criteria rule are not replicated. INCLUDE Objects that best match this replication criteria rule are replicated. Contains the null value if ENTRY_TYPE is not A or D.

Table 171. AUDIT_JOURNAL_M7 table function (continued)

Column Name	Data Type	Description
IASP_NAME	VARCHAR(10)	The name of the ASP group associated with this replication criteria rule, the replicated object, or the SQL QSYS2.CHANGE_RESYNC_ENTRIES procedure. Can contain the special value *SYSBAS. Contains the null value if ENTRY_TYPE is V.
LIBRARY_NAME	VARCHAR(10)	The library name associated with the replication criteria rule, the replicated object, or the SQL QSYS2.CHANGE_RESYNC_ENTRIES procedure. Can contain the special value *ALL. Contains the null value if IASP_NAME is null.
OBJECT_TYPE	VARCHAR(8)	The object type associated with the replication criteria rule, the replicated object, or the SQL QSYS2.CHANGE_RESYNC_ENTRIES procedure. Can contain the special value *ALL. Contains the null value if LIBRARY_NAME is null.
OBJECT_NAME	VARCHAR(10)	The name of the object associated with this replication criteria rule, the replicated object, or the QSYS2.CHANGE_RESYNC_ENTRIES procedure. Contains the null value if OBJECT_TYPE is null.
ORIGINAL_LIBRARY_NAME	VARCHAR(10)	Original library name. Contains the null value if ENTRY_TYPE is not D.
SYSTEM_VALUE	VARCHAR(10)	The name of the system value associated with this replication criteria rule. Contains the null value if ENTRY_TYPE is not A or R, or if OBJECT_NAME or ENVIRONMENT_VARIABLE is not null.
ENVIRONMENT_VARIABLE	VARCHAR(128)	The name of the environment variable associated with this replication criteria rule. Contains the null value if ENTRY_TYPE is not A or R, or if OBJECT_NAME or SYSTEM_VALUE is not null.
APPLY_LABEL	VARCHAR(26)	The label used to identify replication criteria rules. Contains the null value if ENTRY_TYPE is D, S, or U.
NUMBER_OF_OBJECTS	BIGINT	The number of Save/Restore entries added to the OTL for objects affected by this operation. Contains the null value if ENTRY_TYPE is not A, P, R, or S.
AFFECTED_ROWS	BIGINT	The number of OTL rows affected by the SQL QSYS2.CHANGE_RESYNC_ENTRIES procedure. Contains the null value if ENTRY_TYPE is not U.
VERSION_ENTRY_NUMBER	BIGINT	The version entry number. Contains the null value if ENTRY_TYPE is not V, or ENTRY_TYPE is V but ACTION is not ADD or REMOVE.
VERSION_GROUP	VARCHAR(10)	The version group. Contains the null value if ENTRY_TYPE is not V.
VERSION_NAME	VARCHAR(30)	The version name. Can contain the following special value: *ALL All version names in VERSION_GROUP are operated on. Contains the null value if ENTRY_TYPE is not V.
VERSION_IDENTIFIER	VARCHAR(11)	The version identifier. The format is xxx.yyy.zzz where each piece of the version contains the digits 0-9: xxx The major version number. This value is always present for a version number. yyy An optional minor version number. zzz An optional revision number. Contains the null value if ENTRY_TYPE is not V, or ENTRY_TYPE is V but ACTION is not ADD or REMOVE.

Table 171. AUDIT_JOURNAL_M7 table function (continued)

Column Name	Data Type	Description
VERSION_ACTIVATION_TIME	VARCHAR(9)	The version entry activation state indicator. IMMEDIATE This version entry can be activated immediately from an applied state. RESUME This version entry can be activated from an applied state the next time replication is resumed. Contains the null value if ENTRY_TYPE is not V, or ENTRY_TYPE is V but ACTION is not ADD or REMOVE.

Example

- List any replication changes that affected APPLIB1 this week.

```
SELECT * FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_M7(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 7 DAYS
  )
)
WHERE LIBRARY_NAME = 'APPLIB1';
```

AUDIT_JOURNAL_M8 table function

The AUDIT_JOURNAL_M8 table function returns rows from the audit journal that contain information from the M8 (Db2 Mirror Product Services) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 172. AUDIT_JOURNAL_M8 table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the M8 audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. A Add IASP C Change mirror F Change flight recorder H Change health monitor I Set default inclusion state J Change mirror ObjectConnect L Reclone replicated objects O Takeover R Remove IASP S Setup mirror T Terminate mirror W Swap mirror roles
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.

Table 172. AUDIT_JOURNAL_M8 table function (continued)

Column Name	Data Type	Description
ACTION	VARCHAR(15)	<p>Action to perform.</p> <p>When ENTRY_TYPE is A:</p> <p>NEW The IASP is being defined for the first time.</p> <p>RECLONE The IASP is used as the source of a reclone operation.</p> <p>SHADOW The IASP is being pre-defined as an IASP on a PowerHA® disaster recovery system.</p> <p>When ENTRY_TYPE is C:</p> <p>RESUME Resume replication.</p> <p>RESUMEABN Resume abnormal replication.</p> <p>SUSPEND Suspend replication.</p> <p>MAINTENANCE Suspend for maintenance.</p> <p>When ENTRY_TYPE is F:</p> <p>ENDJOB End flight recorder QMRDBLOGR job.</p> <p>RESUME Resume flight recorder logging.</p> <p>STARTJOB Start flight recorder QMRDBLOGR job.</p> <p>SUSPEND Suspend flight recorder logging.</p> <p>When ENTRY_TYPE is J:</p> <p>CHANGE SERVER Change ObjectConnect for Db2 Mirror server.</p> <p>END SERVER End ObjectConnect for Db2 Mirror server.</p> <p>START SERVER Start ObjectConnect for Db2 Mirror server.</p> <p>When ENTRY_TYPE is L:</p> <p>RESUMEABN Reclone replicated objects with abnormal resume.</p> <p>When ENTRY_TYPE is O:</p> <p>ADD Add mirror takeover address.</p> <p>CHANGE Change mirror takeover group.</p> <p>CREATE Create mirror takeover group.</p> <p>DELETE Delete mirror takeover group.</p> <p>REMOVE Remove mirror takeover address.</p> <p>SWAP Swap mirror takeover group.</p> <p>When ENTRY_TYPE is T:</p> <p>DESTROY Db2 Mirror is ended.</p> <p>RECLONE Active replication is ended.</p>
ACTION (continued)		<p>Contains the null value if:</p> <ul style="list-style-type: none"> ENTRY_TYPE is not A, C, F, J, L, O, or T ENTRY_TYPE is C and the replication state was not specified ENTRY_TYPE is F and no action was specified ENTRY_TYPE is L and resume type was not specified
ACTION_DETAIL	VARCHAR(200)	<p>Descriptive text that corresponds to the action.</p> <p>Contains the null value if ACTION is null.</p>
IASP_NAME	VARCHAR(10)	<p>ASP name. Can contain the special value *SYSBAS.</p> <p>Contains the null value if no ASP name applies to this entry.</p>

Table 172. AUDIT_JOURNAL_M8 table function (continued)

Column Name	Data Type	Description
IASP_TYPE	VARCHAR(8)	<p>The type of IASP.</p> <p>DATABASE This IASP is for a database IASP group.</p> <p>IFS This IASP is for an integrated file system ASP group.</p> <p>Contains the null value if ENTRY_TYPE is not A or R.</p>
DEFAULT_INCLUSION_STATE	VARCHAR(7)	<p>When the ENTRY_TYPE is A, the default object inclusion state for objects in IASP_NAME.</p> <p>When ENTRY_TYPE is I, the default inclusion state for objects in *SYSBAS.</p> <p>EXCLUDE Eligible objects not covered by an RCL rule will not be replicated.</p> <p>INCLUDE Eligible objects not covered by an RCL rule will be replicated.</p> <p>RESET Clear the default inclusion state. This value applies when ENTRY_TYPE is I.</p> <p>Contains the null value if ENTRY_TYPE is not A or I.</p>
CLUSTER_RESOURCE_GROUP	VARCHAR(10)	<p>The cluster resource group name.</p> <p>Contains the null value if ENTRY_TYPE is not A.</p>
AUTO_RESUME	VARCHAR(3)	<p>When ENTRY_TYPE is C, whether to automatically resume mirroring.</p> <p>NO Do not automatically resume mirroring.</p> <p>YES Automatically resume mirroring after being suspended.</p> <p>Contains the null value if ENTRY_TYPE is not C or if the value was not changed.</p>
SWAP_ON_PWRDWN SYS	VARCHAR(3)	<p>Swap behavior on power down system.</p> <p>NO Do not automatically swap roles.</p> <p>YES Automatically swap roles.</p> <p>Contains the null value if ENTRY_TYPE is not C or if the value was not changed.</p>
PARALLEL_DEGREE	VARCHAR(5)	<p>The degree of parallelism to be used for Db2 Mirror resynchronization processing. Can contain the special value of NONE.</p> <p>Contains the null value if ENTRY_TYPE is not C or if the value was not changed.</p>
SPLF_RESYNC_INTERVAL	INTEGER	<p>The spooled file resynchronization interval.</p> <p>Contains the null value if ENTRY_TYPE is not C or if the value was not changed.</p>
REPLICATE_USER_INDEX	VARCHAR(7)	<p>The replication choice for user indexes.</p> <p>DISABLE Disable replication of user indexes.</p> <p>ENABLE Enable replication of user indexes.</p> <p>Contains the null value if ENTRY_TYPE is not C or if the value was not changed.</p>
REPLICATE_USER_SPACE	VARCHAR(7)	<p>The replication choice for user spaces.</p> <p>DISABLE Disable replication of user spaces.</p> <p>ENABLE Enable replication of user spaces.</p> <p>Contains the null value if ENTRY_TYPE is not C or if the value was not changed.</p>
REPLICATE_DATA_QUEUE_ENTRIES	VARCHAR(7)	<p>The replication choice for entries in a data queue (*DTAQ).</p> <p>DISABLE Disable replication of data queue entries.</p> <p>ENABLE Enable replication of data queue entries.</p> <p>Contains the null value if ENTRY_TYPE is not C or if the value was not changed.</p>

Table 172. AUDIT_JOURNAL_M8 table function (continued)

Column Name	Data Type	Description
ENCRYPTED_RDMA	VARCHAR(12)	<p>The encrypted RDMA value.</p> <p>NOT REQUIRED Non-encrypted RDMA protocols may be used.</p> <p>REQUIRED Encrypted RDMA protocols must be used.</p> <p>Contains the null value if ENTRY_TYPE is not C or if the value was not changed.</p>
AUTO_TAKEOVER	VARCHAR(7)	<p>The choice for automatic takeover for unplanned outages.</p> <p>DISABLE Disable automatic takeover for unplanned outages.</p> <p>ENABLE Enable automatic takeover for unplanned outages.</p> <p>Contains the null value if ENTRY_TYPE is not C or if the value was not changed.</p>
TAKEOVER_GROUP_NAME	VARCHAR(10)	<p>The takeover group name.</p> <p>Contains the null value if ENTRY_TYPE is not O.</p>
AUTO_SWITCHBACK	VARCHAR(3)	<p>When ENTRY_TYPE is O and ACTION is CREATE or CHANGE, whether the takeover IP address group should be automatically switched back to its preferred node.</p> <p>NO Do not automatically return this takeover IP address group.</p> <p>YES Automatically return this takeover IP address group to its preferred node.</p> <p>Contains the null value if ENTRY_TYPE is not O or if the value was not changed.</p>
PRIMARY_NODE	VARCHAR(8)	<p>When ENTRY_TYPE is O and ACTION is CREATE or CHANGE, the name of the preferred node.</p> <p>When ENTRY_TYPE is S or T, the name of the partition designated as the primary node.</p> <p>When ENTRY_TYPE is W, the name of the new primary node.</p> <p>Contains the null value if ENTRY_TYPE is not O, S, T, or W.</p>
SECONDARY_NODE	VARCHAR(8)	<p>The name of the partition designated as the secondary node.</p> <p>When ENTRY_TYPE is W this is the name of the new secondary node.</p> <p>Contains the null value if ENTRY_TYPE is not S, T, or W.</p>
IP_ADDRESS	VARCHAR(45)	<p>The takeover IP address.</p> <p>Contains the null value if ENTRY_TYPE is not O and ACTION is not ADD or REMOVE.</p>
OBJECTCONNECT_AUTO_START	VARCHAR(3)	<p>Whether to automatically start the ObjectConnect for Db2 Mirror server.</p> <p>NO Do not automatically start the ObjectConnect for Db2 Mirror server.</p> <p>YES Automatically start the ObjectConnect for Db2 Mirror server.</p> <p>Contains the null value if ENTRY_TYPE is not J or if the value was not changed.</p>
OBJECTCONNECT_MINIMUM_JOBS	INTEGER	<p>The minimum number of ObjectConnect for Db2 Mirror server jobs that are started.</p> <p>Contains the null value if ENTRY_TYPE is not J or if the value was not changed.</p>
OBJECTCONNECT_MAXIMUM_JOBS	INTEGER	<p>The maximum number of ObjectConnect for Db2 Mirror server jobs that are started.</p> <p>Contains the null value if ENTRY_TYPE is not J or if the value was not changed.</p>
OBJECTCONNECT_INACTIVE_TIME	INTEGER	<p>The length of time, in minutes, that a ObjectConnect for Db2 Mirror server job will stay inactive before ending.</p> <p>Contains the null value if ENTRY_TYPE is not J or if the value was not changed.</p>
ARCHIVE_RETENTION_DAY_COUNT	INTEGER	<p>The number of days the flight recorder logs are retained.</p> <p>Contains the null value if ENTRY_TYPE is not F.</p>

Table 172. AUDIT_JOURNAL_M8 table function (continued)

Column Name	Data Type	Description
MAX_SYSBAS_PERCENTAGE	INTEGER	The percentage of *SYSBAS allocated for flight recorder logs. Contains the null value if ENTRY_TYPE is not F.
LOGGING_CATEGORY	VARCHAR(26)	The category for which flight recorder entries will be logged. ALL All categories CONFIGURATION PROCESSING Configuration processing DATABASE Database processing DATA QUEUE Data queue handler DB CONNECTION Database connection ENGINE COMMUNICATION Engine communication ENGINE CONNECTION Engine connection ENGINE CONTROLLER Engine controller ENGINE JOB Engine job ENGINE STATE Engine state FLIGHT RECORDER Flight recorder HEALTH MONITOR Health monitor IFS CONNECTION Integrated file system connection LOGGER TESTING Logger testing NRG Network redundancy groups OBJECT CONNECTION Object connection OBJECT RECEIVER Object receiver OBJECT REGISTRY Object registry OBJECT REPLICATION MANAGER Object replication manager OBJECT SYNCHRONIZATION Object synchronization QUORUM SERVER Quorum server RCL Replication criteria list RESYNC Resynchronization process SAVE RESTORE Save and restore processing SECURITY OBJECT Security object handler SPOOL Spooled file handler OUTPUT AND JOB QUEUE Output queue and job queue processing UTILITIES Utilities processing VARY IASP Vary IASP processing WORK MANAGEMENT Work management Contains the null value if ENTRY_TYPE is not F.

Table 172. AUDIT_JOURNAL_M8 table function (continued)

Column Name	Data Type	Description
LOGGING_LEVEL	VARCHAR(7)	The level at which an entry is written to the flight recorder log. DEBUG Log entries for the INFO level are generated, plus debug information. ERROR Log entries are generated for run time errors and unexpected conditions. INFO Log entries for the WARN level are generated, plus interesting run time events. NONE No log entries are generated. SYSTEM When LOGGING_CATEGORY is ALL the shipped default level is set for each category. WARNING Log entries for the ERROR level are generated, plus entries for errors or other run time situations that are unexpected or unusual but not necessarily wrong. Contains the null value if ENTRY_TYPE is not F.

Example

- List when Db2 Mirror active replication was suspended in the last 2 months.

```
SELECT * FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_M8(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 2 MONTHS
  )
)
WHERE ENTRY_TYPE = 'C' AND
      ACTION IN ('SUSPEND', 'MAINTENANCE');
```

AUDIT_JOURNAL_M9 table function

The AUDIT_JOURNAL_M9 table function returns rows from the audit journal that contain information from the M9 (Db2 Mirror Replication State) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in “AUDIT JOURNAL table function common information” on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 173. AUDIT_JOURNAL_M9 table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the M9 audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. C Change to the replication state of an ASP
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
IASP_NAME	VARCHAR(10)	ASP name for which the replication state changed. Can contain the special value *SYSBAS.
REPLICATION_STATE	VARCHAR(12)	Db2 Mirror replication state. ACTIVE BLOCKED NOT MIRRORRED TRACKING

Table 173. AUDIT_JOURNAL_M9 table function (continued)

Column Name	Data Type	Description
PREVIOUS_REPLICATION_STATE	VARCHAR(12)	Previous Db2 Mirror replication state. ACTIVE BLOCKED NOT MIRRORED TRACKING
CHANGE_REASON	INTEGER	The reason code corresponding to the replication state change. See Replication detail info for the list of reason codes. Contains the null value when REPLICATION_STATE or PREVIOUS_REPLICATION_STATE is NOT MIRRORED.
CHANGE_REASON_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the reason code. Contains the null value when REPLICATION_STATE or PREVIOUS_REPLICATION_STATE is NOT MIRRORED.

Example

- List any reasons that IASP1 suspended replication in the past 24 hours.

```
SELECT ENTRY_TIMESTAMP, IASP_NAME, REPLICATION_STATE, CHANGE_REASON_DETAIL
FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_M9(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 24 HOURS )
)
WHERE REPLICATION_STATE <> 'ACTIVE' AND IASP_NAME = 'IASP1'
ORDER BY ENTRY_TIMESTAMP DESC;
```

AUDIT_JOURNAL_NA table function

The AUDIT_JOURNAL_NA table function returns rows from the audit journal that contain information from the NA (Attribute Change) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 174. AUDIT_JOURNAL_NA table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the NA audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. A Change to a network attribute T Change to a TCP/IP attribute
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
ATTRIBUTE_NAME	VARCHAR(10)	The name of the attribute.
ATTRIBUTE_VALUE	VARCHAR(250)	The value of the attribute.
PREV_ATTRIBUTE_VALUE	VARCHAR(250)	The previous value of the attribute.

Example

- List the TCP/IP attributes that were changed in the last two months.

```
SELECT * FROM TABLE(
```

```

SYSTOOLS.AUDIT_JOURNAL_NA(
  STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 2 MONTHS
)
)
WHERE ENTRY_TYPE = 'T';

```

AUDIT_JOURNAL_OM table function

The AUDIT_JOURNAL_OM table function returns rows from the audit journal that contain information from the OM (Object Management Change) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in “AUDIT JOURNAL table function common information” on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 175. AUDIT_JOURNAL_OM table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the OM audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. M Object moved to a different library. R Object renamed.
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
LIBRARY_NAME	VARCHAR(10)	The name of the library to which the object was moved. Contains the null value if there is no new library name.
OBJECT_NAME	VARCHAR(10)	The new name of the object which was moved. Contains the null value if there is no new object name.
OBJECT_TYPE	VARCHAR(7)	The type of object. Contains the null value if there is no object type.
OBJECT_ATTRIBUTE	VARCHAR(10)	The attribute of the object. Contains the null value if there is no object attribute.
PREV_LIBRARY_NAME	VARCHAR(10)	The name of the library in which the previous object resides. Contains the null value if there is no previous library name.
PREV_OBJECT_NAME	VARCHAR(10)	The previous name of the object. Contains the null value if there is no previous object name.
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the object resides. If the new object is in a library, this is the ASP information of the object's library. If the new object is not in a library, this is the ASP information of the object. A value of *SYSBAS indicates the system ASP and all basic user ASPs. Contains the null value if there is no ASP information.
OBJECT_ASP_NUMBER	INTEGER	The number of the ASP device. 1 indicates the system ASP. If the new object is in a library, this is the ASP information of the object's library. If the new object is not in a library, this is the ASP information of the object. Contains the null value if there is no ASP information.
PREV_OBJECT_ASP_NAME	VARCHAR(10)	The previous name of the auxiliary storage pool (ASP) in which the object resides. If the previous object is in a library, this is the ASP information of the object's library. If the previous object is not in a library, this is the ASP information of the object. A value of *SYSBAS indicates the system ASP and all basic user ASPs. Contains the null value if there is no ASP information.

Table 175. AUDIT_JOURNAL_OM table function (continued)

Column Name	Data Type	Description
PREV_OBJECT_ASP_NUMBER	INTEGER	The previous number of the ASP device. 1 indicates the system ASP. If the previous object is in a library, this is the ASP information of the object's library. If the previous object is not in a library, this is the ASP information of the object. Contains the null value if there is no ASP information.
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The new path name of the object. Contains the null value if the path name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PATH_NAME_INDICATOR	VARCHAR(3)	New path name indicator: NO The PATH_NAME column does not contain an absolute path name for the object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name. YES The PATH_NAME column contains the absolute path name for the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the object identified in the PATH_NAME column. Contains the null value when PATH_NAME_INDICATOR is YES, or if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	The name of the new object. Contains the null value if the object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
OBJECT_FILE_ID	BINARY(16)	The file ID of the new object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PARENT_FILE_ID	BINARY(16)	The file ID of the new parent directory. Contains the null value if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PREV_PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The previous path name of the object. Contains the null value if the path name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PREV_PATH_NAME_INDICATOR	VARCHAR(3)	Previous path name indicator: NO The PREV_PATH_NAME column does not contain an absolute path name for the object, instead it contains a relative path name. The PREV_RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name. YES The PREV_PATH_NAME column contains the absolute path name for the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PREV_RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	When PREV_PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the object identified in the PREV_PATH_NAME column. Contains the null value when PREV_PATH_NAME_INDICATOR is YES, or if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PREV_IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	The name of the previous object. Contains the null value if the object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.

Table 175. AUDIT_JOURNAL_OM table function (continued)

Column Name	Data Type	Description
PREV_OBJECT_FILE_ID	BINARY(16)	The file ID of the previous object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PREV_PARENT_FILE_ID	BINARY(16)	The file ID of the previous parent directory. Contains the null value if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
OFFICE_USER	VARCHAR(10)	The name of the office user. Contains the null value if there is no office user.
OFFICE_ON_BEHALF_OF_USER	VARCHAR(10)	User working on behalf of another user. Contains the null value if there is no user name.
DLO_NAME	VARCHAR(12)	The new name of the folder or document. Contains the null value if there is no new folder or document.
FOLDER_PATH	VARCHAR(63)	The new path of the folder. Contains the null value if there is no new folder path.
PREV_DLO_NAME	VARCHAR(12)	The previous name of the folder or document. Contains the null value if there is no previous folder or document.
PREV_FOLDER_PATH	VARCHAR(63)	The previous path of the folder. Contains the null value if there is no previous folder path.

Example

- List any objects that were moved or renamed in the APPLIB library this week.

```
SELECT LIBRARY_NAME, OBJECT_NAME, PREV_LIBRARY_NAME, PREV_OBJECT_NAME, OBJECT_TYPE
FROM TABLE (
    SYSTOOLS.AUDIT_JOURNAL_OM (STARTING_TIMESTAMP => CURRENT DATE - 7 DAYS)
)
WHERE PREV_LIBRARY_NAME = 'APPLIB';
```

AUDIT_JOURNAL_OR table function

The AUDIT_JOURNAL_OR table function returns rows from the audit journal that contain information from the OR (Object Restore) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 176. AUDIT_JOURNAL_OR table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the OR audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. E An existing object was restored to the system. N A new object was restored to the system.
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
OBJECT_LIBRARY	VARCHAR(10)	The name of the library containing the restored object. Contains the null value if there is no library name.
OBJECT_NAME	VARCHAR(10)	The name of the restored object. Contains the null value if there is no object name.

Table 176. AUDIT_JOURNAL_OR table function (continued)

Column Name	Data Type	Description
OBJECT_TYPE	VARCHAR(7)	The type of object. Contains the null value if there is no object type.
OBJECT_ATTRIBUTE	VARCHAR(10)	The attribute of the object. Contains the null value if there is no object attribute.
SAVE_OBJECT_LIBRARY	VARCHAR(10)	The name of the library from which the object was saved. Contains the null value if there is no saved library name.
SAVE_OBJECT	VARCHAR(10)	The name of the saved object. Contains the null value if there is no saved object name.
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the object resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs.
OBJECT_ASP_NUMBER	INTEGER	The number of the ASP device. 1 indicates the system ASP.
PROGRAM_STATE	VARCHAR(8)	The state of the program that was restored. *INHERIT An inherit state program was restored. *SYSTEM A system state program was restored. *USER A user state program was restored. Contains the null value if OBJECT_TYPE is not *PGM or *SRVPGM.
COMMAND_STATE	VARCHAR(7)	Whether the command is a system command. *SYSTEM A system command was restored. *USER A user state command was restored. Contains the null value if OBJECT_TYPE is not *CMD.
SAVE_SYSTEM	VARCHAR(8)	The system from which the object was saved. Contains the null value if the system from which the object was saved was running a release prior to IBM i 7.1, or if a value is not available.
RESTORE_PRIVATE_AUTHORITIES	VARCHAR(3)	Private authorities requested to be restored. YES Private authorities (PVTAUT) was specified as *YES on the restore command. NO Private authorities (PVTAUT) was specified as *NO on the restore command.
PRIVATE_AUTHORITIES_SAVED	INTEGER	Number of private authorities saved.
PRIVATE_AUTHORITIES_RESTORED	INTEGER	Number of private authorities restored.
SIGNATURE_STATUS	VARCHAR(12)	The signature status of the restored object. IGNORED Signature ignored NOT SIGNABLE Unsignable object NOT TRUSTED Untrusted signature NOT VERIFIED Signature exists but is not verified UNMATCHED Signature does not match object content VALID Signature is valid WRONG FORMAT Signature was not in IBM i format Contains the null value if a value is not available.
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The path name of the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.

Table 176. AUDIT_JOURNAL_OR table function (continued)

Column Name	Data Type	Description
PATH_NAME_INDICATOR	VARCHAR(3)	<p>Path name indicator.</p> <p>NO The PATH_NAME column does not contain an absolute path name for the object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name.</p> <p>YES The PATH_NAME column contains complete absolute path name for the object.</p> <p>Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	<p>When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the object identified in the PATH_NAME column.</p> <p>Contains the null value when PATH_NAME_INDICATOR is YES, or if the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	<p>The name of the object.</p> <p>Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
OBJECT_FILE_ID	BINARY(16)	<p>The file ID of the object.</p> <p>Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
PARENT_FILE_ID	BINARY(16)	<p>The file ID of the parent directory.</p> <p>Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
PREV_OBJECT_FILE_ID	BINARY(16)	<p>The file ID of the object that was replaced on the restore.</p> <p>Contains the null value if the object did not exist prior to the restore or is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
SAVE_OBJECT_FILE_ID	BINARY(16)	<p>The file ID (FID) of the saved object. This is the FID the object had on the save system.</p> <p>Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
EXIT_PROGRAM_SCAN	VARCHAR(11)	<p>Whether the object will be scanned when exit programs are registered with any of the integrated file system scan-related exit points.</p> <p>CHANGE ONLY The object will be scanned according to the rules described in the scan-related exit programs only if the object has been modified since the last time the object was scanned. It will not be scanned if the scanning software has been updated. This attribute only takes effect if the Scan file systems control (QSCANFSTCT) system value has *USEOCOATR specified. Otherwise, it will be treated the same as YES.</p> <p>NO The object will not be scanned according to the rules described in the scan-related exit programs.</p> <p>YES The object will be scanned according to the rules described in the scan-related exit programs if the object has been modified or if the scanning software has been updated since the last time the object was scanned.</p> <p>Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>
SET_EFFECTIVE_USER_ID	VARCHAR(3)	<p>The set effective user ID (SETUID) mode indicator for the restored object.</p> <p>NO The SETUID mode bit is not on.</p> <p>YES The SETUID mode bit is on.</p> <p>Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.</p>

Table 176. AUDIT_JOURNAL_OR table function (continued)

Column Name	Data Type	Description
SET_EFFECTIVE_GROUP_ID	VARCHAR(3)	The set effective group ID (SETGID) mode indicator for the restored object. NO The SETGID mode bit is not on. YES The SETGID mode bit is on. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
OFFICE_USER	VARCHAR(10)	The name of the office user. Contains the null value if a value is not available.
OFFICE_ON_BEHALF_OF_USER	VARCHAR(10)	User working on behalf of another user. Contains the null value if a value is not available.
DLO_NAME	VARCHAR(12)	The name of the restored document library object. Contains the null value if there is no document library object.
FOLDER_PATH	VARCHAR(63)	The folder into which the document library object was restored. Contains the null value if there is no folder path.
SAVED_DLO_NAME	VARCHAR(12)	The name of the saved document library object. Contains the null value if there is no saved document library object.
SAVED_FOLDER_PATH	VARCHAR(63)	The folder from which the document library object was saved. Contains the null value if there is no saved folder path.

Example

- List objects that were restored into APPLIB this week.

```
SELECT OBJECT_NAME, OBJECT_TYPE
FROM TABLE (
    SYSTOOLS.AUDIT_JOURNAL_OR (STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 7 DAYS)
)
WHERE OBJECT_LIBRARY = 'APPLIB';
```

AUDIT_JOURNAL_OW table function

The AUDIT_JOURNAL_OW table function returns rows from the audit journal that contain information from the OW (Ownership Change) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 177. AUDIT_JOURNAL_OW table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the OW audit journal entry.		
OBJECT_LIBRARY	VARCHAR(10)	The name of the library where the object is stored.
OBJECT_NAME	VARCHAR(10)	The name of the object.
OBJECT_TYPE	VARCHAR(7)	The type of object.
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the object resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs.
OBJECT_ASP_NUMBER	INTEGER	The number of the ASP device. 1 indicates the system ASP.
PREVIOUS_OWNER	VARCHAR(10)	Previous owner of the object.
NEW_OWNER	VARCHAR(10)	New owner of the object.

Table 177. AUDIT_JOURNAL_OW table function (continued)

Column Name	Data Type	Description
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The path name of the object. Contains the null value if the object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PATH_NAME_INDICATOR	VARCHAR(3)	Path name indicator. NO The PATH_NAME column does not contain an absolute path name for the object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name. YES The PATH_NAME column contains complete absolute path name for the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the object identified in the PATH_NAME column. Contains the null value when PATH_NAME_INDICATOR is YES, or if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	The name of the object. Contains the null value if the object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
OBJECT_FILE_ID	BINARY(16)	The file ID of the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PARENT_FILE_ID	BINARY(16)	The file ID of the parent directory. Contains the null value if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
OFFICE_USER	VARCHAR(10)	The name of the office user.
OFFICE_ON_BEHALF_OF_USER	VARCHAR(10)	User working on behalf of another user.
DLO_NAME	VARCHAR(12)	The name of the document library object.
FOLDER_PATH	VARCHAR(63)	The path of the folder.

Example

- List the objects in APPLIB1 or APPLIB2 that had object ownership changes in the last 3 months.

```
SELECT *
FROM TABLE (
    SYSTOOLS.AUDIT_JOURNAL_OW (STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 3 MONTHS)
)
WHERE OBJECT_LIBRARY IN ('APPLIB1', 'APPLIB2');
```

AUDIT_JOURNAL_PA table function

The AUDIT_JOURNAL_PA table function returns rows from the audit journal that contain information from the PA (Program Adopt) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 178. AUDIT_JOURNAL_PA table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the PA audit journal entry.		

Table 178. AUDIT_JOURNAL_PA table function (continued)

Column Name	Data Type	Description
ENTRY_TYPE	CHAR(1)	The type of entry. A Change program to adopt owner's authority. J Java program adopts owner's authority. M Change object's SETUID, SETGID, or restricted rename and unlink mode indicator.
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
OBJECT_LIBRARY	VARCHAR(10)	The name of the library containing the program. Contains the null value if ENTRY_TYPE is J or if there is no library name.
OBJECT_NAME	VARCHAR(10)	The name of the program. Contains the null value if ENTRY_TYPE is J or if there is no program name.
OBJECT_TYPE	VARCHAR(7)	The type of the object. Contains the null value if there is no object type.
OBJECT_OWNER	VARCHAR(10)	The owner of the object. Contains the null value if there is no object owner.
PRIMARY_GROUP	VARCHAR(10)	The name of the primary group. Contains the null value if there is no primary group.
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the object resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs.
OBJECT_ASP_NUMBER	INTEGER	The number of the ASP device. 1 indicates the system ASP.
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The path name of the object. Contains the null value if the path name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PATH_NAME_INDICATOR	VARCHAR(3)	Path name indicator. NO The PATH_NAME column does not contain an absolute path name for the object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name. YES The PATH_NAME column contains complete absolute path name for the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the object identified in the PATH_NAME column. Contains the null value when PATH_NAME_INDICATOR is YES, or if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	The name of the object. Contains the null value if the object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
OBJECT_FILE_ID	BINARY(16)	The file ID of the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PARENT_FILE_ID	BINARY(16)	The file ID of the parent directory. Contains the null value if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
SET_EFFECTIVE_USER_ID	VARCHAR(3)	The current set effective user ID (SETUID) mode indicator. NO The SETUID mode bit is not on for the object. YES The SETUID mode bit is on for the object. Contains the null value if the information is not available.

Table 178. AUDIT_JOURNAL_PA table function (continued)

Column Name	Data Type	Description
SET_EFFECTIVE_GROUP_ID	VARCHAR(3)	The current set effective group ID (SETGID) mode indicator. NO The SETGID mode bit is not on for the object. YES The SETGID mode bit is on for the object. Contains the null value if the information is not available.
RESTRICT_RENAME_AND_UNLINK	VARCHAR(3)	The current restricted rename and unlink (ISVTX) mode indicator. NO The ISVTX mode bit is not on for the object. YES The ISVTX mode bit is on for the object. Contains the null value if the information is not available.
PREV_SET_EFFECTIVE_USER_ID	VARCHAR(3)	The previous set effective user ID (SETUID) mode indicator. NO The SETUID mode bit was not on for the object. YES The SETUID mode bit was on for the object. Contains the null value if the information is not available.
PREV_SET_EFFECTIVE_GROUP_ID	VARCHAR(3)	The previous set effective group ID (SETGID) mode indicator. NO The SETGID mode bit was not on for the object. YES The SETGID mode bit was on for the object. Contains the null value if the information is not available.
PREV_RESTRICT_RENAME_AND_UNLINK	VARCHAR(3)	The previous restricted rename and unlink (ISVTX) mode indicator. NO The ISVTX mode bit was not on for the object. YES The ISVTX mode bit was on for the object. Contains the null value if the information is not available.

Example

- Find any programs that were changed to adopt the program owner's authority in the last month.

```
SELECT OBJECT_LIBRARY, OBJECT_NAME, OBJECT_TYPE, OBJECT_OWNER FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_PA(
    STARTING_TIMESTAMP => CURRENT DATE - 1 MONTH
  )
) WHERE ENTRY_TYPE = 'A';
```

AUDIT_JOURNAL_PF table function

The AUDIT_JOURNAL_PF table function returns rows from the audit journal that contain information from the PF (PTF Operations) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 179. AUDIT_JOURNAL_PF table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the PF audit journal entry.		

Table 179. AUDIT_JOURNAL_PF table function (continued)

Column Name	Data Type	Description
ENTRY_TYPE	CHAR(1)	The type of entry. I PTF IPL operation L PTF product(s) operation P PTF operations
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
ENTRY_ACTION	VARCHAR(4)	The type of action. When ENTRY_TYPE is I: IPLA Attended IPL performed IPLU Unattended IPL performed When ENTRY_TYPE is L: DELT Product deleted GOPT GO PTF option 7 (Install a program temporary fix from a list) or 8 (Install program temporary fix package) invoked INSP INSPTF command invoked REST Product restored/installed SAVE Product saved SYNC User called QPZSYNC When ENTRY_TYPE is P: DAMG PTF damaged EXTE PTF exit program ended EXTS PTF exit program started LOAD PTF loaded LOGF PTF logged PAPY PTF permanently applied PDLT PTF deleted PRMV PTF permanently removed SUPR PTF superseded TAPY PTF temporarily applied TRMV PTF temporarily removed
ENTRY_ACTION_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry action.
PRODUCT_ID	VARCHAR(7)	Product identifier. Can contain one of the following special values: *ALL All products *FMW Firmware *LIST List of products Contains the null value if ENTRY_TYPE is I.
PRODUCT_RELEASE_LEVEL	VARCHAR(6)	Product version, release, modification in format VvRrMm or *ONLY. Contains the null value if ENTRY_TYPE is I.
PTF_IDENTIFIER	VARCHAR(7)	PTF identifier. Contains the null value if ENTRY_TYPE is I or L.
PRODUCT_OPTION	VARCHAR(4)	Product option or *ALL. Contains the null value if ENTRY_TYPE is I, or ENTRY_TYPE is P or L and a value is not available.
LOAD_ID	VARCHAR(4)	Product load identifier or *ALL. Contains the null value if ENTRY_TYPE is I, or ENTRY_TYPE is P or L and a value is not available.

Table 179. AUDIT_JOURNAL_PF table function (continued)

Column Name	Data Type	Description
PRODUCT_MINIMUM_LEVEL	VARCHAR(2)	Product minimum level. Contains the null value if ENTRY_TYPE is I, or ENTRY_TYPE is P or L and a value is not available.
PRODUCT_MAXIMUM_LEVEL	VARCHAR(2)	Product maximum level. Contains the null value if ENTRY_TYPE is I, or ENTRY_TYPE is P or L and a value is not available.
PRODUCT_LIBRARY	VARCHAR(10)	Product library. Can contain one of the following special values. *ALL All product libraries *FMW Firmware Contains the null value if ENTRY_TYPE is I, or ENTRY_TYPE is P or L and a value is not available.
ACTION_PENDING	VARCHAR(3)	Action pending for PTF. NO No action pending for PTF YES Action pending for PTF Contains the null value if ENTRY_TYPE is not P, or ENTRY_TYPE is P and ENTRY_ACTION is EXTE or EXTS.
IPL_ACTION	VARCHAR(25)	Action to take for PTF on the next IPL. APPLY PERMANENTLY Apply permanently at IPL APPLY PERMANENTLY AT IPL Apply temporarily, and then permanently at IPL APPLY TEMPORARILY Apply temporarily at IPL NONE No IPL action taken REMOVE PERMANENTLY Remove permanently at IPL REMOVE PERMANENTLY AT IPL Remove temporarily, and then permanently at IPL REMOVE TEMPORARILY Remove temporarily at IPL Contains the null value if ENTRY_TYPE is not P, or ENTRY_TYPE is P and ENTRY_ACTION is EXTE or EXTS.
EXIT_PROGRAM_LIBRARY	VARCHAR(10)	The library in which EXIT_PROGRAM resides. Contains the null value if ENTRY_TYPE is not P with an ENTRY_ACTION of EXTE or EXTS.
EXIT_PROGRAM	VARCHAR(10)	The name of the PTF exit program. Contains the null value if ENTRY_TYPE is not P with an ENTRY_ACTION of EXTE or EXTS.
EXIT_PROGRAM_ACTION	VARCHAR(21)	The PTF exit program action. APPLY PERMANENTLY Apply permanently APPLY TEMPORARILY Apply temporarily PREAPPLY PERMANENTLY Pre-apply permanently PREAPPLY TEMPORARILY Pre-apply temporarily PREREMOVE PERMANENTLY Pre-remove permanently PREREMOVE TEMPORARILY Pre-remove temporarily REMOVE PERMANENTLY Remove permanently REMOVE TEMPORARILY Remove temporarily Contains the null value if ENTRY_TYPE is not P with an ENTRY_ACTION of EXTE or EXTS.
SUPERSEDED_BY_PTF	VARCHAR(7)	Superseded-by PTF identifier. Contains the null value if ENTRY_TYPE is not P with an ENTRY_ACTION of SUPR.

Table 179. AUDIT_JOURNAL_PF table function (continued)

Column Name	Data Type	Description
APPLY_TYPE	VARCHAR(8)	<p>PTF install apply type.</p> <p>*DLYALL Mark PTFs for delayed apply</p> <p>*DLYIPL Mark PTFs for delayed apply and IPL</p> <p>*IMMDLY Apply immediate PTFs and mark delayed PTFs for delayed apply</p> <p>*IMMONLY Only apply immediate PTFs</p> <p>Contains the null value if ENTRY_TYPE is not L with an ENTRY_ACTION of GOPT or INSP.</p>
DEVICE_NAME	VARCHAR(10)	<p>PTF install device name. Can contain one of the following special values:</p> <p>*NONE No PTFs are loaded, PTFs already loaded are applied</p> <p>*SERVICE Install PTFs received from service support system</p> <p>Contains the null value if ENTRY_TYPE is not L with an ENTRY_ACTION of GOPT or INSP.</p>
IMAGE_CATALOG	VARCHAR(10)	<p>PTF install image catalog name. Can contain one of the following special values:</p> <p>*NETOPT Network Optical</p> <p>*NONE No image catalog</p> <p>*RMTDEV Remote device</p> <p>Contains the null value if ENTRY_TYPE is not L with an ENTRY_ACTION of GOPT or INSP.</p>
MEDIA_PROMPT	VARCHAR(10)	<p>PTF install prompt for media.</p> <p>*MLTSRV Prompt for volumes in multiple volume sets then load from *SERVICE</p> <p>*MLTVOLSET Prompt for volumes in multiple volume sets</p> <p>*SNGVOLSET Prompt for volumes in single volume set</p> <p>Contains the null value if ENTRY_TYPE is not L with an ENTRY_ACTION of GOPT or INSP.</p>
HIPER_PTFS	VARCHAR(3)	<p>Only HIPER PTFs loaded on PTF install.</p> <p>NO All PTFs loaded.</p> <p>YES Only HIPER PTFs loaded</p> <p>Contains the null value if ENTRY_TYPE is not L with an ENTRY_ACTION of GOPT or INSP.</p>
COPY_SERVICE_PTFS	VARCHAR(3)	<p>Copy PTF save files and cover letters into *SERVICE on PTF install.</p> <p>NO PTFs not copied</p> <p>YES PTFs copied</p> <p>Contains the null value if ENTRY_TYPE is not L with an ENTRY_ACTION of GOPT or INSP.</p>
OMIT_PTFS	VARCHAR(3)	<p>PTFs omitted on PTF install.</p> <p>NO Ftps were not omitted</p> <p>YES PTFs were omitted</p> <p>Contains the null value if ENTRY_TYPE is not L with an ENTRY_ACTION of GOPT or INSP.</p>

Table 179. AUDIT_JOURNAL_PF table function (continued)

Column Name	Data Type	Description
AUTOMATIC_IPL	VARCHAR(3)	Automatic IPL on PTF install. NO No automatic IPL YES Automatic IPL performed Contains the null value if ENTRY_TYPE is not L with an ENTRY_ACTION of GOPT or INSP.
IPL_RESTART_TYPE	VARCHAR(5)	IPL restart type for automatic IPL on PTF install. IPLA IPL attributes *FULL All parts of system, including hardware, are restarted *SYS System determines how much to restart Contains the null value if AUTOMATIC_IPL is not YES.
QPZSYNC_PARAMETER	CHAR(1)	First parameter passed to QPZSYNC. Contains the null value if ENTRY_TYPE is not L with an ENTRY_ACTION of SYNC.
IPL_TYPE	VARCHAR(10)	IPL type. UNATTENDED Unattended IPL ATTENDED Attended IPL INSTALL IPL during operating system install Contains the null value if ENTRY_TYPE is not I.
ABNORMAL_IPL	VARCHAR(3)	Abnormal IPL. NO Normal IPL YES Abnormal IPL Contains the null value if ENTRY_TYPE is not I.
LIC_RESTORED	VARCHAR(3)	LIC restored during this IPL. NO LIC not restored YES LIC restored Contains the null value if ENTRY_TYPE is not I.
LIC_IPL_REQUESTED	VARCHAR(3)	Re-IPL of LIC requested during IPL. NO No re-IPL of LIC requested YES Re-IPL of LIC requested Contains the null value if ENTRY_TYPE is not I.
RESTART_SHARED_ACTIVATION_GROUP	VARCHAR(3)	Restart Shared Activation Group (SAG) during IPL after applying PTFs. NO SAG not restarted YES SAG restarted Contains the null value if ENTRY_TYPE is not I.

Example

- For each PTF action that has been performed today, list the number of times it occurred along with the description of the action.

```
SELECT COUNT(*) AS ACTION_COUNT, ENTRY_ACTION, MIN(ENTRY_ACTION_DETAIL)
FROM TABLE (
    SYSTOOLS.AUDIT_JOURNAL_PF (STARTING_TIMESTAMP => CURRENT DATE)
)
WHERE ENTRY_TYPE = 'P'
GROUP BY ENTRY_ACTION
```

AUDIT_JOURNAL_PG table function

The AUDIT_JOURNAL_PG table function returns rows from the audit journal that contain information from the PG (Primary Group Change) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in “AUDIT JOURNAL table function common information” on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 180. AUDIT_JOURNAL_PG table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the PG audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. A Change primary group.
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
PRIMARY_GROUP	VARCHAR(10)	The new primary group for the object.
PREV_PRIMARY_GROUP	VARCHAR(10)	The previous primary group for the object. Contains the null value if the previous primary group is not available.
REVOKE_PREV_PRIMARY_GROUP	VARCHAR(3)	Indicates whether authority was revoked for the previous primary group. NO Authority was not revoked for previous primary group. YES Authority was revoked for previous primary group.
LIBRARY_NAME	VARCHAR(10)	The name of the library containing the object. Contains the null value if there is no library name.
OBJECT_NAME	VARCHAR(10)	The name of the object. Contains the null value if there is no object name.
OBJECT_TYPE	VARCHAR(7)	The type of object. Contains the null value if there is no object type.
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the object resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs. Contains the null value if there is no ASP information.
OBJECT_ASP_NUMBER	INTEGER	The number of the ASP device. 1 indicates the system ASP. Contains the null value if there is no ASP information.
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The path name of the object. Contains the null value if the path name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PATH_NAME_INDICATOR	VARCHAR(3)	Path name indicator: NO The PATH_NAME column does not contain an absolute path name for the object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name. YES The PATH_NAME column contains the absolute path name for the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.

Table 180. AUDIT_JOURNAL_PG table function (continued)

Column Name	Data Type	Description
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the object identified in the PATH_NAME column. Contains the null value when PATH_NAME_INDICATOR is YES, or if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	The name of the object. Contains the null value if the object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
OBJECT_FILE_ID	BINARY(16)	The file ID of the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PARENT_FILE_ID	BINARY(16)	The file ID of the parent directory. Contains the null value if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
OFFICE_USER	VARCHAR(10)	The name of the office user. Contains the null value if there is no office user.
OFFICE_ON_BEHALF_OF_USER	VARCHAR(10)	User working on behalf of another user. Contains the null value if there is no user name.
DLO_NAME	VARCHAR(12)	The name of the folder or document. Contains the null value if there is no new folder or document.
FOLDER_PATH	VARCHAR(63)	The path of the folder. Contains the null value if there is no new folder path.
AUTHORIZATION_LIST_MANAGEMENT	VARCHAR(3)	Indicates whether the new primary group has authorization list management (*AUTLMGT) authority. NO The new primary group does not have this authority. YES The new primary group has this authority.
OBJECT_EXCLUDE	VARCHAR(3)	Indicates whether the new primary group has exclude (*EXCLUDE) authority. NO The new primary group does not have this authority. YES The new primary group has this authority.
OBJECT_OPERATIONAL	VARCHAR(3)	Indicates whether the new primary group has object operational (*OBJOPR) authority. NO The new primary group does not have this authority. YES The new primary group has this authority.
OBJECT_MANAGEMENT	VARCHAR(3)	Indicates whether the new primary group has object management (*OBJMGT) authority. NO The new primary group does not have this authority. YES The new primary group has this authority.
OBJECT_EXISTENCE	VARCHAR(3)	Indicates whether the new primary group has object existence (*OBJEXIST) authority. NO The new primary group does not have this authority. YES The authority might have changed.
OBJECT_ALTER	VARCHAR(3)	Indicates whether the new primary group has object alter (*OBJALTER) authority. NO The new primary group does not have this authority. YES The new primary group has this authority.

Table 180. AUDIT_JOURNAL_PG table function (continued)

Column Name	Data Type	Description
OBJECT_REFERENCE	VARCHAR(3)	Indicates whether the new primary group has object reference (*OBJREF) authority. NO The new primary group does not have this authority. YES The new primary group has this authority.
DATA_READ	VARCHAR(3)	Indicates whether the new primary group has data read (*READ) authority. NO The new primary group does not have this authority. YES The new primary group has this authority.
DATA_ADD	VARCHAR(3)	Indicates whether the new primary group has data add (*ADD) authority. NO The new primary group does not have this authority. YES The new primary group has this authority.
DATA_UPDATE	VARCHAR(3)	Indicates whether the new primary group has data update (*UPD) authority. NO The new primary group does not have this authority. YES The new primary group has this authority.
DATA_DELETE	VARCHAR(3)	Indicates whether the new primary group has data delete (*DLT) authority . NO The new primary group does not have this authority. YES The new primary group has this authority.
DATA_EXECUTE	VARCHAR(3)	Indicates whether the new primary group has data execute (*EXECUTE) authority. NO The new primary group does not have this authority. YES The new primary group has this authority.
PREV_AUTHORIZATION_LIST_MANAGEMENT	VARCHAR(3)	Indicates whether the previous primary group had authorization list management (*AUTLMGT) authority. NO The previous primary group did not have this authority. YES The previous primary group had this authority. Contains the null value if a previous value is not available.
PREV_OBJECT_EXCLUDE	VARCHAR(3)	Indicates whether the previous primary group had exclude (*EXCLUDE) authority. NO The previous primary group did not have this authority. YES The previous primary group had this authority. Contains the null value if a previous value is not available.
PREV_OBJECT_OPERATIONAL	VARCHAR(3)	Indicates whether the previous primary group had object operational (*OBJOPR) authority. NO The previous primary group did not have this authority. YES The previous primary group had this authority. Contains the null value if a previous value is not available.
PREV_OBJECT_MANAGEMENT	VARCHAR(3)	Indicates whether the previous primary group had object management (*OBJMGT) authority. NO The previous primary group did not have this authority. YES The previous primary group had this authority. Contains the null value if a previous value is not available.

Table 180. AUDIT_JOURNAL_PG table function (continued)

Column Name	Data Type	Description
PREV_OBJECT_EXISTENCE	VARCHAR(3)	Indicates whether the previous primary group had object existence (*OBJEXIST) authority. NO The previous primary group did not have this authority. YES The previous primary group had this authority. Contains the null value if a previous value is not available.
PREV_OBJECT_ALTER	VARCHAR(3)	Indicates whether the previous primary group had object alter (*OBJALTER) authority. NO The previous primary group did not have this authority. YES The previous primary group had this authority. Contains the null value if a previous value is not available.
PREV_OBJECT_REFERENCE	VARCHAR(3)	Indicates whether the previous primary group had object reference (*OBJREF) authority. NO The previous primary group did not have this authority. YES The previous primary group had this authority. Contains the null value if a previous value is not available.
PREV_DATA_READ	VARCHAR(3)	Indicates whether the previous primary group had data read (*READ) authority. NO The previous primary group did not have this authority. YES The previous primary group had this authority. Contains the null value if a previous value is not available.
PREV_DATA_ADD	VARCHAR(3)	Indicates whether the previous primary group had data add (*ADD) authority. NO The previous primary group did not have this authority. YES The previous primary group had this authority. Contains the null value if a previous value is not available.
PREV_DATA_UPDATE	VARCHAR(3)	Indicates whether the previous primary group had data update (*UPD) authority. NO The previous primary group did not have this authority. YES The previous primary group had this authority. Contains the null value if a previous value is not available.
PREV_DATA_DELETE	VARCHAR(3)	Indicates whether the previous primary group had data delete (*DLT) authority. NO The previous primary group did not have this authority. YES The previous primary group had this authority. Contains the null value if a previous value is not available.
PREV_DATA_EXECUTE	VARCHAR(3)	Indicates whether the previous primary group had data execute (*EXECUTE) authority. NO The previous primary group did not have this authority. YES The previous primary group had this authority. Contains the null value if a previous value is not available.

Example

- List the objects in APPLIB or APPLIB2 that had their primary group changed in the last month.

```
SELECT LIBRARY_NAME, OBJECT_NAME, OBJECT_TYPE, PRIMARY_GROUP, PREV_PRIMARY_GROUP,
       REVOKE_PREV_PRIMARY_GROUP
FROM TABLE (
```

```

SYSTOOLS.AUDIT_JOURNAL_PG (STARTING_TIMESTAMP => CURRENT DATE - 1 MONTH)
)
WHERE LIBRARY_NAME IN ('APPLIB', 'APPLIB2')
ORDER BY 1, 3, 2;

```

AUDIT_JOURNAL_PS table function

The AUDIT_JOURNAL_PS table function returns rows from the audit journal that contain information from the PS (Profile Swap) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 181. AUDIT_JOURNAL_PS table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the PS audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. <ul style="list-style-type: none"> A Profile swap during pass-through E End work on behalf of the relationship H Profile handle generated by the QSYGETPH API I All profile tokens were invalidated M Maximum number of profile tokens have been generated P Profile token generated for a user R All profile tokens for a user have been removed S Start work on behalf of the relationship T Exit program profile swap for the Telnet exit program QIBM_QTG_DEVINIT U Exit program profile override for the Telnet exit program QIBM_QTG_DEVINIT or for the FTP exit program QIBM_QTMF_SVR_LOGON V User profile authenticated
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
USER_PROFILE_NAME	VARCHAR(10)	The name of the user profile. Contains the null value if ENTRY_TYPE is T or U.
PROFILE_TOKEN_TYPE	VARCHAR(12)	The type of profile token that was generated. <ul style="list-style-type: none"> MULTIPLE USE Multiple-use profile token REGENERATED Multiple-use regenerated profile token SINGLE USE Single-use profile token Contains the null value if no profile token was generated.

Table 181. AUDIT_JOURNAL_PS table function (continued)

Column Name	Data Type	Description
PROFILE_TOKEN_TIMEOUT	INTEGER	The number of seconds that the profile token is valid. Contains the null value if no profile token was generated.
SOURCE_LOCATION	VARCHAR(8)	Pass-through source location. Contains the null value if this entry is not for pass-through.
PASS_THROUGH_USER_PROFILE_NAME	VARCHAR(10)	The name of the user profile used for pass-through. Contains the null value if ENTRY_TYPE is T or the name is not available.
ORIGINAL_PASS_THROUGH_USER_PROFILE_NAME	VARCHAR(10)	The original name of the user profile used for pass-through. Contains the null value if ENTRY_TYPE is T or the name is not available.
EXIT_PROGRAM_USER_PROFILE_NAME	VARCHAR(10)	When ENTRY_TYPE is T, contains the name of the user profile returned by the exit program. When ENTRY_TYPE is U, contains the name of the user profile used by the exit program. Contains the null value if ENTRY_TYPE is not T or U or the name is not available.
NEGOTIATED_USER_PROFILE_NAME	VARCHAR(10)	The name of the user profile negotiated by the Telnet client. Contains the null value if ENTRY_TYPE is not T or if no user was negotiated.
PORT_NUMBER	INTEGER	The port number of the Telnet or FTP client. Contains the null value if ENTRY_TYPE is not T or U or the port number is not available.
IP_ADDRESS	VARCHAR(45)	The IP address of the Telnet or FTP client. Contains the null value if ENTRY_TYPE is not T or U or the IP address is not available.
DEVICE_NAME	VARCHAR(10)	The name of the device that was requested or set by the exit point. Contains the null value if ENTRY_TYPE is not T or U, or if no device was negotiated, or if FTP is used.
EXIT_POINT_NAME	VARCHAR(30)	The name of the exit point for which the exit program profile is overridden. Contains the null value if ENTRY_TYPE is not T or U or the exit point name is not available.
EXIT_POINT_FORMAT	VARCHAR(8)	The exit point format. Contains the null value if ENTRY_TYPE is not T or U or the exit point format is not available.
OFFICE_USER	VARCHAR(10)	The name of the office user. Contains the null value if there is no office user.
OFFICE_ON_BEHALF_OF_USER	VARCHAR(10)	User working on behalf of the office user. Contains the null value if the user name is not available.

Example

- List the occurrences where a single user profile token was generated for the user QSYS in the last week.

```

SELECT * FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_PS(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 7 DAYS
  )
)
WHERE PROFILE_TOKEN_TYPE = 'SINGLE USE' AND USER_PROFILE_NAME = 'QSECOFR';

```

AUDIT_JOURNAL_PU table function

The AUDIT_JOURNAL_PU table function returns rows from the audit journal that contain information from the PU (PTF Object Change) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in “AUDIT JOURNAL table function common information” on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 182. AUDIT_JOURNAL_PU table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the PU audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. D Directory PTF object L Library PTF object S LIC PTF object
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
ENTRY_ACTION	VARCHAR(7)	The type of action. CHANGED Changed PTF object NEW New PTF object
PTF_OPERATION	VARCHAR(6)	The PTF operation. APPLY The PTF is applied REMOVE The PTF is removed
PRODUCT_ID	VARCHAR(7)	Product ID.
PRODUCT_RELEASE_LEVEL	CHAR(6)	Product version, release, modification in format VvRrMm.
PTF_IDENTIFIER	VARCHAR(7)	PTF identifier.
PRODUCT_OPTION	VARCHAR(4)	Product option.
LOAD_ID	VARCHAR(4)	Product load identifier.
PRODUCT_MINIMUM_LEVEL	VARCHAR(2)	Product minimum level.
PRODUCT_MAXIMUM_LEVEL	VARCHAR(2)	Product maximum level.
PRODUCT_LIBRARY	VARCHAR(10)	Product library.
OBJECT_LIBRARY	VARCHAR(10)	Object library. Contains the null value if ENTRY_TYPE is not L.
OBJECT_NAME	VARCHAR(10)	Object name. Contains the null value if ENTRY_TYPE is not L.
OBJECT_TYPE	VARCHAR(7)	Object type. Contains the null value if ENTRY_TYPE is not L.

Table 182. AUDIT_JOURNAL_PU table function (continued)

Column Name	Data Type	Description
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the object resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs. Contains the null value if ENTRY_TYPE is not D or L.
OBJECT_ASP_NUMBER	INTEGER	The number of the ASP device. 1 indicates the system ASP. Contains the null value if ENTRY_TYPE is not D or L.
LIC_RU_NAME	VARCHAR(8)	The Licensed Internal Code replacement unit (Ru) name. Contains the null value if ENTRY_TYPE is not S.
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The path name of the object. Contains the null value if ENTRY_TYPE is not D or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PATH_NAME_INDICATOR	VARCHAR(3)	Path name indicator. NO The PATH_NAME column does not contain an absolute path name for the object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name. YES The PATH_NAME column contains complete absolute path name for the object. Contains the null value if ENTRY_TYPE is not D or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the object identified in the PATH_NAME column. Contains the null value if ENTRY_TYPE is not D, when PATH_NAME_INDICATOR is YES, or if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	The name of the object. Contains the null value if ENTRY_TYPE is not D or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
OBJECT_FILE_ID	BINARY(16)	The file ID of the object. Contains the null value if ENTRY_TYPE is not D, or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PARENT_FILE_ID	BINARY(16)	The file ID of the parent directory. Contains the null value if ENTRY_TYPE is not D or the object is not in the "root" (/), QOpenSys, or user-defined file systems.

Example

- List objects that were affected by PTFs that were applied to the system in the previous two days.

```
SELECT PTF_IDENTIFIER, OBJECT_LIBRARY, OBJECT_NAME, OBJECT_TYPE
FROM TABLE (
  SYSTOOLS.AUDIT_JOURNAL_PU (STARTING_TIMESTAMP => CURRENT DATE - 2 DAYS)
)
WHERE ENTRY_TYPE = 'L' AND PTF_OPERATION = 'APPLY';
```

AUDIT_JOURNAL_PW table function

The AUDIT_JOURNAL_PW table function returns rows from the audit journal that contain information from the PW (Password) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 183. AUDIT_JOURNAL_PW table function

Column Name	Data Type	Description
<p>The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the PW audit journal entry.</p>		
VIOLATION_TYPE	CHAR(1)	<p>The type of violation.</p> <p>A APPC bind failure.</p> <p>C User authentication with the CHKPWD command failed.</p> <p>D Service tools user ID name not valid (QSYCHGDS API, CRTSSTUSR, CHGSSTUSR, DLTSSSTUSR commands).</p> <p>E Service tools user ID password not valid (QSYCHGDS API, CRTSSTUSR, CHGSSTUSR, DLTSSSTUSR commands).</p> <p>P Password not valid.</p> <p>Q Attempted signon (user authentication) failed because user profile is disabled.</p> <p>R Attempted signon (user authentication) failed because password was expired.</p> <p>S SQL Decryption password is not valid.</p> <p>U User name not valid.</p> <p>X Service tools user ID is disabled.</p> <p>Y Service tools user ID not valid (service tools interface).</p> <p>Z Service tools user ID password not valid (service tools interface).</p>
VIOLATION_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the violation type.
AUDIT_USER_NAME	VARCHAR(10)	<p>The job user name or the service tools user ID name.</p> <p>Contains the null value if no user name is available.</p>
DEVICE_NAME	VARCHAR(40)	<p>The name of the device or communications device on which the password or user ID was entered.</p> <p>Contains the null value when VIOLATION_TYPE is D, E, X, Y, or Z or if the device name is not available.</p>
INTERFACE_NAME	VARCHAR(40)	<p>The name of the interface being used.</p> <p>Contains the null value when VIOLATION_TYPE is not D, E, X, Y, or Z or if the interface name is not available.</p>
REMOTE_LOCATION	VARCHAR(8)	<p>Name of the remote location for the APPC bind.</p> <p>Contains the null value when VIOLATION_TYPE is not A.</p>
LOCAL_LOCATION	VARCHAR(8)	<p>Name of the local location for the APPC bind.</p> <p>Contains the null value when VIOLATION_TYPE is not A.</p>
NETWORK_ID	VARCHAR(8)	<p>Network ID for the APPC bind.</p> <p>Contains the null value when VIOLATION_TYPE is not A.</p>
DECRYPT_HOST_VARIABLE	VARCHAR(3)	<p>Whether the user attempted to decrypt data in a host variable.</p> <p>NO The user did not attempt to decrypt data in a host variable.</p> <p>YES The user attempted to decrypt data in a host variable.</p> <p>Contains the null value if VIOLATION_TYPE is not S.</p>
DECRYPT_OBJECT_LIBRARY	VARCHAR(10)	<p>The library that contains OBJECT_NAME.</p> <p>Contains the null value if VIOLATION_TYPE is not S or if there is no library name.</p>
DECRYPT_OBJECT_NAME	VARCHAR(10)	<p>The name of the object being decrypted.</p> <p>Contains the null value if VIOLATION_TYPE is not S or if there is no object name.</p>
DECRYPT_OBJECT_TYPE	VARCHAR(8)	<p>The type of the object.</p> <p>Contains the null value if VIOLATION_TYPE is not S or if there is no object.</p>

Table 183. AUDIT_JOURNAL_PW table function (continued)

Column Name	Data Type	Description
DECRYPT_OBJECT_ASP_NAME	VARCHAR(10)	The name of the ASP device where OBJECT_NAME resides. Contains the null value if VIOLATION_TYPE is not S or if there is no object name.
DECRYPT_OBJECT_ASP_NUMBER	INTEGER	The number of the ASP device where OBJECT_NAME resides. 1 indicates the system ASP. Contains the null value if VIOLATION_TYPE is not S or if there is no object name.

Example

- For all the password audit journal entries from yesterday and today, list the number of each type of audit violation.

```
SELECT VIOLATION_TYPE CONCAT ' - ' CONCAT VIOLATION_TYPE_DETAIL,
       COUNT(*) AS VIOLATION_COUNT
FROM TABLE (
  SYSTOOLS.AUDIT_JOURNAL_PW ( )
)
GROUP BY VIOLATION_TYPE CONCAT ' - ' CONCAT VIOLATION_TYPE_DETAIL
ORDER BY 2 DESC;
```

AUDIT_JOURNAL_RA table function

The AUDIT_JOURNAL_RA table function returns rows from the audit journal that contain information from the RA (Authority Change for Restored Object) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in “AUDIT JOURNAL table function common information” on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 184. AUDIT_JOURNAL_RA table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the RA audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. A Changes to authority for a restored object
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
OBJECT_LIBRARY	VARCHAR(10)	The name of the library containing the restored object. Contains the null value if there is no library name.
OBJECT_NAME	VARCHAR(10)	The name of the restored object. Contains the null value if there is no restored object name.
OBJECT_TYPE	VARCHAR(7)	The type of the restored object. Contains the null value if there is no restored object type.
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which OBJECT_NAME resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs.
OBJECT_ASP_NUMBER	INTEGER	The number of the auxiliary storage pool to which storage for OBJECT_NAME is allocated. 1 indicates the system ASP.
SAVE_AUTHORIZATION_LIST	VARCHAR(10)	The name of the authorization list for the object on the save media. Contains the null value if there is no authorization list for the object on the save media.

Table 184. AUDIT_JOURNAL_RA table function (continued)

Column Name	Data Type	Description
RESTORE_AUTHORIZATION_LIST	VARCHAR(10)	The name of the authorization list for the object after the restore has completed. Contains the null value if AUTHORIZATION_LIST_REMOVED is YES or there is no authorization list for the object on the save media.
AUTHORIZATION_LIST_REMOVED	VARCHAR(3)	Indicates whether the authorization list was removed from the object. NO The authorization list was not removed. YES The authorization list was removed.
PUBLIC_AUTHORITY_EXCLUDE	VARCHAR(3)	Indicates whether public authority was set to exclude (*EXCLUDE) for the object. NO Public authority was not set to exclude (*EXCLUDE). YES Public authority was set to exclude (*EXCLUDE).
PRIVATE_AUTHORITY_REMOVED	VARCHAR(3)	Indicates whether private authority was removed from the object. NO Private authority was not removed. YES Private authority was removed.
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The path name of the restored object. Contains the null value if the restored object name is not available or the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.
PATH_NAME_INDICATOR	VARCHAR(3)	Path name indicator. NO The PATH_NAME column does not contain an absolute path name for the restored object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name. YES The PATH_NAME column contains complete absolute path name for the restored object. Contains the null value if the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the object identified in the PATH_NAME column. Contains the null value when PATH_NAME_INDICATOR is YES, or if the file ID is not available or the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	The name of the restored object. Contains the null value if the restored object name is not available or the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.
OBJECT_FILE_ID	BINARY(16)	The file ID of the restored object. Contains the null value if the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.
PARENT_FILE_ID	BINARY(16)	The file ID of the parent directory. Contains the null value if the file ID is not available or the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.
DLO_NAME	VARCHAR(12)	The name of the document library object. Contains the null value if there is no document library object.
FOLDER_PATH	VARCHAR(63)	The path of the folder. Contains the null value if there is no folder path.

Example

- List any objects in APPLIB1 where the public authority is not set to *EXCLUDE as a result of restores done in the last day.

```

SELECT OBJECT_LIBRARY, OBJECT_NAME, OBJECT_TYPE, PUBLIC_AUTHORITY_EXCLUDE FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_RA(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 1 DAY)
)
WHERE OBJECT_LIBRARY = 'APPLIB1'
AND PUBLIC_AUTHORITY_EXCLUDE = 'NO';

```

AUDIT_JOURNAL_RO table function

The AUDIT_JOURNAL_RO table function returns rows from the audit journal that contain information from the RO (Ownership Change for Restored Object) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in “AUDIT JOURNAL table function common information” on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 185. AUDIT_JOURNAL_RO table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the RO audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. A Changes to ownership for a restored object
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
OBJECT_LIBRARY	VARCHAR(10)	The name of the library containing the restored object. Contains the null value if there is no library name.
OBJECT_NAME	VARCHAR(10)	The name of the restored object. Contains the null value if there is no restored object name.
OBJECT_TYPE	VARCHAR(7)	The type of the restored object. Contains the null value if there is no restored object type.
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which OBJECT_NAME resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs.
OBJECT_ASP_NUMBER	INTEGER	The number of the auxiliary storage pool to which storage for OBJECT_NAME is allocated. 1 indicates the system ASP.
SAVE_OWNER	VARCHAR(10)	The owner of the object on the save media.
RESTORE_OWNER	VARCHAR(10)	The owner of the object after the restore has completed.
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The path name of the restored object. Contains the null value if the restored object name is not available or the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.
PATH_NAME_INDICATOR	VARCHAR(3)	Path name indicator. NO The PATH_NAME column does not contain an absolute path name for the restored object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name. YES The PATH_NAME column contains complete absolute path name for the restored object. Contains the null value if the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the restored object identified in the PATH_NAME column. Contains the null value when PATH_NAME_INDICATOR is YES, or if the file ID is not available or the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.

Table 185. AUDIT_JOURNAL_RO table function (continued)

Column Name	Data Type	Description
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	The name of the restored object. Contains the null value if the restored object name is not available or the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.
OBJECT_FILE_ID	BINARY(16)	The file ID of the restored object. Contains the null value if the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.
PARENT_FILE_ID	BINARY(16)	The file ID of the parent directory. Contains the null value if the file ID is not available or the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.
DLO_NAME	VARCHAR(12)	The name of the document library object. Contains the null value if there is no document library object.
FOLDER_PATH	VARCHAR(63)	The path of the folder. Contains the null value if there is no folder path.

Example

- List any objects in APPLIB1 that are owned by QSYS as a result of restores done in the last day.

```
SELECT OBJECT_NAME, RESTORE_OWNER FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_RO(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 1 DAY)
)
WHERE OBJECT_LIBRARY = 'APPLIB1' AND
RESTORE_OWNER = 'QSYS';
```

AUDIT_JOURNAL_RZ table function

The AUDIT_JOURNAL_RZ table function returns rows from the audit journal that contain information from the RZ (Primary Group Change for Restored Object) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in “AUDIT JOURNAL table function common information” on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 186. AUDIT_JOURNAL_RZ table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the RZ audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. A Changes to the primary group for a restored object
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
OBJECT_LIBRARY	VARCHAR(10)	The name of the library containing the restored object. Contains the null value if there is no library name.
OBJECT_NAME	VARCHAR(10)	The name of the restored object. Contains the null value if there is no restored object name.
OBJECT_TYPE	VARCHAR(7)	The type of the restored object. Contains the null value if there is no restored object type.
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which OBJECT_NAME resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs.

Table 186. AUDIT_JOURNAL_RZ table function (continued)

Column Name	Data Type	Description
OBJECT_ASP_NUMBER	INTEGER	The number of the auxiliary storage pool to which storage for OBJECT_NAME is allocated. 1 indicates the system ASP.
SAVE_PRIMARY_GROUP	VARCHAR(10)	The primary group for the object on the save media. Contains the null value if there is no primary group for the object on the save media.
RESTORE_PRIMARY_GROUP	VARCHAR(10)	The primary group for the object after the restore has completed. Contains the null value if there is no primary group for the object on the save media.
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The path name of the restored object. Contains the null value if the restored object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PATH_NAME_INDICATOR	VARCHAR(3)	Path name indicator. NO The PATH_NAME column does not contain an absolute path name for the restored object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name. YES The PATH_NAME column contains complete absolute path name for the restored object. Contains the null value if the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the restored object identified in the PATH_NAME column. Contains the null value when PATH_NAME_INDICATOR is YES, or if the file ID is not available or the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	The name of the restored object. Contains the null value if the restored object name is not available or the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.
OBJECT_FILE_ID	BINARY(16)	The file ID of the restored object. Contains the null value if the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.
PARENT_FILE_ID	BINARY(16)	The file ID of the parent directory. Contains the null value if the file ID is not available or the restored object is not in the "root" (/), QOpenSys, or user-defined file systems.
DLO_NAME	VARCHAR(12)	The name of the document library object. Contains the null value if there is no document library object.
FOLDER_PATH	VARCHAR(63)	The path of the folder. Contains the null value if there is no folder path.

Example

- List any objects in APPLIB1 that have the primary group DEVS as a result of restores done in the last day.

```
SELECT OBJECT_NAME, RESTORE_PRIMARY_GROUP FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_RZ(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 1 DAY)
)
WHERE OBJECT_LIBRARY = 'APPLIB1' AND
RESTORE_PRIMARY_GROUP = 'DEVS';
```

AUDIT_JOURNAL_SK table function

The AUDIT_JOURNAL_SK table function returns rows from the audit journal that contain information from the SK (Sockets Connections) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 187. AUDIT_JOURNAL_SK table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the SK audit journal entry.		
ENTRY_TYPE	CHAR(1)	<p>The type of entry.</p> <ul style="list-style-type: none"> A Accept C Connect D DHCP address assigned F Filtered mail I Inbound UDP traffic O Outbound UDP traffic P Port unavailable R Reject mail S Successful secure connection. This means a secure protocol was used, not that the algorithms used are considered secure. A system operator needs to review SECURE_VERSION and SECURE_PROPERTIES to determine the level of security. U DHCP address not assigned X Failed system TLS connection
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
ADDRESS_SPACE_TYPE	CHAR(4)	<p>The address family.</p> <ul style="list-style-type: none"> IPV4 Internet Protocol Version 4 IPV6 Internet Protocol Version 6 <p>Contains the null value when information is not available.</p>
LOCAL_IP_ADDRESS	VARCHAR(45)	<p>The local IP address.</p> <p>Contains the null value when information is not available.</p>
LOCAL_PORT	INTEGER	<p>The local port.</p> <p>Contains the null value when information is not available.</p>
SOCKET_DESCRIPTOR	INTEGER	<p>The socket descriptor.</p> <p>Contains the null value when ENTRY_TYPE is not A, C, R, S, U or X, or if information is not available.</p>
MAC_ADDRESS	VARCHAR(32)	<p>The MAC address of the requesting client.</p> <p>Contains the null value when information is not available.</p>
HOST_NAME	VARCHAR(255)	<p>The host name of the requesting client.</p> <p>Contains the null value when information is not available.</p>
DHCP_IP_ADDRESS	VARCHAR(45)	<p>The IP address that the DHCP server assigned to the requesting client.</p> <p>Contains the null value when ENTRY_TYPE is not D.</p>

Table 187. AUDIT_JOURNAL_SK table function (continued)

Column Name	Data Type	Description
SECURE_VERSION	VARCHAR(10)	The security protocol including the specific version level, if available, used for the connection. Protocol prefixes include: TLS, DTLS, SSL, IKE, IPSEC, SSH. A specific example would be 'TLSv1.2' if the connection is protected by System TLS using TLSv1.2. An entry for a non-operating system connection may contain a raw version value such as '0401' if the system inspection code encounters a version it doesn't understand. Contains the null value when ENTRY_TYPE is not S.
SECURE_PROPERTIES	VARCHAR(100)	The secure properties used for the connection. The content of this column varies based on SECURE_VERSION. Where possible this field contains one or more blank-separated character strings describing the cryptographic algorithms and key sizes used for the connection. The algorithms and key sizes are presented in a character format associated with the secure version field. A TLSv1.2 entry may look like this: TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 ECDSA_SHA512 SECP521R1 An entry for a non-operating system connection may contain a protocol's internal algorithm representation values such as 'C054 0703 29' if the system inspection code encounters unknown values. Contains the null value when ENTRY_TYPE is not S.
SECURE_INFORMATION	VARCHAR(100)	Additional attributes for the secure connection. For example, for IPSEC connections it contains the VPN Connection Name. Contains the null value when ENTRY_TYPE is not S or when information is not available.
TLS_ERROR_CODE	VARCHAR(100)	A string that represents the TLS error code. Contains the null value when ENTRY_TYPE is not X.
TLS_ERROR_DESCRIPTION	VARCHAR(100)	A string that describes the TLS failure. Contains the null value when ENTRY_TYPE is not X.
FILTER_DESCRIPTION	VARCHAR(10)	The specified mail filter. Contains the null value when ENTRY_TYPE is not F.
FILTER_DATA	VARCHAR(512)	The mail filter data. Contains the null value when ENTRY_TYPE is not F.

Example

- List the security protocols and cryptographic algorithms used in the last month.

```
SELECT DISTINCT SECURE_VERSION, SECURE_PROPERTIES FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_SK(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 1 MONTH
  )
)
WHERE ENTRY_TYPE = 'S';
```

AUDIT_JOURNAL_SM table function

The AUDIT_JOURNAL_SM table function returns rows from the audit journal that contain information from the SM (Systems Management Change) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 188. AUDIT_JOURNAL_SM table function

Column Name	Data Type	Description
<p>The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the SM audit journal entry.</p>		
ENTRY_TYPE	CHAR(1)	<p>The type of entry.</p> <p>B Backup list changed C Automatic cleanup options D DRDA F HFS file system M Change DDM TCP/IP Attributes (CHGDDMTCPA) CL command N Network file operation O Backup options changed P Power on/off schedule S System reply list T Access path recovery times changed</p>
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
ACCESS_TYPE	VARCHAR(8)	<p>The type of access.</p> <p>ADD Add CHANGE Change DELETE Delete DISPLAY Display REMOVE Remove RETRIEVE Retrieve or receive</p> <p>Contains the null value when information is not available.</p>
REPLY_SEQUENCE_NUMBER	INTEGER	<p>Sequence number of the action.</p> <p>Contains the null value if ENTRY_TYPE is not S or if ACCESS_TYPE is DISPLAY.</p>
REPLY_MESSAGE_ID	VARCHAR(7)	<p>Message ID associated with the action. Can contain the special value *ANY.</p> <p>Contains the null value if ENTRY_TYPE is not S.</p>
FILE_SYSTEM_NAME	VARCHAR(10)	<p>Name of the file system.</p> <p>Contains the null value if ENTRY_TYPE is not F.</p>
BACKUP_OPTION	VARCHAR(8)	<p>The backup option that was changed. Values are *DAILY, *WEEKLY, and *MONTHLY.</p> <p>Contains the null value if ENTRY_TYPE is not O.</p>
BACKUP_LIST	VARCHAR(4)	<p>The name of the backup list that was changed. Values are *FLD and *LIB.</p> <p>Contains the null value if ENTRY_TYPE is not B.</p>
NETWORK_FILE	VARCHAR(10)	<p>The name of the network file that was used.</p> <p>Contains the null value if ENTRY_TYPE is not N.</p>
NETWORK_FILE_MEMBER	VARCHAR(10)	<p>The name of the member of the network file.</p> <p>Contains the null value if ENTRY_TYPE is not N or if the information is not available.</p>
NETWORK_FILE_NUMBER	INTEGER	<p>The number of the network file.</p> <p>Contains the null value if ENTRY_TYPE is not N.</p>
NETWORK_FILE_OWNER	VARCHAR(10)	<p>The name of the user profile that owns the network file.</p> <p>Contains the null value if ENTRY_TYPE is not N.</p>

Table 188. AUDIT_JOURNAL_SM table function (continued)

Column Name	Data Type	Description
NETWORK_FILE_ORIGINATOR	VARCHAR(8)	The name of the user profile that originated the network file. Contains the null value if ENTRY_TYPE is not N.
NETWORK_FILE_ADDRESS	VARCHAR(8)	The address that originated the network file. Contains the null value if ENTRY_TYPE is not N.
RDB_NAME	VARCHAR(18)	Name of the relational database. When ENTRY_TYPE is D, can contain the following special values: *ALL All entries in the RDB directory were removed. *ALLRMT All entries except the *LOCAL entry in the RDB directory were removed. Contains the null value if ENTRY_TYPE is not D or M.
RDB_ALIAS	VARCHAR(18)	The RDB alias name. This value may be *NONE. Contains the null value if ENTRY_TYPE is not D.
REMOTE_LOCATION_TYPE	VARCHAR(4)	The remote location type. *IP The RDB is found using a host name or an internet address over a TCP/IP connection. *SNA The RDB is accessed using a Systems Network Architecture (SNA) address and protocol. Contains the null value if ENTRY_TYPE is not D or if the information is not available.
REMOTE_LOCATION	VARCHAR(254)	The remote location name of the system on which the RDB is located. remote-location-name The remote location name is in one of the following formats: <ul style="list-style-type: none"> • SNA remote location name (LU name). • SNA remote network identifier and remote location name separated by a period. • IPv4 address in dotted decimal form. • IPv6 address in colon hexadecimal form. • IP host domain name. *ARDPGM The RDB is accessed by using the Application Requester Driver (ARD) program. *LOCAL The system database on this system. *LOOPBACK This value is an alias for the IP address of the host system. *MIRROR The RDB is accessed on the other system for a Db2 Mirror relationship. Contains the null value if ENTRY_TYPE is not D or if the information is not available.
REMOTE_PORT_OR_SERVICE	VARCHAR(14)	The relational database entry port number or service name that is used at the remote location to communicate with the system on which the RDB is located. If *DRDA was specified, the Distributed Relational Database Architecture (DRDA) port 446 is shown. Contains the null value if ENTRY_TYPE is not D, REMOTE_LOCATION_TYPE is not *IP, or if the information is not available.

Table 188. AUDIT_JOURNAL_SM table function (continued)

Column Name	Data Type	Description
PREFERRED_AUTHENTICATION	VARCHAR(10)	<p>The preferred authentication method on a connection request.</p> <p>*ENCRYPTED User ID and encrypted password.</p> <p>*ENCUSRPWD Encrypted user ID and encrypted password.</p> <p>*KERBEROS Authentication occurs using Kerberos.</p> <p>*USRENCPWD User ID and encrypted password</p> <p>*USRID User ID only.</p> <p>*USRIDPWD User ID and password.</p> <p>Contains the null value if ENTRY_TYPE is not D or if the information is not available.</p>
LOWER_AUTHENTICATION	VARCHAR(11)	<p>Whether an authentication method lower than what was specified for the preferred method will be accepted during negotiation with the server.</p> <p>*ALLOWER Allow negotiation of a lower authentication method.</p> <p>*NOALLOWER Do not allow negotiation of a lower authentication method.</p> <p>Contains the null value if ENTRY_TYPE is not D or if the information is not available.</p>
ENCRYPTION_ALGORITHM	VARCHAR(4)	<p>The encryption algorithm to be used initially on the connection request.</p> <p>*AES Advanced Encryption Standard (AES) is to be used initially.</p> <p>*DES Data Encryption Standard (DES) is to be used initially.</p> <p>Contains the null value if ENTRY_TYPE is not D, REMOTE_LOCATION_TYPE is not *IP, or if the information is not available.</p>
SECURE_CONNECTION	VARCHAR(5)	<p>Whether Transport Layer Security (TLS) is to be used on a DDM/DRDA TCP/IP connection request.</p> <p>*NONE TLS is not used.</p> <p>*SSL TLS is used.</p> <p>*TLS TLS is used.</p> <p>Contains the null value if ENTRY_TYPE is not D, REMOTE_LOCATION_TYPE is not *IP, or if the information is not available.</p>
APPC_DEVICE_DESCRIPTION	VARCHAR(10)	<p>The Advanced Program-to-Program Communications (APPC) device description on this system that is used with this RDB entry. Can contain the special value:</p> <p>*LOC If APPC is being used, the system determines which device description is used.</p> <p>Contains the null value if ENTRY_TYPE is not D, REMOTE_LOCATION_TYPE is not *SNA, or if the information is not available.</p>
LOCAL_LOCATION	VARCHAR(8)	<p>The local location name by which this system is identified to the system on which the RDB is located. Can contain one of the following special values:</p> <p>*LOC If APPC is being used, the system determines which local location name is used.</p> <p>*NETATR The LCLLOCNAME value specified in the system network attributes is used.</p> <p>Contains the null value if ENTRY_TYPE is not D, REMOTE_LOCATION_TYPE is not *SNA, or if the information is not available.</p>

Table 188. AUDIT_JOURNAL_SM table function (continued)

Column Name	Data Type	Description
REMOTE_NETWORK_ID	VARCHAR(8)	<p>The remote network identifier of the system on which the RDB is located. Can contain one of the following special values:</p> <p>*LOC If APPC is being used, the system determines which remote network identifier is used.</p> <p>*NETATR The remote network identifier specified in the network attributes is used.</p> <p>*NONE No remote network identifier is used.</p> <p>Contains the null value if ENTRY_TYPE is not D, REMOTE_LOCATION_TYPE is not *SNA, or if the information is not available.</p>
REMOTE_MODE	VARCHAR(8)	<p>The mode name to use with the remote location name to communicate with the system on which the RDB is located. Can contain one of the following special values:</p> <p>*NETATR The mode in the network attributes is used.</p> <p>BLANK A mode name of all blanks is used.</p> <p>Contains the null value if ENTRY_TYPE is not D, REMOTE_LOCATION_TYPE is not *SNA, or if the information is not available.</p>
TRANSACTION_PROGRAM	VARCHAR(8) FOR BIT DATA	<p>The name of the transaction program to use with the RDB entry.</p> <p>transaction-program-name The transaction program name is in one of the following formats:</p> <ul style="list-style-type: none"> • A 4-byte hexadecimal name. For example, X'07F6C4C2'. • An 8-byte character name. • If *DRDA was specified, the Distributed Relational Database Architecture (DRDA) transaction program name, X'07F6C4C2'. <p>Contains the null value if ENTRY_TYPE is not D, REMOTE_LOCATION_TYPE is not *SNA, or if the information is not available.</p>
ARD_LIBRARY	VARCHAR(10)	<p>The library containing the Application Requester Driver (ARD) program. This value can be *LIBL or *CURLIB.</p> <p>Contains the null value if the special value *DRDA was specified on the command, if ENTRY_TYPE is not D, if REMOTE_LOCATION is not *ARDPGM, or if the information is not available.</p>
ARD_PROGRAM	VARCHAR(10)	<p>The ARD program to be called to process SQL requests directed to the RDB.</p> <p>Contains the null value if the special value *DRDA was specified on the command, if ENTRY_TYPE is not D, if REMOTE_LOCATION is not *ARDPGM, or if the information is not available.</p>
PREV_REMOTE_LOCATION_TYPE	VARCHAR(4)	<p>The previous value for the remote location type.</p> <p>Contains the null value if ENTRY_TYPE is not D or if the previous value is not available.</p>
PREV_REMOTE_LOCATION	VARCHAR(254)	<p>The previous value for the remote location name of the system on which the RDB is located.</p> <p>Contains the null value if ENTRY_TYPE is not D or if the previous value is not available.</p>
PREV_REMOTE_PORT_OR_SERVICE	VARCHAR(14)	<p>The previous value for the relational database entry port number or service name that is used at the remote location to communicate with the system on which the RDB is located.</p> <p>Contains the null value if ENTRY_TYPE is not D, if REMOTE_LOCATION_TYPE is not *IP, or if the previous value is not available.</p>
PREV_PREFERRED_AUTHENTICATION	VARCHAR(10)	<p>The previous value for the preferred authentication method on a connection request.</p> <p>Contains the null value if ENTRY_TYPE is not D or if the previous value is not available.</p>

Table 188. AUDIT_JOURNAL_SM table function (continued)

Column Name	Data Type	Description
PREV_LOWER_AUTHENTICATION	VARCHAR(11)	The previous value for whether an authentication method lower than what was specified for the preferred method will be accepted during negotiation with the server. Contains the null value if ENTRY_TYPE is not D or if the previous value is not available.
PREV_ENCRYPTION_ALGORITHM	VARCHAR(4)	The previous value for the encryption algorithm to be used initially on the connection request. Contains the null value if ENTRY_TYPE is not D, if REMOTE_LOCATION_TYPE is not *IP, or if the previous value is not available.
PREV_SECURE_CONNECTION	VARCHAR(5)	The previous value for whether Transport Layer Security (TLS) is to be used on a DDM/DRDA TCP/IP connection request. Contains the null value if ENTRY_TYPE is not D, if REMOTE_LOCATION_TYPE is not *IP, or if the previous value is not available.
PREV_APPC_DEVICE_DESCRIPTION	VARCHAR(10)	The previous value for the Advanced Program-to-Program Communications (APPC) device description on this system that is used with this RDB entry. Contains the null value if ENTRY_TYPE is not D, if the previous value is not available, or REMOTE_LOCATION_TYPE is not *SNA.
PREV_LOCAL_LOCATION	VARCHAR(8)	The previous value for the local location name by which this system is identified to the system on which the RDB is located. Contains the null value if ENTRY_TYPE is not D, if the previous value is not available, or REMOTE_LOCATION_TYPE is not *SNA.
PREV_REMOTE_NETWORK_ID	VARCHAR(8)	The previous value for the remote network identifier of the system on which the RDB is located. Contains the null value if ENTRY_TYPE is not D, if the previous value is not available, or REMOTE_LOCATION_TYPE is not *SNA.
PREV_REMOTE_MODE	VARCHAR(8)	The previous value for the mode name to use with the remote location name to communicate with the system on which the RDB is located. Can contain one of the following special values: Contains the null value if ENTRY_TYPE is not D, if the previous value is not available, or REMOTE_LOCATION_TYPE is not *SNA.
PREV_TRANSACTION_PROGRAM	VARCHAR(8) FOR BIT DATA	The previous value for the name of the transaction program to use with the RDB entry. Contains the null value if ENTRY_TYPE is not D, if the previous value is not available, or REMOTE_LOCATION_TYPE is not *SNA.
PREV_ARD_LIBRARY	VARCHAR(10)	The previous value for the library containing the Application Requester Driver (ARD) program. This value may be *LIBL or *CURLIB. Contains the null value if ENTRY_TYPE is not D, if REMOTE_LOCATION is not *ARDPGM, or if the previous value is not available.
PREV_ARD_PROGRAM	VARCHAR(10)	The previous value for the ARD program to be called to process SQL requests directed to the RDB. Contains the null value if ENTRY_TYPE is not D, if REMOTE_LOCATION is not *ARDPGM, or if the previous value is not available.
AUTOSTART_SERVER	VARCHAR(4)	Whether the DDM server is automatically started. This value was set using the Change DDM TCP/IP Attributes (CHGDDMTCPA) CL command. *NO Do not automatically start the DDM server. *YES Automatically start the DDM server. Contains the null value if ENTRY_TYPE is not M or if the information is not available.

Table 188. AUDIT_JOURNAL_SM table function (continued)

Column Name	Data Type	Description
LOWEST_AUTHENTICATION_METHOD	VARCHAR(10)	<p>The lowest level of password security required. This value was set using the Change DDM TCP/IP Attributes (CHGDDMTCPA) CL command.</p> <p>*ENCRYPTED User ID and encrypted password. Same as *USRENCPWD.</p> <p>*ENCUSRPWD Encrypted user ID and encrypted password.</p> <p>*KERBEROS Authentication occurs using Kerberos.</p> <p>*NO User ID only. Same as *USRID.</p> <p>*USRID User ID only.</p> <p>*USRENCPWD User ID and encrypted password</p> <p>*USRIDPWD User ID and password.</p> <p>*VLDONLY User ID only but if a password is sent on the request, it must be valid.</p> <p>*YES User ID and password. Same as*USRIDPWD.</p> <p>Contains the null value if ENTRY_TYPE is not M or D with an ACCESS_TYPE of ADD, CHANGE, REMOVE, or RETRIEVE, ENTRY_TYPE is D and REMOTE_LOCATION is not *LOCAL, or if the information is not available.</p>
LOWEST_ENCRYPTION_ALGORITHM	VARCHAR(4)	<p>The lowest encryption algorithm allowed on an incoming connection request. This value was set using the Change DDM TCP/IP Attributes (CHGDDMTCPA) CL command.</p> <p>*AES Advanced Encryption Standard (AES) allowed.</p> <p>*DES Data Encryption Standard (DES) or higher encryption algorithm allowed.</p> <p>Contains the null value if ENTRY_TYPE is not M or D with an ACCESS_TYPE of ADD, CHANGE, REMOVE, or RETRIEVE, ENTRY_TYPE is D and REMOTE_LOCATION is not *LOCAL, or if the information is not available.</p>
PREV_AUTOSTART_SERVER	VARCHAR(4)	<p>The previous value for whether the DDM server is automatically started.</p> <p>Contains the null value if ENTRY_TYPE is not M or if the previous value is not available.</p>
PREV_LOWEST_AUTHENTICATION_METHOD	VARCHAR(10)	<p>The previous value for the lowest level of password security required.</p> <p>Contains the null value if ENTRY_TYPE is not M or if the previous value is not available.</p>
PREV_LOWEST_ENCRYPTION_ALGORITHM	VARCHAR(4)	<p>The previous value for the lowest encryption algorithm allowed on an incoming connection request.</p> <p>Contains the null value if ENTRY_TYPE is not M or if the previous value is not available.</p>

Example

- List the DRDA configuration changes related to authentication made this month.

```

SELECT RDB_NAME, PREFERRED_AUTHENTICATION, LOWER_AUTHENTICATION, ENCRYPTION_ALGORITHM,
SECURE_CONNECTION FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_SM(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 1 MONTH
  )
)
WHERE ENTRY_TYPE = 'D';

```

AUDIT_JOURNAL_ST table function

The AUDIT_JOURNAL_ST table function returns rows from the audit journal that contain information from the ST (Service Tools Action) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 189. AUDIT_JOURNAL_ST table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the ST audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. A Service record
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
SERVICE_TOOL	CHAR(2)	The service tool identifier. AR ARM diagnostic trace (see ARMSRV QShell command) AS Storage altered by Display/Alter/Dump service tool or by a remote service tool debugger CD QTACTLDV, QTADMPDV CE QWTCTLTR CS STRCPYSCN CT DMPCLUTRC DC DLTCMNTRC DD DMPDLO DF QWTDMPFR, QWTDMPFL DI QSCDIRD DM DMPMEMINF DO DMPOBJ DS DMPSYSOBJ, QTADMPTS, QTADMPDV, QWTDMPFL DU DMPUSRPRF DW STRDW, ENDDW, ADDDWDFN, RMVDWDFN EC ENDCMNTRC ER ENDRMTSPT FF FFDC (First Failure Data Capture) GS QSMGSSTD HD QYHCHCOP (DASD) HL QYHCHCOP (LPAR) JW STRJW, ENDJW, ADDJWDFN, RMVJWDFN MC QWTMAINT (change) MD QWTMAINT (dump) MP End system job MQ Restart system job OP Operations console PC PRTC MNTRC PE PRTERLOG, QTADMPDV

Table 189. AUDIT_JOURNAL_ST table function (continued)

Column Name	Data Type	Description
SERVICE_TOOL (continued)		PI PRTINTDTA, QTADMPDV PS QPOFPTOS SC STRCMNTRC, QSCCHGCT SE QWTSETTR SF QWCCDSIC, QWVRCSTK (Display internal stack entry) SJ STRSRVJOB SN QPZSYNC SR STRRMTSPT SS QFPHPSF ST STRSST SV QSRSRV TA TRCTCPAPP TC TRCCNN (*FORMAT specified) TE ENDTRC, ENDPEX, TRCJOB(*OFF or *END specified) TI TRCINT, or TRCCNN with SET(*ON), SET(*OFF), or SET(*END) TO QTOBSRV TQ QWCTMQTM TS STRTRC, STRPEX, TRCJOB(*ON specified) UD QTAUPDDV WE ENDWCH, QSCEWCH WS STRWCH, QSCSWCH WT WRKTRC WW WRKWCH, QSCRWCHI, QSCRWCHL
SERVICE_TOOL_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the service tool.
OBJECT_LIBRARY	VARCHAR(10)	Name of the library for OBJECT_NAME. Contains the null value if there is no library name.
OBJECT_NAME	VARCHAR(10)	Name of the object accessed. Contains the null value if there is no object name.
OBJECT_TYPE	VARCHAR(7)	Type of object. Contains the null value if there is no object type.
OBJECT_ASP_NAME	VARCHAR(10)	ASP name for object library. Contains the null value if there is no object ASP name.
OBJECT_ASP_NUMBER	INTEGER	ASP number for object library. 1 indicates the system ASP. Contains the null value if there is no object ASP number.
DLO_NAME	VARCHAR(12)	Name of the document library object. Contains the null value if there is no document library object.
FOLDER_PATH	VARCHAR(63)	The folder containing the document library object Contains the null value if there is no folder.
SOURCE_NODE_ID	VARCHAR(8)	Source node ID. Contains the null value if there is no source node ID.
SOURCE_USER	VARCHAR(10)	Source user. Contains the null value if there is no source user.
TARGET_QUALIFIED_JOB_NAME	VARCHAR(28)	The qualified job name of the target job. Contains the null value if there is no target job.

Table 189. AUDIT_JOURNAL_ST table function (continued)

Column Name	Data Type	Description
TARGET_JOB_NAME	VARCHAR(10)	The job name of the target job. Contains the null value if there is no target job.
TARGET_JOB_USER	VARCHAR(10)	The job user of the target job. Contains the null value if there is no target job.
TARGET_JOB_NUMBER	VARCHAR(6)	The job number of the target job. Contains the null value if there is no target job.
TARGET_JOB_USER_IDENTITY	VARCHAR(10)	The job user identity value of the target job. Contains the null value if there is no target job.
DMPYSOBJ_LIBRARY	VARCHAR(30)	Name of the library for the object for DMPYSOBJ. Contains the null value when SERVICE_TOOL is not DS.
DMPYSOBJ_OBJECT	VARCHAR(30)	Name of the object for DMPYSOBJ. Contains the null value when SERVICE_TOOL is not DS.
DMPYSOBJ_TYPE	VARCHAR(7)	Type of the object for DMPYSOBJ. Contains the null value when SERVICE_TOOL is not DS.
DMPYSOBJ_ASP_NAME	VARCHAR(10)	ASP name for DMPYSOBJ object library. Contains the null value when SERVICE_TOOL is not DS.
DMPYSOBJ_ASP_NUMBER	INTEGER	ASP number for DMPYSOBJ object library. Contains the null value when SERVICE_TOOL is not DS.
AA_COMMAND_NAME	VARCHAR(30)	Advanced Analysis Command name. See QMGTTOOLS: Run AA Macros Contains the null value when SERVICE_TOOL is not GS.
EARLY_TRACE_ACTION	VARCHAR(6)	The action requested for early job tracing *OFF Early tracing turned off *ON Early tracing turned on *RESET Early tracing turned off and trace information deleted. Contains the null value when SERVICE_TOOL is not CE.
ARM_TRACE	VARCHAR(10)	ARM diagnostic trace. ACTIVATE Activate DEACTIVATE Deactivate Contains the null value when SERVICE_TOOL is not AR.
TRCTCPAPP_OPTION	VARCHAR(7)	The trace option specified on TRCTCPAPP. ENDED Collection of trace information ended and all trace information purged (no output created) STARTED Collection of trace information started STOPPED Collection of trace information stopped and trace information written to spooled file Contains the null value when SERVICE_TOOL is not TA.
APPLICATION_TRACED	VARCHAR(10)	The name of the application being traced. Contains the null value when SERVICE_TOOL is not AR or TA.
SERVICE_TOOLS_PROFILE	VARCHAR(10)	The name of the service tools profile used for Start System Service Tools (STRSST). Contains the null value when SERVICE_TOOL is not ST or OP.

Table 189. AUDIT_JOURNAL_ST table function (continued)

Column Name	Data Type	Description
CONSOLE_TYPE	VARCHAR(7)	The console type. *DIRECT *HMC *LAN Contains the null value when SERVICE_TOOL is not OP.
CONSOLE_ACTION	VARCHAR(9)	The console action. *RECOVERY *TAKEOVER Contains the null value when SERVICE_TOOL is not OP.
ADDRESS_FAMILY	VARCHAR(5)	The address family. *IPV4 *IPV6 Contains the null value when SERVICE_TOOL is not OP or CONSOLE_TYPE is not *LAN.
CURRENT_IP_ADDRESS	VARCHAR(45)	The IP address of the current console device for *LAN. Contains the null value when SERVICE_TOOL is not OP or CONSOLE_TYPE is not *LAN.
CURRENT_DEVICE_ID	VARCHAR(10)	The service tools device ID of the current console device for *LAN. Contains the null value when SERVICE_TOOL is not OP or CONSOLE_TYPE is not *LAN.
PREVIOUS_IP_ADDRESS	VARCHAR(45)	The IP address of the previous console device for *LAN. Contains the null value when SERVICE_TOOL is not OP or CONSOLE_TYPE is not *LAN or there is no previous console device.
PREVIOUS_DEVICE_ID	VARCHAR(10)	The service tools device ID of the previous console device for *LAN. Contains the null value when SERVICE_TOOL is not OP or CONSOLE_TYPE is not *LAN or there is no previous console device.
WATCH_SESSION	VARCHAR(10)	Watch session ID. Contains the null value when SERVICE_TOOL is not WE or WS.
SERVICE_TOOL_USERID	VARCHAR(10)	Service tools user ID if storage was altered from DST or *DEBUG if storage was altered by a remote service tool debugger. Contains the null value when SERVICE_TOOL is not AS.
USER_PROFILE	VARCHAR(10)	User profile name if storage was altered from SST. Contains the null value when SERVICE_TOOL is not AS.
LIC_RU_NAME	VARCHAR(8)	The Licensed Internal Code Replaceable Unit name. Contains the null value when SERVICE_TOOL is not AS.
ADDRESS_OF_ALTERED_STORAGE	BINARY(8)	Address of storage that was altered. Contains the null value when SERVICE_TOOL is not AS.
SEGMENT_TYPE	BINARY(2)	Type of segment that was altered. Contains the null value when SERVICE_TOOL is not AS.
NUMBER_OF_ALTERED_BYTES	INTEGER	The number of bytes of storage in ALTERED_STORAGE_VALUE that were changed. Contains the null value when SERVICE_TOOL is not AS.
ALTERED_STORAGE_VALUE	BINARY(16)	Altered storage value. Contains the null value when SERVICE_TOOL is not AS.
PREVIOUS_STORAGE_VALUE	BINARY(16)	Original storage value. Contains the null value when SERVICE_TOOL is not AS.

Example

- Check whether anyone has changed storage using STRSST today.

```
SELECT *
FROM TABLE (
    SYSTOOLS.AUDIT_JOURNAL_ST (STARTING_TIMESTAMP => CURRENT DATE)
)
WHERE SERVICE_TOOL = 'ST' AND NUMBER_OF_ALTERED_BYTES > 0;
```

AUDIT_JOURNAL_SV table function

The AUDIT_JOURNAL_SV table function returns rows from the audit journal that contain information from the SV (Action to System Value) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 190. AUDIT_JOURNAL_SV table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the SV audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. A Change to system values B Change to service attributes C Change to system clock D Adjustment to Coordinated Universal Time (UTC) E Change to option F Change to system-wide journal attribute
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
SYSTEM_VALUE	VARCHAR(10)	The name of the system value or service attribute that was changed. Can contain one of the following special values. CACHEWAIT Changed journal maximum cache wait time JRNRCYCNT Changed journal recovery count value QINPIDCO Change the current install disk configuration option with QINPIDCO API.
OLD_VALUE	VARCHAR(1500)	The value of the system value or service attribute before it was changed.
NEW_VALUE	VARCHAR(1500)	The new value of the system value or service attribute.

Example

- List any system value changes that have been made in the current calendar year.

```
SELECT *
FROM TABLE (
    SYSTOOLS.AUDIT_JOURNAL_SV (STARTING_TIMESTAMP => TRUNC_TIMESTAMP(CURRENT DATE, 'YEAR'))
)
WHERE ENTRY_TYPE = 'A';
```

AUDIT_JOURNAL_VP table function

The AUDIT_JOURNAL_VP table function returns rows from the audit journal that contain information from the VP (Network Password Error) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in “AUDIT JOURNAL table function common information” on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 191. AUDIT_JOURNAL_VP table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the VP audit journal entry.		
ENTRY_TYPE	CHAR(1)	The type of entry. A Authorization list (AUTL) permission failure D NetServer user disabled P Password error
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
SERVER_NAME	VARCHAR(10)	The name of the network server description that registered the event. Can contain the special value *NETSERVER.
SERVER_TIMESTAMP	TIMESTAMP(0)	The date and time when the event was logged on the network server.
AUDIT_USER_NAME	VARCHAR(10)	The name of the user.
COMPUTER_NAME	VARCHAR(45)	The name or IP address of the computer initiating the request. Contains the null value if ENTRY_TYPE is not A.

Example

- Review the Network Server password failures, by day and by server name

```
SELECT DATE(ENTRY_TIMESTAMP) AS "DATE", SERVER_NAME,  
       COUNT(*) AS NETWORK_SERVER_PASSWORD_ERROR_COUNT  
FROM TABLE (  
  SYSTOOLS.AUDIT_JOURNAL_VP(STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 7 DAYS)  
)  
GROUP BY DATE(ENTRY_TIMESTAMP), SERVER_NAME  
ORDER BY "DATE", NETWORK_SERVER_PASSWORD_ERROR_COUNT DESC;
```

AUDIT_JOURNAL_ZC table function

The AUDIT_JOURNAL_ZC table function returns rows from the audit journal that contain information from the ZC (Change to Object) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in “AUDIT JOURNAL table function common information” on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 192. AUDIT_JOURNAL_ZC table function

Column Name	Data Type	Description
The first columns returned by this table function are from the common audit journal entry header. See Common columns returned from the audit journal entry header for the column definitions. After the common columns are the following columns that describe the entry specific data for the ZC audit journal entry.		

Table 192. AUDIT_JOURNAL_ZC table function (continued)

Column Name	Data Type	Description
ENTRY_TYPE	CHAR(1)	The type of entry. C Change of an object U Upgrade of open access to an object
ENTRY_TYPE_DETAIL	VARCHAR(200)	Descriptive text that corresponds to the entry type.
ACCESS_TYPE	INTEGER	Type of access. See Numeric codes for access types for a list of the codes for access types.
ACCESS_TYPE_DETAIL	VARCHAR(50)	Descriptive text that corresponds to ACCESS_TYPE.
LIBRARY_NAME	VARCHAR(10)	The name of the library. Contains the null value if there is no library name.
OBJECT_NAME	VARCHAR(10)	The name of the object. Contains the null value if there is no object name.
OBJECT_TYPE	VARCHAR(7)	The type of object. Contains the null value if there is no object type.
MEMBER_NAME	VARCHAR(10)	The member name for a *FILE object. Contains the null value if OBJECT_TYPE is not *FILE or if there is no member name.
PREV_MEMBER_NAME	VARCHAR(10)	The previous member name for a *FILE object. Contains the null value if OBJECT_TYPE is not *FILE or if ACCESS_TYPE is not 39 (Rename).
OBJECT_ASP_NAME	VARCHAR(10)	The name of the auxiliary storage pool (ASP) in which the object resides. A value of *SYSBAS indicates the system ASP and all basic user ASPs. Contains the null value if there is no ASP information.
OBJECT_ASP_NUMBER	INTEGER	The number of the ASP device. 1 indicates the system ASP. Contains the null value if there is no ASP information.
IFS_ACCESS_TYPE	VARCHAR(50)	Integrated file system access type. See QPOLJRNL in QSYSINC/H for the list of values. Contains the null value if the operation was not for an integrated file system object.
IFS_ACCESS_TYPE_DETAIL	VARCHAR(2000) CCSID 1208	Descriptive text that corresponds to IFS_ACCESS_TYPE. The value is returned as an array within a JSON object. It is formatted as: {"IFS_ACCESS_LIST": ["first-string", "second-string", ...]}
PATH_NAME	VARGRAPHIC(5000) CCSID 1200	The path name of the object. Contains the null value if the path name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PATH_NAME_INDICATOR	VARCHAR(3)	Path name indicator: NO The PATH_NAME column does not contain an absolute path name for the object, instead it contains a relative path name. The RELATIVE_DIRECTORY_FILE_ID can be used to form an absolute path name with this relative path name. YES The PATH_NAME column contains the absolute path name for the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
RELATIVE_DIRECTORY_FILE_ID	BINARY(16)	When PATH_NAME_INDICATOR is NO, contains the file ID of the directory that contains the object identified in the PATH_NAME column. Contains the null value when PATH_NAME_INDICATOR is YES, or if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.

Table 192. AUDIT_JOURNAL_ZC table function (continued)

Column Name	Data Type	Description
IFS_OBJECT_NAME	VARGRAPHIC(512) CCSID 1200	The name of the object. Contains the null value if the object name is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
OBJECT_FILE_ID	BINARY(16)	The file ID of the object. Contains the null value if the object is not in the "root" (/), QOpenSys, or user-defined file systems.
PARENT_FILE_ID	BINARY(16)	The file ID of the parent directory. Contains the null value if the file ID is not available or the object is not in the "root" (/), QOpenSys, or user-defined file systems.
IMGCLGE_ACCESS_TYPE	VARCHAR(10)	Access type for the image catalog entry. READ The file containing the image catalog entry is read-only. READ WRITE The file containing the image catalog entry is read/write capable. Contains the null value if the operation was against an image catalog or the object type is not *IMGCLG.
IMGCLGE_INDEX_NUMBER	INTEGER	Index number of the image catalog entry. Contains the null value if the operation was against an image catalog or the object type is not *IMGCLG.
IMGCLGE_VOLUME_ID	VARCHAR(32)	Volume ID of the image catalog entry. Can contain the special value *GEN. Contains the null value if the operation was against an image catalog or the object type is not *IMGCLG.
IMGCLGE_WRITE_PROTECTION	VARCHAR(3)	The write protection for the image catalog entry. NO The file containing the image catalog entry is not write protected. YES The file containing the image catalog entry is write protected.. Contains the null value if the operation was against an image catalog or the object type is not *IMGCLG.
IMGCLGE_VIRTUAL_DEVICE	VARCHAR(10)	The name of the virtual device for the image catalog entry. Contains the null value if the operation was against an image catalog, the image catalog is not in Ready status, or the object type is not *IMGCLG.

Example

- List objects in the integrated file system that start with the letters 'data' that were modified in the last week.

```
SELECT IFS_OBJECT_NAME, PATH_NAME, ACCESS_TYPE FROM TABLE(
  SYSTOOLS.AUDIT_JOURNAL_ZC(
    STARTING_TIMESTAMP => CURRENT_TIMESTAMP - 7 DAYS
  )
)
WHERE ENTRY_TYPE = 'C' AND
      IFS_OBJECT_NAME LIKE 'data%'
ORDER BY PATH_NAME, IFS_OBJECT_NAME;
```

AUDIT_JOURNAL_ZR table function

The AUDIT_JOURNAL_ZR table function returns rows from the audit journal that contain information from the ZR (Read of Object) journal entries.

Every audit journal table function shares a common authorization requirement and a common set of parameters. These are described in [“AUDIT JOURNAL table function common information”](#) on page 664.

The result of the function is a table containing rows with the format shown in the following table. All the columns are nullable.

Table 193. AUDIT_JOURNAL_ZR table function

Column Name	Data Type	Description
