iv IBM Cognos Analytics Version 11.0: Data Modeling Guide
Chapter 1. Data modeling in Cognos Analytics

You can use data modeling in IBM® Cognos® Analytics to fuse together many sources of data, including relational databases, Hadoop-based technologies, Microsoft Excel spreadsheets, text files, and so on. Using these sources, a data module is created that can then be used in reporting and dashboarding.

Star schemas are the ideal database structure for data modules, but transactional schemas are equally supported.

You can refine a data module by creating calculations, defining filters, referencing additional tables, updating metadata, and more.

After you save data modules, other users can access them. Save the data module in a folder that users, groups, and roles have appropriate permissions to access. This procedure is the same idea as saving a report or dashboard into a folder that controls who can access it.

Data modules can be used in both dashboards and reports. A dashboard can be assembled from multiple data modules.

Tip: Data modeling in Cognos Analytics does not replace IBM Cognos Framework Manager, IBM Cognos Cube Designer, or IBM Cognos Transformer, which remain available for more complex modeling.

Intent-driven modeling

You can use intent-driven modeling to add tables to your data module. Intent-driven modeling proposes tables to include in the module, based on matches between the terms you supply and metadata in the underlying sources.

While you are typing in keywords for intent-driven modeling, text from column and table names in the underlying data sources are retrieved by the Cognos Analytics software. The intent field has a type-ahead list that suggests terms that are found in the source metadata.

Intent-driven modeling recognizes the difference between fact tables and dimension tables by the number of rows, data types, and distribution of values within columns. When possible, the intent-driven modeling proposal is a star or snowflake of tables. If an appropriate star or snowflake cannot be determined, then intent-driven modeling proposes a single table or collection of tables.
Chapter 2. Creating a data module

You can create data modules by combining inputs from other data modules, data servers, uploaded files, data sets, and packages.

When you create a new data module from the home screen of IBM Cognos Analytics, you are presented with five possible input sources in Sources. These sources are described here.

Data modules
Data modules are source objects that contain data from data servers, uploaded files, or other data modules, and are saved in My content or Team content.

Data servers
Data servers are databases for which connections exist. For more information, see Managing IBM Cognos Analytics.

Uploaded files
Uploaded files are data that are stored with the Upload files facility.

Data sets
Data sets contain extracted data from a package or a data module, and are saved in My content or Team content.

Packages
Packages are created in IBM Cognos Framework Manager and contain dimensions, query subjects, and other data contained in Cognos Framework Manager projects. You can use packages as sources for a data module.

You can combine multiple sources into one data module. After you add a source, you can use a combination of data source types in a data module.

Each type of data source is described in the following topics.

Using a data module source

Saved data modules can be used as data sources for other data modules. When a data module is used as a source for another data module, parts of that module are copied into the new data module.

Procedure
1. When you select Data modules in the Sources slide-out panel, you are presented with a list of data modules to use as input. Check one or more data modules to use as sources.
2. Click Start or Done in Selected sources to expand the data module into its component tables.
3. Drag tables into the new data module.
4. Continue to work with your new data module, and then save it.
5. If the source data module or any of its tables are deleted, then the next time that you open the new data module, tables that are no longer available have a red outline in the diagram and missing is listed in the Source fields of the Properties pane of the table.

6. A table in your new data module that is linked is read-only. You cannot modify it in the new data module in any way. You can break the link to the source data module, and modify the table, by clicking Break link in the actions for the table.

---

**Using a data server source**

Data servers are databases for which connections exist and can be used as sources for data modules.

You can use multiple data server sources for your data module.

**Before you begin**

Data server connections must already be created in Manage > Data server connections or Manage > Administration console. For more information, see Managing IBM Cognos Analytics.

**Procedure**

1. When you select Data modules in the Sources slide-out panel, you are presented with a list of data servers to use as input. Select the data server to use as a source.

2. The available schemas in the data server are listed. Choose the schema that you want to use.

   Only schemas for which metadata is preloaded are displayed. If you want to use other schemas, click Manage schemas... to load metadata for other schemas.

3. Click Start or Done in Selected sources to expand the data module into its component tables.

4. To start populating your data module, type some terms into the Intent slide-out panel and then click Go.

5. You are presented with a proposed model. Click Add this proposal to create a data module.

6. You can also drag tables from the data server schema into the data module.

**Example**

For an example data module created from a data server, see "Creating a simple data module" on page 6.

**What to do next**

If the metadata of your data server schemas changes after you create the data module, you can refresh the schema metadata. For more information, see the topic on preloading metadata from a data server connection in the Managing IBM Cognos Analytics.
Using an uploaded file source

Uploaded files are data that is stored with the Upload files facility. You can use these files as sources for a data module.

Before you begin

Supported formats for uploaded files are Microsoft Excel (.xlsx and .xls) spreadsheets, and text files that contain either comma-separated, tab-separated, semicolon-separated, or pipe-separated values. Only the first sheet in Microsoft Excel spreadsheets is uploaded. If you want to upload the data from multiple sheets in a spreadsheet, save the sheets as separate spreadsheets. Uploaded files are stored in a columnar format.

To upload a file, click Upload files on the navigation bar in the IBM Cognos Analytics home screen.

Procedure

1. When you select Uploaded files in the Sources slide-out panel, you are presented with a list of uploaded files to use as input. Check one or more uploaded files to use as sources.
2. Click Start or Done in Selected sources to expand the data module into its component tables.
3. Drag the source uploaded file into your data module to start modeling.

Using a data set source

Data sets contain data that is extracted from a package or a data module, and are saved in My content or Team content.

About this task

Procedure

1. When you select Data sets in the Sources slide-out panel, you are presented with a list of data sets to use as input. Check one or more data sets to use as sources.
2. Click Start or Done in Selected sources to expand the data set into its component tables and queries.
3. Drag tables or queries into the new data module.
4. If the data in the data sets changes, this change is reflected in your data module.

Using a package source

Packages are created in IBM Cognos Framework Manager. You can use relational, dynamic query mode packages as sources for data modules.

Procedure

1. When you select Packages in the Sources slide-out panel, you are presented with a list of packages to use as input. Check one or more packages to use as sources.
2. Click **Start** or **Done** in **Selected sources** to select the packages.
3. Drag the source packages into your data module to start modeling.

**What to do next**

When you use a package as your data source, you cannot select individual tables. You must drag the entire package into your data module. The only actions you can take are to create relationships between query subjects in the package and query subjects in the data module.

**Creating a simple data module**

You can create a simple data module based on the Great Outdoors Warehouse sales database that is included in IBM Cognos Analytics extended samples.

**Before you begin**

Install the Great Outdoors sales data warehouse database and create a connection to the database. For more information, see *Samples for IBM Cognos Analytics*.

**Procedure**

1. In the IBM Cognos Analytics welcome screen, click **New → Data module**.
2. In **Sources**, select **Data servers**.
3. In **Data servers**, select **great_outdoors_warehouse**.
4. In **great_outdoors_warehouse**, select the **GOSALES_DW** schema.
5. In **Selected sources**, click **Done**.
6. In the **Data module** panel, click the intent modeling icon 📊.
7. In the **Intent** panel, type **sales revenue**, and click **Go**. A proposed model is displayed in the **Intent** panel.
8. Click **Add Proposal**. A basic data module is created.

   In the next panel, click the module diagram icon 📊 to see the data module diagram that is automatically generated.
9. You can now explore the data module. For example, click an item in **Data module**, and then click its properties icon to view and modify the item properties. In the diagram view, try changing the **Cardinality** settings to view relationships between tables.

10. To save the data module, you have the **Save** or **Save as** options.

11. To create a report from your data module, click **Try It**. A new tab opens in your browser with IBM Cognos Analytics - Reporting open within it. Your data module is shown in **Source Data items**.

12. Drag **Product Line Code** from **Sls Product Dim** and **Quantity** from **Sls Sales Fact** into the report.

13. Click **Run options** ( ) to select an output format, and then click **Run HTML** to run the report and view the output as a web page.

**Relinking sources**

You can relink a data module source to a different source. After a successful relink, global calculations and relationships in the data module remain valid.

Here are some scenarios in which relinking a source can be useful:

- You build and test a data module against a test source. When the data module is ready, you relink the source to the intended production source.
- The current source in your data module is invalid, and you must use a new, valid source.
- You want to relink your data module from one data server to another data server, or from one schema to another schema.

Relink between different types of data servers is supported, as well as between schemas and catalogs within data servers.

**Tip:** Data server sources can be organized into schemas, catalogs, both, or none.
About this task

The relinked (target) source must be of the same type as the original source. A data server can be relinked only to a data server, an uploaded file to an uploaded file, and so on.

In addition to the matching source types, the following conditions must be met:

- All columns from the original source must exist in the target source, and the columns Identifier properties (case-sensitive) and data types must match.
  For example, file A with columns ColA and ColB can be relinked to file B with columns Co1A and Co1B. Relinking to file B with columns co1A and co1B would not work.

  The data types of the matching columns must be compatible for the data module calculations and relationships to remain valid. For example, if the column data type in the original source is date, the column data type in the target source must also be date, and not string or timestamp.

- For data servers, packages, and data modules, all tables from the original source must exist in the target source, and the tables Identifier properties (case-insensitive) must match.

  If a duplicate match is found in the target source, the last table in the list is used for the match.

- Extra columns and tables can exist in the target source.

  When relinking to a source that contains a table with extra columns, you can add the extra columns to the table in the data module by dragging the table from the Sources pane to the Data module pane.

- The source names, such as file and package names or data server connection names, do not need to match.

  Tip: Columns and tables matching is done by comparing their Identifier property. The column or table Identifier value can be, but not always is, the same as the column or table name (Label). You can view the Identifier value in the column or table Properties pane, Advanced section.

Procedure

1. From Team content or My content, open your data module.
2. In the Sources pane, find the source that you want to relink.
3. From the source context menu, select Relink.
4. Select the source type that matches the original source type. If the original source is data server, select data server, if it's an uploaded file, select a file, and so on.
5. Click Done.

  If the relink was successful, a confirmation message is displayed.

  If the relink finished with errors, a message is displayed that suggests opening the validation view where the relink issues are listed. Resolve the issues, and save the data module. You can also save the data module with unresolved issues.

  Important: The validation process does not detect incompatible data types on columns. If there are columns with incompatible data types in your sources, and all other relink conditions are met, the successful relink message is displayed. This type of data issues must be reconciled in the sources.
Results

After you successfully relink a source in a data module, reports and dashboards that are based on this data module can start using the new source without any involvement from report authors.
Chapter 3. Refining a data module

The initial data module that you create manually or using intent modeling might contain data that is not required for your reporting purposes. Your goal is to create a data module that contains only the data that meets your reporting requirements and that is properly formatted and presented.

For example, you can delete some tables from your initial data module, or add different tables. You can also apply different data formatting, filter and group the data, and change the metadata properties.

You can refine your data module by applying the following modifications:

- Add or delete tables.
- Edit or create new relationships between tables.
- Change column properties.
- Create basic and custom calculations.
- Create navigation paths.
- Define filters.
- Group data.
- Clean the text data.
- Hide tables and columns.

You can initiate these actions from the Data module panel or from the diagram.

When working in a data module, you can use the undo and redo actions in the application bar to revert or restore changes to the data module in the current editing session. You can undo or redo up to 20 times.

Source panel

The source panel shows the sources of data that were selected when the data module was created. The types of sources can include other data modules, data servers, uploaded files, data sets, and packages.

Except for packages, you can expand the specific source to view its tables and columns. Drag tables onto the data module panel or onto the diagram to add them to the data module.

Data module panel

The data module tree shows the tables and columns of data that is included in the data module. This is the primary space for editing the data module.

Click the context menu icon for the module, table, or column to view its modeling and editing context menu options. Here you can start joining tables, creating filters and calculations, or renaming and deleting items.

Click the intent modeling icon in the panel toolbar to add tables to your data module. Intent-driven modeling proposes tables to include in the module that are
based on matches between the terms you supply and metadata in the underlying sources.

**Diagram**

The diagram is a graphical representation of table relationships in a data module. You can use the diagram to examine the relationships, edit the data module, and view the cardinality information for the relationships.

Right-click a table in the diagram to view the table context menu that can be your starting point for creating joins or filters, renaming the table, viewing the table properties, or removing it from the module.

Click any table join to see the join summary information that includes the matching keys. When you right-click the join line, the context menu appears with options for editing or deleting the join.

Select the **Cardinality** check box to show the cardinality of relationships between different tables in your data module. Move the **Degrees of separation** slider. Depending on the slider position, the diagram shows different distances of relationships between tables.

**Data view**

You can use the data view to examine the actual data in table columns and rows.

Select a table in the data module tree or in the diagram, and click the grid icon to open the data view.

**Validation view**

You can use the validation view to examine errors that are identified by the validation process.

The messages are displayed after you start the **Validate** operation anywhere in the modeling user interface, and the failed validation icon is displayed for tables, columns, expressions, or joins where errors are discovered.

**Relationships**

A relationship joins logically related objects that the users want to combine in a single query. Relationships exist between two tables.

You can modify or delete relationships, or create new ones so that the data module properly represents the logical structure of your business. Verify that the relationships that you require exist in the data module, the cardinality is set correctly, and referential integrity is enforced.

The diagram provides a graphical view of table relationships in a data module. You can use the diagram to create, examine, and edit the relationships.

**Creating a relationship from scratch**

You need to create relationships whenever the required relationships are not detected by the IBM Cognos software.
About this task

Relationships can be created between tables from the same source and from different sources.

The diagram is the most convenient place to view all data module relationships, and quickly discover the disconnected tables.

Important: The list of possible keys in the relationship editor excludes measures. This means that if a row in a column was misidentified as a measure, but you want to use it as an identifier, you will not see the row in the key drop-down list. You need to examine the data module to confirm that the usage property is correct on each column in the table.

Procedure

1. In the data module tree or in the diagram, click the table for which you want to create a relationship, and from the context menu, click Create relationship.

   Tip: You can also start creating a relationship using the following methods:
   - In the data module tree or in the diagram, control-click the two tables that you want to join in a relationship, and click Create relationship.
   - On the Relationships tab in the table properties, click Create a relationship.

   If the data module does not include the table that you need, you can drag this table from Selected sources directly onto the diagram.

2. In the relationship editor, specify the second table to include in the relationship, and then select the matching columns in both tables.

   Depending on the method that you used to start the relationship, the second table might already be added, and you only need to match the columns. You can include more than one set of matching rows in both tables.

3. Find the matching columns in both tables, and select Match selected columns.

4. Specify the Relationship Type, Cardinality, and Optimization options for the relationship.

5. Click OK.

Results

The new relationship appears on the Relationships tab in the properties page of the tables that you joined, and in the diagram view.

To view or edit all relationships defined for a table, go to the Relationships tab in the table properties. Click the relationship link, and make the modifications. To view a relationship from the diagram, click the join line to open a small graphical view of the relationship. To edit a relationship from the diagram, right-click the join line, and click Edit relationship.

To delete a relationship for a table, go to the Relationships tab in the table properties, and click the remove icon for the required relationship. To delete the relationship from the diagram, right-click the line joining the two tables, and click Remove.
Calculations

Calculations allow you to answer questions that cannot be answered by the source columns.

The following product features are based on underlying calculations:
- Basic arithmetic calculations and field concatenations.
- Custom groups.
- Cleaning text data.
- Custom calculations.

Creating basic calculations
You can create basic arithmetic calculations for columns with numeric data types, and concatenate text values for columns with the text data type.

About this task
The expression for these calculations is predefined and you only need to select it. For example, you can create a column Revenue by multiplying values for Quantity and Unit price. You can create a column Name by combining two columns: First name and Last name.

Procedure
1. To create a simple arithmetic calculation for columns with numeric data types, use the following steps:
   a. In the data module tree, right-click the column for which you want to create a calculation. For calculations that are based on two columns, use control-click to select the columns.
   b. In the Create calculation box, type a name for the calculation.
   c. If the calculation is based on one column, type the number to use in the calculation.
   
      Tip: The link Use calculation editor opens the expression editor.
   d. Click OK.
2. To create a calculation that concatenates values for columns with the text data type, use the following steps:
   a. In the data module tree, control-click the two columns that you want to combine into a single column. Depending on which column you select first, its value appears at the beginning of the combined string.
   b. Click Create a calculation, and select the suggested option.
   c. Type a name for the calculation.
   d. Click OK.

Results
In the table that you added the calculation to, you can now see a new calculated column at the end of the list of columns.

Grouping data
You can organize the column data into custom groups so that the data is easier to read and analyze.
About this task

You can create two types of custom groups depending on the data type of the column: one group type for columns with numeric data and the second group type for columns with text data. For example, in the Employee code column you can group employees into ranges, such as 0-100, 101-200, 200+. In the Manager column, you can group managers according to their rank, such as First line manager, Senior manager, and so on.

Procedure

1. In the data module tree, right-click the column that you want to group on, and click Custom groups.
2. If you selected a numeric column, specify the grouping in the following way:
   a. Specify how many groups you want to create.
   b. Specify the distribution of the values to be either Equal distribution or Custom.
   c. If you chose Equal distribution, specify the values to be contained in each group by typing the numbers or clicking the scroll bars.
   d. If you chose Custom, you can enter your own range values for the group.
   e. Optional: Change the group name.
   f. Click Create.
3. If you selected a text column, specify the grouping in the following way:
   a. Control-select the values to include in the first group.
   b. In the Groups column, click the plus sign.
   c. Specify the name for the group, and click OK. The values are added in the Group members column, and the name of the group appears in the Groups column. You can add additional values to a group after it is created, and you can remove values from a group. You can also remove a group.
   d. Optional: To add another group, repeat the steps for the first group.
   e. Optional: To create a group that contains all of the values that aren’t already included in a group, select the Group remaining and future values in check box, and specify a name for the group.
   f. Click Create.

Results

The custom group column that is based on your selections appears at the end of the list of columns in the table. A group expression is automatically created in the expression editor. To view the expression, go to the column properties page and click on the expression that is shown for the Expression property.

Tip: To complete the action of creating the custom group, you can click Replace instead of Create. This option will replace the column name in the table with the group name.

Cleaning data

Data is often messy and inconsistent. You might want to impose some formatting order on your data so that it’s clearer and easier to read.
About this task

The Clean options that are available for a column depend on the column data type. Some options can be specified for multiple columns with the same data type, and some for singular columns only.

The following options are available to clean your data:

Whitespace
   Trim leading and trailing whitespace
   Select this check box to remove leading and trailing whitespace from strings.

Convert case to
   UPPERCASE, lowercase, Do not change
   Use this option to change the case of all characters in the string to either uppercase or lowercase, or to ensure that the case of each individual character is unchanged.

Return a substring of characters
   Return a string that includes only part of the original string in each value. For example, an employee code can be stored as CA096670, but you need only the number 096670 so you use this option to remove the CA part. You can specify this option for singular columns only.
   For the Start value, type a number that represents the position of a character in the string that will start the substring. Number 1 represents the first character in the string. For the Length value, specify the number of characters that will be included in the substring.

NULL values

Specify NULL-handling options for columns with text, numeric, date, and time data types that allow NULL values. When Cognos Analytics detects that a column does not allow NULL values, these options are not available for that column.
   The default value for each option depends on the column data type. For text data, the default is an empty string. For numbers, the default is 0. For dates, the default is 2000-01-01. For time and time (timestamp), the default is 12:00:00. For date and time (timestamp), the default is 2000-01-01T12:00:00.
   The entry field for each option also depends on the column data type. For text, the entry field accepts alphanumeric characters, for numbers, the entry field accepts only numeric input. For dates, a date picker is provided to select the date, and for time, a time picker is provided to select the time.
   The following NULL-handling options are available:

Replace this value with NULL
   Replaces the text, numbers, date, and time values, as you specify in the entry field, with NULL.
   For example, if you want to use an empty string instead of NULL in a given column, but your uploaded file sometimes uses the string n/a to indicate that the value is unknown, you can replace n/a with NULL, and then choose to replace NULL with the empty string.

Replace NULL values with
   Replaces NULL values with text, numbers, date, and time values, as you specify in the entry field.
   For example, for the Middle Name column, you can specify the following
values to be used for cells where middle name does not exist: n/a, none, or the default empty string. For the Discount Amount column, you can specify 0.00 for cells where the amount is unknown.

**Procedure**

1. In the data module tree, click the context menu icon \[ icon \] for a column, and click **Clean**.

   **Tip:** To clean data in multiple columns at once, control-select the columns that you want to clean. The **Clean** option is available only if the data type of each selected column is the same.

2. Specify the options that are applicable for the selected column or columns.

3. Click **Clean**.

**Results**

After you complete the **Clean** operation, the expression editor automatically creates an expression for the modified column or columns. To view the expression, open the column properties panel, and click the expression that is shown for the **Expression** property.

**Creating custom calculations**

To create a custom calculation, you must define your own expression using the expression editor.

**About this task**

Custom calculations can be created at the data module level or at the table level. The module-level calculations can reference columns from multiple tables.

For information about the functions that you can use to define your expressions, see [Appendix A, “Using the expression editor,” on page 25](#).

**Procedure**

1. In the data module tree, right-click the data module name or a specific table name, and click **Create custom calculation**.

2. In the **Expression editor** panel, define the expression for your calculation, and specify a name for it.
   - To enter a function for your expression, type the first character of the function name, and select the function from the drop-down list of suggested functions.
   - To add table columns to your expression, drag-and-drop one or more columns from the data module tree to the expression editor panel. The column name is added where you place the cursor in the expression editor.

   **Tip:** You can also double-click the column in the data module tree, and the column name appears in the expression editor.

3. Click **Validate** to check if the expression is valid.

4. After successful validation, click **OK**.
Results

If you created your calculation at the data module level, the calculation is added after the last table in the data module tree. If you created your calculation at the table level, the calculation is added at the end of the list of columns in the table. To view the expression for the calculation, open the calculation properties panel, and click on the expression that is shown for the Expression property.

Creating navigation paths

A navigation path is a collection of non-measure columns that business users might associate for data exploration.

When a data module contains navigation paths, the dashboard users can drill down and back to change the focus of their analysis by moving between levels of information. The users can drill down from column to column in the navigation path by either following the order of columns in the navigation path, or by choosing the column to which they want to proceed.

About this task

You can create a navigation path with columns that are logically related, such as year, month, quarter, week. You can also create a navigation path with columns that are not logically related, such as product, customer, state, city.

Columns from different tables can be added to a navigation path. The same column can be added to multiple navigation paths.

A data module can have multiple navigation paths.

Procedure

1. In the data module panel, start creating a navigation path by using one of the following methods:

   - From the data module context menu, click Properties, and then click the Navigation paths tab. Click Add a navigation path. In the Create navigation path dialog box, drag columns from the data module panel to the navigation path panel. Change the order of columns as needed. Click OK.
   - In the data module tree, select one or more columns, and from the context menu of any of the selected columns, click Create navigation path. The selected columns are listed in the Create navigation path dialog box. Click OK.

   Tip: The default name of the navigation path includes names of the first and last column in the path. You can change this name.

2. Save the data module to preserve the navigation path.

3. To modify a navigation path, from the data module context menu, click Properties, and then click the Navigation paths tab. Click the Edit link for the path that you want to modify. In the Edit navigation path dialog box, you can make the following modifications:

   - To add different columns, drag the columns from the data module to the navigation path. You can multi-select columns and drag them all at once.
Results

The navigation path is added to the data module and is available to users in dashboards and stories. If you select the option Identify navigation path members in the data module toolbar, the columns that are members of the navigation path are underlined.

What to do next

The modeler can modify the navigation path at any time, and re-save the data module.

To view the navigation path that a column belongs to, from the column context menu, click Properties > Navigation paths. Click the navigation path name to view or modify its definition.

To view all navigation paths in a data module, from the data module context menu, click Properties > Navigation paths. Click the navigation path name to view or modify its definition. To delete a navigation path, click the remove icon for the path.

Filtering data

A filter specifies the conditions that rows must meet to be retrieved from a table.

About this task

The filter is based on a specific column in a table, but it affects the whole table. Also, only rows that meet the filter criteria are retrieved from other tables.

You can create filters at the table level, which allows you to add multiple filters at once, or at the column level.

Procedure

1. In the data module tree or in the diagram, locate the table for which you want to create filters.
2. Expand the table in the data module panel, and from the column context menu, click Filter.
   
   Tip: You can also right-click the table in the diagram, and click Manage filters from there.
3. Select the filter values in the following way:
   a. If the column data type is integer, you have two options to specify the values: Range and Individual items. When you choose Range, use the
slider to specify the value ranges. When you choose Individual items, select the check boxes associated with the values.

b. For columns with numeric data types other than integer, use the slider to specify the range values.

c. For columns with date and time (timestamp) data types, specify a range of values before, after, or between the selected date and time, or select individual values.

d. For columns with text data types, select the check boxes associated with the values.

4. Optional: To select values that are outside the range that you specified, click Invert.

5. Click OK.

Results

After you create a filter, the filter icon is added for the table and column in the data module panel and in the diagram.

What to do next

To view, edit, or remove the filters defined for a table, select the Manage filters context menu option for the table, and click the Filters tab in the table properties.

To edit the filter, click its expression, make the modifications, and click OK. To remove a filter from the table, select the remove icon for the filter.

Tip: To edit a filter on a single column, from the column context menu in the data module panel, click Filter to open the filter definition.

Hiding tables and columns

You can hide a table or column in a data module. The hidden tables or columns remain visible in the modeling interface, but they are not visible in the reporting and dashboar ding interfaces. The hidden items are fully functional in the product.

About this task

Use this feature to provide an uncluttered view of metadata for the report and dashboard users. For example, when you hide columns that are referenced in a calculation, the metadata tree in the reporting and dashboar ding interfaces shows only the calculation column, but not the referenced columns. When you hide the identifier columns used as keys for joins, the keys are not exposed in the dashboar ding and reporting interfaces, but the joins are functional in all interfaces.

Procedure

1. In the data module tree, click the context menu icon for a table or column, and click Hide.
   You can also select multiple tables or columns to hide them at once.
Tip: To un-hide the items, click the context menu icon for the hidden table or column, and click Show.

2. Save the data module.

Results

The labels on the hidden tables and columns are grayed out in the data module tree and in the diagram. Also, on the General tab of the table or column properties, the check box This item is hidden from users is selected.

The hidden tables and columns are not visible in the reporting and dashboarding interfaces.

Validating data modules

Use the validation feature to check for invalid object references within a data module.

About this task

Validation identifies the following errors:

- A table or column that a data module is based on no longer exists in the source.
- A calculation expression is invalid.
- A filter references a column that no longer exists in the data module.
- A table or column that is referenced in a join no longer exists in the data module.

Errors in the data module are identified by the failed validation icon.

Procedure

1. In the data module tree, click the data module context menu icon, and click Validate.

   If errors are identified, the failed validation icon is displayed in the data module tree, in the diagram, and in the properties panel, next to the column or expression where the error exists. The descriptions of errors are displayed in the validation view.

   Tip: To open the validation view, click its icon.

2. Click the failed validation icon for a module, column, expression, or join to view a pop-up box that informs you of the number of errors for the selected item. Double-click the failed validation icon in the pop-up box to view the error details.

Results

Using the validation messages, try to resolve the errors. You can save a data module with validation errors in it.
Table and column properties

You can view and modify the table and column properties in a data module.

The properties can be accessed from the table or column context menu, on the Properties panel, General tab.

Label

Specifies the table or column name. You can change the name as needed.

This item is hidden from users

Use this property to hide a table or column in a data module. The hidden tables or columns remain visible in the modeling interface, but are not visible in the reporting and dashboarding interfaces. For more information, see “Hiding tables and columns” on page 20.

Expression

Shows the underlying expression for a column. Clicking the expression opens the expression editor where you can modify the expression.

Comments

Use this property to specify optional information about the table or column. The comment is not available outside of the modeling environment.

Screen tip

Use this property to specify an optional, short description of the table or column. The screen tip appears when you pause your pointer over the table or column name in the modeling, reporting, or dashboarding environment.

Usage

This property identifies the intended use for the data in the column.

The initial property value is based on the type of data that the column represents in the source. You need to verify that the property is set correctly. For example, if you import a numeric column that participates in a relationship, the Usage property is set to Identifier. You can change this property.

The following Usage types are supported:

- Identifier
  Represents a column that is used to group or summarize data in a Measure column with which it has a relationship. It can also represent an index, date, or time column type. For example, Invoice number, or Invoice date.
- Measure
  Represents a column that contains numeric data that can be grouped or summarized, such as Product Cost.
- Attribute
  Represents a column that is not an Identifier or a Measure, such as Description.
**Aggregate**

The **Aggregate** property defines the type of aggregation that is applied to a column that summarizes data in a report or dashboard. For example, if the **Aggregate** property value of the Quantity column is **Total**, and it is grouped by **Product Name** in a report, the Quantity column in the report shows the total quantity of each product. Aggregated data improves query performance and helps to retrieve data faster.

The default type of aggregation is inherited from the source. When modifying this property, you can select values that the source does not provide, such as average or maximum. To know which aggregate value is required, you must understand what your data represents. For example, if you aggregate **Part number**, the aggregate values that apply are count, count distinct, maximum, and minimum.

The following aggregation types are supported:
- None (no aggregation is set up for a column)
- Average
- Count
- Count distinct
- Maximum
- Minimum
- Total

**Data type**

The column data type is inherited from the source and can’t be modified in the data module.

**Represents**

Use this property to specify whether a column includes the date/time or geographic location type of data. This information is used in the reporting and dashboarding environments to suggest the most appropriate default visualizations, among other possibilities.
- Geographic location
  - The values include **Continent**, **Sub Continent**, **Country**, **Region**, **State Province**, **County**, **City**, **Postal code**, **Street Address**, **Position**, **Latitude**, and **Longitude**.
- Time
  - The values include **Date**, **Year**, **Quarter**, **Season**, **Month**, **Week**, **Day**, **Hour**, **Minute**, and **Second**.

**Sorting**

Use this property to enable or disable sorting for a column, and to specify the row to sort by, the sorting order, and the placement of NULL values in the column.

**Identifier**

For tables and columns, the property value is inherited from the source and cannot be changed in the data module. The column or table **Identifier** value can be, but not always is, the same as the column or table name (**Label**).
You can view the **Identifier** property in the **Advanced** section of the **Properties** panel.

**Source**

Shows the source name and path for a table or column. You can view the **Source** property in the **Advanced** section of the **Properties** panel.
Appendix A. Using the expression editor

An expression is any combination of operators, constants, functions, and other components that evaluates to a single value. You build expressions to create calculation and filter definitions. A calculation is an expression that you use to create a new value from existing values that are contained within a data item. A filter is an expression that you use to retrieve a specific subset of records.

Operators

Operators specify what happens to the values on either side of the operator. Operators are similar to functions, in that they manipulate data items and return a result.

(  
Identifies the beginning of an expression.

Syntax

( expression )

)  
Identifies the end of an expression.

Syntax

( expression )

*  
Multiplies two numeric values.

Syntax

value1 * value2

/  
Divides two numeric values.

Syntax

value1 / value2

||  
Concatenates, or joins, strings.

Syntax

string1 || string2

+  
Adds two numeric values.

Syntax

value1 + value2
- Subtracts two numeric values or negates a numeric value.

**Syntax**

```
value1 - value2
or
- value
```

<

Compares the values that are represented by "value1" against "value2" and retrieves the values that are less than "value2".

**Syntax**

```
value1 < value2
```

<=

Compares the values that are represented by "value1" against "value2" and retrieves the values that are less than or equal to "value2".

**Syntax**

```
value1 <= value2
```

<>

Compares the values that are represented by "value1" against "value2" and retrieves the values that are not equal to "value2".

**Syntax**

```
value1 <> value2
```

=

Compares the values that are represented by "value1" against "value2" and retrieves the values that are equal to "value2".

**Syntax**

```
value1 = value2
```

>

Compares the values that are represented by "value1" against "value2" and retrieves the values that are greater than "value2".

**Syntax**

```
value1 > value2
```

>=

Compares the values that are represented by "value1" against "value2" and retrieves the values that are greater than or equal to "value2".

**Syntax**

```
value1 >= value2
```
and

Returns "true" if the conditions on both sides of the expression are true.

**Syntax**

```
argument1 and argument2
```

between

Determines if a value falls in a given range.

**Syntax**

```
expression between value1 and value2
```

**Example**

```
[Revenue] between 200 and 300
```

**Result**

Returns the number of results with revenues between 200 and 300.

**Result data**

<table>
<thead>
<tr>
<th>Revenue</th>
<th>Between</th>
</tr>
</thead>
<tbody>
<tr>
<td>$332.06</td>
<td>false</td>
</tr>
<tr>
<td>$230.55</td>
<td>true</td>
</tr>
<tr>
<td>$107.94</td>
<td>false</td>
</tr>
</tbody>
</table>

case

Works with when, then, else, and end. Case identifies the beginning of a specific situation, in which when, then, and else actions are defined.

**Syntax**

```
case expression { when expression then expression } [ else expression ] end
```

contains

Determines if "string1" contains "string2".

**Syntax**

```
string1 contains string2
```

distinct

A keyword used in an aggregate expression to include only distinct occurrences of values. See also the function unique.

**Syntax**

```
distinct dataItem
```

**Example**

```
count ( distinct [OrderDetailQuantity] )
```

**Result**

else

Works with the if or case constructs. If the if condition or the case expression are not true, then the else expression is used.

**Syntax**

```
if ( condition ) then .... else ( expression ) , or case .... else ( expression ) end
```

end

Indicates the end of a case or when construct.

**Syntax**

```
case .... end
```

ends with

Determines if "string1" ends with "string2".

**Syntax**

```
string1 ends with string2
```

if

Works with the then and else constructs. If defines a condition; when the if condition is true, the then expression is used. When the if condition is not true, the else expression is used.

**Syntax**

```
if ( condition ) then ( expression ) else ( expression )
```

in

Determines if "expression1" exists in a given list of expressions.

**Syntax**

```
expression1 in ( expression_list )
```

is missing

Determines if "value" is undefined in the data.

**Syntax**

```
value is missing
```

like

Determines if "string1" matches the pattern of "string2", with the character "char" optionally used to escape characters in the pattern string.

**Syntax**

```
string1 LIKE string2 [ ESCAPE char ]
```
Example 1

[PRODUCT_LINE] like 'G%'

Result

All product lines that start with 'G'.

Example 2

[PRODUCT_LINE] like '%G%' escape 'a'

Result

All the product lines that end with 'G%'.

lookup

Finds and replaces data with a value you specify. It is preferable to use the case construct.

Syntax

lookup( name ) in ( value1 --> value2 ) default( expression )

Example

lookup ( [Country] ) in ( 'Canada' --> ( [List Price] * 0.60), 'Australia' --> ( [List Price] * 0.80 ) ) default( [List Price] )

not

Returns TRUE if "argument" is false or returns FALSE if "argument" is true.

Syntax

NOT argument

or

Returns TRUE if either of "argument1" or "argument2" are true.

Syntax

argument1 or argument2

starts with

Determines if "string1" starts with "string2".

Syntax

string1 starts with string2

then

Works with the if or case constructs. When the if condition or the when expression are true, the then expression is used.

Syntax

if ( condition ) then ... , or case expression when expression then ... end
when
Works with the case construct. You can define conditions to occur when the WHEN expression is true.

Syntax
case [expression] when ... end

Summaries
This list contains predefined functions that return either a single summary value for a group of related values or a different summary value for each instance of a group of related values.

Statistical functions
This list contains predefined summary functions of statistical nature.

standard-deviation
Returns the standard deviation of selected data items.

Syntax
standard-deviation ( expression [ auto ] )
standard-deviation ( expression for [ all | any ] expression { , expression } )
standard-deviation ( expression for report )

Example
standard-deviation ( ProductCost )

Result
Returns a value indicating the deviation between product costs and the average product cost.

variance
Returns the variance of selected data items.

Syntax
variance ( expression [ auto ] )
variance ( expression for [ all | any ] expression { , expression } )
variance ( expression for report )

Example
variance ( Product Cost )

Result
Returns a value indicating how widely product costs vary from the average product cost.

average
Returns the average value of selected data items. Distinct is an alternative expression that is compatible with earlier versions of the product.
Syntax
average ( [ distinct ] expression [ auto ] )
average ( [ distinct ] expression for [ all|any ] expression { , expression } )
average ( [ distinct ] expression for report )

Example
average ( Sales )

Result
Returns the average of all Sales values.

count
Returns the number of selected data items excluding null values. Distinct is an alternative expression that is compatible with earlier versions of the product. All is supported in DQM mode only and it avoids the presumption of double counting a data item of a dimension table.

Syntax
count ( [ all | distinct ] expression [ auto ] )
count ( [ all | distinct ] expression for [ all | any ] expression { , expression } )
count ( [ all | distinct ] expression for report )

Example
count ( Sales )

Result
Returns the total number of entries under Sales.

maximum
Returns the maximum value of selected data items. Distinct is an alternative expression that is compatible with earlier versions of the product.

Syntax
maximum ( [ distinct ] expression [ auto ] )
maximum ( [ distinct ] expression for [ all | any ] expression { , expression } )
maximum ( [ distinct ] expression for report )

Example
maximum ( Sales )

Result
Returns the maximum value out of all Sales values.

median
Returns the median value of selected data items.
Syntax
median ( expression [ auto ] )
median ( expression for [ all|any ] expression { , expression } )
median ( expression for report )

minimum
Returns the minimum value of selected data items. Distinct is an alternative expression that is compatible with earlier versions of the product.

Syntax
minimum ( [ distinct ] expression [ auto ] )
minimum ( [ distinct ] expression for [ all|any ] expression { , expression } )
minimum ( [ distinct ] expression for report )

Example
minimum ( Sales )

Result
Returns the minimum value out of all Sales values.

percentage
Returns the percent of the total value for selected data items. The "<for-option>" defines the scope of the function. The "at" option defines the level of aggregation and can be used only in the context of relational datasources.

Syntax
percentage ( numeric_expression [ at expression { , expression } ]
[ <for-option> ] [ prefiltex ] )
percentage ( numeric_expression [ <for-option> ] [ prefiltex ] )
<for-option> ::= for expression { , expression } | for report | auto

Example
percentage ( Sales 98 )

Result
Returns the percentage of the total sales for 1998 that is attributed to each sales representative.

Result data

<table>
<thead>
<tr>
<th>Employee</th>
<th>Sales 98</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gibbons</td>
<td>60646</td>
<td>7.11%</td>
</tr>
<tr>
<td>Flertjan</td>
<td>62523</td>
<td>7.35%</td>
</tr>
<tr>
<td>Cornel</td>
<td>22396</td>
<td>2.63%</td>
</tr>
</tbody>
</table>

percentile
Returns a value, on a scale of one hundred, that indicates the percent of a distribution that is equal to or below the selected data items. The "<for-option>" defines the scope of the function. The "at" option defines the level of aggregation and can be used only in the context of relational datasources.
Syntax

percentile ( numeric_expression [ at expression { , expression } ]
[ <for-option> ] [ prefilter ] )
percentile ( numeric_expression [ <for-option> ] [ prefilter ] )
<for-option> ::= for expression { , expression } for report|auto

Example

percentile ( Sales 98 )

Result

For each row, returns the percentage of rows that are equal to or less than the quantity value of that row.

Result data

<table>
<thead>
<tr>
<th>Qty</th>
<th>Percentile (Qty)</th>
</tr>
</thead>
<tbody>
<tr>
<td>800</td>
<td>1</td>
</tr>
<tr>
<td>700</td>
<td>0.875</td>
</tr>
<tr>
<td>600</td>
<td>0.75</td>
</tr>
<tr>
<td>500</td>
<td>0.625</td>
</tr>
<tr>
<td>400</td>
<td>0.5</td>
</tr>
<tr>
<td>400</td>
<td>0.5</td>
</tr>
<tr>
<td>200</td>
<td>0.25</td>
</tr>
<tr>
<td>200</td>
<td>0.25</td>
</tr>
</tbody>
</table>

quantile

Returns the rank of a value within a range that you specify. It returns integers to represent any range of ranks, such as 1 (highest) to 100 (lowest). The "<for-option>" defines the scope of the function. The "at" option defines the level of aggregation and can be used only in the context of relational datasources.

Syntax

quantile ( numeric_expression , numeric_expression [ at expression { ,
expression } ] [ <for-option> ] [ prefilter ] )
quantile ( numeric_expression , numeric_expression [ <for-option> ]
[ prefilter ] )
<for-option> ::= for expression { , expression } for report|auto

Example

quantile ( Qty , 4 )

Result

Returns the quantity, the rank of the quantity value, and the quantity values broken down into 4 quantile groups (quartiles).

Result data

<table>
<thead>
<tr>
<th>Qty</th>
<th>Rank</th>
<th>Quantile (Qty, 4)</th>
</tr>
</thead>
<tbody>
<tr>
<td>800</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>700</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>600</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>500</td>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>400</td>
<td>5</td>
<td>3</td>
</tr>
</tbody>
</table>
quartile

Returns the rank of a value, represented as integers from 1 (highest) to 4 (lowest), relative to a group of values. The "<for-option>" defines the scope of the function. The "at" option defines the level of aggregation and can be used only in the context of relational datasources.

Syntax

quartile ( numeric_expression [ at expression { , expression } ] [ <for-option> ] [ prefilter ] )
quartile ( numeric_expression [ <for-option> ] [ prefilter ] )
<for-option> ::= for expression { , expression }|for report|auto

Example

quartile ( Qty )

Result

Returns the quantity and the quartile of the quantity value represented as integers from 1 (highest) to 4 (lowest).

Result data

<table>
<thead>
<tr>
<th>Qty</th>
<th>Quartile (Qty)</th>
</tr>
</thead>
<tbody>
<tr>
<td>450</td>
<td>1</td>
</tr>
<tr>
<td>400</td>
<td>1</td>
</tr>
<tr>
<td>350</td>
<td>2</td>
</tr>
<tr>
<td>300</td>
<td>2</td>
</tr>
<tr>
<td>250</td>
<td>3</td>
</tr>
<tr>
<td>200</td>
<td>3</td>
</tr>
<tr>
<td>150</td>
<td>4</td>
</tr>
<tr>
<td>100</td>
<td>4</td>
</tr>
</tbody>
</table>

rank

Returns the rank value of selected data items. The sort order is optional; descending order (DESC) is assumed by default. If two or more rows tie, then there is a gap in the sequence of ranked values (also known as Olympic ranking). The "<for-option>" defines the scope of the function. The "at" option defines the level of aggregation and can be used only in the context of relational datasources. Distinct is an alternative expression that is compatible with earlier versions of the product. Null values are ranked last.

Syntax

rank ( expression [ ASC|DESC ] { , expression [ ASC|DESC ] } [ at expression { , expression } ] [ <for-option> ] [ prefilter ] )
rack ( [ distinct ] expression [ ASC|DESC ] { , expression [ ASC|DESC ] } [ <for-option> ] [ prefilter ] )
<for-option> ::= for expression { , expression }|for report|auto
Example

```plaintext
rank ( Sales 98 )
```

Result

For each row, returns the rank value of sales for 1998 that is attributed to each sales representative. Some numbers are skipped when a tie between rows occurs.

Result data

<table>
<thead>
<tr>
<th>Employee</th>
<th>Sales 98</th>
<th>Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gibbons</td>
<td>60000</td>
<td>1</td>
</tr>
<tr>
<td>Flertjan</td>
<td>50000</td>
<td>2</td>
</tr>
<tr>
<td>Cornel</td>
<td>50000</td>
<td>2</td>
</tr>
<tr>
<td>Smith</td>
<td>48000</td>
<td>4</td>
</tr>
</tbody>
</table>

**tertile**

Returns the rank of a value as High, Middle, or Low relative to a group of values.

**Syntax**

```plaintext
tertile ( expression [ auto ] )
tertile ( expression for [ all|any ] expression { , expression } )
tertile ( expression for report )
```

**Example**

```plaintext
tertile ( Qty )
```

Result

Returns the quantity, the quantile rank value of the quantity as broken down into tertiles, and the quantile rank label as broken down into tertiles.

Result data

<table>
<thead>
<tr>
<th>Qty</th>
<th>Quantile (Qty, 3)</th>
<th>Tertile (Qty)</th>
</tr>
</thead>
<tbody>
<tr>
<td>800</td>
<td>1</td>
<td>H</td>
</tr>
<tr>
<td>700</td>
<td>1</td>
<td>H</td>
</tr>
<tr>
<td>500</td>
<td>2</td>
<td>M</td>
</tr>
<tr>
<td>400</td>
<td>2</td>
<td>M</td>
</tr>
<tr>
<td>200</td>
<td>3</td>
<td>L</td>
</tr>
<tr>
<td>200</td>
<td>3</td>
<td>L</td>
</tr>
</tbody>
</table>

**total**

Returns the total value of selected data items. Distinct is an alternative expression that is compatible with earlier versions of the product.

**Syntax**

```plaintext
total ( [ distinct ] expression [ auto ] )
total ( [ distinct ] expression for [ all|any ] expression { , expression } )
total ( [ distinct ] expression for report )
```
Example

total ( Sales )

Result

Returns the total value of all Sales values.

---

**Business Date/Time Functions**

This list contains business functions for performing date and time calculations.

_**_add_seconds_

Returns the time or datetime, depending on the format of "time_expression", that results from adding "integer_expression" seconds to "time_expression".

**Syntax**

_**_add_seconds ( time_expression, integer_expression )_

**Example 1**

_**_add_seconds ( 13:04:59 , 1 )_

Result

13:05:00

**Example 2**

_**_add_seconds ( 2002-04-30 12:10:10.000 , 1 )_

Result

2002-04-30 12:10:11.000

**Example 3**

_**_add_seconds ( 2002-04-30 00:00:00.000 , 1/100 )_

Note that the second argument is not a whole number. This is supported by some database technologies and increments the time portion.

Result

2002-04-30 00:00:00.010

_**_add_minutes_

Returns the time or datetime, depending on the format of "time_expression", that results from adding "integer_expression" minutes to "time_expression".

**Syntax**

_**_add_minutes ( time_expression, integer_expression )_

**Example 1**

_**_add_minutes ( 13:59:00 , 1 )_

Result
Example 2
_add_minutes ( 2002-04-30 12:59:10.000, 1 )

Result
2002-04-30 13:00:10.000

Example 3
_add_minutes ( 2002-04-30 00:00:00.000, 1/60 )

Note that the second argument is not a whole number. This is supported by some database technologies and increments the time portion.

Result
2002-04-30 00:01:00.000

_add_hours

Returns the time or datetime, depending on the format of "time_expression", that results from adding "integer_expression" hours to "time_expression".

Syntax
_add_hours ( time_expression, integer_expression )

Example 1
_add_hours ( 13:59:00 , 1 )

Result
14:59:00

Example 2
_add_hours ( 2002-04-30 12:10:10.000, 1 )

Result
2002-04-30 13:10:10.000,

Example 3
_add_hours ( 2002-04-30 00:00:00.000, 1/60 )

Note that the second argument is not a whole number. This is supported by some database technologies and increments the time portion.

Result
2002-04-30 00:01:00.000

_add_days

Returns the date or datetime, depending on the format of "date_expression", that results from adding "integer_expression" days to "date_expression".
**Syntax**

_add_days ( date_expression, integer_expression )

**Example 1**

_add_days ( 2002-04-30 , 1 )

Result

2002-05-01

**Example 2**

_add_days ( 2002-04-30 12:10:10.000 , 1 )

Result

2002-05-01 12:10:10.000

**Example 3**

_add_days ( 2002-04-30 00:00:00.000 , 1/24 )

Note that the second argument is not a whole number. This is supported by some database technologies and increments the time portion.

Result

2002-04-30 01:00:00.000

**_add_months**

Adds "integer_expression" months to "date_expression". If the resulting month has fewer days than the day of month component, then the last day of the resulting month is returned. In all other cases the returned value has the same day of month component as "date_expression".

**Syntax**

_add_months ( date_expression, integer_expression )

**Example 1**

_add_months ( 2012-04-15 , 3 )

Result

2012-07-15

**Example 2**

_add_months ( 2012-02-29 , 1 )

Result

2012-03-29

**Example 3**

_last_of_month ( _add_months ( 2012-02-29 , 1 ) )

Result
Example 4
_
_add_months ( 2012-01-31 , 1 )

Result
2012-02-29

Example 5
_
_add_months ( 2002-04-30 12:10:10.000 , 1 )

Result
2002-05-30 12:10:10.000

_add_years

Adds "integer_expression" years to "date_expression". If the "date_expression" is
February 29 and resulting year is non leap year, then the resulting day is set to
February 28. In all other cases the returned value has the same day and month as
"date_expression".

Syntax
_
_add_years ( date_expression, integer_expression )

Example 1
_
_add_years ( 2012-04-15 , 1 )

Result
2013-04-15

Example 2
_
_add_years ( 2012-02-29 , 1 )

Result
2013-02-28

Example 3
_
_add_years ( 2002-04-30 12:10:10.000 , 1 )

Result
2003-04-30 12:10:10.000

_age

Returns a number that is obtained from subtracting "date_expression" from today's
date. The returned value has the form YYYYMMDD, where YYYY represents the
number of years, MM represents the number of months, and DD represents the
number of days.

Syntax
_
age ( date_expression )
Example
_age ( 1990-04-30 ) (if today's date is 2003-02-05)

Result

120906, meaning 12 years, 9 months, and 6 days.

current_date
Returns a date value representing the current date of the computer that the database software runs on.

Syntax
current_date

Example
current_date

Result

2003-03-04

current_time
Returns a time with time zone value, representing the current time of the computer that runs the database software if the database supports this function. Otherwise, it represents the current time of the IBM Cognos Analytics server.

Syntax
current_time

Example
current_time

Result

16:33:17.354+05:00

current_timestamp
Returns a datetime with time zone value, representing the current time of the computer that runs the database software if the database supports this function. Otherwise, it represents the current time of the server.

Syntax
current_timestamp

Example
current_timestamp

Result

2003-03-03 16:40:15.535+05:00
_day_of_week

Returns the day of week (1 to 7), where 1 is the first day of the week as indicated by the second parameter (1 to 7, 1 being Monday and 7 being Sunday). Note that in ISO 8601 standard, a week begins with Monday being day 1.

Syntax
_day_of_week ( date_expression, integer )

Example
_day_of_week ( 2003-01-01 , 1 )

Result
3

_day_of_year

Returns the day of year (1 to 366) in "date_expression". Also known as Julian day.

Syntax
_day_of_year ( date_expression )

Example
_day_of_year ( 2003-03-01 )

Result
61

_days_between

Returns a positive or negative number representing the number of days between "date_expression1" and "date_expression2". If "date_expression1" < "date_expression2", then the result will be a negative number.

Syntax
_days_between ( date_expression1 , date_expression2 )

Example
_days_between ( 2002-04-30 , 2002-06-21 )

Result
-52

_days_to_end_of_month

Returns a number representing the number of days remaining in the month represented by "date_expression".

Syntax
_days_to_end_of_month ( date_expression )
Example
_days_to_end_of_month ( 2002-04-20 14:30:22.123 )

Result
10

_end_of_day
Returns the end of today as a timestamp.

Syntax
_end_of_day

Example
_end_of_day

Result
2014-11-23 23:59:59

_first_of_month
Returns a date or datetime, depending on the argument, by converting "date_expression" to a date with the same year and month but with the day set to 1.

Syntax
_first_of_month ( date_expression )

Example 1
_first_of_month ( 2002-04-20 )

Result
2002-04-01

Example 2
_first_of_month ( 2002-04-20 12:10:10.000 )

Result
2002-04-01 12:10:10.000

_from_unixtime
Returns the unix time specified by an integer expression as a timestamp with time zone.

Syntax
_from_unixtime ( integer_expression )

Example
_from_unixtime ( 1417807335 )

Result
2014-12-05 19:22:15+00:00
_hour

Returns the value of the hour field in a date expression.

Syntax

_hour( date_expression )

Example

_hour( 2002-01-31 12:10:10.254 )

Result

12

_last_of_month

Returns a date or datetime, depending on the argument, that is the last day of the month represented by "date_expression".

Syntax

_last_of_month( date_expression )

Example 1

_last_of_month( 2002-01-14 )

Result

2002-01-31

Example 2

_last_of_month( 2002-01-14 12:10:10.000 )

Result

2002-01-31 12:10:10.000

_make_timestamp

Returns a timestamp constructed from "integer_expression1" (the year), "integer_expression2" (the month), and "integer_expression3" (the day). The time portion defaults to 00:00:00.000.

Syntax

_make_timestamp( integer_expression1, integer_expression2, integer_expression3 )

Example

_make_timestamp( 2002 , 01 , 14 )

Result

2002-01-14 00:00:00.000

_minute

Returns the value of the minute field in a date expression.
**Syntax**

```plaintext
_minute( date_expression )
```

**Example**

```plaintext
_minute ( 2002-01-31 12:10:10.254 )
```

**Result**

10

**_month**

Returns the value of the month field in a date expression.

**Syntax**

```plaintext
_month( date_expression )
```

**Example**

```plaintext
_month ( 2003-03-01 )
```

**Result**

3

**_months_between**

Returns a positive or negative integer number representing the number of months between "date_expression1" and "date_expression2". If "date_expression1" is earlier than "date_expression2", then a negative number is returned.

**Syntax**

```plaintext
_months_between ( date_expression1, date_expression2 )
```

**Example**

```plaintext
_months_between ( 2002-04-03 , 2002-01-30 )
```

**Result**

2

**_second**

Returns the value of the second field in a date expression.

**Syntax**

```plaintext
_second( date_expression )
```

**Example**

```plaintext
_second ( 2002-01-31 12:10:10.254 )
```

**Result**

10.254

**_shift_timezone**

Shifts a timestamp value from one time zone to another time zone. This function honors the Daylight Savings Time when applicable. If the first argument is of type "timestamp", then the second and third arguments represent the "from" and
"target" time zones, respectively. If the first argument is of type "timestamp with time zone", then the "from" time zone is already implied in the first argument therefore the second argument represents the "target" time zone. The data type of the first argument will also determine the data type of the return value. The second and third arguments are of type "string" and represent time zone identifiers. A list of these identifiers can be found below. Note: using this function will cause local processing.

**Syntax**

\[
\text{\_shift\_timezone ( timestamp\_value , from\_time\_zone , target\_time\_zone )}
\]

\[
\text{\_shift\_timezone ( timestamp\_with\_time\_zone\_value , target\_time\_zone )}
\]

**Example 1**

\[
\text{\_shift\_timezone( 2013-06-30 12:00:00 , 'EST' , 'GMT' )}
\]

Result

2013-06-30 16:00:00

**Example 2**

\[
\text{\_shift\_timezone( 2013-11-30 12:00:00-05:00 , 'PST' )}
\]

Result

2013-11-30 09:00:00-08:00

**Example 3**

Time zone abbreviations:

Result data

- **GMT** (GMT+00:00) Greenwich Mean Time
- **UTC** (GMT+00:00) Coordinated Universal Time
- **WET** (GMT+00:00) Western Europe Time: Lisbon, Faeroe Islands, Canary Islands
- **ECT** (GMT+01:00) European Central Time: Amsterdam, Brussels, Paris, Rome, Vienna
- **MET** (GMT+01:00) Middle European Time
- **ART** (GMT+02:00) Egypt Time: Cairo, Damascus, Beirut, Amman, Nicosia
- **CAT** (GMT+02:00) Central African Time: Johannesburg, Blantyre, Harare, Tripoli
- **EET** (GMT+02:00) Eastern Europe Time: Athens, Kiev, Sofia, Minsk, Bucharest, Vilnius, Tallinn
- **EAT** (GMT+03:00) East Africa Time: Addis Ababa, Asmera, Kampala, Nairobi, Mogadishu, Khartoum
- **NET** (GMT+04:00) Near East Time
- **PLT** (GMT+05:00) Pakistan Lahore Time
- **IST** (GMT+05:30) Indian Time
- **BST** (GMT+06:00) Bangladesh Time
- **VST** (GMT+07:00) Vietnam Time
- **CTT** (GMT+08:00) Asia, Hong Kong S.A.R. of China
- **JST** (GMT+09:00) Japan Time: Tokyo
- **ACT** (GMT+09:30) Australian Central Time: Darwin
- **AET** (GMT+10:00) Australian Eastern Time: Sydney, Melbourne, Canberra
- **SST** (GMT+11:00) Solomon Time
- **AGT** (GMT-03:00) Argentina Time
- **BET** (GMT-03:00) Brazil Eastern Time: Sao Paulo, Buenos Aires
- **CNT** (GMT-03:30) Newfoundland Time: St. Johns
- **PRT** (GMT-04:00) Puerto Rico and U.S. Virgin Islands Time
- **EST** (GMT-05:00) Eastern Time: Ottawa, New York, Toronto, Montreal,
Jamaica, Porto Acre
CST (GMT-06:00) Central Time: Chicago, Cambridge Bay, Mexico City
MST (GMT-07:00) Mountain Time: Edmonton, Yellowknife, Chihuahua
PST (GMT-08:00) Pacific Time: Los Angeles, Tijuana, Vancouver
AST (GMT-09:00) Alaska Time: Anchorage, Juneau, Nome, Yakutat
HST (GMT-10:00) Hawaii Time: Honolulu, Tahiti
MIT (GMT-11:00) Midway Islands Time: Midway, Apia, Niue, Pago Pago

Example 4
A customized time zone identifier may also be used, using the format
GMT(+-)HH:MM. For example, GMT-06:30 or GMT+02:00.
A more complete
list of time zone identifiers (including longer form identifiers such
as "Europe/Amsterdam") may be found in the "i18n_res.xml" file from
the product's configuration folder.

_start_of_day
Returns the start of today as a timestamp.

Syntax
_start_of_day

Example
_start_of_day

Result
2014-11-23 00:00:00

_week_of_year
Returns the number of the week of the year of "date_expression" according to the
ISO 8601 standard. Week 1 of the year is the first week of the year to contain a
Thursday, which is equivalent to the first week containing January 4th. A week
starts on Monday (day 1) and ends on Sunday (day 7).

Syntax
_week_of_year ( date_expression )

Example
_week_of_year ( 2003-01-01 )

Result
1

_timezone_hour
Returns the value of the timezone hour field in a date expression.

Syntax
_timezone_hour( date_expression )

Example
_timezone_hour ( 2002-01-31 12:10:10.254-05:30 )

Result
_timezone_minute
Returns the value of the timezone minute field in a date expression.

Syntax
_timezone_minute( date_expression )

Example
_timezone_minute ( 2002-01-31 12:10:10.254-05:30 )
Result
30

_unix_timestamp
Returns the unix time specified by an integer expression as a timestamp with timezone.

Syntax
_unix_timestamp

Example
_unix_timestamp
Result
1416718800

_year
Returns the value of the year field in a date expression.

Syntax
_year( date_expression )

Example
_year ( 2003-03-01 )
Result
2003

_years_between
Returns a positive or negative integer number representing the number of years between "date_expression1" and "date_expression2". If "date_expression1" < "date_expression2" then a negative value is returned.

Syntax
_years_between ( date_expression1, date_expression2 )

Example
_years_between ( 2003-01-30, 2001-04-03 )
Result
**ymdint_between**

Returns a number representing the difference between "date_expression1" and "date_expression2". The returned value has the form YYYYMMDD, where YYYY represents the number of years, MM represents the number of months, and DD represents the number of days.

**Syntax**

`ymdint_between(date_expression1, date_expression2)`

**Example**

`ymdint_between('1990-04-30', '2003-02-05')`

**Result**

120906, meaning 12 years, 9 months and 6 days.

---

**Common Functions**

**abs**

Returns the absolute value of "numeric_expression". Negative values are returned as positive values.

**Syntax**

`abs(numeric_expression)`

**Example 1**

`abs(15)`

**Result**

15

**Example 2**

`abs(-15)`

**Result**

15

**cast**

Converts "expression" to a specified data type. Some data types allow for a length and precision to be specified. Make sure that the target is of the appropriate type and size. The following can be used for "datatype_specification": character, varchar, char, numeric, decimal, integer, bigint, smallint, real, float, date, time, timestamp, time with time zone, timestamp with time zone, and interval. When type casting to an interval type, one of the following interval qualifiers must be specified: year, month, or year to month for the year-to-month interval datatype; day, hour, minute, second, day to hour, day to minute, day to second, hour to minute, hour to second, or minute to second for the day-to-second interval datatype. Notes: When you convert a value of type timestamp to type date, the time portion of the timestamp value is ignored. When you convert a value of type timestamp to type
time, the date portion of the timestamp is ignored. When you convert a value of type date to type timestamp, the time components of the timestamp are set to zero. When you convert a value of type time to type timestamp, the date component is set to the current system date. It is invalid to convert one interval datatype to the other (for instance because the number of days in a month is variable). Note that you can specify the number of digits for the leading qualifier only, i.e. YEAR(4) TO MONTH, DAY(5). Errors will be reported if the target type and size are not compatible with the source type and size.

**Syntax**

```sql
cast ( expression , datatype_specification )
```

**Example 1**

```sql
cast ( '123' , integer )
```

Result

123

**Example 2**

```sql
cast ( 12345 , varchar ( 10 ) )
```

Result

a string containing 12345

**ceiling**

Returns the smallest integer that is greater than or equal to "numeric_expression".

**Syntax**

```sql
ceiling ( numeric_expression )
```

**Example 1**

```sql
ceiling ( 4.22 )
```

Result

5

**Example 2**

```sql
ceiling ( -1.23 )
```

Result

-1

**char_length**

Returns the number of logical characters in "string_expression". The number of logical characters can be distinct from the number of bytes in some East Asian locales.

**Syntax**

```sql
char_length ( string_expression )
```
Example
cchar_length ( 'Canada' )

Result
6

coaalesce
Returns the first non-null argument (or null if all arguments are null). Requires two or more arguments in "expression_list".

Syntax
coaalesce ( expression_list )

Example
coaalesce ( [Unit price], [Unit sale price] )

Result
Returns the unit price, or the unit sale price if the unit price is null.

dexp
Returns 'e' raised to the power of "numeric_expression". The constant 'e' is the base of the natural logarithm.

Syntax
dexp ( numeric_expression )

Example
dexp ( 2 )

Result
7.389056

dfloor
Returns the largest integer that is less than or equal to "numeric_expression".

Syntax
dfloor ( numeric_expression )

Example 1
dfloor ( 3.22 )

Result
3

Example 2
dfloor ( -1.23 )

Result
\textbf{ln}

Returns the natural logarithm of "numeric_expression".

**Syntax**

\texttt{ln ( numeric_expression )}

**Example**

\texttt{ln ( 4 )}

Result

1.38629

\textbf{lower}

Returns "string_expression" with all uppercase characters shifted to lowercase.

**Syntax**

\texttt{lower ( string_expression )}

**Example**

\texttt{lower ( 'ABCDEF' )}

Result

abcdef

\textbf{mod}

Returns the remainder (modulus) of "integer_expression1" divided by "integer_expression2". "Integer_expression2" must not be zero or an exception condition is raised.

**Syntax**

\texttt{mod ( integer_expression1, integer_expression2 )}

**Example**

\texttt{mod ( 20, 3 )}

Result

2

\textbf{nullif}

Returns null if "expression1" equals "expression2", otherwise returns "expression1".

**Syntax**

\texttt{nullif ( expression1, expression2 )}

\textbf{position}

Returns the integer value representing the starting position of "string_expression1" in "string_expression2" or 0 when the "string_expression1" is not found.
**Syntax**

position ( string_expression1, string_expression2 )

**Example 1**

position ( 'C', 'ABCDEF' )

Result

3

**Example 2**

position ( 'H', 'ABCDEF' )

Result

0

**position_regex**

Returns the integer value representing the beginning or ending position of the substring in "string_expression" that matches the regular expression "regex_expression". The search starts at position "integer_expression1", which has a default value of 1. The occurrence of the pattern to search for is specified by "integer_expression2", which has a default value of 1. The return option, specified by the first argument, specifies what is returned in relation to the occurrence. If you specify "start", the position of the first character of the occurrence is returned. If you specify "after", the position of the character following the occurrence is returned. If you don’t specify a return option, "start" is implicit. Flags to set options for the interpretation of the regular expression are specified by "flags_expression". Individual letters are used to define the flags, with valid values being ‘s’, ‘m’, ‘i’, and ‘x’.

**Syntax**

position_regex ([ start|after ] regex_expression, string_expression [, integer_expression1 [, integer_expression2 [, flags_expression ]]])

**Example 1**

position_regex ( '.er', 'Flicker Lantern' )

Result

5

**Example 2**

position_regex ( after '.er', 'Flicker Lantern' )

Result

8

**Example 3**

position_regex ( '.er', 'Flicker Lantern', 1, 2 )

Result
power

Returns "numeric_expression1" raised to the power "numeric_expression2". If "numeric_expression1" is negative, then "numeric_expression2" must result in an integer value.

Syntax

\[
\text{power ( numeric_expression1, numeric_expression2 )}
\]

Example

\[
\text{power ( 3, 2 )}
\]

Result

9

_round

Returns "numeric_expression" rounded to "integer_expression" decimal places. Notes: "integer_expression" must be a non-negative integer. Rounding takes place before data formatting is applied.

Syntax

\[
\text{_round ( numeric_expression, integer_expression )}
\]

Example

\[
\text{_round ( 1220.42369, 2 )}
\]

Result

1220.42

sqrt

Returns the square root of "numeric_expression". "Numeric_expression" must be non-negative.

Syntax

\[
\text{sqrt ( numeric_expression )}
\]

Example

\[
\text{sqrt ( 9 )}
\]

Result

3

substring

Returns the substring of "string_expression" that starts at position "integer_expression1" for "integer_expression2" characters or to the end of "string_expression" if "integer_expression2" is omitted. The first character in "string_expression" is at position 1.
Syntax
substring ( string_expression , integer_expression1 [ , integer_expression2 ] )

Example
substring ( 'abcdefg' , 3 , 2 )

Result
cd

substring_regex
Returns a substring of "string_expression" that matches the regular expression "regex_expression". The search starts at position "integer_expression1", which has a default value of 1. The occurrence of the pattern to search for is specified by "integer_expression2", which has a default value of 1. Flags to set options for the interpretation of the regular expression are specified by "flags_expression". Individual letters are used to define the flags, with valid values being 's', 'm', 'i', and 'x'.

Syntax
substring_regex ( regex_expression , string_expression [ , integer_expression1 [ , integer_expression2 ] , flags_expression ] )

Example 1
substring_regex ( '.er' , 'Flicker Lantern' )

Result
ker

Example 2
substring_regex ( '.er' , 'Flicker Lantern' , 1 , 2 )

Result
ter

trim
Returns "string_expression" trimmed of leading and trailing blanks or trimmed of a certain character specified in "match_character_expression". 'Both' is implicit when the first argument is not stated and blank is implicit when the second argument is not stated.

Syntax
trim ( [ [ trailing|leading|both ] [ match_character_expression ] ] string_expression )

Example 1
trim ( trailing 'A' , 'ABCDEFA' )

Result
ABCDEF
Example 2
trim ( both , ' ABCDEF ' )

Result
ABCDEF

upper
Returns "string_expression" with all lowercase characters converted to uppercase.

Syntax
upper ( string_expression )

Example
upper ( 'abcdef' )

Result
ABCDEF

Trigonometric functions

arccos
Returns the arc cosine of the argument, where the argument is in the range of -1 to 1 and the result is a value expressed in radians.

Syntax
arccos ( numeric_expression )

Example
arccos ( -1 )

Result
3.1415

arcsin
Returns the arc sine of the argument, where the argument is in the range of -1 to 1 and the result is a value expressed in radians.

Syntax
arcsin ( numeric_expression )

Example
arcsin ( 0 )

Result
3.1415

arctan
Returns the arc tangent of the argument, where the argument is in the range of -1 to 1 and the result is a value expressed in radians.
**Syntax**
arctan ( numeric_expression )

**Example**
arctan ( 0 )

Result

3.1415

**cos**
Returns the cosine of the argument, where the argument is expressed in radians.

**Syntax**
cos ( numeric_expression )

**Example**
cos ( 0.3333 * 3.1415 )

Result

0.5

**coshyp**
Returns the hyperbolic cosine of the argument, where the argument is expressed in radians.

**Syntax**
coshyp ( numeric_expression )

**Example**
coshyp ( 0 )

Result

1

**sin**
Returns the sine of the argument, where the argument is expressed in radians.

**Syntax**
sin ( numeric_expression )

**Example**
sin ( 0.1667 * 3.1415 )

Result

0.5

**sinhyp**
Returns the hyperbolic sine of the argument, where the argument is expressed in radians.
**Syntax**
sinhyp ( numeric_expression )

**Example**
sinhyp ( 0 )

Result

0

**tan**
Returns the tangent of the argument, where the argument is expressed in radians.

**Syntax**
tan ( numeric_expression )

**Example**
tan ( 0.25 * 3.1415 )

Result

1

**tanhyp**
Returns the hyperbolic tangent of the argument, where the argument is expressed in radians.

**Syntax**
tanhyp ( numeric_expression )

**Example**
tanhyp ( 0 )

Result

0
Appendix B. About this guide

This document is intended for use with IBM Cognos Analytics. Cognos Analytics integrates reporting, modeling, analysis, dashboards, metrics, and event management so you can understand your organization’s data, and make effective business decisions.

To find product documentation on the web, including all translated documentation, access IBM Knowledge Center (http://www.ibm.com/support/knowledgecenter).

Accessibility features

Accessibility features help users who have a physical disability, such as restricted mobility or limited vision, to use information technology products successfully. For information on accessibility features in Cognos Analytics, see the Cognos Analytics Accessibility Guide.

Forward-looking statements

This documentation describes the current functionality of the product. References to items that are not currently available may be included. No implication of any future availability should be inferred. Any such references are not a commitment, promise, or legal obligation to deliver any material, code, or functionality. The development, release, and timing of features or functionality remain at the sole discretion of IBM.

Samples disclaimer

The Sample Outdoors Company, Great Outdoors Company, GO Sales, any variation of the Sample Outdoors or Great Outdoors names, and Planning Sample depict fictitious business operations with sample data used to develop sample applications for IBM and IBM customers. These fictitious records include sample data for sales transactions, product distribution, finance, and human resources. Any resemblance to actual names, addresses, contact numbers, or transaction values is coincidental. Other sample files may contain fictional data manually or machine generated, factual data compiled from academic or public sources, or data used with permission of the copyright holder, for use as sample data to develop sample applications. Product names referenced may be the trademarks of their respective owners. Unauthorized duplication is prohibited.
