WITHOUT HOLD
WITH HOLD
```

**returnability:**

```plaintext
WITHRETURN
WITHOUT RETURN
WITH RETURN
TO CALLER
TO CLIENT
```

**rowset-positioning:**

```plaintext
WITHRWSET POSITIONING
WITHOUT ROWSET POSITIONING
```

**Description**

`cursor-name`

Names the cursor. The name must not identify a cursor that has already been
declared in the source program. The name is usually VARCHAR(128); however, if the cursor is defined WITH RETURN, the name is limited to VARCHAR(30).

**NO SCROLL or SCROLL**
Specifies whether the cursor is scrollable or not scrollable.

**NO SCROLL**
Specifies that the cursor is not scrollable. This is the default.

**SCROLL**
Specifies that the cursor is scrollable. For a scrollable cursor, whether the cursor has sensitivity to inserts, updates, or deletes depends on the cursor sensitivity option in effect for the cursor. If a sensitivity option is not specified, ASENSITIVE is the default.

**ASENSITIVE**
Specifies that the cursor should be as sensitive as possible. This is the default.

A cursor that defined as ASENSITIVE will be either insensitive or sensitive dynamic; it will not be sensitive static. For information about how the effective sensitivity of the cursor is returned to the application with the GET DIAGNOSTICS statement or in the SQLCA, see "OPEN" on page 2101.

The sensitivity of a cursor is a factor in the choice of access path. Explicitly specify the sensitivity level that you need, instead of specifying ASENSITIVE.

**INSENSITIVE**
Specifies that the cursor does not have sensitivity to inserts, updates, or deletes that are made to the rows underlying the result table. As a result, the size of the result table, the order of the rows, and the values for each row do not change after the cursor is opened. In addition, the cursor is read-only. The SELECT statement or attribute-string of the PREPARE statement cannot contain a FOR UPDATE clause, and the cursor cannot be used for positioned updates or deletes.

**SENSITIVE**
Specifies that the cursor has sensitivity to changes that are made to the database after the result table is materialized. The cursor is always sensitive to updates and deletes that are made using the cursor (that is, positioned updates and deletes using the same cursor). When the current value of a row no longer satisfies the select-statement or statement-name, that row is no longer visible through the cursor. When a row of the result table is deleted from the underlying base table, the row is no longer visible through the cursor.

If DB2 cannot make changes visible to the cursor, then an error is issued at bind time for OPEN CURSOR. DB2 cannot make changes visible to the cursor when the cursor implicitly becomes read-only. For example, when the result table must be materialized, as when the FROM clause of the SELECT statement contains more than one table or view. The current list of conditions that result in an implicit read-only cursor can be found in Read-only cursors.

The default is DYNAMIC.

**DYNAMIC**
Specifies that the result table of the cursor is dynamic, meaning that the size of the result table might change after the cursor is
opened as rows are inserted into or deleted from the underlying
table, and the order of the rows might change. Rows that are
inserted, deleted, or updated by statements that are executed by
the same application process as the cursor are visible to the cursor
immediately. Rows that are inserted, deleted, or updated by
statements that are executed by other application processes are
visible only after the statements are committed. If a column for an
ORDER BY clause is updated via a cursor or any means outside
the process, the next FETCH statement behaves as if the updated
row was deleted and re-inserted into the result table at its correct
location. At the time of a positioned update, the cursor is
positioned before the next row of the original location and there is
no current row, making the row appear to have moved.

If a SENSITIVE DYNAMIC cursor is not possible, an error is
returned. For example, if a temporary table is needed an error is
returned. The SELECT statement of a cursor that is defined as
SENSITIVE DYNAMIC cannot contain an SQL data change
statement.

The FETCH FIRST $n$ ROWS ONLY clause must not be specified for
the outermost fullselect for a sensitive dynamic cursor.

**STATIC**

Specify that the size of the result table and the order of the rows
do not change after the cursor is opened. Rows inserted into the
underlying table are not added to the result table regardless of
how the rows are inserted. Rows in the result table do not move if
columns in the ORDER BY clause are updated in rows that have
already been materialized. Positioned updates and deletes are
allowed if the result table is updatable. The SELECT statement of a
cursor that is defined as SENSITIVE STATIC cannot contain an
SQL data change statement.

A STATIC cursor has visibility to changes made by *this* cursor
using positioned updates or deletes. Committed changes made
outside this cursor are visible with the SENSITIVE option of the
FETCH statement. A FETCH SENSITIVE can result in a *hole* in the
result table (that is, a difference between the result table and its
underlying base table). If an updated row in the base table of a
cursor no longer satisfies the predicate of its SELECT statement, an
update hole occurs in the result table. If a row of a cursor was
deleted in the base table, a delete hole occurs in the result table.
When a FETCH SENSITIVE detects an update hole, no data is
returned (a warning is issued), and the cursor is left positioned on
the update hole. When a FETCH SENSITIVE detects a delete hole,
no data is returned (a warning is issued), and the cursor is left
positioned on the delete hole.

Updates through a cursor result in an automatic re-fetch of the
row. This re-fetch means that updates can create a hole themselves.
The re-fetched row also reflects changes as a result of triggers
updating the same row. It is important to reflect these changes to
maintain the consistency of data in the row.

Using a function that is not deterministic (built-in or user-defined)
in the WHERE clause of the `select-statement` or `statement-name`
of a SENSITIVE STATIC cursor can cause misleading results. This
situation occurs because DB2 constructs a temporary result table
and retrieves rows from this table for FETCH INSENSITIVE statements. When DB2 processes a FETCH SENSITIVE statement, rows are fetched from the underlying table and predicates are re-evaluated. Using a function that is not deterministic can yield a different result on each FETCH SENSITIVE of the same row, which could also result in the row no longer being considered a match.

A FETCH INSENSITIVE on a SENSITIVE STATIC SCROLL cursor is not sensitive to changes made outside the cursor, unless a previous FETCH SENSITIVE has already refreshed that row; however, positioned updates and delete changes with the cursor are visible.

STATIC cursors are insensitive to insertions.

**WITHOUT HOLD or WITH HOLD**

Specifies whether the cursor should be prevented from being closed as a consequence of a commit operation.

**WITHOUT HOLD**

Does not prevent the cursor from being closed as a consequence of a commit operation. This is the default.

**WITH HOLD**

Prevents the cursor from being closed as a consequence of a commit operation. A cursor declared with WITH HOLD is closed at commit time if one of the following is true:

- The connection associated with the cursor is in the release pending status.
- The bind option DISCONNECT(AUTOMATIC) is in effect.
- The environment is one in which the option WITH HOLD is ignored.

When WITH HOLD is specified, a commit operation commits all of the changes in the current unit of work. For example, with a non-scrollable cursor, an initial FETCH statement is needed after a COMMIT statement to position the cursor on the row that follows the row that the cursor was positioned on before the commit operation.

WITH HOLD has no effect on an SQL data change statement within a SELECT statement. When a COMMIT is issued, the changes caused by the SQL data change statement are committed, regardless of whether or not the cursor is declared WITH HOLD.

All cursors are implicitly closed by a connect (Type 1) or rollback operation. A cursor is also implicitly closed by a commit operation if WITH HOLD is ignored or not specified.

Cursors that are declared with WITH HOLD in CICS or in IMS non-message-driven programs will not be closed by a rollback operation if the cursor was opened in a previous unit of work and no changes have been made to the database in the current unit of work. The cursor cannot be closed because CICS and IMS do not broadcast the rollback request to DB2 for a null unit of work.

If a cursor is closed before the commit operation, the effect is the same as if the cursor was declared without the option WITH HOLD.

WITH HOLD is ignored in IMS message driven programs (MPP, IFP, and message-driven BMP). WITH HOLD maintains the cursor position in a CICS pseudo-conversational program until the end-of-task (EOT).
For details on restrictions that apply to declaring cursors with WITH HOLD, see DB2 Application Programming and SQL Guide.

**WITHOUT RETURN or WITH RETURN**

Specifies whether the result table of the cursor is intended to be used as a result set that will be returned from a procedure. If `statement-name` is specified, the default is the corresponding prepare attribute of the statement. Otherwise, the default is **WITHOUT RETURN**.

**WITHOUT RETURN**

Specifies that the result table of the cursor is not intended to be used as a result set that will be returned from a procedure.

**WITH RETURN**

Specifies that the result table of the cursor is intended to be used as a result set that will be returned from a procedure. **WITH RETURN** is relevant only if the DECLARE CURSOR statement is contained within the source code for a procedure. In other cases, the precompiler might accept the clause, but it has not effect.

When a cursor that is declared using the **WITH RETURN TO CALLER** clause remains open at the end of a program or routine, that cursor defines a result set from the program or routine. Use the CLOSE statement to close a cursor that is not intended to be a result set from the program or routine. Although DB2 will automatically close any cursors that are not declared using with a **WITH RETURN** clause, the use of the CLOSE statement is recommended to increase the portability of applications.

For non-scrollable cursors, the result set consists of all rows from the current cursor position to the end of the result table. For scrollable cursors, the result set consists of all rows of the result table.

**TO CALLER**

Specifies that the cursor can return a result set to the caller of the procedure. The caller is the program or routine that executed the SQL CALL statement that invokes the procedure that contains the DECLARE CURSOR statement. For example, if the caller is a procedure, the result set, is returned to the procedure. If the caller is a client application, the result set is returned to the client application.

If the statement is contained within the source code for a procedure, **WITH RETURN TO CALLER** specifies that the cursor can be used as a result set cursor. A result set cursor is used when the result table of a cursor is to be returned from a procedure. Specifying **TO CALLER** is optional.

In other cases, the clause is ignored and the cursor cannot be used as a result set cursor.

**TO CLIENT**

Specifies that the cursor can return a result set to the client application. This cursor is invisible to any intermediate nested procedures. If a function or trigger calls the procedure (either directly or indirectly), the result set cannot be returned to the client and the cursor will be closed after the procedure finishes.

**rowset-positioning**

Specifies whether multiple rows of data can be accessed as a rowset on a single FETCH statement for the cursor. The default is **WITHOUT ROWSET POSITIONING**.
WITHOUT ROWSET POSITIONING

Specifies that the cursor can be used only with row-positioned FETCH statements. The cursor is to return a single row for each FETCH statement and the FOR n ROWS clause cannot be specified on a FETCH statement for this cursor. WITHOUT ROWSET POSITIONING or single row access refers to how data is fetched from the database engine. For remote access, data might be blocked and returned to the client in blocks.

WITH ROWSET POSITIONING

Specifies that the cursor can be used with either row-positioned or rowset-positioned FETCH statements. This cursor can be used to return either a single row or multiple rows, as a rowset, with a single FETCH statement. ROWSET POSITIONING refers to how data is fetched from the database engine. For remote access, if any row qualifies, at least 1 row is returned as a rowset. The size of the rowset depends on the number of rows specified on the FETCH statement and on the number of rows that qualify. Data might be blocked and returned to the client in blocks.

DB2 REXX applications do not support cursors that are declared WITH ROWSET POSITIONING. To allow a cursor for a SELECT statement in a DB2 REXX application to be used with row-positioned or rowset-positioned FETCH statements, specify WITH ROWSET POSITIONING in the attribute string of the PREPARE statement for the SELECT statement.

select-statement

Specifies the result table of the cursor. See “select-statement” on page 1149 for an explanation of select-statement.

The SELECT statement must not include parameter markers (except for REXX), but can include references to host variables. In host languages, other than REXX, the declarations of the host variables must precede the DECLARE CURSOR statement in the source program. In REXX, parameter markers must be used in place of host variables and the statement must be prepared.

The USING clause of the OPEN statement can be used to specify host variables that will override the values of the host variables or parameter markers that are specified as part of the statement in the DECLARE CURSOR statement.

The SELECT statement must not contain an SQL data change statement if the cursor is defined as SENSITIVE DYNAMIC or SENSITIVE STATIC.

statement-name

Identifies the prepared SELECT statement that specifies the result table of the cursor whenever the cursor is opened. The statement-name must not be identical to a statement name specified in another DECLARE CURSOR statement of the source program. For an explanation of prepared SELECT statements, see “PREPARE” on page 2106.

The prepared SELECT statement must not contain an SQL data change statement if the cursor is defined as SENSITIVE DYNAMIC or SENSITIVE STATIC.

Notes

A cursor in the open state designates a result table and a position relative to the rows of that table. The table is the result table specified by the SELECT statement of the cursor.

Read-only cursors:
If the result table is *read-only*, the cursor is *read-only*. The cursor that references a view with instead of triggers are read-only since positioned UPDATE and positioned DELETE statements are not allowed using those cursors. The result table is *read-only* if one or more of the following statements is true about the *select-statement* of the cursor:

- The first FROM clause identifies or contains any of the following:
  - More than one table or view
  - A catalog table with no updatable columns
  - A read-only view
  - A nested table expression
  - A table function
  - A system-maintained materialized query table
  - A single table that is a system-period temporal table and a period specification is used
- The first SELECT clause specifies the keyword DISTINCT, contains an aggregate function, or uses both
- It contains an SQL data change statement
- The outer subselect contains a GROUP BY clause, a HAVING clause, or both clauses
- It contains a subquery such that the base object of the outer subselect, and of the subquery, is the same table
- Any of the following operators or clauses are specified:
  - A set operator
  - An ORDER BY clause (except when the cursor is declared as SENSITIVE STATIC scorable)
  - A FOR READ ONLY clause
- It is executed with isolation level UR and a FOR UPDATE clause is not specified.
- It is a VALUES clause.

If the result table is not read-only, the cursor can be used to update or delete the underlying rows of the result table.

**Tables for which row or column access controls are enforced:**

The *select-statement* of the cursor can reference a table for which row or column access controls are enforced. The row or column access controls do not effect the determination of whether the cursor is read-only and do not effect the cursor sensitivity.

**Work file database requirement for static scrollable cursors:**

To use a static scrollable cursor, you must first create a work file database and at least one table space with a 32KB page size in this database because a static scrollable cursor requires a temporary table for its result table while the cursor is open. DB2 chooses a table space to use for the temporary result table. Dynamic scrollable cursors do not require a declared temporary table.

For static scrollable cursor declarations that contain empty strings, DB2 assigns one byte in the temporary table space for each empty string. The following example shows a scrollable cursor declaration with an empty string:
EXEC SQL DECLARE CSROWSTAT SENSITIVE STATIC SCROLL CURSOR
   WITH ROWSET POSITIONING WITH HOLD FOR
   SELECT ID1,''
   FROM TB;

Cursors in COBOL and Fortran programs:
In COBOL and Fortran source programs, the DECLARE CURSOR statement must precede all statements that explicitly refer to the cursor by name. This rule does not necessarily apply to the other host languages because the precompiler provides a two-pass option for these languages. This rule applies to other host languages if the two-pass option is not used.

Cursors in REXX:
If host variables are used in a DECLARE CURSOR statement within a REXX procedure, the DECLARE CURSOR statement must be the object of a PREPARE and EXECUTE.

Scope of a cursor:
The scope of cursor-name is the source program in which it is defined; that is, the application program submitted to the precompiler. Thus, you can only refer to a cursor by statements that are precompiled with the cursor declaration. For example, a COBOL program called from another program cannot use a cursor that was opened by the calling program. Furthermore, a cursor defined in a Fortran subprogram can only be referred to in that subprogram. Cursors that specify WITH RETURN in a procedure and are left open are returned as result sets.

Although the scope of a cursor is the program in which it is declared, each package (or DBRM of a plan) created from the program includes a separate instance of the cursor, and more than one instance of the cursor can be used in the same execution of the program. For example, assume a program is precompiled with the CONNECT(2) option and its DBRM is used to create a package at location X and a package at location Y. The program contains the following SQL statements:

```
DECLARE C CURSOR FOR ...
CONNECT TO X
OPEN C
FETCH C INTO ...
CONNECT TO Y
OPEN C
FETCH C INTO ...
```

The second OPEN C statement does not cause an error because it refers to a different instance of cursor C. The same notion applies to a single location if the packages are in different collections.

A SELECT statement is evaluated at the time the cursor is opened. If the same cursor is opened, closed, and then opened again, the results can be different. If the SELECT statement of the cursor contains CURRENT DATE, CURRENT TIME or CURRENT TIMESTAMP, all references to these special registers yields the same respective datetime value on each FETCH operation. The value is determined when the cursor is opened. Multiple cursors using the same SELECT statement can be opened concurrently. They are each considered independent activities.

Blocking of data:
To process data more efficiently, DB2 might block data for read-only cursors. If a cursor is not going to be used in a positioned UPDATE or positioned DELETE statement, define the cursor as FOR READ ONLY.
Positioned deletes and isolation level UR:
Specify FOR UPDATE if you want to use the cursor for a positioned
DELETE and the isolation level is UR because of a BIND option. In this
case, the isolation level is CS.

Returning a result set from a stored procedure:
A cursor that is declared in a stored procedure returns a result set when all
of the following conditions are true:
- The cursor is declared with the WITH RETURN option. In a distributed
  environment, blocks of each result set of the cursor’s data are returned
  with the CALL statement reply.
- The cursor is left open after exiting from the stored procedure. A cursor
  declared with the SCROLL option must be left positioned before the first
  row before exiting from the stored procedure.
- The cursor is declared with the WITH HOLD option if the stored
  procedure is defined to commit on return.

The result set is the set of all rows after the current position of the cursor
after exiting the stored procedure. The result set is assumed to be
read-only. If that same procedure is invoked again, open result set cursors
for a stored procedure at a given site are automatically closed by the
database management system.

Scrollable cursors specified with user-defined functions:
A row can be fetched more than once with a scrollable cursor. Therefore, if
a scrollable cursor is defined with a function that is not deterministic in the
select list of the cursor, a row can be fetched multiple times with different
results for each fetch. (However, the value of a function that is not
deterministic in the WHERE clause of a scrollable cursor is captured when
the cursor is opened and remains unchanged until the cursor is closed.)
Similarly, if a scrollable cursor is defined with a user-defined function with
external action, the action is executed with every fetch.

Multiple instances of a cursor that is defined with RETURN TO CLIENT:
If the cursor is declared in a native SQL procedure, a cursor that is
declared as WITH RETURN TO CLIENT can be opened even when a
cursor with the same name is already in the open state. In this case, the
already open cursor becomes a result set cursor and is no longer accessible
by using its cursor name. A new cursor is opened and becomes accessible
by using the cursor name. When a CLOSE statement is issued, the last
instance of the cursor will be closed. Closing the new cursor does not
make the cursor that was previously accessible by that name accessible by
the cursor name again. Cursors that become result set cursors in this way
cannot be accessed at the server and can be processed only at the client.

Examples

The statements in the following examples are assumed to be in PL/I programs.

Example 1: Declare C1 as the cursor of a query to retrieve data from the table
DSN8A10.DEPT. The query itself appears in the DECLARE CURSOR statement.

EXEC SQL DECLARE C1 CURSOR FOR
SELECT DEPTNO, DEPTNAME, MGRNO
FROM DSN8A10.DEPT
WHERE ADMRDEPT = 'A00';
Example 2: Declare C1 as the cursor of a query to retrieve data from the table DSN8A10.DEPT. Assume that the data will be updated later with a searched update and should be locked when the query executes. The query itself appears in the DECLARE CURSOR statement.

```
EXEC SQL DECLARE C1 CURSOR FOR
    SELECT DEPTNO, DEPTNAME, MGRNO
    FROM DSN8A10.DEPT
    WHERE ADMRDEPT = 'A00'
    FOR READ ONLY WITH RS USE AND KEEP EXCLUSIVE LOCKS;
```

Example 3: Declare C2 as the cursor for a statement named STMT2.

```
EXEC SQL DECLARE C2 CURSOR FOR STMT2;
```

Example 4: Declare C3 as the cursor for a query to be used in positioned updates of the table DSN8A10.EMP. Allow the completed updates to be committed from time to time without closing the cursor.

```
EXEC SQL DECLARE C3 CURSOR WITH HOLD FOR
    SELECT * FROM DSN8A10.EMP
    FOR UPDATE OF WORKDEPT, PHONENO, JOB, EDLEVEL, SALARY;
```

Instead of specifying which columns should be updated, you could use a FOR UPDATE clause without the names of the columns to indicate that all updatable columns are updated.

Example 5: In stored procedure SP1, declare C4 as the cursor for a query of the table DSN8A10.PROJ. Enable the cursor to return a result set to the caller of SP1, which performs a commit on return.

```
EXEC SQL DECLARE C4 CURSOR WITH HOLD WITH RETURN FOR
    SELECT PROJNO, PROJNAME
    FROM DSN8A10.PROJ
    WHERE DEPTNO = 'A01';
```

Example 6: In the following example, the DECLARE CURSOR statement associates the cursor name C5 with the results of the SELECT and specifies that the cursor is scrollable. C5 allows positioned updates and deletes because the result table can be updated.

```
EXEC SQL DECLARE C5 SENSITIVE STATIC SCROLL CURSOR FOR
    SELECT DEPTNO, DEPTNAME, MGRNO
    FROM DSN8A10.DEPT
    WHERE ADMRDEPT = 'A00';
```

Example 7: In the following example, the DECLARE CURSOR statement associates the cursor name C6 with the results of the SELECT and specifies that the cursor is scrollable.

```
EXEC SQL DECLARE C6 INSENSITIVE SCROLL CURSOR FOR
    SELECT DEPTNO, DEPTNAME, MGRNO
    FROM DSN8A10.DEPT
    WHERE DEPTNO;
```

Example 8: The following example illustrates how an application program might use dynamic scrollable cursors. First create and populate a table.

```
CREATE TABLE ORDER
    (ORDERNUM INTEGER,
    CUSTNUM INTEGER,
    CUSTNAME VARCHAR(20),
    ORDERDATE CHAR(8),
    ORDERAMT DECIMAL(8,3),
    COMMENTS VARCHAR(20));
```
Populate the table by inserting or loading about 500 rows.

```sql
EXEC SQL DECLARE CURSOR ORDERSCROLL
SENSITIVE DYNAMIC SCROLL FOR
SELECT ORDERNUM, CUSTNAME, ORDERAMT, ORDERDATE FROM ORDER
WHERE ORDERAMT > 1000
FOR UPDATE OF COMMENTS;
```

Open the scrollable cursor.

```sql
OPEN CURSOR ORDERSCROLL;
```

Fetch forward from the scrollable cursor.

```sql
-- Loop-to-fill-screen
   -- do 10 times
   FETCH FROM ORDERSCROLL INTO :HV1, :HV2, :HV3, :HV4;
   -- end
```

Fetch RELATIVE from the scrollable cursor.

```sql
-- Skip-forward-100-rows
   FETCH RELATIVE +100
   FROM ORDERSCROLL INTO :HV1, :HV2, :HV3, :HV4;
-- Skip-backward-50-rows
   FETCH RELATIVE -50
   FROM ORDERSCROLL INTO :HV1, :HV2, :HV3, :HV4;
```

Fetch ABSOLUTE from the scrollable cursor.

```sql
-- Re-read-the-third-row
   FETCH ABSOLUTE +3
   FROM ORDERSCROLL INTO :HV1, :HV2, :HV3, :HV4;
```

Fetch RELATIVE from scrollable cursor.

```sql
-- Read-the-third-row-from current position
   FETCH SENSITIVE RELATIVE +3
   FROM ORDERSCROLL INTO :HV1, :HV2, :HV3, :HV4;
```

Do a positioned update through the scrollable cursor.

```sql
-- Update-the-current-row
   UPDATE ORDER SET COMMENTS = "Expedite"
   WHERE CURRENT OF ORDERSCROLL;
```

Close the scrollable cursor.

```sql
CLOSE CURSOR ORDERSCROLL;
```

Example 9: Declare C1 as the cursor of a query to retrieve a rowset from the table DEPT. The prepared statement is MYCURSOR.

```sql
EXEC SQL DECLARE C1 CURSOR
   WITH ROWSET POSITIONING FOR MYCURSOR;
```
DECLARE GLOBAL TEMPORARY TABLE

The DECLARE GLOBAL TEMPORARY TABLE statement defines a declared temporary table for the current application process. The declared temporary table resides in the work file database and its description does not appear in the system catalog. It is not persistent and cannot be shared with other application processes. Each application process that defines a declared temporary table of the same name has its own unique description and instance of the temporary table. When the application process terminates, the temporary table is dropped.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None are required, unless the LIKE clause or AS fullselect is specified. In those cases, additional privileges might be required.

PUBLIC implicitly has the following privileges without GRANT authority for declared temporary tables:

- The CREATETAB privilege to define a declared temporary table in the database that is defined AS WORKFILE, which is the database for declared temporary tables.
- The USE privilege to use the table spaces in the database that is defined as WORKFILE.
- All table privileges on the table and authority to drop the table. (Table privileges for a declared temporary table cannot be granted or revoked.)

These implicit privileges are not recorded in the DB2 catalog and cannot be revoked.
Syntax

```
DECLARE GLOBAL TEMPORARY TABLE table-name
    column-definition
    LIKE table-name
    copy-options
    view-name
    as-result-table

Notes:
1. The same clause must not be specified more than one time.
```

column-definition:

```
column-name data-type

Notes:
1. The same clause must not be specified more than once.
```

data-type:

```
built-in-type

Notes:
```

built-in-type:
as-result-table:

```sql
AS (fullselect) WITH NO DATA
```

copy-options:
Notes:
1  These clauses can be specified in any order and must not be specified more than one time.
2  EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, and USING TYPE DEFAULTS must not be specified with the LIKE clause.

identity-options:

Notes:
1  Separator commas can be specified between the attributes when an identity column is defined.

Description

table-name

Names the temporary table. The qualifier, if specified explicitly, must be SESSION. If the qualifier is not specified, it is implicitly defined to be SESSION.

If a table, view, synonym, or alias already exists with the same name and an implicit or explicit qualifier of SESSION:

- The declared temporary table is still defined with SESSION.table-name. An error is not issued because the resolution of a declared temporary table name does not include the persistent and shared names in the DB2 catalog tables.
• Any references to SESSION.table-name will resolve to the declared temporary table rather than to any existing SESSION.table-name whose definition is persistent and is in the DB2 catalog tables.

column-definition
Defines the attributes of a column for each instance of the table. The number of columns defined must not exceed 750. The maximum record size must not exceed 32683 bytes. The maximum row size must not exceed 32675 bytes (8 bytes less than the maximum record size).

column-name
Names the column. The name must not be qualified and must not be the same as the name of another column in the table.

data-type
Specifies the data type of the column. The data type can be any built-in data type that can be specified for the CREATE TABLE statement except for a LOB (BLOB, CLOB, and DBCLOB), ROWID, or XML type. The FOR subtype DATA clause can be specified as part of data-type. For more information on the data types and the rules that apply to them, see built-in-type.

DEFAULT
Specifies a default value for the column. This clause must not be specified more than once in the same column-definition.

Omission of NOT NULL and DEFAULT from a column-definition is an implicit specification of DEFAULT NULL.

If DEFAULT is specified without a value after it, the default value of the column depends on the data type of the column, as follows:

Data type
   Default value
Numeric
   0
Fixed-length character string
   A string of blanks
Fixed-length graphic string
   A string of blanks
Fixed-length binary string
   Hexadecimal zeros
Varying-length string
   A string of length 0
Date
   CURRENT DATE
Time
   CURRENT TIME
Timestamp
   CURRENT TIMESTAMP(p) where p is the corresponding timestamp precision.
   CURRENT TIMESTAMP(p) WITH TIME ZONE where p is the corresponding timestamp precision.

A default value other than the one that is listed above can be specified in one of the following forms:

constant
Specifies a constant as the default value for the column. The value of the constant must conform to the rules for assigning that value to the column. A hexadecimal graphic string constant (GX) cannot be specified.
SESSION_USER or USER
Specifies the value of the SESSION_USER (USER) special register at the
time of an insert or update operation or LOAD as the default value for the
column. The data type of the column must be a character string with a
length attribute greater than or equal to the length attribute of the
SESSION_USER special register.

CURRENT SQLID
Specifies the value of the SQL authorization ID of the process at the time
of an SQL data change statement or LOAD as the default value for the
column. The data type of the column must be a character string with a
length attribute greater than or equal to the length attribute of the
CURRENT SQLID special register.

NULL
Specifies null as the default value for the column. If NOT NULL was
specified, DEFAULT NULL must not be specified within the same
column-definition.

GENERATED
Specifies that DB2 generates values for the column. GENERATED must be
specified if the column is to be considered an IDENTITY column. If DEFAULT
is specified for the column for an update operation, DB2 generates a value for
both GENERATED ALWAYS and GENERATED BY DEFAULT.

ALWAYS
Specifies that DB2 always generates a value for the column when a row is
inserted into the table.

BY DEFAULT
Specifies that DB2 generates a value for the column when a row is inserted
into the table unless a value is specified. BY DEFAULT is the
recommended value only when you are using data propagation.

Defining a column as GENERATED BY DEFAULT does not necessarily
guarantee the uniqueness of the values. To ensure uniqueness of the
values, define a unique, single-column index on the column.

AS IDENTITY
Specifies that the column is an identity column for the table. A table can have
only one identity column. AS IDENTITY can be specified only if the data type
for the column is an exact numeric type with a scale of zero (SMALLINT,
INTEGER, BIGINT, DECIMAL with a scale of zero).

An identity column is implicitly NOT NULL. An identity column cannot have
a DEFAULT clause. For the descriptions of the identity attributes, see the
description of the AS IDENTITY clause in "CREATE TABLE" on page 1730.

NOT NULL
Specifies that the column cannot contain nulls. Omission of NOT NULL
indicates that the column can contain nulls.

LIKE table-name or view-name
Specifies that the columns of the table have the same name, data type, and
nullability attributes as the columns of the identified table or view. If a table is
identified, the column default attributes are also defined by that table. If row
permissions or column access control is enforced for the table specified by
table-name, row and column access controls are not inherited by the new table.
The name specified must identify a table, view, synonym, or alias that exists at
the current server. The identified table must not be an auxiliary table or an
accelerator-only table.
The privilege set must include the SELECT privilege on the identified table or view.

This clause is similar to the LIKE clause on CREATE TABLE, but it has the following differences:

- If LIKE results in a column having a LOB data type, a ROWID data type, or distinct type, the DECLARE GLOBAL TEMPORARY TABLE statement fails.
- In addition to these data type restrictions, if any column has any other attribute value that is not allowed in a declared temporary table, that attribute value is ignored. The corresponding column in the new temporary table has the default value for that attribute unless otherwise indicated.

When the identified object is a table, the column name, data type, nullability, and default attributes are determined from the columns of the specified table; any identity column attributes are inherited only if the INCLUDING IDENTIFY COLUMN ATTRIBUTES clause is specified.

**as-result-table**

Specifies that the table definition is based on the column definitions from the result of a query expression.

The behavior of these column attributes is controlled with the INCLUDING or USING TYPE DEFAULTS clauses, which are defined below.

**AS** *(fullselect)*

Specifies an implicit definition of n columns for the declared global temporary table, where n is the number of columns that would result from the fullselect. The columns of the new table are defined by the columns that result from the fullselect. Every select list element must have a unique name. The AS clause can be used in the select-clause to provide unique names. The implicit definition includes the column name, data type, and nullability characteristic of each of the result columns of fullselect. A column of the new table that corresponds to an implicitly hidden column of a base table referenced in the fullselect is not considered hidden in the new table. Row and column access controls that are enforced on the base table are not inherited by the new table.

The result table of the fullselect must not contain a column that has a LOB data type, a ROWID data type, an XML data type or a distinct type.

If fullselect results in other column attributes that are not applicable for a declared temporary table, those attributes are ignored in the implicit definition for the declared temporary table.

If fullselect results in a row change timestamp column, the corresponding column of the new table inherits only the data type of the row change timestamp column. The new column is not considered as a generated column.

The fullselect must not refer to host variables or include parameter markers (question marks). The outermost SELECT list of the fullselect must not reference data that is encoded with different encoding schemes.

**WITH NO DATA**

Specifies that the fullselect is not executed. You can use the INSERT INTO statement with the same fullselect specified in the AS clause to populate the declared temporary table with the set of rows from the result table of the fullselect.
copy-options
   Specifies whether identity column attributes and column defaults are inherited from the definition of the source of the result table.

**EXCLUDING IDENTITY COLUMN ATTRIBUTES or INCLUDING IDENTITY COLUMN ATTRIBUTES**
   Specifies whether identity column attributes are inherited from the columns resulting from the `fullselect`, `table-name`, or `view-name`.

**EXCLUDING IDENTITY COLUMN ATTRIBUTES**
   Specifies that the table does not inherit the identity attributes of the columns resulting from the `fullselect, table-name, or view-name`.

**INCLUDING IDENTITY COLUMN ATTRIBUTES**
   Specifies that the table inherits the identity attributes, if any, of the columns resulting from the `fullselect or table-name`. In general, the identity attributes are copied if the element of the corresponding column in the table or `fullselect` is the name of a table column that directly or indirectly maps to the name of a base table column that is an identity column.

If the INCLUDING IDENTITY COLUMN ATTRIBUTES clause is specified with the AS `fullselect` clause, the columns of the new table do not inherit the identity attribute in the following cases:

- The select list of the `fullselect` includes multiple instances of an identity column name (that is, selecting the same column more than once).
- The select list of the `fullselect` includes multiple identity columns (that is, it involves a join).
- The identity column is included in an expression in the select list.
- The `fullselect` includes a set operation.

If including identity column attributes is not specified, the new table will not have an identity column.

If the LIKE clause identifies a view, INCLUDING IDENTITY COLUMN ATTRIBUTES must not be specified.

**EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, or USING TYPE DEFAULTS**
   Specifies whether the table inherits the default values of the columns of the `fullselect`. EXCLUDING COLUMN DEFAULTS, INCLUDING COLUMN DEFAULTS, and USING TYPE DEFAULTS must not be specified if the LIKE clause is specified.

**EXCLUDING COLUMN DEFAULTS**
   Specifies that the table does not inherit the default values of the columns of the `fullselect`. The default values of the column of the new table are either null or there are no default values. If the column can be null, the default is the null value. If the column cannot be null, there is no default value, and an error occurs if a value is not provided for a column on an insert operation for the new table.

**INCLUDING COLUMN DEFAULTS**
   Specifies that the table inherits the default values of the columns of the `fullselect`. A default value is the value that is assigned to the column when a value is not specified on an insert operation or LOAD.
Columns resulting from the fullselect that are not updatable will not have a default defined in the corresponding column of the created table.

**USING TYPE DEFAULTS**

Specifies that the default values for the declared temporary table depend on the data type of the columns that result from fullselect, as follows:

<table>
<thead>
<tr>
<th>Data type</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric</td>
<td>0</td>
</tr>
<tr>
<td>Fixed-length character string</td>
<td>Blanks</td>
</tr>
<tr>
<td>Fixed-length graphic string</td>
<td>Blanks</td>
</tr>
<tr>
<td>Fixed-length binary string</td>
<td>Hexadecimal zeros</td>
</tr>
<tr>
<td>Varying-length string</td>
<td>A string of length 0</td>
</tr>
<tr>
<td>Date</td>
<td>CURRENT DATE</td>
</tr>
<tr>
<td>Time</td>
<td>CURRENT TIME</td>
</tr>
<tr>
<td>Timestamp</td>
<td>CURRENT TIMESTAMP(p)</td>
</tr>
<tr>
<td></td>
<td>where p is the corresponding timestamp precision.</td>
</tr>
<tr>
<td>Timestamp(integer) with time zone</td>
<td>CURRENT TIMESTAMP(p) WITH TIME ZONE where p is the corresponding timestamp precision.</td>
</tr>
</tbody>
</table>

**CCSID encoding-scheme**

Specifies the encoding scheme for string data that is stored in the table. For declared temporary tables, the encoding scheme for the data cannot be specified for the table space or database, and all data in one table space or the database need not use the same encoding scheme. Because there can be only one work file database for all declared temporary tables for each DB2 member, there can be a mixture of encoding schemes in both the database and each table space.

For declared temporary tables, the CCSID clause can be specified whether or not the LIKE clause is specified. If the CCSID clause is specified, the encoding scheme of the new table is the scheme that is specified in the CCSID clause. If the CCSID clause is not specified, the encoding scheme of the new table is the same as the scheme for the table specified in the LIKE clause or as the scheme for the table identified by the AS (fullselect) clause.

**ASCII**  Specifies that the data is encoded by using the ASCII CCSIDs of the server.

**EBCDIC**  Specifies that the data is encoded by using the EBCDIC CCSIDs of the server.

**UNICODE**  Specifies that the data is encoded by using the UNICODE CCSIDs of the server.

An error occurs if the CCSIDs for the encoding scheme have not been defined. Usually, each encoding scheme requires only a single CCSID. Additional CCSIDs are needed when mixed, graphic, or UNICODE data is used.
ON COMMIT
Specifies what happens to the table for a commit operation. The default is ON COMMIT DELETE ROWS.

DELETE ROWS
Specifies that all of the rows of the table are deleted if there is no open cursor that is defined as WITH HOLD that references the table.

PRESCRIBE ROWS
Specifies that all of the rows of the table are preserved. Thread reuse capability is not available to any application process or thread that contains, at its most recent commit, an active declared temporary table that was defined with the ON COMMIT PRESERVE ROWS clause.

DROP TABLE
Specifies that the table is implicitly dropped at commit if there is no open cursor that is defined as WITH HOLD that references the table. If there is an open cursor defined as WITH HOLD on the table at commit, the rows are preserved.

Notes
Instantiation, scope, and termination
For the following explanations, P denotes an application process, and T is a declared temporary table executed in P:

- An empty instance of T is created when a DECLARE GLOBAL TEMPORARY TABLE statement is executed in P.
- Any SQL statement in P can reference T, and any of those references to T in P is a reference to that same instance of T. ()
  If a DECLARE GLOBAL TEMPORARY statement is specified within an SQL PL compound statement, the scope of the declared temporary table is the application process and not just the compound statement. A declared temporary table cannot be defined multiple times by the same name in other compound statements in that application process, unless the table has been dropped explicitly.
- If T was declared at a remote server, the reference to T must use the same DB2 connection that was used to declare T and that connection must not have been terminated after T was declared. When the connection to the database server at which T was declared terminates, T is dropped.
- If T was defined with the ON COMMIT DELETE ROWS clause specified implicitly or explicitly, when a commit operation terminates a unit of work in P and there is no open WITH HOLD cursor in P that is dependent on T, the commit deletes all rows from T.
- If T is defined with the ON COMMIT DROP TABLE clause, when a commit operation terminates a unit of work in P and no program in P has a WITH HOLD cursor open that is dependent on T, the commit includes the operation DROP TABLE T.
- When a rollback operation terminates a unit of work or savepoint in P, and that unit of work or savepoint includes the declaration of SESSION.T, the changes to table T are undone.
  When a rollback operation terminates a unit of work or savepoint in P, and that unit of work or savepoint includes the declaration of SESSION.T, the rollback drops table T.
When a rollback operation terminates a unit of work or savepoint in P, and that unit of work or savepoint includes the drop of the declaration of declared temporary table SESSION.T, the rollback undoes the drop of table T.

- When the application process that declared T terminates, T is dropped.

**Privileges**

When a declared temporary table is defined, PUBLIC is implicitly granted all table privileges on the table and authority to drop the table. These implicit privileges are not recorded in the DB2 catalog and cannot be revoked. This enables any SQL statement in the application process to reference a declared temporary table that has already been defined in that application process.

**Referring to a declared temporary table in other SQL statements**

Many SQL statements support declared temporary tables. To refer to a declared temporary table in an SQL statement other than DECLARE GLOBAL TEMPORARY TABLE, you must qualify the table name with SESSION. You can either specify SESSION explicitly in the table name or use the QUALIFIER bind option to specify SESSION as the qualifier for all SQL statements in the plan or package.

If you use SESSION as the qualifier for a table name but the application process does not include a DECLARE GLOBAL TEMPORARY TABLE statement for the table name, DB2 assumes that you are not referring to a declared temporary table. DB2 resolves such table references to a table whose definition is persistent and appears in the DB2 catalog tables.

With the exception of the DECLARE GLOBAL TEMPORARY TABLE statement, any static SQL statement that references a declared temporary table is incrementally bound at run time. This is because the definition of the declared temporary table does not exist until the DECLARE GLOBAL TEMPORARY statement is executed in the application process that contains those SQL statements and the definition does not persist when the application process finishes running.

When a plan or package is bound, any static SQL statement (other than the DECLARE GLOBAL TEMPORARY TABLE statement) that references a table-name that is qualified by SESSION, regardless of whether the reference is for a declared temporary table, is not completely bound. However, the bind of the plan or package succeeds if there are no other errors. No object dependencies, including non-DECLARE GLOBAL TEMPORARY TABLE objects, are recorded in the DB2 catalog for any such statements. These static SQL statements are then incrementally bound at run time when the static SQL statement is issued.

The incremental binds are necessary for the following reasons:

- The definition of the declared temporary table does not exist until the DECLARE GLOBAL TEMPORARY TABLE statement for the table is executed in the same application process that contains those SQL statements. Therefore, DB2 must wait until the plan or package is run to determine if SESSION.table-name refers to a base table or a declared temporary table.

- The definition of a declared temporary table does not persist after the table it is explicitly dropped (DROP statement), implicitly dropped (ON COMMIT DROP TABLE), or the application process that defined it finishes running. When the application process terminates or is re-used as a reusable application thread, the instantiated rows of the table are
deleted and the definition of the declared temporary table is dropped if it has not already been explicitly or implicitly dropped.

After the plan or package is bound, any static SQL statement that refers to a *table-name* that is qualified by SESSION has a new statement status of M in the DB2 catalog table (STATUS column of SYSIBM.SYSSTMT or SYSIBM.SYSPACKSTMT).

**Thread reuse**

If a declared temporary table is defined in an application process that is running as a local thread, the application process or local thread that declared the table qualifies for explicit thread reuse if:

- The table was defined with the ON COMMIT DELETE ROWS attribute, which is the default.
- The table was defined with the ON COMMIT PRESERVE ROWS attribute and the table was explicitly dropped with the DROP TABLE statement before the thread’s commit operation.
- The table was defined with the ON COMMIT DROP TABLE attribute. When a declared temporary table is defined with the ON COMMIT DROP TABLE and a commit occurs, the table is implicitly dropped if there are no open cursors defined with the WITH HOLD option.

When the thread is reused, the declared temporary table is dropped and its rows are destroyed. However, if you do not explicitly or implicitly drop all declared temporary tables before or when your thread performs a commit and the thread becomes idle waiting to be reused, as with all thread reuse situations, the idle thread holds resources and locks. This includes some declared temporary table resources and locks on the table spaces and the database descriptor (DBD) for the work file database. So, instead of using the implicit drop feature of thread reuse to drop your declared temporary tables, it is recommended that you:

- Use the DROP TABLE statement to explicitly drop your declared temporary tables before the thread performs a commit and becomes idle.
- Define the declared temporary tables with ON COMMIT DROP TABLE clause so that the tables are implicitly dropped when a commit occurs.

Explicitly dropping the tables before a commit occurs or having them implicitly dropped when the commit occurs enables you to maximize the use of declared temporary table resources and release locks when multiple threads are using declared temporary table.

Remote threads qualify for thread reuse differently than local threads. If a declared temporary table is defined (with or without ON COMMIT DELETE ROWS) in an application process that is running as a remote or DDF thread (also known as Database Access Thread or DBAT), the remote thread qualifies for thread reuse only when the declared temporary table is explicitly dropped before the thread performs a commit operation. Dropping the declared temporary table enables the remote thread to qualify for the implicit thread reuse that is supported for DDF threads via connection pooling and to become an inactive DBAT (type 1 inactive thread) or an inactive connection (type 2 inactive thread).

**Parallelism support**

Only I/O and CP parallelism are supported. Any query that involves a declared temporary table is limited to parallel tasks on a single CPC.

**Restrictions on the use of declared temporary tables**

Declared temporary tables cannot:
• Be specified in referential constraints.
• Be referenced in any SQL statements that are defined in an SQL function body (CREATE FUNCTION or ALTER FUNCTION statements), a trigger body (CREATE TRIGGER statement). If you refer a table name that is qualified with SESSION in a trigger body, DB2 assumes that you are referring to a base table.
• Be referenced in a CREATE INDEX statement unless the schema name of the index is SESSION.

In addition, do not refer to a declared temporary table in any of the following statements.

<table>
<thead>
<tr>
<th>ALTER INDEX</th>
<th>CREATE VIEW</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER TABLE</td>
<td>GRANT (table or view privileges)</td>
</tr>
<tr>
<td>COMMENT</td>
<td>LABEL</td>
</tr>
<tr>
<td>CREATE ALIAS</td>
<td>LOCK TABLE</td>
</tr>
<tr>
<td>CREATE FUNCTION (TABLE LIKE clause)</td>
<td>REFRESH TABLE</td>
</tr>
<tr>
<td>CREATE PROCEDURE (TABLE LIKE clause)</td>
<td>RENAME</td>
</tr>
<tr>
<td>CREATE TRIGGER</td>
<td>REVOKE (table or view privileges)</td>
</tr>
</tbody>
</table>

**Declared global temporary tables and dynamic statement caching**

The DB2 dynamic statement cache feature does not support dynamic SQL statements that reference declared temporary tables, even if the SQL statement also includes references to base or persistent tables. DB2 will not insert such statements into the dynamic statement cache. Instead, these dynamic statements are processed as if statement caching is not in effect. Declared temporary tables are unique and specific to an application process or DB2 thread, cannot be shared across threads, are not described in the DB2 catalog, and do not persist beyond termination of the DB2 thread or application process. These attributes prevent the use of the dynamic statement cache feature where tables and SQL statements are shared across threads or application processes.

**Table space requirements in the work file database**

DB2 stores all declared temporary tables in the work file database. You cannot define a declared temporary table unless a table space with at least an 32KB page size exists in the work file database.

**Alternative syntax and synonyms**

To provide compatibility with previous releases, DB2 allows you to specify:

• LONG VARCHAR as a synonym for VARCHAR(integer) and LONG VARGRAPHIC as a synonym for VARGRAPHIC(integer) when defining the data type of a column.
  However, the use of these synonyms is not encouraged because after the statement is processed, DB2 considers a LONG VARCHAR column to be VARCHAR and a LONG VARGRAPHIC column to be VARGRAPHIC.

• DEFINITION ONLY as a synonym for WITH NO DATA.
• TIMEZONE can be specified as an alternative to TIME ZONE.

**Examples**

*Example 1:* Define a declared temporary table with column definitions for an employee number, salary, commission, and bonus.
DECLARE GLOBAL TEMPORARY TABLE SESSION.TEMP_EMP
(EMPNO CHAR(6) NOT NULL,
SALARY DECIMAL(9, 2),
BONUS DECIMAL(9, 2),
COMM DECIMAL(9, 2))
CCSID EBCDIC
ON COMMIT PRESERVE ROWS;

Example 2: Assume that base table USER1.EMPTAB exists and that it contains three columns, one of which is an identity column. Declare a temporary table that has the same column names and attributes (including identity attributes) as the base table.

DECLARE GLOBAL TEMPORARY TABLE TEMPTAB1
LIKE USER1.EMPTAB
INCLUDING IDENTITY
ON COMMIT PRESERVE ROWS;

In the above example, DB2 uses SESSION as the implicit qualifier for TEMPTAB1.
DECLARE STATEMENT

The DECLARE STATEMENT statement is used for application program documentation. It declares names that are used to identify prepared SQL statements.

Invocation

This statement can only be embedded in an application program. It is not an executable statement.

Authorization

None required.

Syntax

```
DECLARE statement-name STATEMENT
```

Description

`statement-name STATEMENT`

Lists one or more names that are used in your application program to identify prepared SQL statements.

Example

This example shows the use of the DECLARE STATEMENT statement in a PL/I program.

```
EXEC SQL DECLARE OBJECT_STATEMENT STATEMENT;

EXEC SQL INCLUDE SQlda;
EXEC SQL DECLARE C1 CURSOR FOR OBJECT_STATEMENT;

( SOURCE_STATEMENT IS "SELECT DEPTNO, DEPTNAME,
  MGRNO FROM DSN8A10.DEPT WHERE ADMRDEPT = 'A00'"
 )

EXEC SQL PREPARE OBJECT_STATEMENT FROM SOURCE_STATEMENT;
EXEC SQL DESCRIBE OBJECT_STATEMENT INTO SQlda;

/* Examine SQlda */
EXEC SQL OPEN C1;
DO WHILE (SQLCODE = 0);
  EXEC SQL FETCH C1 USING DESCRIPTOR SQlda;
/* Print results */
END;
EXEC SQL CLOSE C1;
```
DECLARE TABLE

The DECLARE TABLE statement is used for application program documentation. It also provides the precompiler with information used to check your embedded SQL statements. (The DCLGEN subcommand can be used to generate declarations for tables and views described in any accessible DB2 catalog.

For more information about DCLGEN, see Declaring table and view definitions (DB2 Application programming and SQL) and DCLGEN (DECLARATIONS GENERATOR) (DSN) (DB2 Commands).

Invocation

This statement can only be embedded in an application program. It is not an executable statement.

Authorization

None required.

Syntax

```
DECLARE table-name
    view-name

TABLE(
    column-name built-in-type distinct-type-name NOT NULL NOT NULL WITH DEFAULT)
```

built-in-type:
Description

table-name or view-name
Specify the name of the table or view to document. If the table is defined in your application program, the description of the table in the SQL statement in which it is defined (for example, CREATE TABLE or DECLARE GLOBAL TEMPORARY TABLE statement) and the DECLARE TABLE statement must be identical.

column-name
Specify the name of a column of the table or view.
The precompiler uses these names to check for consistency of names within your SQL statements. It also uses the data type to check for consistency of names and data types within your SQL statements.

built-in-type
Specify the built-in data type of the column. Use one of the built-in data types.

SMALLINT
For a small integer.

INTEGER or INT
For a large integer.

BIGINT
For a big integer.

DECIMAL(integer, integer) or DEC(integer, integer)
DECIMAL(integer) or DEC(integer)

For a decimal number. The first integer is the precision of the number. That is, the total number of digits, which can range from 1 to 31. The second integer is the scale of the number. That is, the number of digits to the right of the decimal point, which can range from 0 to the precision of the number.

You can use DECIMAL(p) for DECIMAL(p,0) and DECIMAL for DECIMAL(5,0).

You can also use the word NUMERIC instead of DECIMAL. For example, NUMERIC(8) is equivalent to DECIMAL(8). Unlike DECIMAL, NUMERIC has no allowable abbreviation.

FLOAT(integer)

FLOAT

For a floating-point number. If integer is between 1 and 21 inclusive, the format is single precision floating-point. If the integer is between 22 and 53 inclusive, the format is double precision floating-point.

You can use DOUBLE PRECISION or FLOAT for FLOAT(53).

REAL
For single precision floating-point.

DOUBLE or DOUBLE PRECISION
For double precision floating-point

DECFLOAT(integer)
For a decimal floating-point number. The value of integer must be either 16
or 34 and represents the number of significant digits that can be stored. If integer is omitted, the DECFLOAT column will be capable of representing 34 significant digits.

**CHARACTER(integer) or CHAR(integer)**

For a fixed-length character string of length integer, which can range from 1 to 255. If the length specification is omitted, a length of 1 character is assumed.

**VARCHAR(integer), CHAR VARYING(integer), or CHARACTER VARYING(integer)**

For a varying-length character string of maximum length integer, which can range from 1 to the maximum record size minus 10 bytes. See Table 178 on page 1791 to determine the maximum record size.

**CLOB(integer [K|M|G]), CHAR LARGE OBJECT(integer [K|M|G]), or CHARACTER LARGE OBJECT(integer [K|M|G])**

For a character large object (CLOB) string of the specified maximum length in bytes. The maximum length must be in the range of 1 to 2,147,483,647. A CLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see “Restrictions using LOBs” on page 116.

When integer is not specified, the default length is 1M. The maximum value that can be specified for integer depends on whether a units indicator is also specified as shown in the following list.

- **integer** The maximum value for integer is 2,147,483,647. The maximum length of the string is integer.
- **integer K** The maximum value for integer is 2,097,152. The maximum length is 1,024 times integer.
- **integer M** The maximum value for integer is 2,048. The maximum length is 1,048,576 times integer.
- **integer G** The maximum value for integer is 2. The maximum length is 1,073,741,824 times integer.

If you specify a value that evaluates to 2 gigabytes (2,147,483,648), DB2 uses a value that is one byte less, or 2,147,483,647.

**GRAPHIC(integer)**

For a fixed-length graphic string of length integer, which can range from 1 to 127. If the length specification is omitted, a length of 1 character is assumed.

**VARGRAPHIC(integer)**

For a varying-length graphic string of maximum length integer, which must range from 1 to n/2, where n is the maximum row size minus 2 bytes.

**DBCLOB(integer [K|M|G])**

For a double-byte character large object (DBCLOB) string of the specified maximum length in double-byte characters. The maximum length must be in the range of 1 through 1,073,741,823. A DBCLOB column has a
varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see “Restrictions using LOBs” on page 116.

When integer is not specified, the default length is 1M. The meaning of integer K|M|G is similar to CLOB. The difference is that the number specified is the number of double-byte characters.

**BINARY(integer)**

A fixed-length binary string of length integer. The integer can range from 1 through 255. If the length specification is omitted, a length of 1 byte is assumed.

**BINARY VARYING(integer) or VARBINARY(integer)**

A varying-length binary string of maximum length integer, which can range from 1 through 32704. The length is limited by the page size of the table space.

**BLOB (integer [K|M|G] or BINARY LARGE OBJECT(integer [K|M|G])**

For a binary large object (BLOB) string of the specified maximum length in bytes. The maximum length must be in the range of 1 through 2,147,483,647. A BLOB column has a varying-length. It cannot be referenced in certain contexts regardless of its maximum length. For more information, see “Restrictions using LOBs” on page 116.

When integer is not specified, the default length is 1M. The meaning of integer K|M|G is the same as for CLOB.

**DATE**

For a date.

**TIME**

For a time.

**TIMESTAMP(integer)**

For a timestamp. integer specifies the optional timestamp precision attribute and must be in the range from 0 to 12. The timestamp precision denotes the number of fractional second digits that are included in the timestamp. The default is 6.

**TIMESTAMP(integer) WITH TIME ZONE**

For a timestamp with time zone. integer specifies the optional timestamp precision attribute and must be in the range from 0 to 12. The timestamp precision denotes the number of fractional second digits that are included in the timestamp. The default is 6.

**ROWID**

For a row ID type.

A table can have only one ROWID column. The values in a ROWID column are unique for every row in the table and cannot be updated. You must specify NOT NULL with ROWID.

**XML**

For an XML document. Only well-formed XML documents can be inserted into an XML column.

If the XML column is the first XML column that you create for the table, a BIGINT DOCID column is implicitly created and is used to store a unique document identifier for the XML columns of a row.
distinct-type-name
   Specifies the distinct type (user-defined data type) of the column. An implicit or explicit schema name qualifies the name.

NOT NULL
   Specifies that the column does not allow null values and does not provide a default value.

NOT NULL WITH DEFAULT
   Specifies that the column does not allow null values but provides a default value.

Notes

Error handling during processing: If an error occurs during the processing of the DECLARE TABLE statement, a warning message is issued, and the precompiler continues processing your source program.

Documenting a distinct type column: Although you can specify the name of a distinct type as the data type of a column in the DECLARE TABLE statement, use the built-in data type on which the distinct type is based instead. Using the base type enables the precompiler to check the embedded SQL statements for errors; otherwise, error checking is deferred until bind time.

To determine the source data type of the distinct type, check the value of column SOURCETYPE in catalog table SYSDATATYPES.

Examples

Example 1: Declare the sample employee table, DSN8A10.EMP.

EXEC SQL DECLARE DSN8A10.EMP TABLE
   (EMPNO CHAR(6) NOT NULL,
    FIRSTNME VARCHAR(12) NOT NULL,
    MIDINIT CHAR(1) NOT NULL,
    LASTNAME VARCHAR(15) NOT NULL,
    WORKDEPT CHAR(3),
    PHONENO CHAR(4),
    HIREDATE DATE,
    JOB CHAR(8),
    EDLEVEL SMALLINT,
    SEX CHAR(1),
    BIRTHDATE DATE,
    SALARY DECIMAL(9,2),
    BONUS DECIMAL(9,2),
    COMM DECIMAL(9,2));

Example 2: Assume that table CANADIAN_SALES keeps information for your company’s sales in Canada. The table was created with the following definition:

CREATE TABLE CANADIAN_SALES
   (PRODUCT_ITEM INTEGER,
    MONTH INTEGER,
    YEAR INTEGER,
    TOTAL CANADIAN_DOLLAR);

CANADIAN_DOLLAR is a distinct type that was created with the following statement:

CREATE TYPE CANADIAN_DOLLAR AS DECIMAL(9,2);
Declare the CANADIAN_SALES table, using the source type for CANADIAN_DOLLAR instead of the distinct type name.

```sql
DECLARE TABLE CANADIAN_SALES
(PRODUCT_ITEM INTEGER,
 MONTH INTEGER,
 YEAR INTEGER,
 TOTAL DECIMAL(9,2);
```
**DECLARE VARIABLE**

The DECLARE VARIABLE statement defines a CCSID for a host variable and the subtype of the variable. When it appears in an application program, the DECLARE VARIABLE statement causes the DB2 precompiler to tag a host variable with a specific CCSID. When the host variable appears in an SQL statement, the DB2 precompiler places this CCSID into the structures that it generates for the SQL statement.

**Invocation**

This statement can only be embedded in an application program. It is not an executable statement.

**Authorization**

None required.

**Syntax**

```
DECLARE host-variable VARIABLE CCSID [ASCII | EBCDIC | UNICODE] FOR [SBCS DATA | MIXED DATA | BIT DATA] CCSID integer-constant
```

**Description**

*host-variable*

Identifies a character or graphic string host variable defined in the program. An indicator variable cannot be specified for the host-variable.

*CCSID ASCII, EBCDIC, or UNICODE*

Specifies that the appropriate default CCSID for the specified encoding scheme of the server should be used.

*CCSID ASCII*

Specifies that the default ASCII CCSID for the type of the variable at the server should be used.

*CCSID EBCDIC*

Specifies that the default EBCDIC CCSID for the type of the variable at the server should be used. CCSID EBCDIC is the default if this option is not specified.

*CCSID UNICODE*

Specifies that the default UNICODE CCSID for the type of the variable at the server should be used.

*FOR SBCS DATA, FOR MIXED DATA, or FOR BIT DATA*

Specifies the type of data contained in the variable *host-variable*. The FOR clause cannot be specified when declaring a graphic host variable.
For ASCII or EBCDIC data, if this clause is not specified when declaring a character host variable, the default is FOR SBCS DATA if MIXED DATA = NO on the installation panel DSNTIPF. The default is FOR MIXED DATA if MIXED DATA = YES on the installation panel DSNTIPF.

For UNICODE data, the default is always FOR MIXED DATA, regardless of the setting of MIXED DATA on the installation panel DSNTIPF.

**FOR SBCS DATA**

Specifies that the values of the host variable can contain only SBCS (single-byte character set) data.

**FOR MIXED DATA**

Specifies that the values of the host variable can contain both SBCS data and DBCS data.

**FOR BIT DATA**

Specifies that the values of the host-variable are not associated with a coded character set and, therefore, are never converted. The CCSID of a FOR BIT DATA host variable is 65535.

**CCSID integer-constant**

Specifies that the values of the host variable contain data that is encoded using CCSID integer-constant. If the integer is an SBCS CCSID, the host variable is SBCS data. If the integer is a mixed data CCSID, the host variable is mixed data. For character host variables, the CCSID specified must be an SBCS, mixed CCSID, or UNICODE (UTF-8) CCSID. For graphic host variables, the CCSID specified must be a DBCS or UNICODE (UTF-16) CCSID. The valid range of values for the integer is 1 - 65533.

**Notes**

**Placement of statement:** The DECLARE VARIABLE statement can be specified anywhere in an application program that SQL statements are valid with the following exception. The DECLARE VARIABLE statement must occur before an SQL statement that refers to a host variable specified in the DECLARE VARIABLE statement.

**CCSID exceptions for EXECUTE IMMEDIATE or PREPARE:** When the host variable appears in an SQL statement, the DB2 precompiler places the appropriate numeric CCSID into the structures it generates for the SQL statement. This placement of the CCSID occurs for any SQL statement other than the EXECUTE IMMEDIATE or PREPARE statements. The placement of the CCSID also occurs for a host-variable in an EXECUTE IMMEDIATE or PREPARE statement, but it does not occur for a variable in a string-expression in an EXECUTE IMMEDIATE or PREPARE statement.

If a PL/1 application program contains at least one DECLARE VARIABLE statement, a string-expression in any EXECUTE IMMEDIATE or PREPARE statement cannot be preceded by a colon. An expression that consists of just a variable name preceded by a colon is interpreted as a host-variable.

**Specific host languages:** If a DECLARE VARIABLE statement is used in an assembler source program, the ONEPASS SQL processing option must not be used. If a DECLARE VARIABLE statement is used in a C, C++, or PL/1 source program, the TWOPASS SQL processing option must be used. For those languages, or COBOL, the host-variable definition can either precede or follow a DECLARE VARIABLE statement that refers to that variable. If a DECLARE VARIABLE
statement is used in a FORTRAN source program, then the host-variable definition must precede the DECLARE VARIABLE statement.

**Example**

*Example:* Define the following host variables using PL/I data types: FRED as fixed length bit data, JEAN as fixed length UTF-8 (mixed) data, DAVE as varying length UTF-8 (mixed) data, PETE as fixed length graphic UTF-16 data, and AMBER as varying length graphic UTF-16 data.

Use the DECLARE VARIABLE statement to specify a data subtype or CCSID for these host variables: FRED as CCSID EBCDIC, JEAN as CCSID 1208 or CCSID UNICODE, DAVE as CCSID 1208 or CCSID UNICODE, PETE as CCSID 1200 or CCSID UNICODE, and AMBER as CCSID 1200 or CCSID UNICODE.

```sql
EXEC SQL BEGIN DECLARE SECTION;
  DCL FRED CHAR(10);
  EXEC SQL DECLARE :FRED VARIABLE CCSD EBCDIC FOR BIT DATA;
  DCL JEAN CHAR(30);
  EXEC SQL DECLARE :JEAN VARIABLE CCSD 1208;
  DCL DAVE CHAR(9) VARYING;
  EXEC SQL DECLARE :DAVE VARIABLE CCSD UNICODE;
  DCL PETE GRAPHIC(10);
  EXEC SQL DECLARE :PETE VARIABLE CCSD 1200;
  DCL AMBER GRAPHIC(20) VARYING;
  EXEC SQL DECLARE :AMBER VARIABLE CCSD UNICODE;
EXEC SQL END DECLARE SECTION;
```
DELETE

The DELETE statement deletes rows from a table or view or activates an instead of delete trigger. The table or view can be at the current server or any DB2 subsystem with which the current server can establish a connection. Deleting a row from a view deletes the row from the table on which the view is based if no instead of trigger is defined for the delete operation on this view. If such a trigger is defined, the trigger is activated instead of the delete operation.

There are two forms of this statement:
- The searched DELETE form is used to delete one or more rows, optionally determined by a search condition.
- The positioned DELETE form specifies that one or more rows corresponding to the current cursor position are to be deleted.

Invocation

This statement can be embedded in an application program or issued interactively. A positioned DELETE is embedded in an application program. Both the embedded and interactive forms are executable statements that can be dynamically prepared.

Authorization

Authority requirements depend on whether the object identified in the statement is a user-defined table, a catalog table, or a view, and whether the statement is a searched DELETE and SQL standard rules are in effect:

When a table other than a catalog table is identified: The privilege set must include at least one of the following:
- The DELETE privilege on the table
- Ownership of the table
- DBADM authority on the database that contains the table
- SYSADM authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

When a catalog table is identified: The privilege set must include at least one of the following:
- DBADM authority on the catalog database
- SYSCTRL authority
- SYSADM authority

When a view is identified: The privilege set must include at least one of the following:
- The DELETE privilege on the view
- SYSADM authority

If the search-condition in a searched DELETE contains a reference to a column of the table or view, or the expression in the assignment-clause contains a reference to a column of the table or view, the privilege set must include at least one of the following:
- The SELECT privilege on the table or view
Ownership of the table or view
- DBADM authority on the database that contains the table, if the target is a table and that table that is not a catalog table
- DATAACCESS
- SYSADM authority

If the search-condition in a searched DELETE includes a subquery, or if the assignment-clause includes a scalar-fullselect or a row-fullselect, see Authorization for an explanation of the authorization required.

The owner of a view, unlike the owner of a table, might not have DELETE authority on the view (or might have DELETE authority without being able to grant it to others). The nature of the view itself can preclude its use for DELETE. For more information, see the description of authority in "CREATE VIEW" on page 1862.

If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 152 on page 1171 (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see "Authorization IDs and dynamic SQL" on page 95.

searched delete:

```
DELETETABLE name
[ view-name ]
[ period-clause ]
[ correlation-name ]

[ include-column ]
[ SET assignment-clause ]
[ WHERE search-condition ]

(1)
[ isolation-clause ]
[ QUERYNO integer ]
```

Notes:
1. The same clause must not be specified more than one time.

positioned delete:
DELETE FROM `table-name`
    `view-name` `correlation-name`
WHERE CURRENT OF `cursor-name`

FOR ROW `host-variable` OF ROWSET `integer-constant`

period-clause:

FOR PORTION OF BUSINESS_TIME FROM `value1` TO `value2`

assignment clause:
isolation-clause:

WITH RR
  RS
  CS

Description

FROM table-name or view-name
  Identifies the table or view from which rows are to be deleted. The name must identify a table or view that exists at the DB2 subsystem that is identified by the implicitly or explicitly specified location name. The name must not identify:
  • An auxiliary table
  • A catalog table for which deletes are not allowed
  • A view of such a catalog table
  • A directory table
  • A read-only view (see CREATE VIEW)
  • A system-maintained materialized query table
  • A table that is implicitly created for an XML column

In an IMS or CICS application, the DB2 subsystem that contains the identified table or view must be a remote server that supports two-phase commit.

period-clause
  Specifies that a period clause applies to the target of the delete operation. The same period name must not be specified more than one time. The table reference must not specify a view.

FOR PORTION OF BUSINESS_TIME
  Specifies that the delete only applies to row values for the portion of the BUSINESS_TIME period in the row that is specified by the period clause.
  BUSINESS_TIME must be a period that is defined on the table.

Notes:
1  The number of expressions and NULL keywords must match the number of column-names.
2  The number of columns in the select list must match the number of column-names.
FOR PORTION OF BUSINESS_TIME must not be specified if the value of the CURRENT TEMPORAL BUSINESS_TIME special register is not NULL when the BUSTIMESENSITIVE bind option is set to YES.

FROM value1 TO value2
Specifies that the delete operation applies to rows for the period that is specified from value1 to value2. No rows are deleted if value1 is greater than or equal to value2, or if value1 or value2 is the null value.

For the period condition that is specified with FROM value1 TO value2, the period that is specified by period-name in a row of the target table of the delete:

- Overlaps the beginning of the specified period if the value of the begin column is less than value1 and the value of the end column is greater than value1.
- Overlaps the end of the specified period if the value of the end column is greater than or equal to value2 and the value of the begin column is less than value2.
- Is fully contained within the specified period if the value for the begin column for period-name in the row is greater than or equal to value1 and the value for the corresponding end column in the row is less than or equal to value2.
- Is partially contained in the specified period if the row overlaps the beginning of the specified period or the end of the specified period.
- Fully overlaps the specified period if the period in the row overlaps the beginning of the specified period and overlaps the end of the specified period.
- Is not contained in the period if both columns of period-name are less than or equal to value1 or are greater than value2.

If the period period-name in a row is not contained in the specified period, the row is not deleted. Otherwise, the delete operation is applied based on the specification of the PORTION OF clause and how the values in the columns of period-name overlap the specified period as follows:

- If the period period-name in a row is fully contained within the specified period, the row is deleted.
- If the period period-name in a row is partially contained in the specified period and overlaps the beginning of the specified period:
  - The row is deleted.
  - A row is inserted using the original values from the row, except that the end column is set to value1, and new values are used for other generated columns.
- If the period period-name in a row is partially contained in the specified period and overlaps the end of the specified period:
  - The row is deleted.
  - A row is inserted using the original values from the row, except that the begin column is set to value2, and new values are used for other generated columns.
- If the period period-name in a row fully overlaps the specified period:
  - The row is deleted.
  - A row is inserted using the original values from the row, except that the end column is set to value1, and new values are used for other generated columns.
An additional row is inserted using the original values from the row, except that the begin column is set to value2, and new values are used for other generated columns.

Any existing delete triggers are activated for the rows that are deleted, and any existing insert triggers are activated for the rows that are implicitly inserted.

value1, value2

Specifies expressions that return a value of a built-in data type. The result of each expression must be comparable to the data type of the columns of the specified period. See the comparison rules described in Assignment and comparison. Each expression can contain any of the following supported operands:

- A constant
- A special register
- A variable
- A built-in scalar function whose arguments are supported operands
- A CAST specification where the cast operand is a supported operand
- An expression that uses arithmetic operators and operands

Each expression must not have a timestamp precision that is greater than the precision of the columns for the period.

If the begin and end columns of the period are defined as TIMESTAMP WITHOUT TIME ZONE, each expression must not return a value of a timestamp with a time zone.

correlation-name

Specifies an alternate name that can be used within the search-condition to designate the table or view. (For an explanation of correlation names, see “Correlation names” on page 220.)

include-column

Specifies a set of columns that are included, along with the columns of table-name or view-name, in the result table of the DELETE statement when it is nested in the FROM clause of the outer fullselect that is used in a subselect, SELECT statement, or in a SELECT INTO statement. The included columns are appended to the end of the list of columns that is identified by table-name or view-name. If no value is assigned to a column that is specified by an include-column, a NULL value is returned for that column.

INCLUDE

Introduces a list of columns that are to be included in the result table of the DELETE statement. The included columns are only available if the DELETE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement.

column-name

Specifies the name for a column of the result table of the DELETE statement that is not the same name as another included column nor a column in the table or view that is specified in table-name or view-name.

data-type

Specifies the data type of the included column. The included columns are nullable.
**built-in-type**
Specifies a built-in data type. See “CREATE TABLE” on page 1730 for a description of each built-in type.

**distinct-type**
Specifies a distinct type. Any length, precision, or scale attributes for the column are those of the source type of the distinct type as specified by using the CREATE TYPE statement.

**SET**
Introduces the assignment of values to columns.

**assignment-clause**
The assignment-clause introduces a list of one or more column-names and the values that are to be assigned to the columns. The column-names are the only columns that can be set using the assignment-clause.

**column-name**
Identifies an INCLUDE column.

Assignments to included columns are only processed when the DELETE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement. The columns that are named in the INCLUDE clause are the only columns that can be set using the SET clause. The null value is returned for an included column that is not set by using an explicit SET clause.

**expression**
Indicates the new value of the column. The expression is any expression of the type described in “Expressions” on page 246. It must not include an aggregate function.

A column-name in an expression must identify a column of the table or view. For each row that is deleted, the value of the column in the expression is the value of the column in the row before the row is deleted.

**NULL**
Specifies the null value as the new value of the column. Specify NULL only for nullable columns.

**row-fullselect**
Specifies a fullselect that returns a single row. The column values are assigned to each of the corresponding column-names. If the fullselect returns no rows, the null value is assigned to each column; an error occurs if any column that is to be deleted is not nullable. An error also occurs if there is more than one row in the result.

If the fullselect refers to columns that are to be deleted, the value of such a column in the fullselect is the value of the column in the row before the row is deleted.

**WHERE**
Specifies the rows to be deleted. You can omit the clause, give a search condition, or specify a cursor. For a created temporary table or a view of a created temporary table, you must omit the clause. When the clause is omitted, all the rows of the table or view are deleted.

**search-condition**
Is any search condition as described in Chapter 2, “Language elements,” on page 75. Each column-name in the search condition, other than in a subquery, must identify a column of the table or view.
The search condition is applied to each row of the table or view and the deleted rows are those for which the result of the search condition is true.

If the search condition contains a subquery, the subquery can be thought of as being executed each time the search condition is applied to a row, and the results used in applying the search condition. In actuality, a subquery with no correlated references is executed just once, whereas it is possible that a subquery with a correlated reference must be executed once for each row.

Let T2 denote the object table of a DELETE statement and let T1 denote a table that is referred to in the FROM clause of a subquery of that statement. T1 must not be a table that can be affected by the DELETE on T2. Thus, the following rules apply:

- T1 must not be a dependent of T2 in a relationship with a delete rule of CASCADE or SET NULL, unless the result of the subquery is materialized before the DELETE action is executed.
- T1 must not be a dependent of T3 in a relationship with a delete rule of CASCADE or SET NULL if deletes of T2 cascade to T3.

**WHERE CURRENT OF** cursor-name

Identifies the cursor to be used in the delete operation. cursor-name must identify a declared cursor as explained in the description of the DECLARE CURSOR statement in "DECLARE CURSOR" on page 1870. If the DELETE statement is embedded in a program, the DECLARE CURSOR statement must include select-statement rather than statement-name.

The table or view named must also be named in the FROM clause of the SELECT statement of the cursor, and the result table of the cursor must be capable of being deleted. For an explanation of read-only result tables, see Read-only cursors. Note that the object of the DELETE statement must not be identified as the object of the subquery in the WHERE clause of the SELECT statement of the cursor.

If the cursor is ambiguous and the plan or package was bound with CURRENTDATA(NO), DB2 might return an error to the application if DELETE WHERE CURRENT OF is attempted for any of the following:

- A cursor that is using block fetching
- A cursor that is using query parallelism
- A cursor that is positioned on a row that has been modified by this or another application process

When the DELETE statement is executed, the cursor must be open and positioned on a row or rowset of the result table.

- If the cursor is positioned on a single row, that row is the one deleted, and after the deletion the cursor is positioned before the next row of its result table. If there is no next row, the cursor positioned after the last row.
- If the cursor is positioned on a rowset, all rows corresponding to the rows of the current rowset are deleted, and after the deletion the cursor is positioned before the next rowset of its result table. If there is no next rowset, the cursor positioned after the last rowset.

A positioned DELETE must not be specified for a cursor that references a view on which an instead of delete trigger is defined, even if the view is an updatable view.

**FOR ROW n OF ROWSET**

Specifies which row of the current rowset is to be deleted. The corresponding
row of the rowset is deleted, and the cursor remains positioned on the current rowset. If the rowset consists of a single row, or all other rows in the rowset have already been deleted, then the cursor is positioned before the next rowset of the result table. If there is no next rowset, the cursor is positioned after the last rowset.

`host-variable` or `integer-constant` is assigned to an integral value `k`. If `host-variable` is specified, it must be an exact numeric type with scale zero, must not include an indicator variable, and `k` must be in the range of 1 to 32767. The cursor must be positioned on a rowset, and the specified value must be a valid value for the set of rows most recently retrieved for the cursor.

If the specified row cannot be deleted, an error is returned. It is possible that the specified row is within the bounds of the rowset most recently requested, but the current rowset contains less than the number of rows that were implicitly or explicitly requested when that rowset was established.

If, via a positioned delete against a sensitive static cursor that specifies a particular row of the current rowset, and that row has been identified as a delete hole (that is, a row in the result table whose corresponding row has deleted from the base table), an error is returned.

If, via a positioned delete against a sensitive static cursor that specifies a particular row of the current rowset, and that row has been identified as an update hole (that is, a row in the result table whose corresponding row has been updated so that it no longer satisfies a predicate of the SELECT statement), an error is returned.

It is possible for another application process to delete a row in the base table of the SELECT statement so that the specified row of the cursor no longer has a corresponding row in the base table. An attempt to delete such a row results in an error.

If the FOR ROW `n` OF ROWSET clause is not specified, the current position of cursor determines the rows that are affected by the statement:

- If the cursor is positioned on a single row, that row is the one deleted. After the row is deleted, the cursor is positioned before the next row of its result table. If there is no next row, the cursor positioned after the last row.
- If the cursor is positioned on a rowset, all rows corresponding to the rows of the current rowset are deleted. After the rows are deleted, the cursor is positioned before the next rowset of its result table. If there is no next rowset, the cursor positioned after the last rowset.

`isolation-clause`

Specifies the isolation level used when locating the rows to be deleted by the statement.

**WITH**

Introduces the isolation level, which may be one of the following:

- **RR** Repeatable read
- **RS** Read stability
- **CS** Cursor stability

The default isolation level of the statement is the isolation level of the package or plan in which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

**SKIP LOCKED DATA**

The SKIP LOCKED DATA clause specifies that rows are skipped when
incompatible locks are held on the row by other transactions. These rows can belong to any accessed table that is specified in the statement. SKIP LOCKED DATA can be used only when isolation CS or RS is in effect and applies only to row level or page level locks.

For DELETE statements, SKIP LOCKED DATA can be specified only in the searched form of the DELETE statement. SKIP LOCKED DATA is ignored if it is specified when the isolation level that is in effect is repeatable read (WITH RR) or uncommitted read (WITH UR). The default isolation level of the statement depends on the isolation level of the package or plan with which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

**QUERYNO** integer

Specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO column of the plan table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If the clause is omitted, the number associated with the SQL statement is the statement number assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Using the QUERYNO clause to assign unique numbers to the SQL statements in a program is helpful:

- For simplifying the use of optimization hints for access path selection
- For correlating SQL statement text with EXPLAIN output in the plan table

For information on using optimization hints, such as enabling the system for optimization hints and setting valid hint values, and for information on accessing the plan table, see *Managing DB2 Performance*.

**Notes**

**Delete operation errors:**

If an error occurs during the execution of any delete operation, no changes are made. If an error occurs during the execution of a positioned delete, the position of the cursor is unchanged. However, it is possible for an error to make the position of the cursor invalid, in which case the cursor is closed. It is also possible for a delete operation to cause a rollback, in which case the cursor is closed.

**Position of cursor:**

If an application process deletes a row on which any of its cursors are positioned, those cursors are positioned before the next row of the result table. Let C be a cursor that is positioned before row R (as a result of an OPEN, a DELETE through C, a DELETE through some other cursor, or a searched DELETE). In the presence of an SQL data change statements that affect the base table from which R is derived, the next FETCH operation referencing C does not necessarily position C on R. For example, the operation can position C on R', where R' is a new row that is now the next row of the result table.

**Locking:**

Unless appropriate locks already exist, one or more exclusive locks are acquired during the execution of a successful delete operation. Until the locks are released by a commit or rollback operation, the effect of the
Delete operation can only be perceived by the application process that performed the deletion and the locks can prevent other application processes from performing operations on the table. Locks are not acquired when rows are deleted from a declared temporary table unless all the rows are deleted (DELETE FROM T). When all the rows are deleted from a declared temporary table, a segmented table lock is acquired on the pages for the table and no other table in the table space is affected.

**Triggers:**
Delete operations can cause triggers to be activated. A trigger might cause other statements to be executed or might raise error conditions that are based on the deleted rows. If a DELETE statement on a view causes an INSTEAD OF trigger to be activated, referential integrity is checked against the updates that are performed in the trigger and not against the underlying tables of the view that cause the trigger to be activated.

**Triggers defined on a table for which row or column access control is also enforced:**
Row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row and column access control that is enforced for the triggering table is also ignored for any transition variables or transition tables that are referenced in the trigger body or that are passed as arguments to user-defined functions that are invoked in the trigger body. To ensure that no security concern exists for SQL statements in the trigger action (access to sensitive data in transition variables and transition tables, for example), the trigger must be secure. For information about securing a trigger, see CREATE TRIGGER and ALTER TRIGGER.

**Referential integrity:**
If the identified table or the base table of the identified view is a parent, the rows selected must not have any dependents in a relationship with a delete rule of RESTRICT or NO ACTION. In addition, the delete operation must not cascade to descendant rows that have dependents in a relationship with a delete rule of RESTRICT or NO ACTION.

If the delete operation is not prevented by a RESTRICT or NO ACTION delete rule, the selected rows are deleted and any rows that are dependents of the selected rows are also deleted.

- The nullable columns of foreign keys in any rows that are their dependents in a relationship governed by a delete rule of SET NULL are set to the null value.
- Any rows that are their dependents in a relationship governed by a delete rule of CASCADE are also deleted, and these rules apply, in turn, to those rows.

The only difference between NO ACTION and RESTRICT is when the referential constraint is enforced. RESTRICT (IBM SQL rules) enforces the rule immediately, and NO ACTION (SQL standard rules) enforces the rule at the end of the statement. This difference matters only in the case of a searched DELETE involving a self-referencing constraint that deletes more than one row. NO ACTION might allow the DELETE to be successful where RESTRICT (if it were allowed) would prevent it.

**Check constraint:**
A check constraint can prevent the deletion of a row in a parent table when there are dependents in a relationship with a delete rule of SET NULL. If deleting a row in the parent table would cause a column in a
dependent table to be set to null and there is a check constraint that specifies that the column must not be null, the row is not deleted.

**Referential constraints defined on a table for which row or column access control is enforced:**
Row and column access controls do not effect referential constraints.

**Nesting user-defined functions or stored procedures:**
A DELETE statement can implicitly or explicitly refer to user-defined functions or stored procedures. This is known as *nesting* of SQL statements. A user-defined function or stored procedure that is nested within the DELETE must not access the table from which you are deleting rows.

**Indexes with VARBINARY columns:**
If the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type, that index column cannot specify the DESC attribute. To use the SQL data change operation on the identified table, either drop the index or alter the data type of the column to BINAR and then rebuild the index.

**Number of rows deleted:**
Except as noted below, a delete operation sets SQLERRD(3) in the SQLCA to the number of deleted rows. This number does not include any rows that were deleted as a result of a CASCADE delete rule or a trigger.

*DELETE FROM T without a WHERE clause deletes all rows of T.* If a table T is contained in a segmented table space and is not a parent table, this deletion will be performed without accessing T. The SQLERRD(3) field is set to -1. (For a complete description of the SQLCA, including exceptions to the above, see “SQL communication area (SQLCA)” on page 2377.

**Rules for positioned DELETE with SENSITIVE STATIC scrollable cursor:**
When a SENSITIVE STATIC scrollable cursor has been declared, the following rules apply:

- *Delete attempt of delete holes or update holes.* If, with a positioned delete against a SENSITIVE STATIC scrollable cursor, an attempt is made to delete a row that has been identified as a delete hole (that is, a row in the result table whose corresponding row has been deleted from the base table), an error occurs.
If an attempt is made to delete a row that has been identified as an update hole (that is, a row in the result table whose corresponding row has been updated so that it no longer satisfies the predicate of the SELECT statement), an error occurs.

- *Delete operations.* Positioned delete operations with SENSITIVE STATIC scrollable cursors perform as follows:
  1. The SELECT list items in the target row of the base table of the cursor are compared with the values in the corresponding row of the result table (that is, the result table must still agree with the base table). If the values are not identical, the delete operation is rejected and an error occurs. The operation can be attempted again after a successful FETCH SENSITIVE has occurred for the target row.
  2. The WHERE clause of the SELECT statement is re-evaluated to determine whether the current values in the base table still satisfy the search criteria. The values in the SELECT list are compared to determine that these values have not changed. If the WHERE clause evaluates as true, and the values in the SELECT list have not
changed, the delete operation is allowed to proceed. Otherwise, an error occurs, the delete operation is rejected, and an update hole appears in the cursor.

3. After the base table row is successfully deleted, the temporary result table is updated and the row is marked as a delete hole.

- **Rollback of delete holes.** Delete holes are usually permanent. Once a delete hole is identified, it remains a delete hole until the cursor is closed. However, if a positioned delete using this cursor actually caused the creation of the hole (that is, this cursor was used to make the changes that resulted in the hole) and the delete was subsequently rolled back, then the row is no longer considered a delete hole.

- **Result table.** Any deletes, either positioned or searched, to rows of the base table on which a SENSITIVE STATIC scrollable cursor is defined are reflected in the result table if a positioned update or positioned delete is attempted with the scrollable cursor. A SENSITIVE STATIC scrollable cursor sees these deletes when a FETCH SENSITIVE is attempted.

If the FOR ROW n OF ROWSET clause is not specified, the entire rowset fetched by the most recent FETCH statement that returned data for the specified cursor is deleted.

**Deleting rows from a table with multilevel security:**

When you delete rows from a table with multilevel security, DB2 compares the security label of the user (the primary authorization ID) to the security label of the row. The delete proceeds according to the following rules:

- If the security label of the user and the security label of the row are equivalent, the row is deleted.
- If the security label of the user dominates the security label of the row, the user’s write-down privilege determines the security the result of the DELETE statement:
  - If the user has write-down privilege or write-down control is not enabled, the row is deleted.
  - If the user does not have write-down privilege and write-down control is enabled, the row is not deleted.
- If the security label of the row dominates the security label of the user, the row is not deleted.

**Deleting rows from a table for which row and column access control is enforced:**

When a DELETE statement is issued for a table for which row access control is enforced, the rules specified in the row permissions affect whether a row can be deleted. Typically those rules are based on the authorization ID or role of the process.

A table for which row access control is enforced has at least one row permission, the default row permission that prevents all access to the table. When multiple row permissions are defined and enabled for a table, a row access control search condition is derived by using the logical OR operator to the search condition in each enabled permission. This row access control search condition is applied to the table to determine which rows are accessible to the authorization ID or role of the DELETE statement. If the WHERE clause is specified in the DELETE statement, the user-specified predicates are applied on the accessible rows to determine the rows to be deleted. If there is no WHERE clause, the accessible rows are the rows to be deleted.
If there are rows to be deleted, and there is a DELETE trigger for the table, the trigger is activated.

When a DELETE statement is issued for a table for which column access control is enforced, column masks do not affect the DELETE statement.

The preceding rules are not applicable to include-columns. include-columns are subject to the rules for the select list because they are not the columns of the object table of the DELETE statement.

Other SQL statements in the same unit of work:
The following statements cannot follow a DELETE statement in the same unit of work:
- An ALTER TABLE statement that changes the data type of a column (ALTER COLUMN SET DATA TYPE)
- An ALTER INDEX statement that changes the padding attribute of an index with varying-length columns (PADDED to NOT PADDED or vice versa)
- A CREATE TABLE statement that creates an accelerator-only table.
- An INSERT, UPDATE or DELETE statement that updates an accelerator-only table from a different accelerator

Considerations for a system-period temporal table:
If the DELETE statement has a search condition that contains a correlated subquery that references the history table (explicitly referencing the name of the history table or implicitly referenced through the use of a period specification in the FROM clause), the deleted rows that are stored as historical rows are potentially visible for delete operations for the rows that are subsequently processed for the statement.

The mass delete operation is not used for a DELETE statement that does not contain a search condition if the table is defined as a system-period temporal table.

Considerations for a history table:
When a row of a system-period temporal table is deleted, a historical copy of the row is inserted into the corresponding history table and the end timestamp of the historical row is captured in the form of a system determined value that corresponds to the time of the data change operation. DB2 generates a value using the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to a row-begin or transaction-start-ID column in a table. This also occurs when a row in a system-period temporal table is deleted. DB2 ensures the uniqueness of the generated values for an end column in a history table across transactions. If a conflicting transaction is updating the same row in the system-period temporal table and the row that is to be inserted into the associated history table will have a value for the end column that is greater than the value of the corresponding begin column, an error is returned.

Considerations for an application-period temporal table:
A DELETE statement that contains a FOR PORTION OF BUSINESS_TIME clause for an application-period temporal table indicates the two points in time between which the specified delete operations are effective.

Suppose that FOR PORTION OF BUSINESS_TIME is specified and the period value for a row is only partially contained in the period that is specified from value1 up to value2. (The period value for a row is specified by the values of the begin column and end column.) In this case, the row
is deleted and one or two rows are automatically inserted to represent the
portion of the row that is not deleted. For each row that is automatically
inserted as a result of a delete operation on the table, new values are
generated for each generated column in the application-period temporal
table. If a generated column is defined as part of a unique or primary key,
parent key in a referential constraint, or unique index, an automatic insert
might violate a constraint or index. In this case, an error is returned.

Syntax alternatives:
For compatibility with other SQL implementations, the FROM keyword
that immediately follows the DELETE keyword can be omitted.

Examples

Assume that the statements in the examples are embedded in PL/I programs.

Example 1: From the table DSN8A10.EMP delete the row on which the cursor C1 is
currently positioned.

EXEC SQL DELETE FROM DSN8A10.EMP WHERE CURRENT OF C1;

Example 2: From the table DSN8A10.EMP, delete all rows for departments E11 and
D21.

EXEC SQL DELETE FROM DSN8A10.EMP
WHERE WORKDEPT = 'E11' OR WORKDEPT = 'D21';

Example 3: From employee table X, delete the employee who has the most
absences.

EXEC SQL DELETE FROM EMP X
WHERE ABSENT = (SELECT MAX(ABSENT) FROM EMP Y
WHERE X.WORKDEPT = Y.WORKDEPT);

Example 4: Assuming that cursor CS1 is positioned on a rowset consisting of 10
rows of table T1, delete all 10 rows in the rowset.
EXEC SQL DELETE FROM T1 WHERE CURRENT OF CS1;

Example 5: Assuming cursor CS1 is positioned on a rowset consisting of 10 rows of
table T1, delete the fourth row of the rowset.
EXEC SQL DELETE FROM T1 WHERE CURRENT OF CS1 FOR ROW 4 OF ROWSET;
DESCRIBE

The DESCRIBE statement obtains information about an object. You can obtain the following types of information with this statement, each of which is described separately.

- **Cursors**
  Gets information about the result set that is associated with the cursor. This information, such as column information, is put into a descriptor. See [DESCRIBE CURSOR](#).

- **Input parameter markers of a prepared statement.**
  Gets information about the input parameter markers in a prepared statement. This information is put into a descriptor. See [DESCRIBE INPUT](#).

- **The output of a prepared statement**
  Gets information about a prepared statement or information about the select list columns in a prepared SELECT statement. This information is put into a descriptor. See [DESCRIBE OUTPUT](#).

- **Procedures**
  Gets information about the result sets returned by a stored procedure. The information, such as the number of result sets, is put into a descriptor. See [DESCRIBE PROCEDURE](#).

- **Tables**
  Gets information about a table or view. This information is put into a descriptor. See [DESCRIBE TABLE](#).
DESCRIBE CURSOR

The DESCRIBE CURSOR statement obtains information about the result set that is associated with the cursor. The information, such as column information, is put into a descriptor. Use DESCRIBE CURSOR for result set cursors from stored procedures. The cursor must be defined with the ALLOCATE CURSOR statement.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

None required.

Syntax

```
DESCRIBE CURSOR cursor-name INTO descriptor-name host-variable
```

Description

cursor-name or host-variable

Identifies a cursor by the specified cursor-name or the cursor name contained in host-variable. The name must identify a cursor that has already been allocated in the source program.

If host-variable is used:

- It must be a character string variable that has a maximum length of 18 bytes.
- It must not be followed by an indicator variable.
- The cursor name must be left justified within the host variable and must not contain embedded blanks.
- If the length of the cursor name is less than the length of the host variable, it must be padded on the right with blanks.

Exception: The syntax described above applies to all languages except REXX.
For REXX, the syntax is DESCRIBE CURSOR :hostvar.

INTO descriptor-name

Identifies an SQL descriptor area (SQLDA). The information returned in the SQLDA describes the columns in the result set associated with the named cursor.

The considerations for allocating and initializing the SQLDA are similar to those of a varying-list SELECT statement. For more information, see DB2 Application Programming and SQL Guide.

For REXX: The SQLDA is not allocated before it is used.

After the DESCRIBE CURSOR statement is executed, the contents of the SQLDA are the same as after a DESCRIBE for a SELECT statement, with the following exceptions:

- The first 5 bytes of the SQLDAID field are set to 'SQLRS'.
• Bytes 6 to 8 of the SQLDAID field are reserved. If the cursor is declared WITH HOLD in a stored procedure, the high-order bit of the 8th byte is set to 1.

These exceptions do not apply to a REXX SQLDA, which does not include the SQLDAID field.

Notes

Using cursors for result sets: Column names are included in the information that DESCRIBE CURSOR obtains when the statement that generates the result set is either:
• Dynamic
• Static and the value of field DESCRIBE FOR STATIC on installation panel DSNTIP4 was YES when the package or stored procedure was bound. If the value of the field was NO, the returned information includes only the data type and length of the columns.

Using host variables: If the DESCRIBE CURSOR statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

Examples

The statements in the following examples are assumed to be in PL/I programs.

Example 1: Place information about the result set associated with cursor C1 into the descriptor named by :sqlda1.
EXEC SQL DESCRIBE CURSOR C1 INTO :sqlda1

Example 2: Place information about the result set associated with the cursor named by :hv1 into the descriptor named by :sqlda2.
EXEC SQL DESCRIBE CURSOR :hv1 INTO :sqlda2
DESCRIBE INPUT

The DESCRIBE INPUT statement obtains information about the input parameter markers of a prepared statement.

For an explanation of prepared statements, see PREPARE.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

The statement can be executed if the privilege set for PREPARE includes the EXPLAIN privilege.

Syntax

```
DESCRIBE INPUT statement-name INTO descriptor-name
```

Description

*statement-name*

Identifies the prepared statement. When the DESCRIBE INPUT statement is executed, the name must identify a statement that has been prepared by the application process at the current server.

*INTO descriptor-name*

Identifies an SQL descriptor area (SQLDA), which is described in SQL descriptor area (SQLDA). See Identifying an SQLDA in C or C++ for how to represent `descriptor-name` in C. The information returned in the SQLDA describes the parameter markers.

Before the DESCRIBE INPUT statement is executed, the user must set the SQLN field in the SQLDA and the SQLDA must be allocated. Considerations for initializing and allocating the SQLDA are similar to those for the DESCRIBE statement (see DESCRIBE). An occurrence of an extended SQLVAR is needed for each parameter in addition to the required base SQLVAR only if the input data contains LOBs.

For REXX: The SQLDA is not allocated before it is used.

After the DESCRIBE INPUT statement is executed, all the fields in the SQLDA except SQLN are either set by DB2 or ignored. The SQLDA contents are similar to the contents returned for the DESCRIBE statement (see The SQLDA contents returned after DESCRIBE) with these exceptions:

- In the SQLDAID, DB2 sets the value of the seventh byte only to the space character or '2'. A value of '3' is never used. The value '2' indicates that two SQLVAR entries (an occurrence of both a base SQLVAR and an extended SQLVAR) are required for each parameter because the input data contains LOBs. The seventh byte is a space character when either of the following conditions is true:
The input data does not contain LOBs. Only a base SQLVAR occurrence is needed for each parameter.

Only a base SQLVAR occurrence is needed for each column of the result, and the SQLDA is not large enough to contain the returned information.

- The SQLD field is set to the number of parameter markers being described. The value is 0 if the statement being described does not have input parameter markers.
- The SQLNAME field is not used.
- The SQLDATATYPE is set to a nullable, regardless of the usage of the parameter markers in the prepared statement.
- The SQLDATATYPE-NAME is not used if an extended SQLVAR entry is present. DESCRIBE INPUT does not return information about distinct types.

For complete information on the contents of the fields, see **SQL descriptor area (SQLDA)**

### Notes

**Preparing the SQLDA for OPEN or EXECUTE:** This note is relevant if you are applying DESCRIBE INPUT to a prepared statement and you intend to use the SQLDA in an OPEN or EXECUTE statement. To prepare the SQLDA for that purpose:

- Set SQLDATA to a valid address.
- If SQLTYPE is odd, set SQLIND to a valid address.

For the meaning of those fields in that context, see **SQL descriptor area (SQLDA)**

**Support for extended dynamic SQL in a distributed environment:** Unlike the DESCRIBE statement, which can be used in a distributed environment to describe static SQL statements generated by extended dynamic SQL, you cannot describe host variables in static SQL statements that are generated by extended dynamic SQL. A DESCRIBE INPUT statement issued against such static SQL statements always fails.

For information on how the DESCRIBE statement supports extended dynamic SQL, see **Support for extended dynamic SQL in a distributed environment**

**Using host variables:** If the DESCRIBE INPUT statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

### Example

Execute a DESCRIBE INPUT statement with an SQLDA that has enough SQLVAR occurrences to describe any number of input parameters a prepared statement might have. Assume that five parameter markers at most will need to be described and that the input data does not contain LOBs.

```sql
/* STMT1_STR contains INSERT statement with VALUES clause */
EXEC SQL PREPARE STMT1_NAME FROM :STMT1_STR;
... /* code to set SQLN to 5 and to allocate the SQLDA */
EXEC SQL DESCRIBE INPUT STMT1_NAME INTO :SQLDA;
```
This example uses the first technique described in *Allocating the SQLDA* to allocate the SQLDA.
DESCRIBE OUTPUT

The DESCRIBE OUTPUT statement obtains information about a prepared statement.

For an explanation of prepared statements, see PREPARE

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

The statement can be executed if the privilege set for PREPARE includes the EXPLAIN privilege.

See PREPARE for the authorization required to create a prepared statement.

Syntax

```
DESCRIBE OUTPUT statement-name INTO descriptor-name
               USING NAMES LABELS ANY BOTH
```

Description

OUTPUT

When a `statement-name` is specified, optional keyword to indicate that the describe will return information about the select list columns in a the prepared SELECT statement.

`statement-name`

Identifies the prepared statement. When the DESCRIBE statement is executed, the name must identify a statement that has been prepared by the application process at the current server.

`INTO descriptor-name`

Identifies an SQL descriptor area (SQLDA), which is described in SQL descriptor area (SQLDA). See Identifying an SQLDA in C or C++ for how to represent `descriptor-name` in C.

For languages other than REXX: Before the DESCRIBE statement is executed, the user must set the following variable in the SQLDA and the SQLDA must be allocated.

SQLN Indicates the number of SQLVAR occurrences provided in the SQLDA. DB2 does not change this value. For techniques to determine the number of required occurrences, see Allocating the SQLDA.
For REXX: The SQLDA is not allocated before it is used. An SQLDA consists of a set of stem variables. There is one occurrence of variable stem.SQLD, followed by zero or more occurrences of a set of variables that is equivalent to an SQLVAR structure. Those variables begin with stem.n.

After the DESCRIBE statement is executed, all the fields in the SQLDA except SQLN are either set by DB2 or ignored. For information on the contents of the fields, see The SQLDA contents returned after DESCRIBE.

USING
Indicates what value to assign to each SQLNAME variable in the SQLDA. If the requested value does not exist, SQLNAME is set to a length of 0.

NAMES
Assigns the name of the column. This is the default.

LABELS
Assigns the label of the column. (Column labels are defined by the LABEL statement.)

ANY
Assigns the column label, and if the column has no label, the column name.

BOTH
Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the result set contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to 2×n or 3×n, where n is the number of columns in the object being described. For each of the columns, the first n occurrences of SQLVAR, which are the base SQLVAR entries, contain the column names. Either the second or third n occurrences of SQLVAR, which are the extended SQLVAR entries, contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

Notes

Using PREPARE INTO clause: Information about a prepared statement can also be obtained by using the INTO clause of the PREPARE statement.

Allocating the SQLDA: Before the DESCRIBE or PREPARE INTO statement is executed, the value of SQLN must be set to a value greater than or equal to zero to indicate how many occurrences of SQLVAR are provided in the SQLDA. Also, enough storage must be allocated to contain the number of occurrences that SQLN specifies. To obtain the description of the columns of the result table of a prepared SELECT statement, the number of occurrences of SQLVAR must be at least equal to the number of columns. Furthermore, if USING BOTH is specified, or if the columns include LOBs or distinct types, the number of occurrences of SQLVAR should be two or three times the number of columns. See Determining how many SQLVAR occurrences are needed for more information.

First technique: Allocate an SQLDA with enough occurrences of SQLVAR to accommodate any select list that the application will have to process. At the extreme, the number of SQLVARs could equal three times the maximum number of columns allowed in a result table. After the SQLDA is allocated, the application can use the SQLDA repeatedly.
This technique uses a large amount of storage that is never deallocated, even when most of this storage is not used for a particular select list.

Second technique: Repeat the following two steps for every processed select list:
1. Execute a DESCRIBE statement with an SQLDA that has no occurrences of SQLVAR; that is, an SQLDA for which SQLN is zero.
2. Allocate a new SQLDA with enough occurrences of SQLVAR. Use the values that are returned in SQLD and SQLCODE to determine the number of SQLVAR entries that are needed. The value of SQLD is the number of columns in the result table, which is either the required number of occurrences of SQLVAR or a fraction of the required number (see Determining how many SQLVAR occurrences are needed for details). If the SQLCODE is +236, +237, +238, or +239, the number of SQLVAR entries that is needed is two or three times the value in SQLD, depending on whether USING BOTH was specified. Set SQLN to reflect the number of SQLVAR entries that have been allocated.
3. Execute the DESCRIBE statement again, using the new SQLDA.

This technique allows better storage management than the first technique, but it doubles the number of DESCRIBE statements.

Third technique: Allocate an SQLDA that is large enough to handle most (hopefully, all) select lists but is also reasonably small. If an execution of DESCRIBE fails because SQLDA is too small, allocate a larger SQLDA and execute the DESCRIBE statement again.

For the new larger SQLDA, use the values that are returned in SQLD and SQLCODE from the failing DESCRIBE statement to calculate the number of occurrences of SQLVAR that are needed, as described in technique two. Remember to check for SQLCODEs +236, +237, +238, and +239, which indicate whether extended SQLVAR entries are needed because the data includes LOBs or distinct types.

This third technique is a compromise between the first two techniques. Its effectiveness depends on a good choice of size for the original SQLDA.

The SQLDA contents returned on DESCRIBE: After a DESCRIBE statement is executed, the following list describes the contents of the SQLDA fields as they are set by DB2 or ignored. These descriptions do not necessarily apply to the uses of an SQLDA in other SQL statements (EXECUTE, OPEN, FETCH). For more on the other uses, see SQL descriptor area (SQLDA).

**SQLDAID**
DB2 sets the first 6 bytes to 'SQLDA ' (5 letters followed by the space character) and the eighth byte to a space character. The seventh byte is set to indicate the number of SQLVAR entries that are needed to describe each column of the result table as follows:

<table>
<thead>
<tr>
<th>space</th>
<th>The value of space occurs when:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• USING BOTH was not specified and the columns being described do not include LOBs or distinct types. Each column only needs one SQLVAR entry. If the SQL standard option is yes, DB2 sets SQLCODE to warning code +236. Otherwise, SQLCODE is zero.</td>
</tr>
<tr>
<td></td>
<td>• USING BOTH was specified and the columns being described do not include LOBs or distinct types. Each column needs two</td>
</tr>
</tbody>
</table>
SQLVAR entries. DB2 sets SQLD to two times the number of columns of the result table. The second set of SQLVARs is used for the labels.

2 Each column needs two SQLVAR entries. Two entries per column are required when:
   - USING BOTH was not specified and the columns being described include LOBs or distinct types or both. DB2 sets the second set of SQLVAR entries with information for the LOBs or distinct types being described.
   - USING BOTH was specified and the columns include LOBs but not distinct types. DB2 sets the second set of SQLVAR entries with information for the LOBs and labels for the columns being described.

3 Each column needs three SQLVAR entries. Three entries are required only when USING BOTH is specified and the columns being described include distinct types. The presence of LOB data does not matter. It is the distinct types and not the LOBs that cause the need for three SQLVAR entries per column when labels are also requested. DB2 sets the second set of SQLVAR entries with information for the distinct types (and LOBs, if any) and the third set of SQLVAR entries with the labels of the columns being described.

A REXX SQLDA does not contain this field.

SQLDABC
The length of the SQLDA in bytes. DB2 sets the value to SQLN×44+16.

A REXX SQLDA does not contain this field.

SQLD
If the prepared statement is a query, DB2 sets the value to the number of columns in the object being described (the value is actually twice the number of columns in the case where USING BOTH was specified and the result table does not include LOBs or distinct types). Otherwise, if the statement is not a query, DB2 sets the value to 0.

SQLVAR
An array of field description information for the column being described. There are two types of SQLVAR entries—the base SQLVAR and the extended SQLVAR.

If the value of SQLD is 0, or is greater than the value of SQLN, no values are assigned to any occurrences of SQLVAR. If the value of SQLN was set so that there are enough SQLVAR occurrences to describe the specified columns (columns with LOBs or distinct types and a request for labels increase the number of SQLVAR entries that are needed), the values are assigned to the first n occurrences of SQLVAR so that the first occurrence of SQLVAR contains a description of the first column, the second occurrence of SQLVAR contains a description of the second column, and so on. This first set of SQLVAR entries are referred to as base SQLVAR entries. Each column always has a base SQLVAR entry.

If the DESCRIBE statement included the USING BOTH clause, or the columns being described include LOBs or distinct types, additional SQLVAR entries are needed. These additional SQLVAR entries are referred to as the extended SQLVAR entries. There can be up to two sets of extended SQLVAR entries for each column.
For REXX, the SQLVAR is a set of stem variables that begin with `stem.n`, instead of a structure. The REXX SQLDA uses only a base SQLVAR. The way in which DB2 assigns values to the SQLVAR variables is the same as for other languages. That is, the `stem.1` variables describe the first column in the result table, the `stem.2` variables describe the second column in the result table, and so on. If USING BOTH is specified, the `stem.n+1` variables also describe the first column in the result table, the `stem.n+2` variables also describe the second column in the result table, and so on.

**The base SQLVAR:**

**SQLTYPE**
A code that indicates the data type of the column and whether the column can contain null values. For the possible values of SQLTYPE, see [SQLTYPE and SQLLEN](#).

**SQLLEN**
A length value depending on the data type of the result columns. SQLLEN is 0 for LOB and XML data types. For the other possible values of SQLLEN, see [SQLTYPE and SQLLEN](#).

In a REXX SQLDA, for DECIMAL or NUMERIC columns, DB2 sets the SQLPRECISION and SQLSCALE fields instead of the SQLLEN field.

**SQLDATA**
The CCSID of a string column. For possible values, see [SQLDATA](#).

In a REXX SQLDA, DB2 sets the SQLCCSID field instead of the SQLDATA field.

**SQLIND**
Reserved.

**SQLNAME**
The unqualified name or label of the column, depending on the value of USING (NAMES, LABELS, ANY, or BOTH). The field is a string of length 0 if the column does not have a name or label. For more details on unnamed columns, see the discussion of the names of result columns under [select-clause](#). This value is returned in the encoding scheme specified by the ENCODING bind option for the plan or package that contains the statement.

**The extended SQLVAR:**

**SQLLONGLEN**
The length attribute of a BLOB, CLOB, or DBCLOB column.

* Reserved.

**SQLDATALEN**
Not Used.

**SQLDATATYPE-NAME**
For a distinct type, the fully qualified distinct type name. Otherwise, the value is the fully qualified name of the built-in data type.

For a label, the label for the column.

This value is returned in the encoding scheme specified by the ENCODING bind option for the plan or package that contains this statement.
The REXX SQLDA does not use the extended SQLVAR.

**Performance considerations:** Although DB2 does not change the value of SQLN, you might want to reset this value after the DESCRIBE statement is executed. If the contents of SQLDA from the DESCRIBE statement is used in a later FETCH statement, set SQLN to \( n \) (where \( n \) is the number of columns of the result table) before executing the FETCH statement. For details, see [Preparing the SQLDA for data retrieval](#).

**Preparing the SQLDA for data retrievals:** This note is relevant if you are applying DESCRIBE to a prepared query and you intend to use the SQLDA in the FETCH statements you employ to retrieve the result table rows. To prepare the SQLDA for that task, you must set the SQLDATA field of SQLVAR. SQLIND must be set if SQLTYPE is odd, and SQLNAME must be set when overriding the CCSID. For the meaning of those fields in that context, see [SQL descriptor area (SQLDA)](#).

Also, SQLN and SQLDABC should be reset (if necessary) to \( n \) and \( n \times 44 + 16 \), where \( n \) is the number of columns in the result table. Doing so can improve performance when the rows of the result table are fetched.

**Support for extended dynamic SQL in a distributed environment:** In a distributed environment where DB2 for z/OS is the server and the requester supports extended dynamic SQL, such as DB2 Server for VSE & VM, a DESCRIBE statement that is executed against an SQL statement in the extended dynamic package appears to DB2 as a DESCRIBE statement against a static SQL statement in the DB2 package. A DESCRIBE statement cannot normally be issued against a static SQL statement. However, a DESCRIBE against a static SQL statement that is generated by extended dynamic SQL executes without error if the package has been rebound after field DESCRIBE FOR STATIC on installation panel DSNTIP4 has been set to YES.

YES indicates that DB2 generates an SQLDA for the DESCRIBE at bind time so that DESCRIBE requests for static SQL statements can be satisfied at execution time. For more information, see [DB2 Installation Guide](#).

**Avoiding double preparation when using REOPT(ALWAYS) or REOPT(ONCE):** If bind option REOPT(ALWAYS) or REOPT(ONCE) is in effect, DESCRIBE causes the statement to be prepared if it is not already prepared. If issued before an OPEN or an EXECUTE, the DESCRIBE causes the statement to be prepared without input variables. If the statement has input variables, the statement must be prepared again when it is opened or executed. When REOPT(ONCE) is in effect, the statement is always prepared twice even if there are no input variables. Therefore, to avoid preparing statements twice, issue the DESCRIBE after the OPEN. For non-cursor statements, open and fetch processing are performed on the EXECUTE. So, if a DESCRIBE must be issued, the statement will be prepared twice.

The use of a prepared statement for an EXPLAIN statement can cause duplicate entries in the explain tables when the prepared statement specifies the REOPT(ALWAYS) bind option and is executed using the jcc driver.

**Errors occurring on DESCRIBE:** In local and remote processing, the DEFER(PREPARE) and REOPT(ALWAYS)/REOPT(ONCE) bind options can cause some errors that are normally issued during PREPARE processing to be issued on DESCRIBE.
**Considerations for implicitly hidden columns**: A DESCRIBED OUTPUT statement only returns information about implicitly hidden columns if the column (of a base table that is defined as implicitly hidden) is explicitly specified as part of the SELECT list of the final result table of the query described. If implicitly hidden columns are not part of the result table of a query, a DESCRIBE OUTPUT statement that returns information about that query will not contain information about any implicitly hidden columns.

**Using host variables**: If the DESCRIBE statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

**Example**

In a PL/I program, execute a DESCRIBE statement with an SQLDA that has no occurrences of SQLVAR. If SQLD is greater than zero, use the value to allocate an SQLDA with the necessary number of occurrences of SQLVAR and then execute a DESCRIBE statement using that SQLDA. This is the second technique described in Allocating the SQLDA.

```pli
EXEC SQL BEGIN DECLARE SECTION;
  DCL STMT1_STR CHAR(200) VARYING;
EXEC SQL END DECLARE SECTION;
EXEC SQL INCLUDE SQLDA;
EXEC SQL DECLARE DYN_CURSOR CURSOR FOR STMT1_NAME;
  ... /* code to prompt user for a query, then to generate */
  /* a select-statement in the STMT1_STR */
EXEC SQL PREPARE STMT1_NAME FROM :STMT1_STR;
  ... /* code to set SQLN to zero and to allocate the SQLDA */
EXEC SQL DESCRIBE STMT1_NAME INTO :SQLDA;
  ... /* code to check that SQLD is greater than zero, to set */
  /* SQLN to SQLD, then to re-allocate the SQLDA */
EXEC SQL DESCRIBE STMT1_NAME INTO :SQLDA;
  ... /* code to prepare for the use of the SQLDA */
EXEC SQL OPEN DYN_CURSOR;
  ... /* loop to fetch rows from result table */
EXEC SQL FETCH DYN_CURSOR USING DESCRIPTOR :SQLDA;
```

Chapter 7. Statements 1935
DESCRIBE PROCEDURE

The DESCRIBE PROCEDURE statement gets information about the result sets returned by a stored procedure. The information, such as the number of result sets, is put into a descriptor.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

None required.

Syntax

```
DESCRIBE PROCEDURE procedure-name INTO descriptor-name
```

Description

procedure-name or host-variable

Identifies the stored procedure that returned one or more result sets. When the DESCRIBE PROCEDURE statement is executed, the procedure name must identify a stored procedure that the requester has already invoked using the SQL CALL statement. The procedure name can be specified as a one, two, or three-part name. The procedure name in the DESCRIBE PROCEDURE statement must be specified the same way that it was specified on the CALL statement. For example, if a two-part procedure name was specified on the CALL statement, you must specify a two-part procedure name in the DESCRIBE PROCEDURE statement.

If a host variable is used:

- It must be a character string variable with a length attribute that is not greater than 254.
- It must not be followed by an indicator variable.
- The value of the host variable is a specification that depends on the database server. Regardless of the server, the specification must:
  - Be left justified within the host variable
  - Not contain embedded blanks
  - Be padded on the right with blanks if its length is less than that of the host variable

Exception: The syntax described above applies to all languages except REXX. For REXX, the syntax is DESCRIBE PROCEDURE :hostvar.

INTO descriptor-name

Identifies an SQL descriptor area (SQLDA). The information returned in the SQLDA describes the result sets returned by the stored procedure.

Considerations for allocating and initializing the SQLDA are similar to those for DESCRIBE TABLE.
The contents of the SQLDA after executing a DESCRIBE PROCEDURE statement are:

- The first 5 bytes of the SQLDAID field are set to 'SQLPR'.
  A REXX SQLDA does not contain SQLDAID.
- Bytes 6 to 8 of the SQLDAID field are reserved.
- The SQLD field is set to the total number of result sets. A value of 0 in the field indicates there are no result sets.
- There is one SQLVAR entry for each result set.
- The SQLDATA field of each SQLVAR entry is set to the result set locator value associated with the result set.
  For a REXX SQLDA, SQLLOCATOR is set to the result set locator value.
- The SQLIND field of each SQLVAR entry is set to the estimated number of rows in the result set
  For a REXX SQLDA, the SQLIND field is not used for DESCRIBE.
- The SQLNAME field is set to the name of the cursor used by the stored procedure to return the result set. This value is returned in the encoding scheme specified by the ENCODING bind option for the plan or package that contains this statement.

Notes

**SQLDA information:** A value of -1 in the SQLIND field indicates that an estimated number of rows in the result set is not provided. DB2 for z/OS always sets SQLIND to -1. For a REXX SQLDA, the SQLIND field is not used for DESCRIBE.

DESCRIBE PROCEDURE does not return information about the parameters expected by the stored procedure.

**Assignment of locator values:** Locator values are assigned to the SQLVAR entries in the SQLDA in the order that the associated cursors are opened at run time. Locator values are not provided for cursors that are closed when control is returned to the invoking application. If a cursor was closed and later re-opened before returning to the invoking application, the most recently executed OPEN CURSOR statement for the cursor is used to determine the order in which the locator values are returned for the procedure result sets. For example, assume procedure P1 opens three cursors A, B, C, closes cursor B and then issues another OPEN CURSOR statement for cursor B before returning to the invoking application. The locator values are assigned in the order A, C, B.

Alternatively, an ASSOCIATE LOCATORS statement can be used to copy the locator values to result set locator variables.

**Using host variables:** If the DESCRIBE PROCEDURE statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

Examples

The statements in the following examples are assumed to be in PL/I programs.
Example 1: Place information about the result sets returned by stored procedure P1 into the descriptor named by SQLDA1. Assume that the stored procedure is called with a one-part name from current server SITE2.

```sql
EXEC SQL CONNECT TO SITE2;
EXEC SQL CALL P1;
EXEC SQL DESCRIBE PROCEDURE P1 INTO :SQLDA1;
```

Example 2: Repeat the scenario in Example 1, but use a two-part name to specify an explicit schema name for the stored procedure to ensure that stored procedure P1 in schema MYSHEMA is used.

```sql
EXEC SQL CONNECT TO SITE2;
EXEC SQL CALL MYSHEMA.P1;
EXEC SQL DESCRIBE PROCEDURE MYSHEMA.P1 INTO :SQLDA1;
```

Example 3: Place information about the result sets returned by the stored procedure identified by host variable HV1 into the descriptor named by SQLDA2. Assume that host variable HV1 contains the value SITE2.MYSHEMA.P1 and the stored procedure is called with a three-part name.

```sql
EXEC SQL CALL SITE2.MYSHEMA.P1;
EXEC SQL DESCRIBE PROCEDURE :HV1 INTO :SQLDA2;
```

The preceding example would be invalid if host variable HV1 had contained the value MYSHEMA.P1, a two-part name. For the example to be valid with that two-part name in host variable HV1, the current server must be the same as the location name that is specified on the CALL statement as the following statements demonstrate. This is the only condition under which the names do not have to be specified the same way and a three-part name on the CALL statement can be used with a two-part name on the DESCRIBE PROCEDURES statement.

```sql
EXEC SQL CONNECT TO SITE2;
EXEC SQL CALL SITE2.MYSHEMA.P1;
EXEC SQL ASSOCIATE LOCATORS (:LOC1, :LOC2) WITH PROCEDURE :HV1;
```
DESCRIBE TABLE

The DESCRIBE TABLE statement obtains information about a designated table or view.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

The privileges that are held by the authorization ID that owns the plan or package must include at least one of the following (if there is a plan, authorization checking is done only against the plan owner):

- Ownership of the table or view
- The SELECT, INSERT, UPDATE, DELETE, or REFERENCES privilege on the object
- The ALTER or INDEX privilege on the object (tables only)
- DBADM authority over the database that contains the object (tables only)
- SYSADM authority
- SYSCTRL authority (catalog tables only)
- ACCESSCTRL authority (catalog tables only)
- System DBADM
- DATAACCESS authority
- EXPLAIN authority
- SQLADM authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

For an RRSAF application that does not have a plan and in which the requester and the server are DB2 for z/OS systems, authorization to execute the package is performed against the primary or secondary authorization ID of the process.

Syntax

```
DESCRIBE TABLE host-variable INTO descriptor-name
```

Description

**TABLE host-variable**

Identifies the table or view. The name must not identify an auxiliary table. When the DESCRIBE statement is executed, the host variable must contain a name which identifies a table or view that exists at the current server. This
variable must be a fixed-length or varying-length character string with a length attribute less than 256. The name must be followed by one or more blanks if the length of the name is less than the length of the variable. It cannot contain a period as the first character and it cannot contain embedded blanks. In addition, the quotation mark is the escape character regardless of the value of the string delimiter option. An indicator variable must not be specified for the host variable.

**INTO descriptor-name**

Identifies an SQL descriptor area (SQLDA), which is described in SQL descriptor area (SQLDA). See Identifying an SQLDA in C or C++ for how to represent descriptor-name in C.

For languages other than REXX: Before the DESCRIBE statement is executed, the user must set the following variable in the SQLDA and the SQLDA must be allocated.

**SQLN** Indicates the number of SQLVAR occurrences provided in the SQLDA. DB2 does not change this value. For techniques to determine the number of required occurrences, see Allocating the SQLDA.

For REXX: The SQLDA is not allocated before it is used. An SQLDA consists of a set of stem variables. There is one occurrence of variable stem.SQLD, followed by zero or more occurrences of a set of variables that is equivalent to an SQLVAR structure. Those variables begin with stem.n.

After the DESCRIBE statement is executed, all the fields in the SQLDA except SQLN are either set by DB2 or ignored. For information on the contents of the fields, see The SQLDA contents returned after DESCRIBE.

**USING**

Indicates what value to assign to each SQLNAME variable in the SQLDA. If the requested value does not exist, SQLNAME is set to a length of 0.

**NAMES**

Assigns the name of the column. This is the default.

**LABELS**

Assigns the label of the column. (Column labels are defined by the LABEL statement.)

**ANY**

Assigns the column label, and if the column has no label, the column name.

**BOTH**

Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the result set contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to 2xn or 3xn, where n is the number of columns in the object being described. For each of the columns, the first n occurrences of SQLVAR, which are the base SQLVAR entries, contain the column names. Either the second or third n occurrences of SQLVAR, which are the extended SQLVAR entries, contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

For a declared temporary table, the name of the column is assigned regardless of the value specified in the USING clause because declared temporary tables cannot have labels.
Notes

See [DESCRIBE OUTPUT] for information about the following topics:
- Allocating the SQLDA
- The SQLDA contents that are returned on DESCRIBE
- Performance considerations for DESCRIBE
- Using host variables in DESCRIBE statements

Considerations for implicitly hidden columns: A DESCRIBE TABLE statement does return information about implicitly hidden columns in tables.
The DROP statement removes an object at the current server. Except for storage groups, any objects that are directly or indirectly dependent on that object are deleted. Whenever an object is deleted, its description is deleted from the catalog at the current server, and any packages that refer to the object are invalidated.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

**Authorization**

To drop the following objects, the privilege set must include at least one of the listed authorities or privileges:

**Table, table space, or index:**
- Ownership of the object (for an index, the owner is the owner of the table or index)
- DBADM authority
- SYSADM or SYSCTRL authority
- System DBADM

If the table space is in a database that is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

**Database:**
- The DROP privilege on the database
- DBADM or DBCTRL authority for the database
- SYSADM or SYSCTRL authority
- System DBADM

If the database is implicitly created, the privileges must be on the implicit database or on DSNDB04.

**Alias, storage group, or view:**
- Ownership of the object
- SYSADM or SYSCTRL authority
- System DBADM

**Package:**
- Ownership of the package
- The BINDAGENT privilege granted from the package owner
- PACKADM authority for the collection or for all collections
- SYSADM or SYSCTRL authority

**Synonym:**
- Ownership of the synonym

**Role or trusted context:**
- Ownership of the object
- SYSADM or SYSCTRL authority
- SECADM
If the installation parameter SEPARATE SECURITY is NO, SYSADM authority has implicit SECADM and SYSCTRL authority and can drop a role or trusted context.

**Row permission or column mask:**
- At least SECADM authority

**Distinct type, sequence, stored procedure, trigger, or user-defined function:**
- Ownership of the object
- The DROPIN privilege on the schema
- SYSADM or SYSCTRL authority
- System DBADM

The authorization ID that matches the schema name implicitly has the DROPIN privilege on the schema.

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process. If running in a trusted context with a role, the privilege set also includes those privileges that are held by the role that is associated with the primary authorization ID. However, the implicit schema match does not apply to the role when determining if DROPIN schema privilege is held.

---

36. Not applicable for stored procedures defined in releases of DB2 for z/OS prior to Version 6.
Notes:
1 AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.
Description

**ALIAS alias-name**

Identifies the alias to drop. The name must identify an alias that exists at the current server. Dropping an alias has no effect on any view, materialized query table, or synonym that was defined using the alias.

If the alias is referenced in the definition of a row permission or a column mask, it cannot be dropped.

**DATABASE database-name**

Identifies the database to drop. The name must identify a database that exists
at the current server. DSNDB04 or DSNDB06 must not be specified. The privilege set must include SYSADM authority.

Whenever a database is dropped, all of its table spaces, tables, index spaces, and indexes are also dropped. Any pending changes to the definitions of the table spaces and indexes in the database are also dropped.

You can drop a database that contains a history table only if the database also contains the associated system-period temporal table. You can drop a database that contains a system-period temporal table when the associated history table is in another database. In this case, the action cascades to drop the history table in the other database.

The database cannot be dropped if it is associated with an accelerator-only table.

**FUNCTION or SPECIFIC FUNCTION**

Identifies the function to drop. The function must exist at the current server, and it must have been defined with the CREATE FUNCTION statement. The particular function can be identified by its name, function signature, or specific name.

Functions that are implicitly generated by the CREATE TYPE statement cannot be dropped using the DROP statement. They are implicitly dropped when the distinct type is dropped.

As indicated by the default keyword RESTRICT, the function is not dropped if any of the following dependencies exist:

- Another function is sourced on the function.
- A view uses the function.
- A trigger package uses the function.
- The definition of a materialized query table uses the function.
- The definition of a row permission or a column mask uses the function.

When a function is dropped, all privileges on the function are also dropped. Any packages that are dependent on the function dropped are made inoperative.

**FUNCTION function-name**

Identifies the function by its name. The function-name must identify exactly one function. The function can have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

**FUNCTION function-name (parameter-type,...)**

Identifies the function by its function signature, which uniquely identifies the function. The function-name (parameter-type, ...) must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance which is to be dropped. Synonyms for data types are considered a match.

If the function was defined with a table parameter (the LIKE TABLE name AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.
If `function-name()` is specified, the function identified must have zero parameters.

`function-name`

Identifies the name of the function.

`parameter-type,...`

Identifies the parameters of the function.

If an unqualified distinct type name is specified, DB2 searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, `DEC()` will be considered a match for a parameter of a function defined with a data type of `DEC(7,2)`. Similarly `DECFLOAT()` will be considered a match for `DECFLOAT(16)` or `DECFLOAT(34)`. However, `FLOAT` cannot be specified with empty parenthesis because its parameter value indicates a specific data type (`REAL` or `DOUBLE`).

- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the `CREATE FUNCTION` statement. If the data type is `FLOAT`, the precision does not have to exactly match the value that was specified because matching is based on the data type (`REAL` or `DOUBLE`).

- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the `CREATE FUNCTION` statement.

For data types with a subtype or encoding scheme attribute, specifying the `FOR subtype` DATA clause or the `CCSID` clause is optional. Omission of either clause indicates that DB2 ignores the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the `CREATE FUNCTION` statement.

**AS LOCATOR**

Specifies that the function is defined to receive a locator for this parameter. If `AS LOCATOR` is specified, the data type must be a LOB or a distinct type based on a LOB.

**SPECIFIC FUNCTION** `specific-name`

Identifies the function by its specific name. The `specific-name` must identify a specific function that exists at the current server.

**INDEX** `index-name`

Identifies the index to drop. The name must identify a user-defined index that exists at the current server but must not identify a populated index on an auxiliary table or an index that was implicitly created for a table that contains an XML column. (For details on dropping user-defined indexes on catalog tables, see “SQL statements allowed on the catalog” on page 2718.) A populated index on an auxiliary table can only be dropped by dropping the base table. The name must not identify an auxiliary table for an object that is involved in a clone relationship.
If the index that is dropped was created by specifying the ENDING AT clause to define partition boundaries, the table is converted to use table-controlled partitioning. The high limit key for the last partition is set to the highest possible value for ascending key columns or the lowest possible value for descending key columns.

Whenever an index is directly or indirectly dropped, its index space is also dropped. The name of a dropped index space cannot be reused until a commit operation is performed. Any pending changes to the definitions of the index is also dropped.

If the index is a unique index used to enforce a unique constraint (primary or unique key), the unique constraint must be dropped before the index can be dropped. In addition, if a unique constraint supports a referential constraint, the index cannot be dropped unless the referential constraint is dropped.

However, a unique index (for a unique key only) can be dropped without first dropping the unique key constraint if the unique key was created in a release of DB2 before Version 7 and if the unique key constraint has no associated referential constraints. For information about dropping constraints, see “ALTER TABLE” on page 1324.

If the table space is explicitly created and a unique index is dropped and that index was defined on a ROWID column that is defined as GENERATED BY DEFAULT, the table can still be used, but rows cannot be inserted into that table.

If the table space is implicitly created, the index cannot be dropped if it is defined on a ROWID column that is defined as GENERATED BY DEFAULT.

If an empty index on an auxiliary table is dropped, the base table is marked incomplete. If the base table space is implicitly created, the index on an auxiliary table cannot be dropped.

Drop index will result in the deletion of rows in the SYSCOLDIST and SYSCOLDISTATS catalog tables if no other indexes on the table have the same column group in their key sequence prefix.

MASK mask-name

Identifies the column mask to drop. The name must identify a column mask that exists at the current server.

PACKAGE collection-id.package-name

Identifies the package version to drop. The name plus the implicitly or explicitly specified version-id must identify a package version that exists at the current server. Omission of the version-id is an implicit specification of the null version.

The name must not identify a trigger package or a package that is associated with an SQL routine. A trigger package can only be dropped by dropping the associated trigger or subject table. A package that is associated with a native SQL procedure can only be dropped with an ALTER PROCEDURE statement with a DROP VERSION clause that specifies the particular version that is to be dropped, or with a DROP PROCEDURE statement if it is the only version that is defined for the procedure.

Specify this clause to drop a package that is created as the result of a BIND COPY command used to deploy a version of a native SQL procedure.

If a package has current, previous, and original copies, the DROP statement will drop all copies.
**VERSION** version-id  

version-id is the version identifier that was assigned to the package's DBRM when the DBRM was created. If version-id is not specified, a null version is used as the version identifier.

Delimit the version identifier when it:
- Is generated by the VERSION(AUTO) precompiler option
- Begins with a digit
- Contains lowercase or mixed-case letters

For more on version identifiers, see the information on preparing an application program for execution in *DB2 Application Programming and SQL Guide*.

**PERMISSION** permission-name  

Identifies the row permission to drop. The name must identify a row permission that exists at the current server. The name must not identify the default row permission that was created implicitly by DB2.

**PROCEDURE** procedure-name  

Identifies the stored procedure to drop. The name must identify a stored procedure that has been defined with the CREATE PROCEDURE statement at the current server.

All versions of the native SQL procedure are dropped; all privileges on the procedure are also dropped. In addition, any packages that are dependent on the procedure are marked invalid.

If the procedure is a native SQL procedure, use an ALTER PROCEDURE statement with the DROP VERSION clause to drop a specific version of a procedure. Use a DROP PACKAGE statement to drop a package for a version of the procedure that is created using the BIND COPY command.

**ROLE** role-name  

Identifies the role to drop. role-name must identify a role that exists at the current server.

When a role is dropped, all privileges and authorities that have been previously granted to that role are revoked. If the role that is dropped is the owner of statements in the dynamic statement cache, the cached statements are invalidated.

The role is not dropped if any REVOKE restrictions are encountered. REVOKE restrictions include the following:
- Restrictions that are encountered when dependent privileges are included when the privileges of a role are revoked.
- The role is the grantor of any privilege or authority that used ACCESSCTRL or SECADM authority to perform the grant.

If RESTRICT is specified, the role is not dropped is any of the following dependencies exist:
- The role is associated with any trusted context or any user in a trusted context.
- The role is associated with a currently running thread.
- The role is the owner of any of the following objects:
SEQUENCE sequence-name

Identifies the sequence to drop. The name must identify an existing sequence at the current server.

.sequence-name must not be the name of an internal sequence object that is used by DB2 (including an implicitly generated sequence for a DB2_GENERATED_DOCID_FOR_XML column). Sequences that are generated by the system for identity columns or implicitly created databases cannot be dropped by using the DROP SEQUENCE statement. A sequence object for an identity column is implicitly dropped when the table that contains the identifier column is dropped.

The default keyword RESTRICT indicates that the sequence is not dropped if any of the following dependencies exist:

- A trigger that uses the sequence in a NEXT VALUE or PREVIOUS VALUE expression exists.
- An inline SQL function that uses the sequences in a NEXT VALUE or PREVIOUS VALUE expression exists.

Whenever a sequence is dropped, all privileges on the sequence are also dropped, and the packages that refer to the sequence are invalidated. Dropping a sequence, even if the drop process is rolled back, results in the loss of the still-unassigned cache values for the sequence.

STOGROUP stogroup-name

Identifies the storage group to drop. The name must identify a storage group that exists at the current server but not a storage group that is used by any table space or index space.

For information on the effect of dropping the default storage group of a database, see [Dropping a default storage group](#).

SYNONYM synonym

Identifies the synonym to drop. In a static DROP SYNONYM statement, the name must identify a synonym that is owned by the owner of the plan or package. In a dynamic DROP SYNONYM statement, the name must identify a synonym that is owned by the SQL authorization ID. Thus, using interactive SQL, a user with SYSADM authority can drop any synonym by first setting CURRENT SQLID to the owner of the synonym.

Dropping a synonym has no effect on any view, materialized query table, or alias that was defined using the synonym, nor does it invalidate any packages that use such views, materialized query tables, or aliases.

If the synonym is referenced in the definition of a row permission or a column mask, it cannot be dropped.
**TABLE** `table-name` or `alias-name`

Identifies the table to drop. The name must identify a table that exists at the current server. It must not identify a catalog table, a directory table, a table in a partitioned table space, a table that is implicitly created for an XML column, or a populated auxiliary table. A table in a partitioned table space can be dropped only by dropping the table space. A populated auxiliary table or a table that is implicitly created for an XML column can be dropped only by dropping the associated base table.

If `alias-name` is specified, the actual table is dropped as if `table-name` were specified. However, the alias is not dropped. It can be dropped by using the DROP ALIAS statement.

When a table is directly or indirectly dropped, the following items are also dropped:

- All privileges on the table
- All referential constraints in which the table is a parent or dependent
- All synonyms, views, and indexes that are defined on the table
- All row permissions (including the default row permission)
- All column masks that are created for the table

If the table space for the table was implicitly created, it is also dropped. However, if the containing database was implicitly created, it is not dropped. Any pending changes to the definitions of the dropped table space and indexes are also dropped.

For more information, see [Dropping an implicitly created database](#).

When a table is directly or indirectly dropped, all materialized query tables that are defined on the table are also dropped. When a materialized query table is directly or indirectly dropped, the following items are also dropped:

- All privileges on the materialized query table
- All synonyms, views, and indexes that are defined on the materialized query table

Any alias that is defined on the materialized query table is not dropped. Any packages that are dependent on the dropped materialized query table are marked invalid.

You cannot use DROP TABLE to drop a clone table. You must use the ALTER TABLE statement with the DROP CLONE clause to drop a clone table. If a base table that is involved in a clone relationship is dropped, the associated clone table is also dropped. You cannot drop an auxiliary table for an object that is involved in a clone relationship.

The table cannot be dropped if it is defined as a history table for a system-period temporal table.

The table cannot be dropped if it is referenced in the definition of a row permission or a column mask.

To drop a system-period temporal table, the privilege set must also contain the authorization that is required to drop the history table. The history table is dropped when a system-period temporal table is dropped.

If a table with LOB columns is dropped, the auxiliary tables that are associated with the table and the indexes on the auxiliary tables are also dropped. Any LOB table spaces that were implicitly created for the auxiliary tables are also dropped.
If a table with XML columns is dropped, all implicitly created objects for all XML columns are also dropped.

If an empty auxiliary table is dropped, the definition of the base table is marked incomplete. If the base table space is implicitly created, the auxiliary table cannot be dropped.

If the table has a security label column, the primary authorization ID of the DROP statement must have a valid security label, and the RACF SECLABEL class must be active.

If a table that uses hash organization is dropped, all catalog entries for the hash organization are cleaned up.

**TABLESPACE** 

Identifies the table space to drop. The name must identify a table space that exists at the current server. The database name must not be DSNDB01 or DSNDB06. Omission of the database name is an implicit specification of DSNDB04. `table-space-name` must not identify a table space that is implicitly created for an XML column.

Whenever a table space is directly or indirectly dropped, all the tables in the table space are also dropped. The name of a dropped table space cannot be reused until a commit operation is performed. Any pending changes to the definitions of the table space and its indexes are also dropped.

A LOB table space can be dropped only if it does not contain an auxiliary table. If the LOB table space is implicitly created, it cannot be dropped.

Whenever a base table space that contains tables with LOB columns is dropped, all the auxiliary tables and indexes on those auxiliary tables that are associated with the base table space are also dropped.

Whenever a base table space that contains tables with XML columns is dropped, all implicitly created objects for all XML columns are also dropped.

The table space cannot be dropped if it contains a history table or is associated with an accelerator-only table.

**TRIGGER** 

Identifies the trigger to drop. The name must identify a trigger that exists at the current server.

Whenever a trigger is directly or indirectly dropped, all privileges on the trigger are also dropped and the associated trigger package is freed. The name of that trigger package is the same as the trigger name and the collection ID is the schema name.

When an INSTEAD OF trigger is dropped, the associated privilege is revoked from anyone that possesses the privilege as a result of an implicit grant that occurred when the trigger is created.

Dropping triggers causes certain packages to be marked invalid. For example, if `trigger-name` specifies an INSTEAD OF trigger on a view V, another trigger might depend on `trigger-name` through an update to the view V, and that trigger package is invalidated.

If a trigger has current, previous, and original copies, the DROP statement will drop all copies.

**TRUSTED CONTEXT** 

Identifies the trusted context to drop. The `context-name` must identify a trusted context that exists at the current server. When a trusted context is dropped, all
associations to attributes (IP addresses, job names) and associations to users of
the trusted context are dropped. If the trusted context is dropped while trusted
connections for the context are active, the connections remain active until they
terminate or the next attempt at reuse is made.

**TYPE** distinct-type-name

Identifies the distinct type to drop. The name must identify a distinct type that
exists at the current server. The default keyword RESTRICT indicates that the
distinct type is not dropped if any of the following dependencies exist:

- The definition of a column of a table uses the distinct type.
- The definition of an input or result parameter of a user-defined function
  uses the distinct type.
- The definition of a parameter of a stored procedure uses the distinct type.
- The definition of an extended index uses a cast function that is implicitly
  generated for the distinct type.
- The definition of an SQL variable in a procedure or function uses the distinct
type.
- The definition of a row permission or a column mask uses the distinct type.
- A sequence exists for which the data type of the sequence is the distinct
type.
- One of the following dependencies exists on one of the cast functions that
  are generated for the distinct type:
  - Another function is sourced from one of the cast functions
  - A view uses one of the cast functions
  - A trigger package uses one of the cast functions
  - The definition of a materialized query table uses one of the cast functions

Whenever a distinct type is dropped, all privileges on the distinct type are also
dropped. In addition, the cast functions that were generated when the distinct
type was created and the privileges on those cast functions are also dropped.

**VIEW** view-name or alias-name

Identifies the view to drop. The name must identify a view that exists at the
current server.

Whenever a view is directly or indirectly dropped, all privileges on the view
and all synonyms and views that are defined on the view are also dropped.
Whenever a view is directly or indirectly dropped, all materialized query
tables defined on the view are also dropped.

If alias-name is specified, the actual view will be dropped as if view-name were
specified. However, the alias is not dropped and can be dropped using the
DROP ALIAS statement.

If the view is referenced in the definition of a row permission or a column
mask, it cannot be dropped.

**Notes**

**Restrictions on DROP:**

- DROP is subject to these restrictions:
  - DROP DATABASE cannot be performed while a DB2 utility has control
    of any part of the database.
  - DROP INDEX cannot be performed while a DB2 utility has control of
    the index or its associated table space.
DROP INDEX cannot be performed if the index is a unique index that is defined on a ROWID column that is defined as GENERATED BY DEFAULT and there are pending changes to the definition of the table space or to any objects within the table space that are explicitly created.

DROP INDEX cannot be performed if the index is an empty index on an auxiliary table that resides in an explicitly created LOB table space and there are pending changes to the definition of the base table space or to any objects within the base table space.

DROP INDEX cannot be performed if the index is the hash overflow index for a table that uses hash organization.

DROP TABLE cannot be performed while a DB2 utility has control of the table space that contains the table.

DROP TABLE cannot be performed if the table space was explicitly created and there are pending changes to the definition of the table space.

DROP TABLE cannot be performed if the table is an empty auxiliary table and there are any pending changes to the definition of the base table space.

DROP TABLESPACE cannot be performed while a DB2 utility has control of the table space.

In a data sharing environment, the following restrictions also apply:

- If any member has an active resource limit specification table (RLST) you cannot drop the database or table space that contains the table, the table itself, or any index on the table.
- If the member executing the drop cannot access the DB2-managed data sets, only the catalog and directory entries for those data sets are removed.

Objects that have certain dependencies cannot be dropped. For information on these restrictions, see Table 196 on page 1959.

Recreating objects:

After an index or table space is dropped, a commit must be performed before the object can be re-created with the same name. If a table that was created without an IN clause (thereby causing a table space to be implicitly created) is dropped, a table cannot be re-created with the same name until a commit is performed.

Dropping a parent table:

DROP is not DELETE and therefore does not involve delete rules.

Dropping a default storage group:

If you drop the default storage group of a database, the database no longer has a legitimate default. You must then specify USING in any statement that creates a table space or index in the database. You must do this until you either:

- Create another storage group with the same name using the CREATE STOGROUP statement, or
- Designate another default storage group for the database using the ALTER DATABASE statement.

Dropping an accelerator-only table:

- When an accelerator-only table is dropped and the accelerator is not active, use the SYSACCEL_DROP_TABLE procedure to drop the table in the accelerator.
A DROP TABLE statement that identifies an accelerator-only table should be issued in a separate unit of work from other SQL statements.

Dropping an implicitly created database:
When a table that resides in an implicitly created table space is dropped, the implicitly created table space and related objects are dropped. However, the implicitly created database is not dropped. This can result in a large number of empty databases in a system. These databases might be eventually reused for newly created implicit table spaces. These implicitly created databases can be dropped using DROP DATABASE.

Dropping a table space or index:
To drop a table space or index, the size of the buffer pool associated with the table space or index must not be zero.

Dropping a LOB table space:
If the base table space is explicitly created, both explicitly created LOB table spaces and implicitly created LOB table spaces can be dropped if it does not contain any auxiliary tables. If the LOB table space is implicitly created, it will be dropped automatically when the auxiliary table is dropped. If the LOB table space is explicitly created, it is not dropped when the auxiliary table is dropped, and can be explicitly dropped later.

If the base table space is implicitly created, the LOB table space cannot be dropped. If the LOB table space is explicitly created, it can be dropped when the auxiliary table is dropped. The following table shows the relationship between the base table space, the LOB table space, and the use of DROP for the LOB table space and base table space:

<table>
<thead>
<tr>
<th>How base table was created</th>
<th>How LOB table space was created</th>
<th>Whether DROP can be used on LOB table space</th>
<th>State of LOB table space if base table space is dropped</th>
</tr>
</thead>
<tbody>
<tr>
<td>Explicitly</td>
<td>Explicitly</td>
<td>Yes</td>
<td>LOB table space remains</td>
</tr>
<tr>

<td>Implicitly</td>
<td>Yes</td>
<td>LOB table space is dropped</td>
</tr>
<tr>
<td>Implicitly</td>
<td>Explicitly</td>
<td>Yes</td>
<td>LOB table space remains</td>
</tr>
<tr>
<td>Implicitly</td>
<td>Implicitly</td>
<td>No</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Dropping a database when data sets for DB2 objects have already been deleted:
When some of the data sets for DB2 objects that associated with the database have already been deleted, DROP DATABASE will perform in the following manner:

For DB2-managed objects:
The DROP DATABASE statement will delete the underlying data sets if they exist. If the data sets do not exist, DROP DATABASE will delete only the catalog entries for those data sets.

For user-managed objects:
The DROP DATABASE statement will delete only the catalog entries for the data sets. The underlying data sets will need to be manually deleted after the DROP DATABASE statement is complete.
Dropping a table space in a work file database:
If one member of a data sharing group drops a table space in a work file database, or an entire work file database, that belongs to another member, DB2-managed data sets that the executing member cannot access are not dropped. However, the catalog and directory entries for those data sets are removed.

Dropping resource limit facility (governor) indexes, tables, and table spaces:
While the RLST is active, you cannot issue a DROP DATABASE, DROP INDEX, DROP TABLE, or DROP TABLESPACE statement for an object associated with an RLST that is active on any member of a data sharing group. See Resource limit facility implications for data sharing (DB2 Data Sharing Planning and Administration) for details.

Dropping a temporary table:
To drop a created temporary table or a declared temporary table, use the DROP TABLE statement.

Dropping a materialized query table:
To drop a materialized query table, use the DROP TABLE statement.

Dropping an alias:
Dropping a table or view does not drop its aliases. However, if you use the DROP TABLE statement and specify an alias for a table or view, the table or view will be dropped. To drop an alias, use the DROP ALIAS statement.

Dropping a table from an implicitly created table space:
If you drop a table from an implicitly created table space, the following related objects are also dropped:
• The enforcing primary and unique key indexes
• Any LOB table spaces, auxiliary tables, and auxiliary indexes
• The ROWID index (if the ROWID column is defined as GENERATED BY DEFAULT)

If any LOB columns are defined on the table, the LOB table space is dropped if it was implicitly created. You can use the DROP statement to drop a LOB table space only if one of the following conditions it true:
• The base table space is explicitly created
• The base table space is implicitly created but the LOB table space is explicitly created

You cannot use the DROP statement to drop a LOB table space if both the base table space and the LOB table space are implicitly created.

Dropping an index on an auxiliary table and an auxiliary table:
You can explicitly drop an empty index on an auxiliary table with the DROP INDEX statement, unless the base table space is implicitly created. An empty or populated index on an auxiliary table is implicitly dropped when:
• The auxiliary table is empty and it is explicitly dropped (empty indexes only).
• The associated base table for the auxiliary table is dropped.
• The base table space that contains the associated base table is dropped.

You can explicitly drop an empty auxiliary table with the DROP TABLE statement, unless the base table space is implicitly created. An empty or populated auxiliary table is implicitly dropped when:
• The associated base table for the auxiliary table is dropped.
• The base table space that contains the associated base table is dropped.

The following table shows which DROP statements implicitly or explicitly cause an auxiliary table and the index on that table to be dropped, as indicated by the ‘D’ in the column.

<table>
<thead>
<tr>
<th>Statement</th>
<th>Auxiliary table</th>
<th>Index on auxiliary table</th>
</tr>
</thead>
<tbody>
<tr>
<td>DROP TABLESPACE (base table space)</td>
<td>D</td>
<td>D</td>
</tr>
<tr>
<td>DROP TABLE (base table)</td>
<td>D</td>
<td>D</td>
</tr>
<tr>
<td>DROP TABLE (auxiliary table)</td>
<td>D</td>
<td>D</td>
</tr>
<tr>
<td>DROP INDEX (index on auxiliary table)</td>
<td>D</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** D indicates that the table or index is dropped.

**Dropping a migrated index or table space:**
Here, “migration” means migrated by the Hierarchical Storage Manager (DFSMShsm). DB2 does not wait for any recall of the migrated data sets. Hence, recall is not a factor in the time it takes to execute the statement.

**Dropping a trusted context:**
The drop of a trusted context takes effect after the DROP TRUSTED CONTEXT statement is committed. If the DROP TRUSTED CONTEXT statement results in an error or is rolled back, the trusted context is not dropped.

**Avoiding DROP failure due to excessive locking**
Dropping a table space, database, or index with the COPY YES attribute deletes all corresponding records in the SYSCOPI and SYSLGRNX catalog statistics tables. The DROP fails if the lock structure size cannot accommodate the number of locks obtained during DROP processing. DROP failure is more likely if the SYSCOPI, SYSLGRNX, or other catalog statistics tables contain many entries, especially if the object you are dropping was created long ago or contains many partitions. DROP failure is also more likely if objects are copied frequently while the MODIFY RECOVERY and MODIFY STATISTICS utilities are run relatively infrequently.

To avoid DROP failure, run the MODIFY RECOVERY and MODIFY STATISTICS utilities on objects before dropping them. If you drop a clone table, you need to specify the CLONE keyword to delete recovery and statistics information for the clone objects from the catalog and directory. You can Specify AGE(*) or DATE(*) to remove all recovery and statistics information regardless of past update, copy, or cleanup frequency. Be aware that running the MODIFY utility with AGE(*) or DATE(*) will leave objects unrecoverable after they are dropped unless you make a copy or other form of back-up first.

Also, ensure that your applications commit drops frequently, especially for databases containing multiple table spaces, and table spaces containing...
multiple tables. You can also increase the size of your lock structures to accommodate the surge in lock requests during this type of activity.

**Invalidation of packages and dynamic cached statements after dropping row permissions or column masks:**
If row or column access control is currently enforced for the table, dropping the row permission or the column mask invalidates all packages and dynamic cached statements that reference the table. Otherwise no package or dynamic cached statement is invalidated.

**Dependencies when dropping objects:**
Whenever an object is directly or indirectly dropped, other objects that depend on the dropped object might also be dropped. (The catalog stores information about the dependencies of objects on each other.) The following semantics determine what happens to a dependent object when the object that it depends on (the underlying object) is dropped:

**Cascade (D)**
Dropping the underlying object causes the dependent object to be dropped. However, if the dependent object cannot be dropped because it has a restrict dependency on another object, the drop of the underlying object fails.

**Restrict (D)**
The underlying object cannot be dropped if a dependent object exists.

**Inoperative (O)**
Dropping the underlying object causes the dependent object to become inoperative.

**Invalidation (V)**
Dropping the underlying object causes the dependent object to become invalidated.

For objects that directly depend on others, the following table uses the letter abbreviations above to summarize what happens to a dependent object when its underlying object is specified in a DROP statement. Additional objects can be indirectly affected, too.

To determine the indirect effects of a DROP statement, assess what happens to the dependent object and whether the dependent object has objects that depend on it. For example, assume that view B is defined on table A and view C is defined on view B. In the following table, the 'D' in the VIEW column of the DROP TABLE row indicates that view B is dropped when table A is dropped. Next, because view C is dependent on view B, check the VIEW column for DROP VIEW. The 'D' in the column indicates that view C will be dropped, too.

The letters in the following table have the following meanings:

<table>
<thead>
<tr>
<th></th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>Dependent object is dropped.</td>
</tr>
<tr>
<td>O</td>
<td>Dependent object is made inoperative.</td>
</tr>
<tr>
<td>V</td>
<td>Dependent object is invalidated.</td>
</tr>
<tr>
<td>R</td>
<td>DROP statement fails.</td>
</tr>
</tbody>
</table>

</tbody>
</table>

**Notes:**

1. The PACKAGE column represents packages for user-defined functions, procedures, and triggers, as well as other packages. The PACKAGE column also applies for plans.
2. The index space associated with the index is dropped.
3. If a function is dependent on the distinct type being dropped, the distinct type cannot be dropped unless the function is one of the cast functions that was created for the distinct type.
4. If the definition of a parameter of a stored procedure uses the distinct type, the distinct type cannot be dropped.
5. If other user-defined functions are sourced on the user-defined function being dropped, the function cannot be dropped.
6. An index on an auxiliary table cannot be explicitly dropped.
7. A trigger package cannot be explicitly dropped with DROP PACKAGE. A trigger package is implicitly dropped when the associated trigger or subject table is dropped.
8. A storage group cannot be dropped if it is used by any table space or index space.
9. An auxiliary table cannot be explicitly dropped with DROP TABLE. An auxiliary table is implicitly dropped when the associated base table is dropped.
10. If an implicit table space was created when the table was created, the table space is also dropped.
11. When a subject table is dropped, any associated triggers and related trigger packages are also dropped.
12. A LOB table space cannot be dropped until the base table with the LOB columns is dropped.
13. This restriction is only for SQL functions.
14. The index in this case must be an expression-based index.
15. When a subject view is dropped, any associated triggers and related trigger packages are also dropped.
16. Any packages that have a dependency on an INSTEAD OF trigger will be marked invalid.
17. A routine that is referenced by a non-inline SQL scalar function cannot be dropped.
18. A routine that is referenced by a native SQL procedure cannot be dropped.
19. Only dependent table functions are dropped.

**Alternative syntax and synonyms:**

To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports the following keywords:

- DATA TYPE or DISTINCT TYPE as a synonym for TYPE
- PROGRAM as a synonym for PACKAGE
Examples

Example 1: Drop table DSN8A10.DEPT.
   DROP TABLE DSN8A10.DEPT;

Example 2: Drop table space DSN8S10D in database DSN8D10A.
   DROP TABLESPACE DSN8D10A.DSN8S10D;

Example 3: Drop the view DSN8A10.VPROJRE1:
   DROP VIEW DSN8A10.VPROJRE1;

Example 4: Drop the package DSN8CC0 with the version identifier VERSZZZZ. The package is in the collection DSN8CC61. Use the version identifier to distinguish the package to be dropped from another package with the same name in the same collection.
   DROP PACKAGE DSN8CC61.DSN8CC0 VERSION VERSZZZZ;

Example 5: Drop the package DSN8CC0 with the version identifier "1994-07-14-09.56.30.196952". When a version identifier is generated by the VERSION(AUTO) precompiler option, delimit the version identifier.
   DROP PACKAGE DSN8CC61.DSN8CC0 VERSION "1994-07-14-09.56.30.196952";

Example 6: Drop the distinct type DOCUMENT, if it is not currently in use:
   DROP TYPE DOCUMENT;

Example 7: Assume that you are SMITH and that ATOMIC_WEIGHT is the only function with that name in schema CHEM. Drop ATOMIC_WEIGHT.
   DROP FUNCTION CHEM.ATOMIC_WEIGHT;

Example 8: Assume that you are SMITH and that you created the function CENTER in schema SMITH. Drop CENTER, using the function signature to identify the function instance to be dropped.
   DROP FUNCTION CENTER(INTEGER, FLOAT);

Example 9: Assume that you are SMITH and that you created another function named CENTER, which you gave the specific name FOCUS97, in schema JOHNSON. Drop CENTER, using the specific name to identify the function instance to be dropped.
   DROP SPECIFIC FUNCTION JOHNSON.FOCUS97;

Example 10: Assume that you are SMITH and that stored procedure OSMOSIS is in schema BIOLOGY. Drop OSMOSIS.
   DROP PROCEDURE BIOLOGY.OSMOSIS;

Example 11: Assume that you are SMITH and that trigger BONUS is in your schema. Drop BONUS.
   DROP TRIGGER BONUS;

Example 12: Drop the role CTXROLE:
   DROP ROLE CTXROLE;

Example 13: Drop the trusted context CTX1:
   DROP TRUSTED CONTEXT CTX1;
END DECLARE SECTION

The END DECLARE SECTION statement marks the end of an SQL declare section.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

Authorization

None required.

Syntax

```
END DECLARE SECTION
```

Description

The END DECLARE SECTION statement can be coded in the application program wherever declarations can appear in accordance with the rules of the host language. It is used to indicate the end of an SQL declare section. An SQL declare section starts with a BEGIN DECLARE SECTION statement described in `BEGIN DECLARE SECTION`.

The following rules are enforced by the precompiler only if the host language is C or the STDSQL(YES) precompiler option is specified:

- A variable referred to in an SQL statement must be declared within an SQL declare section of the source program.
- BEGIN DECLARE SECTION and END DECLARE SECTION statements must be paired and must not be nested.
- SQL declare sections can contain only host variable declarations, SQL INCLUDE statements that include host variable declarations, or DECLARE VARIABLE statements.

Notes

SQL declare sections are only required if the STDSQL(YES) option is specified or the host language is C. However, SQL declare sections can be specified for any host language so that the source program can conform to IBM SQL. If SQL declare sections are used, but not required, variables declared outside an SQL declare section should not have the same name as variables declared within an SQL declare section.

Example

```
EXEC SQL BEGIN DECLARE SECTION;
-- host variable declarations
EXEC SQL END DECLARE SECTION;
```
EXCHANGE

The EXCHANGE statement switches the content of a base table and its associated clone table.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set that is defined below must include at least one of the following privileges:

- The INSERT and DELETE privileges on both the base table and the clone table
- Ownership of the both the base table and the clone table
- DBADM authority for the database
- SYSADM authority
- DATAACCESS authority

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process.

Syntax

```
EXCHANGE DATA BETWEEN TABLE—table-name1—AND—table-name2
```

Description

table-name1 and table-name2

Identifies the base table and the associated clone table for which the exchange of data will take place. Either table-name1 or table-name2 can identify the base table. The other table name must identify a clone table that is associated with the specified base table. The name of the base table and the name of the clone table remain unchanged after a data exchange.

Notes

Rules and restrictions: Data exchanges cannot be done for a subset of a table’s partitions. There must be a commit between consecutive data exchanges using the EXCHANGE statement.

Examples

Example: Exchange the data of the EMPLOYEE table and its clone table, EMPCLONE.

```
EXCHANGE DATA BETWEEN TABLE EMPCLONE AND EMPLOYEE;
```
EXECUTE

The EXECUTE statement executes a prepared SQL statement.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

See PREPARE for the authorization required to create a prepared statement.

Syntax

```
EXECUTE statement-name
  USING host-variable
  USING DESCRIPTOR descriptor-name (1)
  source-row-data
```

Notes:
1. This option can be specified only when `statement-name` refers to a dynamic INSERT or MERGE statement that is prepared with FOR MULTIPLE ROWS and is specified as part of the ATTRIBUTES clause on the PREPARE statement.

source-row-data:

```
USING host-variable-array (1)
USING DESCRIPTOR descriptor-name
FOR host-variable ROWS integer-constant
```

Notes:
1. The FOR n ROWS clause is required on the EXECUTE statement if it is not specified as part of the MERGE statement and a host variable array is specified. The FOR n ROWS clause is also required if MERGE is used with multiple rows of source data. For an INSERT statement, the FOR n ROWS clause can only be specified for a dynamic statement that contains only a single multiple-row INSERT statement.

Description

`statement-name` Identifies the prepared statement to be executed. `statement-name` must identify a statement that was previously prepared within the unit of work and the prepared statement must not be a select-statement.
USING
Introduces a list of host variables whose values are substituted for the parameter markers (question marks) in the prepared statement. (For an explanation of parameter markers, see PREPARE.) If the prepared statement includes parameter markers, you must include USING in the EXECUTE statement. USING is ignored if there are no parameter markers.

For more on the substitution of values for parameter markers, see Parameter marker replacement.

host-variable,...
Identifies structures or variables that must be described in the application program in accordance with the rules for declaring host structures and variables. A reference to a structure is replaced by a reference to each of its variables. The number of variables must be the same as the number of parameter markers in the prepared statement. The n th variable supplies the value for the n th parameter marker in the prepared statement.

USING DESCRIPTOR descriptor-name
Identifies an SQLDA that contains a valid description of the input host variables.

Before invoking the EXECUTE statement, you must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR occurrences that are provided in the SQLDA
  A REXX SQLDA does not contain this field.
- SQLABC to indicate the number of bytes of storage that are allocated for the SQLDA
- SQLD to indicate the number of variables that are used in the SQLDA when processing the statement
- SQLVAR entries to indicate the attributes of the variables

The SQLDA must have enough storage to contain all SQLVAR entries. If an SQLVAR entry includes a LOB value or a distinct type based on a LOB, there must be additional SQLVAR entries for each parameter. For more information on the SQLDA, which includes a description of the SQLVAR and an explanation on how to determine the number of SQLVAR entries, see SQL descriptor area (SQLDA).

SQLD must be set to a value that is greater than or equal to zero and less than or equal to SQLN. It must be the same as the number of parameter markers in the prepared statement. The n th variable described by the SQLDA corresponds to the n th parameter marker in the prepared statement.

See Identifying an SQLDA in C or C++ for how to represent descriptor-name in C.

source-row-data
The prepared statement must be an INSERT or MERGE statement for which the FOR MULTIPLE ROWS clause is specified as part of the ATTRIBUTES clause on the PREPARE statement.

USING host-variable-array or host-variable
Introduces a list of host variables or host variable arrays whose values are substituted for the parameter markers (question marks) in the prepared INSERT or MERGE statement. The number of columns specified in the INSERT or MERGE statement must be less than or equal to the total number of host variables or host variable arrays that are specified.
**host-variable-array**

Identifies a host-variable array that must be defined in the application program in accordance with the rules for declaring a host variable array. A reference to a structure is replaced by a reference to each of its variables. The number of variables must be the same as the number of parameter markers in the prepared statement. The \( n \)th variable supplies the value for the \( n \)th parameter marker in the prepared statement.

**host-variable**

Identifies a variable that must be described in the application program in accordance with the rules for declaring host variables.

**USING DESCRIPTOR descriptor-name**

Identifies an SQLDA that must contain a valid description of the host variable arrays or host variables that contain the values to insert.

Before invoking the EXECUTE statement for a dynamic INSERT or MERGE statement, you must set the following fields in the SQLDA:

- **SQLN** to indicate the number of SQLVAR entries that are provided in the SQLDA.
- **SQLABC** to indicate the number of bytes of storage that are allocated for the SQLDA.
- **SQLD** to indicate the number of variables, plus one, that are used in the SQLDA that provide values for columns that are the source of the INSERT or MERGE statement. SQLD must be set to a value that is greater than or equal to zero and less than or equal to SQLN.
- **SQLVAR** entries to indicate the attributes of an element of the host variable array for the SQLVAR entries that correspond to values that are provided for the source columns of the INSERT or MERGE statement. Within each SQLVAR, the following fields are set:
  - **SQLTYPE** indicates the data type of the elements of the host variable array.
  - **SQLDATA** points to the corresponding host variable array.
  - **SQLLEN** and **SQLLONGLEN** indicate the length of a single element of the array.
- **SQLNAME**, the fifth and sixth bytes must contain a flag field and the seventh and eighth bytes must contain a binary small integer (halfword) that contains the dimension of the host-variable array and, if specified, the corresponding indicator array.

The SQLDA must have enough storage to contain a SQLVAR entry for each target column for which values are provided, plus an additional SQLVAR entry for the number of rows. The DB2 system generates code to enter the required information for this extra SQLVAR entry. Each SQLVAR entry describes a host variable, host variable array, or buffer that contains the values for a column of the source table. The last SQLVAR entry contains the number of rows of data. For example, if the INSERT or MERGE statement is providing values for five columns of the target table, six SQLVAR entries must be provided. If any value is a LOB value, twice as many SQLVAR entries must be provided, and SQLN must be set to the number of SQLVAR entries. Thus, if the INSERT or MERGE statement is providing values for five columns of the source table, and some of the values to insert are LOB values, 12 SQLVAR entries must be provided.

The **SQLVAR** entry for the number of rows must also contain a flag value. See [Field descriptions of an occurrence of a base SQLVAR](#) for more information.
You set the SQLDATA and SQLIND pointers to the beginning of the corresponding arrays.

**FOR host-variable or integer-constant ROWS**

Specifies the number of rows of source data. The values for the insert or merge operation are specified in the USING clause.

*host-variable or integer-constant* is assigned to an integral value k. If *host-variable* is specified, it must be an exact numeric type with a scale of zero and must not include an indicator variable. k must be in the range 0 to 32767.

FOR n ROWS cannot be specified on the EXECUTE statement if the statement being processed is a dynamic INSERT or MERGE statement that includes a FOR n ROWS clause.

**Notes**

**Excessive processor time:**

DB2 can stop the execution of a prepared SQL statement if the statement is taking too much processor time to finish. When this happens, an error occurs. The application that issued the statement is not terminated; it is allowed to issue another SQL statement.

**Parameter marker replacement:**

Before the prepared statement is executed, each parameter marker in the statement is effectively replaced by its corresponding host variable. The replacement is an assignment operation in which the source is the value of the host variable and the target is a variable within DB2. The assignment rules are those described for assignment to a column in Assignment and comparison. For a typed parameter marker, the attributes of the target variable are those specified by the CAST specification. For an untyped parameter marker, the attributes of the target variable are determined according to the context of the parameter marker. For the rules that affect parameter markers, see Parameter markers.

Let V denote a host variable that corresponds to parameter marker P. The value of V is assigned to the target variable for P in accordance with the rules for assigning a value to a column:

- V must be compatible with the target.
- If V is a string, its length must not be greater than the length attribute of the target.
- If V is a number, the absolute value of its integral part must not be greater than the maximum absolute value of the integral part of the target.
- If the attributes of V are not identical to the attributes of the target, the value is converted to conform to the attributes of the target.
- If the target cannot contain nulls, V must not be null.

When the prepared statement is executed, the value used in place of P is the value of the target variable for P. For example, if V is CHAR(6) and the target is CHAR(8), the value used in place of P is the value of V padded on the right with two blanks.

**Errors occurring on EXECUTE:**

In local and remote processing, the DEFER(PREPARE) and REOPT(ALWAYS)/REOPT(ONCE) bind options can cause some errors that are normally issued during PREPARE processing to be issued on EXECUTE.
Examples

Example 1: In this example, an INSERT statement with parameter markers is prepared and executed. S1 is a structure that corresponds to the format of DSN8A10.DEPT.

```
EXEC SQL PREPARE DEPT_INSERT FROM
    'INSERT INTO DSN8A10.DEPT VALUES(?,?,?,?)';
-- Check for successful execution and read values into S1
EXEC SQL EXECUTE DEPT_INSERT USING :S1;
```

Example 2: Assume that the IWH.PROGPARM table has 9 columns. Prepare and execute a dynamic INSERT statement that inserts 5 rows of data into the IWH.PROGPARM table. The values to be inserted are provided in arrays, where all the values for a column are provided in an host-variable-array with the EXECUTE statement.

```
STMT = 'INSERT INTO IWH.PROGPARM (IWHID, UPDATE_BY, UPDATE_TS, NAME,
    SHORT_DESCRIPTION, ORDERNO, PARMDATA, PARMDATALONG, VWPROGKEY)
VALUES (? , ?, ?, ?, ?, ?, ?, ?)';
ATTRVAR = 'FOR MULTIPLE ROWS';
EXEC SQL PREPARE INS_STMT ATTRIBUTES :ATTRVAR FROM :STMT;
NROWS = 5;
EXEC SQL EXECUTE INS_STMT FOR :NROWS ROWS
```

In this example, each host variable in the USING clause represents an array of values for the corresponding column of the target of the INSERT statement.

Example 3: Using dynamically supplied values for an employee row, update the master EMPLOYEE table if the data is for an existing employee or insert a new row if the data is for a new employee.

```
hv_stmt =
"MERGE INTO EMPLOYEE AS T
    USING (VALUES (CAST (? AS CHAR(6)), CAST (? AS VARCHAR(12)),
    CAST (? AS CHAR(1)), CAST (? AS VARCHAR(15)),
    CAST (? AS INTEGER)))
    AS S (EMPNO, FIRSTNAME, MI, LASTNAME, SALARY)
    ON T.EMPNO = S.EMPNO
    WHEN MATCHED THEN UPDATE
        SET SALARY = S.SALARY
    WHEN NOT MATCHED THEN INSERT
        VALUES (S.EMPNO, S.FIRSTNAME, S.MI, S.LASTNAME, S.SALARY)
    NOT ATOMIC CONTINUE ON SQLERROR';
hv_attr = 'FOR MULTIPLE ROWS';
EXEC SQL
    PREPARE merge_stmt
        ATTRIBUTES :hv_attr FROM :hv_stmt;
hv_nrows = 5;
/* Initialize the hostvar array of hv_empno, hv_firstname... */
EXEC SQL
    EXECUTE merge_stmt
    USING :hv_empno, :hv_firstname, :hv_mi,
        :hv_lastname, :hv_salary
    FOR :hv_nrows ROWS;
```
EXECUTE IMMEDIATE

EXECUTE IMMEDIATE combines the basic functions of the PREPARE and EXECUTE statements. It can be used to prepare and execute an SQL statement that contains neither host variables nor parameter markers.

The EXECUTE IMMEDIATE statement:
• Prepares an executable form of an SQL statement from a string form of the statement
• Executes the SQL statement
• Destroys the executable form

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

The authorization rules are those defined for the dynamic preparation of the SQL statement specified by EXECUTE IMMEDIATE. For example, see “INSERT” on page 2062 for the authorization rules that apply when an INSERT statement is executed using EXECUTE IMMEDIATE.

Syntax

```
EXECUTE IMMEDIATE host-variable string-expression
```

Description

host-variable

For languages other than PL/I, host-variable must be specified. It must identify a host variable that is described in the application program in accordance with the rules for declaring character or graphic string variables. If the source string is over 32KB in length, the host-variable must be a CLOB or DBCLOB variable. The maximum source length is 2MB although the host variable can be declared larger than 2MB. An indicator variable must not be specified. In Assembler, C, COBOL, and PL/I, the host variable must be a varying-length string variable. In C, it must not be a NUL-terminated string. In SQL PL, an SQL variable is used in place of a host variable and the value must not be null.

string-expression

string-expression is any PL/I expression that yields a string. string-expression cannot be preceded by a colon. Variables that are within string-expression that include operators or functions should not be preceded by a colon. When string-expression is specified, the precompiler-generated structures for string-expression use an EBCDIC CCSID and an informational message is returned.
Notes

Allowable SQL statements:
The value of the identified host variable or the specified string-expression is called the statement string.

The statement string must be one of the following SQL statements, and cannot be a select-statement:

<table>
<thead>
<tr>
<th>ALLOWABLE SQL STATEMENT</th>
<th>ALLOWABLE SQL STATEMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATE CURSOR</td>
<td>REVOKE</td>
</tr>
<tr>
<td>ALTER</td>
<td>ROLLBACK</td>
</tr>
<tr>
<td>ASSOCIATE LOCATORS</td>
<td>SAVEPOINT</td>
</tr>
<tr>
<td>COMMENT</td>
<td>SET CURRENT DEGREE</td>
</tr>
<tr>
<td>COMMIT</td>
<td>SET CURRENT DECFLOAT ROUNDDING MODE</td>
</tr>
<tr>
<td>CREATE</td>
<td>SET CURRENT DEBUG MODE</td>
</tr>
<tr>
<td>DECLARE GLOBAL TEMPORARY TABLE</td>
<td>SET CURRENT LOCALE LC_CTYPE</td>
</tr>
<tr>
<td>TABLE</td>
<td>SET CURRENT MAINTAINED TABLE TYPES</td>
</tr>
<tr>
<td>DELETE</td>
<td>FOR OPTIMIZATION</td>
</tr>
<tr>
<td>DROP</td>
<td>SET CURRENT OPTIMIZATION HINT</td>
</tr>
<tr>
<td>EXPLAIN</td>
<td>SET CURRENT PRECISION</td>
</tr>
<tr>
<td>FREE LOCATOR</td>
<td>SET CURRENT QUERY ACCELERATION</td>
</tr>
<tr>
<td>GRANT</td>
<td>SET CURRENT REFRESH AGE</td>
</tr>
<tr>
<td>HOLD LOCATOR</td>
<td>SET CURRENT ROUTINE VERSION</td>
</tr>
<tr>
<td>INSERT</td>
<td>SET CURRENT RULES</td>
</tr>
<tr>
<td>LABEL</td>
<td>SET CURRENT SQLID</td>
</tr>
<tr>
<td>LOCK TABLE</td>
<td>SET ENCRYPTION PASSWORD</td>
</tr>
<tr>
<td>MERGE</td>
<td>SET PATH</td>
</tr>
<tr>
<td>REFRESH TABLE</td>
<td>SET SCHEMA</td>
</tr>
<tr>
<td>RELEASE SAVEPOINT</td>
<td>SIGNAL</td>
</tr>
<tr>
<td>RENAME</td>
<td>TRUNCATE</td>
</tr>
<tr>
<td></td>
<td>UPDATE</td>
</tr>
</tbody>
</table>

The statement string must not:

- Begin with EXEC SQL
- End with END-EXEC or a semicolon
- Include references to variables
- Include parameter markers

Errors and error handling:

When an EXECUTE IMMEDIATE statement is executed, the specified statement string is parsed and checked for errors. If the SQL statement is invalid, it is not executed and the error condition that prevents its execution is reported in the SQLCA. If the SQL statement is valid, but an error occurs during its execution, that error condition is reported in the SQLCA.

DB2 can stop the execution of a prepared SQL statement if the statement is taking too much CPU time to finish. When this happens an error occurs. The application that issued the statement is not terminated; it is allowed to issue another SQL statement.

Effect of the CURRENT EXPLAIN MODE special register:

If the CURRENT EXPLAIN MODE special register is set to EXPLAIN, the statement is prepared for explain only and is not executable, unless the statement is a SET statement. Attempting to execute the prepared statement will return an error. See the "CURRENT EXPLAIN MODE" on page 189 special register for more information.
Performance considerations:
If the same SQL statement is to be executed more than once, it is more efficient to use the PREPARE and EXECUTE statements rather than the EXECUTE IMMEDIATE statement.

Examples

Example 1: In this PL/I example, the EXECUTE IMMEDIATE statement is used to execute a DELETE statement in which the rows to be deleted are determined by a search-condition specified by the value of PREDs.

```plaintext
EXEC SQL EXECUTE IMMEDIATE 'DELETE FROM DSN8A10.DEPT
  WHERE || PREDs;
```

Example 2: Use C to execute the SQL statement in the host variable Qstring.

```plaintext
EXEC SQL INCLUDE SQLCA;
void main ()
{
  EXEC SQL BEGIN DECLARE SECTION;
  char Qstring[100M =
    "INSERT INTO WORK_TABLE SELECT * FROM EMPLOYEES WHERE ACTNO >= 100";
  EXEC SQL END DECLARE SECTION;
  EXEC SQL EXECUTE IMMEDIATE :Qstring;
  return;
}
```
The EXPLAIN statement obtains information about access path selection for an explainable statement. A statement is explainable if it is a SELECT, MERGE, or INSERT statement, or the searched form of an UPDATE or DELETE statement. The information that is obtained is placed in a set of supplied user tables that are called EXPLAIN tables.

The plan table contains information about the access path for the specified statement or statements. The statement table can be populated with information about the estimated cost of executing the explainable statement. The function table can be populated with information about how DB2 resolves the user-defined functions that are referred to in the explainable statement. Other EXPLAIN tables can be populated with additional information about the execution of the explainable statement. For a complete list of EXPLAIN tables, see EXPLAIN tables (DB2 Performance).

Using EXPLAIN for queries that reference system-period temporal tables that are enabled for system data versioning, the result will show the system-period temporal tables and the history tables in EXPLAIN output if the query needs to reference both tables to satisfy the query.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The authorization rules are those defined for the SQL statement specified in the EXPLAIN statement. For example, see the description of the DELETE statement for the authorization rules that apply when EXPLAIN records are captured for DELETE statements.

If the EXPLAIN statement is embedded in an application program, the authorization rules that apply are those defined for embedding the specified SQL statement in an application program. In addition, the owner of the plan or package must also have one of the following characteristics:

- Be the owner of a plan table named PLAN_TABLE
- Have an alias on a plan table named owner.PLAN_TABLE and have SELECT and INSERT privileges on the table

If the EXPLAIN statement is dynamically prepared, the authorization rules that apply are those defined for dynamically preparing the specified SQL statement. In addition, the SQL authorization ID of the process or the role this is associated with the process (if the EXPLAIN statement is running in a trusted context that specifies the ROLE AS OBJECT OWNER AND QUALIFIER clause) must also have one of the following characteristics:

- Be the creator of a plan table named PLAN_TABLE
- Have an alias on a plan table named creator.PLAN_TABLE and have SELECT and INSERT privileges on the table
For EXPLAIN statements with the PLAN and ALL keywords, the privilege set that is defined below must include at least one of the following:

- EXPLAIN
- SQLADM
- System DBADM
- The authorization rules that are defined for the SQL statement specified in the EXPLAIN statement. For example, the authorization rules that apply when EXPLAIN records are captured for a DELETE statement are the authorization rules for the DELETE statement.

The authorization rules are different if the STMTCACHE keyword is specified. The privilege set must include at least one of the following:

- SQLADM authority
- SYSADM authority
- The authority that is required to share the cached statement.
- System DBADM authority

For EXPLAIN statements that contain the STMTCACHE ALL clause, the privilege set must include at least one of the following:

- SQLADM authority
- System DBADM authority
- SYSADM authority

If the privilege set does not have the required authority, EXPLAIN records are captured only those statements that have the same authorization ID as the privilege set.

For the PACKAGE keyword, the privilege set must include at least one of the following:

- SQLADM authority
- SYSADM authority
- SYSOPR authority
- SYSTCTRL authority

Privilege set: The privilege set comprises the union of authorities that are held by the authorization IDs of the process. If the process is running in a trusted context with a role, this role would be included as an authorization ID of the process.

Syntax
Description

PLAN

Specifies that access path information is captured for the SQL statement. Under this option, DB2 uses the access path selection process to generate the EXPLAIN records for the statement. One row is inserted into the PLAN_TABLE for each step used in executing explainable-sql-statement. The steps for enforcing referential constraints are not included.

If a statement table exists, one row that provides a cost estimate of processing the explainable statement is inserted into the statement table. If the explainable statement is a SELECT FROM data-change-statement, two rows are inserted into the statement table.

If a function table exists, one row is inserted into the function table for each user-defined function that is referred to by the explainable statement.

If additional EXPLAIN tables exist, rows are also inserted into those tables.

Related reference:
- EXPLAIN tables (DB2 Performance)
- PLAN_TABLE (DB2 Performance)
- DSN_STATEMENT_TABLE (DB2 Performance)
- DSN_FUNCTION_TABLE (DB2 Performance)

ALL

Has the same effect as PLAN.

SET QUERYNO = integer

Associates integer with explainable-sql-statement. The column QUERYNO is given the value integer in every row inserted into the plan table, statement table, or function table by the EXPLAIN statement. If QUERYNO is not specified, DB2 itself assigns a number. For an embedded EXPLAIN statement, the number is the statement number that was assigned by the precompiler and placed in the DBRM.

FOR explainable-sql-statement

Specifies the text of an SQL statement for which EXPLAIN records are captured. explainable-sql-statement can be any explainable SQL statement. If the EXPLAIN statement is embedded in a program, the statement can contain references to host variables. If EXPLAIN is dynamically prepared, the statement can contain parameter markers. Host variables that appear in the statement must be defined in the statement's program.

The statement must refer to objects at the current server.
**explainable-sql-statement** must not contain a QUERYNO clause. To specify the value of the QUERYNO column, use the SET QUERYNO = integer clause of the EXPLAIN statement.

**explainable-sql-statement** cannot be a statement-name or a host-variable. To use capture EXPLAIN records for dynamic SQL statements, you must prepare the entire EXPLAIN statement dynamically.

To obtain information about an explainable SQL statement that references a declared temporary table, the EXPLAIN statement must be executed in the same application process in which the table was declared. For static EXPLAIN statements, the information is not obtained at bind-time but at run time when the EXPLAIN statement is incrementally bound.

**STMTCACHE**

Specifies that EXPLAIN records for the specified dynamic SQL statements in the dynamic statement cache are extracted and written to EXPLAIN tables. Under this option, no new access path selection processing occurs. The EXPLAIN records are extracted from the existing access paths that were selected when the dynamic SQL statements were prepared and entered the statement cache. In a data-sharing environment, the EXPLAIN records are extracted from the dynamic statement cache of the data sharing member where EXPLAIN STMTCACHE statement is executed.

**ALL**

Specifies that EXPLAIN records are extracted for all cached statements. STMTCACHE ALL returns one row for each cached statement to the DSN_STATEMENT_CACHE_TABLE. These rows contain identifying information about the statements in the cache, as well as statistics that reflect the execution of the statements by all processes that have executed the statement. Records are not returned to other EXPLAIN tables when STMTCACHE ALL is specified.

**STMTID id-host-variable or integer-constant**

Specifies that EXPLAIN records are extracted for the cached statement with the specified statement ID. The value contained in id-host-variable or specified by integer-constant identifies the statement ID. STMTCACHE STMTID returns rows to the following EXPLAIN tables:

- PLAN_TABLE
- DSN_STATEMENT_TABLE
- DSN_FUNCTION_TABLE
- DSN_STATEMENT_CACHE_TABLE

The statement ID is an integer that uniquely identifies a statement that has been cached in the dynamic statement cache. The statement ID of a cached statement can be retrieved through IFI monitor facilities from IFCID 0316 or 0124. Some diagnostic trace records, such as IFCIDs 0173, 0196, and 0337, also show the statement ID.

The QUERYNO column of each EXPLAIN table record that is returned contains the statement ID value.

**STMTTOKEN id-host-variable or string-constant**

Specifies that EXPLAIN records are extracted for the cached statements with the specified statement token and written to certain EXPLAIN tables. The value contained in token-host-variable or specified by string-constant identifies the statement token. STMTCACHE STMTTOKEN writes records to the following EXPLAIN tables:

- PLAN_TABLE
The statement token must be a character string that is no longer than 240 bytes. The application program that originally prepares and inserts a statement into the cache associates a statement token with the cached statement. The program can make this association with the RRSAF SET_ID function, or the sqleseti API if the program is connected remotely.

The STMTTOKEN column of each PLAN_TABLE record that is returned contains the statement token value. The QUERYNO column of each EXPLAIN table record that is returned contains the statement ID value.

Related information:

DSN_STATEMENT_CACHE_TABLE (DB2 Performance)

PACKAGE

Specifies that EXPLAIN records for all static SQL statements in the package that matches the specified scope are extracted and written to EXPLAIN tables. Under this option, no new access path selection processing occurs. The records are extracted from the existing access paths that were selected when the package was bound. The EXPLAIN information is added to the PLAN_TABLE that is owned by the current user. Other EXPLAIN tables are not populated.

No EXPLAIN records are extracted from packages that are bound prior to DB2 Version 9.1 for z/OS.

COLLECTION collection-name

Specifies that EXPLAIN records are captured only for statements under the specified collection-name. collection-name is a string constant or a host variable that represents the collection name.

PACKAGE package-name

Specifies that EXPLAIN records are captured only for statements under the specified package-name. package-name is a string constant or a host variable that represents the package name.

VERSION version-name

Specifies that EXPLAIN records are captured only for statements under the specified version-name. version-name is a string constant or a host variable that represents the version name. If version-name is all blanks or an empty string, records are captured only for those versions of the package that contain all blanks for the version name.

If the VERSION clause is not specified, EXPLAIN records are captured for statements in all versions of the package package-name.

COPY copy-id

Specifies that EXPLAIN records are captured only for statements under the specified copy-id. copy-id must be one of the following values:

- CURRENT
- PREVIOUS
- ORIGINAL

If the COPYID clause is not specified, statements, EXPLAIN records are captured for all copies that exist for that package (CURRENT, PREVIOUS, and ORIGINAL).
The HINT_USED column in the PLAN_TABLE is populated with EXPLAIN PACKAGE: copy-id. copy-id in the HINT_USED column will be one of the following values:

- “0” - the current copy
- “1” - the previous copy
- “2” - the original copy

Notes

Output from EXPLAIN:

DB2 inserts one or more rows of data into a plan table and other existing EXPLAIN tables. For a list of all EXPLAIN tables, see EXPLAIN tables (DB2 Performance).

A plan table must exist before the operation that results in EXPLAIN output. You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the prefix.SDSNSAMP library.

Unless you need the information that is provided by the additional EXPLAIN tables, it is not necessary to create those tables to use EXPLAIN. However, a statement cache table is required when the STMTCACHE ALL keyword is specified as part of an EXPLAIN statement.

DB2 uses the access path selection process to generate EXPLAIN records only for certain types of EXPLAIN statements, as shown in the following table.

<table>
<thead>
<tr>
<th>Options Specified</th>
<th>How DB2 Creates EXPLAIN records</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXPLAIN PLAN FOR explainable-sql-statement</td>
<td>Uses the access path selection process to generate the EXPLAIN records</td>
</tr>
<tr>
<td>EXPLAIN PACKAGE ...</td>
<td>Extracts existing access path information from the package to create the EXPLAIN records.</td>
</tr>
<tr>
<td>EXPLAIN STMTCACHE ...</td>
<td>Extracts access path information from the dynamic statement cache to create the EXPLAIN records.</td>
</tr>
</tbody>
</table>

Each row in an EXPLAIN table describes some aspect of a step in the execution of a query or subquery in an explainable statement. The column values for the row identify, among other things, the query or subquery, the tables and other objects involved, the methods used to carry out each step, and cost information about those methods.

Instances of these tables might also be created and used by certain optimization tools. For information about the meanings of different values in plan table and other EXPLAIN tables, see .

For information about how to correlate information across EXPLAIN tables, see Correlating information across EXPLAIN tables (DB2 Performance).

EXPLAIN tables might contain names that begin with “DSN” that have been generated by DB2.

Important: Do not manually manipulate the data in EXPLAIN tables that are created by optimization tools.
Column access control or row permissions enforced for EXPLAIN tables:

Column access control and row permissions can be enforced for EXPLAIN tables. However, row permissions and column masks are not applied when DB2 inserts rows into those tables.

If the specified statement references tables for which row or column access control is activated, the following information from row permission and column mask definitions created for the tables might appear in the EXPLAIN tables:

- DSN_FUNCTION_TABLE - user-defined functions
- DSN_PREDICAT_TABLE - predicates (except predicates in CASE WHEN clauses)
- DSN_STRUCT_TABLE - query blocks
- PLAN_TABLE - access path of subqueries

In addition, the complete or partial definition text might appear in EXPLAIN tables like DSN_FUNCTION_TABLE, DSN_PREDICAT_TABLE, DSN_QUERY_TABLE, DSN_SORTKEY_TABLE, DSN_STATEMENT_CACHE_TABLE, and DSN_STATEMENT_RUNTIME_INFO.

Impact to the existing access paths when the table has enforced column access control or row permissions:

The predicates from the row permissions are considered in the access path selection. Therefore, they are shown in the EXPLAIN tables for the performance tuning purpose.

Considerations when capturing EXPLAIN records for the acceleration of rowset queries:

A rowset query cannot be passed to an accelerator server for processing in the following cases:

- If the rowset query is run remotely
- If the rowset query is declared WITH RETURN
- If the rowset query is run under an SQL PL routine

You cannot use a static EXPLAIN statement to determine whether a rowset query is passed to an accelerator server, because you cannot specify the WITH ROWSET POSITIONING cursor attribute for a static EXPLAIN statement. Instead, you must use a dynamic EXPLAIN statement, where the WITH ROWSET POSITIONING clause is specified in the attribute string. You also can specify the WITH RETURN clause in the attribute string to see the ineligibility of result sets.

Also, the EXPLAIN statement cannot be used to determine that a rowset query cannot be passed to an accelerator server because the query is being run remotely or under an SQL PL routine. If the PREPARE of the EXPLAIN statement is run locally, DB2 determines if the rowset query can be accelerated as a local query offload. However, if the PREPARE of the EXPLAIN statement runs remotely, DB2 indicates that the rowset query cannot be accelerated. Instead, you can use the CURRENT EXPLAIN MODE special register to determine the behavior for eligible dynamic SQL statements during application execution. For more information, see CURRENT EXPLAIN MODE.

EXPLAIN tables
Examples

Example 1: Determine the steps required to execute the query 'SELECT X.ACTNO...'. Assume that no set of rows in the PLAN_TABLE has the value 13 for the QUERYNO column.

```
EXPLAIN PLAN SET QUERYNO = 13
FOR SELECT X.ACTNO, X.PROJNO, X.EMPNO, Y.JOB, Y.EDLEVEL
   FROM DSN8A10.EMPPROJACT X, DSN8A10.EMP Y
   WHERE X.EMPNO = Y.EMPNO
   AND X.EMPTIME > 0.5
   AND (Y.JOB = 'DESIGNER' OR Y.EDLEVEL >= 12)
ORDER BY X.ACTNO, X.PROJNO;
```

Example 2: Retrieve the information returned in Example 1. Assume that a statement table exists, so also retrieve the estimated cost of processing the query. Use the following query, which joins the plan table and the statement table.

```
SELECT *
FROM PLAN_TABLE A, DSN_STATEMNT_TABLE B
WHERE A.QUERYNO = 13 and B.QUERYNO = 13
ORDER BY A.QBLOCKNO, A.PLANNO, A.MIXOPSEQ;
```

Example 3: Extract existing access path information to capture EXPLAIN records for the cached statement with statement ID 124. Assume that host variable SID contains 124.

```
EXPLAIN STMTCACHE STMTID :SID;
```

Example 4: Extract existing access path information to capture one row of EXPLAIN data for each statement in the dynamic statement cache. The records are written only to the DSN_STATEMENT_CACHE_TABLE.

```
EXPLAIN STMTCACHE ALL;
```

Example 5: Assume that you want to use the plan table that was created by ADMF001 and your authorization ID is SYSADM. If you have an alias on ADMF001.PLAN_TABLE (CREATE ALIAS SYSADM.PLAN_TABLE FOR ADMF001.PLAN_TABLE) and sufficient INSERT and SELECT privileges on the table, the following EXPLAIN statement will execute and ADMF001.PLAN_TABLE will be populated.

```
EXPLAIN PLAN SET QUERYNO = 101
FOR SELECT * FROM DSN8A10.EMP;
```

Example 6: Extract existing access path information to capture EXPLAIN records to the current user's PLAN_TABLE for all static SQL statements in the current copy of the package 'COLLA.PACK52604':

```
EXPLAIN PACKAGE COLLECTION 'COLLA' PACKAGE 'PACK52604' COPY 'CURRENT';
```

EXPLAIN bind option (DB2 Commands)

“DSNAEXP stored procedure” on page 970
FETCH

The FETCH statement positions a cursor on a row of its result table. It can return zero, one, or multiple rows and assigns the values of the rows to variables if there is a target specification.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. Multiple row fetch is not supported in REXX, Fortran, or SQL Procedure applications\(^ {37} \). The FETCH statement with the WITH CONTINUE clause is not supported in REXX.

Authorization

See DECLARE CURSOR for an explanation of the authorization required to use a cursor.

Syntax

![Syntax diagram for FETCH statement]

Notes:
1. If INSENSITIVE or SENSITIVE is specified, single-row-fetch or multiple-row-fetch must be specified.
2. If WITH CONTINUE is specified, single-row-fetch must be specified.
3. If multiple-row-fetch is specified, a rowset-positioned fetch orientation must also be specified.

fetch-orientation

---

\(^{37}\) ASSEMBLER and other languages are supported, but this support is limited to statements that allow USING DESCRIPTOR. The precompiler does not recognize host-variable-arrays except in C/C++, COBOL, and PL/1.
fetch-orientation:

(1)
- BEFORE
(1)
- AFTER

row-positioned:

- NEXT
- PRIOR
- FIRST
- LAST
- CURRENT
- ABSOLUTE
- RELATIVE

rowset-positioned:

- NEXT ROWSET
- PRIOR ROWSET
- FIRST ROWSET
- LAST ROWSET
- CURRENT ROWSET
- ROWSET STARTING AT

Notes:

1. If BEFORE or AFTER is specified, SENSITIVE, INSENSITIVE, single-row-fetch, or multiple-row-fetch must not be specified.

2. A row-positioned fetch orientation can be specified only if multiple-row-fetch is not specified.

3. If multiple-row-fetch is specified, a rowset-positioned fetch orientation must also be specified.
single-row-fetch:

```
INTO host-variable
INTO DESCRIPTOR descriptor-name
```

multiple-row-fetch:

```
FOR host-variable ROWS integer-constant
INTO host-variable-array
INTO DESCRIPTOR descriptor-name
```

Notes:

1. For single-row-fetch, a host-variable-array can be specified instead of a host variable and the descriptor can describe host-variable-arrays. In either case, data is returned only for the first entry of the host-variable-array.

2. This clause must not be specified if a row-positioned fetch orientation or if no fetch orientation was specified.

3. This clause is optional. If this clause is not specified and either a rowset size has not been established yet or a row positioned FETCH statement was the last type of FETCH statement issued for this cursor, the rowset size is implicitly one. If the last FETCH statement issued for this cursor was a rowset positioned FETCH statement and this clause is not specified, the rowset size is the same size as the previous rowset positioned FETCH.

Description

**INSENSITIVE**

Returns the row from the result table as it is. If the row has been previously fetched with a FETCH SENSITIVE, it reflects changes made outside this cursor before the FETCH SENSITIVE statement was issued. Positioned updates and deletes are reflected with FETCH INSENSITIVE if the same cursor was used for the positioned update or delete.

INSENSITIVE can only be specified for cursors declared as INSENSITIVE or SENSITIVE STATIC (or if the cursor is declared as ASENSITIVE and DB2 defaults to INSENSITIVE). Otherwise, if the cursor is declared as SENSITIVE DYNAMIC (or if the cursor is declared as ASENSITIVE and DB2 defaults to SENSITIVE DYNAMIC), an error occurs and the FETCH statement has no effect. For an INSENSITIVE cursor, specifying INSENSITIVE is optional because it is the default.

**SENSITIVE**

Updates the fetched row in the result table from the corresponding row in the base table of the cursor’s SELECT statement and returns the current values. Thus, it reflects changes made outside this cursor. SENSITIVE can only be specified for a sensitive cursor. Otherwise, if the cursor is insensitive, an error occurs and the FETCH statement has no effect. For a SENSITIVE cursor, specifying SENSITIVE is optional because it is the default.
When the cursor is declared as SENSITIVE STATIC and a FETCH SENSITIVE is requested, the following steps are taken:

1. DB2 retrieves the row of the database that corresponds to the row of the result table that is about to be fetched.

2. If the corresponding row has been deleted, a "delete hole" occurs in the result table, a warning is issued, the cursor is repositioned on the "hole", and no data is fetched. (DB2 marks a row in the result table as a "delete hole" when the corresponding row in the database is deleted.)

3. If the corresponding row has not been deleted, the predicate of the underlying SELECT statement is re-evaluated. If the row no longer satisfies the predicate, an "update hole" occurs in the result table, a warning is issued, the cursor is repositioned on the "hole," and no data is fetched. (DB2 marks a row in the result table as an "update hole" when an update to the corresponding row in the database causes the row to no longer qualify for the result table.)

4. If the corresponding row does not result in a delete or an update hole in the result table, the cursor is repositioned on the row of the result table and the data is fetched.

**WITH CONTINUE**

Specifies that the DB2 subsystem should prepare to allow subsequent FETCH CURRENT CONTINUE operations to access any truncated LOB or XML result column following an initial FETCH operation that provides output variables that are not large enough to hold the entire LOB or XML columns. When the WITH CONTINUE clause is specified, the DB2 subsystem takes the following actions that can differ from the case where the FETCH statement does not include the WITH CONTINUE clause:

- If truncation occurs when returning an XML or LOB column, the DB2 subsystem will remember the truncation position and will not discard the remaining data.

- If truncation occurs when returning an XML or LOB column, the DB2 subsystem returns the total length that would have been required to hold all of the data of the LOB or XML column. This will either be in the first four bytes of the LOB host variable structure or in the 4 byte area that is pointed to by the SQLDATALEN pointer in the SQLVAR entry of the SQLDA for that host variable. What is returned depends on the programming method that is used. See [SQL descriptor area (SQLDA)](SQL%20descriptor%20area%20(SQLDA)) for details about the SQLDA contents.

- If returning XML data, the result column will be fully materialized in the database before the data is returned.

If the CURRENT CONTINUE clause is specified, the WITH CONTINUE behavior is assumed.

**AFTER**

Positions the cursor after the last row of the result table. Values are not assigned to host variables. The number of rows of the result table are returned in the SQLLERRD1 and SQLLERRD2 fields of the SQLCA for cursors with an effective sensitivity of INSENSITIVE or SENSITIVE STATIC.

**BEFORE**

Positions the cursor before the first row of the result table. Values are not assigned to host variables.

**row-positioned**

Positioning of the cursor with row-positioned fetch orientations NEXT, PRIOR, CURRENT and RELATIVE is done in relation to the current cursor position.
Following a successful row-positioned FETCH statement, the cursor is positioned on a single row of data. If the cursor is enabled for rowsets, positioning is performed relative to the current row or the first row of the current rowset, and the cursor is positioned on a rowset consisting of a single row.

**NEXT**

Positions the cursor on the next row or rows of the result table relative to the current cursor position, and returns data if a target is specified. NEXT is the only row-positioned fetch operation that can be explicitly specified for cursors that are defined as NO SCROLL. NEXT is the default if no other cursor positioning is specified. If a specified row reflects a hole, a warning is issued and data values are not assigned to host variables for that row.

Table 198 lists situations for different cursor positions and the results when NEXT is used.

Table 198. Results when NEXT is used with different cursor positions

<table>
<thead>
<tr>
<th>Current state of the cursor</th>
<th>Result of FETCH NEXT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before the first row</td>
<td>Cursor is positioned on the first row and data is returned if requested.</td>
</tr>
<tr>
<td>On the last row or after the last row</td>
<td>A warning occurs, values are not assigned to host variables, and the cursor position is unchanged.</td>
</tr>
<tr>
<td>Before a hole</td>
<td>For a SENSITIVE STATIC cursor, a warning occurs for a delete hole or an update hole, values are not assigned to host variables, and the cursor is positioned on the hole.</td>
</tr>
<tr>
<td>Unknown</td>
<td>An error occurs, values are not assigned to host variables, and the cursor position remains unknown.</td>
</tr>
</tbody>
</table>

**Note:**

1. This row is not applicable in the case of a forward-only cursor (that is when NO SCROLL was specified implicitly or explicitly).

**PRIOR**

Positions the cursor on the previous row or rows of the result table relative to the current cursor position, and returns data if a target is specified. If a specified row reflects a hole, a warning is issued, and data values are not assigned to host variables for that row.

Table 199 lists situations for different cursor positions and the results when PRIOR is used.

Table 199. Results when PRIOR is used with different cursor positions

<table>
<thead>
<tr>
<th>Current state of the cursor</th>
<th>Result of FETCH PRIOR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before the first row or on the first row</td>
<td>A warning occurs, values are not assigned to host variables, and the cursor position is unchanged.</td>
</tr>
<tr>
<td>After a hole</td>
<td>For a SENSITIVE STATIC cursor, a warning occurs for a delete hole or an update hole, values are not assigned to host variables, and the cursor is positioned on the hole.</td>
</tr>
<tr>
<td>After the last row</td>
<td>Cursor is positioned on the last row.</td>
</tr>
</tbody>
</table>
Table 199. Results when PRIOR is used with different cursor positions (continued)

<table>
<thead>
<tr>
<th>Current state of the cursor</th>
<th>Result of FETCH PRIOR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unknown</td>
<td>An error occurs, values are not assigned to host variables, and the cursor position remains unknown.</td>
</tr>
</tbody>
</table>

**FIRST**

Positions the cursor on the first row of the result table, and returns data if a target is specified. For a SENSITIVE STATIC cursor, if the first row of the result table is a hole, a warning occurs for a delete hole or an update hole and values are not assigned to host variables.

**LAST**

Positions the cursor on the last row of the result table, and returns data if a target is specified. The number of rows of the result table is returned in the SQLERRD1 and SQLERRD2 fields of the SQLCA for an insensitive or sensitive static cursor. For a SENSITIVE STATIC cursor, if the last row of the result table is a hole, a warning occurs for a delete hole or an update hole and values are not assigned to host variables.

**CURRENT**

The cursor position is not changed, data is returned if a target is specified. If the cursor was positioned on a rowset of more than one row, the cursor position is on the first row of the rowset.

[Table 200](#) lists situations in which errors occur with the CURRENT clause.

Table 200. Situations in which errors occur with CURRENT

<table>
<thead>
<tr>
<th>Current state of the cursor</th>
<th>Result of FETCH CURRENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before the first row or after the last row</td>
<td>A warning occurs, values are not assigned to host variables, and the cursor position is unchanged.</td>
</tr>
</tbody>
</table>

| On a hole | For a SENSITIVE STATIC, a warning occurs for a delete hole or an update hole, values are not assigned to host variables, and the cursor is positioned on the hole. |

If the cursor is defined as a rowset cursor, with isolation level UR or a sensitive dynamic scrollable cursor, it is possible that a different row will be returned than the FETCH that established the most recent cursor position. This can occur while fetching a row again when it is determined to not be there anymore. In this case, fetching continues moving forward to get the row of data.

| Unknown | An error occurs, values are not assigned to host variables, and the cursor position remains unknown. |

**CONTINUE**

The cursor positioning is not changed, and data is returned if a target is specified. The FETCH CURRENT CONTINUE statement retrieves remaining data for any LOB or XML column result values that were truncated on a previous FETCH or FETCH CURRENT CONTINUE statement. It assigns the remaining data for those truncated columns to
the host variables that are referenced in the statement or pointed to by the descriptor. The data that is returned for previously-truncated result values begins at the point of truncation. This form of the CURRENT clause must only be used after a single-row FETCH WITH CONTINUE or FETCH CURRENT CONTINUE statement that has returned partial data for one or more LOB or XML columns. The cursor must be open and positioned on a row.

FETCH CURRENT CONTINUE must pass host variables entries for all columns in the SELECT list, even though the non-LOB columns or non-XML columns will not return any data.

**ABSOLUTE**

*host-variable* or *integer-constant* is assigned to an integral value *k*. If a *host-variable* is specified, it must be an exact numeric type with zero scale and must not include an indicator variable. The possible data types for the host variable are DECIMAL(*n*,0) or integer. The DECIMAL data type is limited to DECIMAL(18,0). An *integer-constant* can be up to 31 digits, depending on the application language.

If *k*=0, the cursor is positioned before the first row of the result table. Otherwise, ABSOLUTE positions the cursor to row *k* of the result table if *k>*0, or to *k* rows from the bottom of the table if *k*<0. For example, "ABSOLUTE -1" is the same as "LAST".

Data is returned if the specified position is within the rows of the result table, and a target is specified.

If an absolute position is specified that is before the first row or after the last row of the result table, a warning occurs, values are not assigned to host variables, and the cursor is positioned either before the first row or after the last row. If the resulting cursor position is after the last row for INSENSITIVE and SENSITIVE STATIC scrollable cursors, the number of rows of the result table are returned in the SQLERRD1 and SQLERRD2 fields of the SQLCA. If row *k* of the result table is a hole, a warning occurs and values are not assigned to host variables.

FETCH ABSOLUTE 0 results in positioning before the first row and a warning is issued. FETCH BEFORE results in positioning before the first row and no warning is issued.

Table 201 lists some synonymous specifications.

<table>
<thead>
<tr>
<th>Specification</th>
<th>Alternative</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABSOLUTE 0 (but with a warning)</td>
<td>BEFORE (without a warning)</td>
</tr>
<tr>
<td>ABSOLUTE +1</td>
<td>FIRST</td>
</tr>
<tr>
<td>ABSOLUTE -1</td>
<td>LAST</td>
</tr>
<tr>
<td>ABSOLUTE -m, 0&lt;m≤n</td>
<td>ABSOLUTE n+1-m</td>
</tr>
<tr>
<td>ABSOLUTE n</td>
<td>LAST</td>
</tr>
<tr>
<td>ABSOLUTE -n</td>
<td>FIRST</td>
</tr>
<tr>
<td>ABSOLUTE x (with a warning)</td>
<td>AFTER (without a warning)</td>
</tr>
<tr>
<td>ABSOLUTE -x (with a warning)</td>
<td>BEFORE (without a warning)</td>
</tr>
</tbody>
</table>

**Note:** Assume: 0≤m≤n≤x Where, *n* is the number of rows in the result table.
**RELATIVE**

A *host-variable* or *integer-constant* is assigned to an integral value $k$. If a *host-variable* is specified, it must be an exact numeric type with zero scale and must not include an indicator variable. The possible data types for the host variable are `DECIMAL(n,0)` or integer. The `DECIMAL` data type is limited to `DECIMAL(18,0)`.

If the cursor is positioned before the first row, or after the last row of the result table, the cursor position is determined as follows:

- If $n$ is 0, the cursor position is unchanged, values are not assigned to host variables, and a warning occurs.
- If $n$ is positive, and the cursor is positioned before the first row, the cursor is positioned on a rowset starting at row $n$.
- If $n$ is positive, and the cursor is positioned after the last row, a warning occurs.
- If $n$ is negative, and the cursor is positioned before the first row, a warning occurs.
- If $n$ is negative, and the cursor is positioned after the last row, the cursor is positioned on a rowset starting as row $n$ from the end of the result table.

An *integer-constant* can be up to 31 digits, depending on the application language.

Data is returned if the specified position is within the rows of the result table, and a target is specified.

RELATIVE positions the cursor to the row in the result table that is either $k$ rows after the current row if $k>0$, or $\text{ABS}(k)$ rows before the current row if $k<0$. For example, "RELATIVE -1" is the same as "PRIOR". If $k=0$, the position of the cursor does not change (that is, "RELATIVE 0" is the same as "CURRENT").

If a relative position is specified that results in positioning before the first row or after the last row, a warning is issued, values are not assigned to host variables, and the cursor is positioned either before the first row or after the last row. If the resulting cursor position is after the last row for INSENSITIVE and SENSITIVE STATIC scrollable cursors, the number of rows of the result table is returned in the SQLERRD1 and SQLERRD2 fields of the SQLCA. If the cursor is positioned on a hole and RELATIVE 0 is specified or if the target row is a hole, a warning occurs and values are not assigned to host variables.

If the cursor is defined as a rowset cursor, with isolation level UR or a sensitive dynamic scrollable cursor, it is possible that a different row will be returned than the FETCH that established the most recent cursor position. This can occur while fetching a row again when it is determined not to be there anymore. In this case, fetching continues moving forward to get the row data.

If the cursor position is unknown and RELATIVE 0 is specified, an error occurs.

Table 202 lists some synonymous specifications.

---

**Table 202. Synonymous Scroll Specifications for RELATIVE**

<table>
<thead>
<tr>
<th>Specification</th>
<th>Alternative</th>
</tr>
</thead>
<tbody>
<tr>
<td>RELATIVE +1</td>
<td>NEXT</td>
</tr>
</tbody>

<tr>
<td>RELATIVE ( +r ) (with a warning)</td>
<td>AFTER (without a warning)</td>
</tr>
<tr>
<td>RELATIVE ( -r ) (with a warning)</td>
<td>BEFORE (without a warning)</td>
</tr>
</tbody>
</table>

**Note:** \( r \) has to be large enough to position the cursor beyond either end of the result table.

**rowset-positioned**

Positioning of the cursor with rowset-positioned fetch orientations NEXT ROWSET, PRIOR ROWSET, CURRENT ROWSET, and ROWSET STARTING AT RELATIVE is done in relation to the current cursor position. Following a successful rowset-positioned FETCH statement, the cursor is positioned on a rowset of data. The number of rows in the rowset is determined either explicitly or implicitly. The FOR \( n \) ROWS clause in the multiple-row-fetch clause is used to explicitly specify the size of the rowset. Positioning is performed relative to the current row or first row of the current rowset, and the cursor is positioned on all rows of the rowset.

A rowset-positioned fetch orientation must not be specified if the current cursor position is not defined to access rowsets. NEXT ROWSET is the only rowset-positioned fetch orientation that can be specified for cursors that are defined as NO SCROLL.

If a row of the rowset reflects a hole, a warning is returned, data values are not assigned to host variable arrays for that row (that is, the corresponding positions in the target host variable arrays are untouched), and -3 is returned in all provided indicator variables for that row. If a hole is detected, and at least one indicator variable is not provided, an error occurs.

**NEXT ROWSET**

Positions the cursor on the next rowset of the result table relative to the current cursor position, and returns data if a target is specified. The next rowset is logically obtained by fetching the row that follows the current rowset and fetching additional rows until the number of rows that is specified implicitly or explicitly in the FOR \( n \) ROWS clause is obtained or the last row of the result table is reached.

If the cursor is positioned before the first row of the result table, the cursor is positioned on the first rowset.

If the cursor is positioned on the last row or after the last row of the result table, the cursor position is unchanged, values are not assigned to host variable arrays, and a warning occurs.

If a row of the rowset reflects a hole, the following actions occur:

- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned.
If the cursor is not positioned because of a prior error, values are not assigned to the host-variable-array, and an error is returned. If a row of the rowset would be after the last row of the result table, values are not assigned to host-variable-arrays for that row and any subsequent requested rows of the rowset, and a warning is returned.

NEXT ROWSET is the only rowset positioned fetch orientation that can be explicitly be specified for cursors that are defined as NO SCROLL.

PRIOR ROWSET
Positions the cursor on the previous rowset of the result table relative to the current position, and returns data if a target is specified.

The prior rowset is logically obtained by fetching the row that precedes the current rowset and fetching additional rows until the number of rows that is specified implicitly or explicitly in the FOR n ROWS clause is obtained or the last row of the result table is reached.

If the cursor is positioned after the last row of the result table, the cursor is positioned on the last rowset.

If the cursor is positioned before the first row or on the first row of the result table, the cursor position is unchanged, values are not assigned to host variable arrays, and a warning occurs.

If a row would be before the first row of the result table, the cursor is positioned on a partial rowset that consists of only those rows that are prior to the current position of the cursor starting with the first row of the result table, and a warning is returned. Values are not assigned to the host-variable-arrays for the rows in the rowset for which the warning is returned.

Although the rowset is logically obtained by fetching backwards from before the current rowset, the data is returned to the application starting with the first row of the rowset, to the end of the rowset.

If a row of the rowset reflects a hole, the following actions occur:
- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned.

If the cursor is not positioned because of a prior error, values are not assigned to the host-variable-array, and an error is returned.

FIRST ROWSET
Positions the cursor on the first rowset of the result table, and returns data if a target is specified.

If a row of the rowset reflects a hole, the following actions occur:
- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.
If a hole is detected and at least one indicator variable is not provided, an error is returned.

If the result table contains fewer rows than specified implicitly or explicitly in the FOR \( n \) ROWS clause, values are not assigned to host-variable-arrays after the last row of the result table, and a warning is returned.

**LAST ROWSET**
Positions the cursor on the last rowset of the result table and returns data if a target is specified. The last rowset is logically obtained by fetching the last row of the result table and fetching prior rows until the number of rows in the rowset is obtained or the first row of the result table is reached. Although the rowset is logically obtained by fetching backwards from the bottom of the result table, the data is returned to the application starting with the first row of the rowset, to the end of the rowset, which is also the end of the result table.

If a row of the rowset reflects a hole, the following actions occur:
- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned.

If the result table contains fewer rows than specified implicitly or explicitly in the FOR \( n \) ROWS clause, the last rowset is the same as the first rowset, values are not assigned to host-variable-arrays after the last row of the result table, and a warning is returned.

**CURRENT ROWSET**
If the FOR \( n \) ROWS clause specifies a number different from the number of rows specified implicitly or explicitly in the FOR \( n \) ROWS clause on the most recent FETCH statement for this cursor, the cursor is repositioned on the specified number of rows, starting with the first row of the current rowset. If the cursor is positioned before the first row, or after the last row of the result table, the cursor position is unchanged, values are not assigned to host variable arrays, and a warning occurs. If the FOR \( n \) ROWS clause is not specified, it is possible that the FETCH statement will position the cursor on a partial rowset when the FETCH CURRENT ROWSET statement is processed. In this case, DB2 attempts to position the cursor on a full rowset starting with the first row of the current rowset. Otherwise, the position of the cursor on the current rowset is unchanged. Data is returned if a target is specified.

With isolation level UR or a sensitive dynamic scrollable cursor, it is possible that different rows will be returned than the FETCH that established the most recent rowset cursor position. This can occur while refetching the first row of the rowset when it is determined to not be there anymore. In this case, fetching continues moving forward to get the first row of data for the rowset. This can also occur when changes have been made to other rows in the current rowset such that they no longer exist or have been logically moved within (or out of) the result table of the cursor.

If the cursor is not positioned because of a prior error, values are not assigned to the host-variable-array, and an error occurs.
If the current rowset contains fewer rows than specified implicitly or explicitly in the FOR n ROWS clause, values are not assigned to host-variable-arrays after the last row, and a warning is returned.

**ROWSET STARTING AT ABSOLUTE or RELATIVE host-variable or integer-constant**

Positions the cursor on the rowset beginning at the row of the result table that is indicated by the ABSOLUTE or RELATIVE specification, and returns data if a target is specified.

*host-variable or integer-constant* is assigned to an integral value *k*. If *host-variable* is specified, it must be an exact numeric type with scale zero, and must not include an indicator variable. The possible data types for the host variable are DECIMAL(n,0) or integer, where the DECIMAL data type is limited to DECIMAL(18,0). If a constant is specified, the value must be an integer.

If a row of the result table would be after the last row or before the first row of the result table, values are not assigned to host-variable-arrays for that row and a warning is returned.

**ABSOLUTE**

If *k*=0, an error occurs. If *k*>0, the first row of the rowset is row *k*. If *k*<0, the rowset is positioned on the ABS(*k*) rows from the bottom of the result table. Assume that ABS(*k*) is equal to the number of rows for the rowset and that there are enough rows to return a complete rowset:

- FETCH ROWSET STARTING AT ABSOLUTE -*k* is the same as FETCH LAST ROWSET.
- FETCH ROWSET STARTING AT ABSOLUTE 1 is the same as FETCH FIRST ROWSET.

**RELATIVE**

If *k*=0 and the FOR n ROWS clause does not specify a number different from the number most recently specified implicitly or explicitly for this cursor, then the position of the cursor does not change (that is, "RELATIVE ROWSET 0" is the same as "CURRENT ROWSET"). If *k*=0 and the FOR n ROWS clause specifies a number different from the number most recently specified implicitly or explicitly for this cursor, then the cursor is repositioned on the specified number of rows, starting with the first row of the current rowset.

If the cursor is positioned before the first row, or after the last row of the result table, the cursor position is determined as follows:

- If *n* is 0, the cursor position is unchanged, values are not assigned to host variables, and a warning occurs. This is the same as FETCH CURRENT ROWSET.
- If *n* is positive, and the cursor is positioned before the first row, the cursor is positioned on a rowset starting a row *n*.
- If *n* is positive, and the cursor is positioned after the last row, a warning occurs.
- If *n* is negative, and the cursor is positioned before the first row, a warning occurs.
- If *n* is negative, and the cursor is positioned after the last row, the cursor is positioned on a rowset starting at row *n* from the bottom of the result table.
Otherwise, RELATIVE repositions the cursor so that the first row of the new rowset cursor position is on the row in the result table that is either k rows after the first row of the current rowset cursor position if \( k > 0 \), or ABS(k) rows before the first row of the current rowset cursor position if \( k < 0 \). Assume that ABS(k) is equal to the number of rows for the resulting rowset.

- FETCH ROWSET STARTING AT RELATIVE -k is the same as FETCH PRIOR ROWSET.
- FETCH ROWSET STARTING AT RELATIVE k is the same as FETCH NEXT ROWSET.
- FETCH ROWSET STARTING AT RELATIVE 0 is the same as FETCH CURRENT ROWSET.

When ROWSET STARTING AT RELATIVE -n is specified and there are not enough rows between the current position of the cursor and the beginning of the result table to return a complete rowset:
- A warning is returned.
- Values are not assigned to the host-variable-arrays.
- The cursor is positioned before the first row.

If a row of the rowset reflects a hole, if a row of the rowset reflects a hole, the following actions occur:
- A warning is returned.
- Data values are not assigned to the host-variable-arrays for that row (that is, the corresponding positions in the target host-variable-arrays are untouched).
- A value of -3 is returned in all of the indicator variables that are provided for the row.

If a hole is detected and at least one indicator variable is not provided, an error is returned. If a row of the rowset is unknown, values are not assigned to host variable arrays for that row, and an error is returned. If a row of the rowset would be after the last row or before the first row of the result table, values are not assigned to host-variable-arrays for that row, and a warning is returned.

**cursor-name**

Identifies the cursor to be used in the fetch operation. The cursor name must identify a declared cursor, as explained in the description of the DECLARE CURSOR statement in [DECLARE CURSOR](#) or an allocated cursor, as explained in [ALLOCATE CURSOR](#) When the FETCH statement is executed, the cursor must be in the open state.

If a single-row-fetch or multiple-row-fetch clause is not specified, the cursor position is adjusted as specified, but no data is returned to the user.

**single-row-fetch**

When single-row-fetch is specified, SENSITIVE or INSENSITIVE can be specified though there is a default. The default depends on the sensitivity of the cursor. If the sensitivity of the cursor is INSENSITIVE, then the default is INSENSITIVE. If the effective sensitivity of the cursor is SENSITIVE DYNAMIC or SENSITIVE STATIC, then the default is SENSITIVE. The single-row-fetch or multiple-row-fetch clause must not be specified when the FETCH BEFORE or FETCH AFTER option is specified. They are required when FETCH BEFORE or FETCH AFTER is not specified. If an individual fetch operation causes the cursor to be positioned or to remain positioned on a row if there is a target specification, the values of the result table are assigned to host variables as specified by the single-fetch-clause.
**INTO** *host-variable,...*

 Specifies a list of host variables. Each *host-variable* must identify a structure or variable that is described in the application program in accordance with the rules for declaring host structures and variables. A reference to a structure is replaced by a reference to each of its variables. The first value in the result row is assigned to the first host variable, the second value to the second host variable, and so on.

**INTO DESCRIPTOR** *descriptor-name*

 Identifies an SQLDA that contains a valid description of the host output variables. Result values from the associated SELECT statement are returned to the application program in the output host variables.

 Before the FETCH statement is processed, you must set the following fields in the SQLDA:

 - SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA
   
   A REXX SQLDA does not contain this field.

 - SQLABC to indicate the number of bytes of storage allocated in the SQLDA

 - SQLD to indicate the number of variables used in the SQLDA when processing the statement

 - SQLVAR occurrences to indicate the attributes of the variables

 The SQLDA must have enough storage to contain all SQLVAR occurrences. Each SQLVAR occurrence describes a host variable or buffer into which a value in the result table is to be assigned. If LOBs are present in the results, there must be additional SQLVAR entries for each column of the result table. If the result table contains only base types and distinct types, multiple SQLVAR entries are not needed for each column. However, extra SQLVAR entries are needed for distinct types as well as for LOBs in DESCRIBE and PREPARE INTO statements. For more information on the SQLDA, which includes a description of the SQLVAR and an explanation on how to determine the number of SQLVAR occurrences, see [SQL descriptor area (SQLDA)](http://www.example.com).

 SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN.

 See [Identifying an SQLDA in C or C++] for how to represent *descriptor-name* in C.

**multiple-row-fetch**

 Retrieves multiple rows of data from the result table of a query. The FOR n ROWS clause of the FETCH statement controls how many rows are returned on a single FETCH statement. The fetch orientation determines whether the resulting cursor position (for example, on a single row, rowset, before, or after the result table). Fetching stops when an error is returned, all requested rows are fetched, or the end of data condition is reached.

 Fetching multiple rows of data can be done with scrollable or non-scrollable cursors. The operations used to define, open, and close a cursor used for fetching multiple rows of data are the same as for those used for single row FETCH statements.

 If the BEFORE or AFTER option is specified, neither single-row-fetch or multiple-row-fetch can be specified.
FOR host-variable or integer-constant ROWS

host-variable or integer-constant is assigned to an integral value k. If a host variable is specified, it must be an exact numeric type with a scale of zero and must not include an indicator variable. Furthermore, k must be in the range, 0<k<=32767.

This clause must not be specified if a row-positioned fetch-orientation clause was specified. This clause must also not be specified for a cursor that is defined without rowset access.

If a rowset fetch orientation is specified and this clause is not specified, the number of rows in the resulting rowset is determined as follows:

- If the most recent FETCH statement for this cursor was a rowset- positioned FETCH, the number of rows of the rowset is implicitly determined by the number of rows that was most recently specified (implicitly or explicitly) for this cursor.
- When the most recent FETCH statement for this cursor was either FETCH BEFORE or FETCH AFTER and the most recent FETCH statement for this cursor prior to that was a rowset- positioned FETCH, the number of rows of the rowset is implicitly determined by the number of rows that were most recently specified (implicitly or explicitly) for this cursor.
- Otherwise, the rowset consists of a single row.

For result set cursors, the number of rows for a rowset cursor position, established in the procedure that defined the rowset, is not inherited by the caller when the rowset is returned. Use the FOR n ROWS clause on the first rowset FETCH statement for the result set in the calling program to establish the number of rows for the cursor. Otherwise, the rowset consists of a single row.

The cursor is positioned on the row or rowset that is specified by the orientation clause (for example, NEXT ROWSET), and those rows are fetched if a target is specified. After the cursor is positioned on the first row being fetched, the next k-1 rows are fetched. Fetching moves forward from the cursor position in the result table and continues until the end of data condition is returned, k-1 rows have been fetched, or an assignment error is returned.

The resulting cursor position depends on the fetch orientation that is specified:

- For a row-positioned fetch orientation, the cursor is positioned at the last row successfully retrieved.
- For a rowset-positioned fetch orientation, the cursor is positioned on all the rows retrieved.

The values from each individual fetch are placed in data areas that are described in the INTO or USING clause. If a target specification is provided for a rowset- positioned FETCH, the host variable arrays must be specified as the target specification, and the arrays must be defined with a dimension of 1 or greater. The target specification must be defined as an array for a rowset- positioned FETCH even if the number of rows that is specified implicitly or explicitly is one. See Diagnostics information for rowset positioned FETCH statements.

INTO host-variable-array

Identifies for each column of the result table a host-variable-array to receive the data that is retrieved with this FETCH statement. If the number
of host-variable-arrays is less than the number of columns of the result table, the SQLWARN3 field of the SQLCA is set to 'W'. No warning is given if there are more host-variable-arrays than the number of columns in the result table.

Each host-variable-array must be defined in the application program in accordance with the rules for declaring an array. A host-variable-array is used to return the values for a column of the result table. The number of rows to be fetched must be less than or equal to the dimension of each of the host-variable-arrays.

An optional indicator array can be specified for a host-variable-array. It should be specified if the SQLTYPE of any SQLVAR occurrence indicates that the column of the result table is nullable. Additionally, if an operation may result in null values, such as an UPDATE operation that results in a hole, is performed in the application, an indicator array should be specified. Otherwise an error occurs if null values are encountered. The indicators are returned as small integers.

**INTO DESCRIPTOR** descriptor-name

Identifies an SQLDA that must contain a valid description of zero or more host-variable-arrays or buffers into which the values for a column of the result table are to be returned.

Before the FETCH statement is processed, you must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA.
- SQLABC to indicate the number of bytes of storage allocated for the SQLDA.
- SQLD to indicate the number of variables used in the SQLDA when processing the statement.
- SQLVAR occurrences to indicate the attributes of an element of the host-variable-array. Within each SQLVAR representing an array:
  - SQLTYPE indicates the data type of the elements of the host-variable-array.
  - SQLDATA field points to the first element of the host-variable-array.
  - The length fields (SQLLEN and SQLLONGLEN) are set to indicate the maximum length of a single element of the array.
  - SQLNAME - The length of SQLNAME must be set to 8, and the first two bytes of the data portion of SQLNAME must be initialized to X'0000'. The fifth and sixth bytes must contain a flag field and the seventh and eighth bytes must be initialized to a binary small integer (half word) representation of the dimension of the host-variable-array, and the corresponding indicator array, if one is specified.

The SQLVAR entry for the number of rows must also contain a flag value. The number of rows to be fetched must be less than or equal to the dimension of each of the host-variable arrays.

You set the SQLDATA and SQLIND pointers to the beginning of the corresponding arrays. The SQLDA must have enough storage to contain all SQLVAR occurrences. Each SQLVAR occurrence describes a host-variable-array or buffer into which the values for a column in the result table are to be returned. If any column of the result table is a LOB, two SQLVAR entries must be provided for each SQLVAR, and SQLN must
be set to two times the number of SQLVARS. SQLD must be set to a value
greater than or equal to zero and less than or equal to SQLN.

Notes

Assignment to host variables:
The n<sup>th</sup> variable identified by the INTO clause or described in the SQLDA
corresponds to the n<sup>th</sup> column of the result table of the cursor. The data
type of a host variable must be compatible with its corresponding value. If
the value is numeric, the variable must have the capacity to represent the
whole part of the value. For a datetime value, the variable must be a
character string variable of a minimum length as defined in String
representations of datetime values If the value is null, an indicator
variable must be specified.

Assignments are made in sequence through the list. Each assignment to a
variable is made according to the rules described in Language elements. If
the number of variables is less than the number of values in the row, the
SQLWARN3 field of the SQLCA is set to W. There is no warning if there
are more variables than the number of result columns. If the value is null,
an indicator variable must be provided. If an assignment error occurs, the
value is not assigned to the variable and no more values are assigned to
variables. Any values that have already been assigned to variables remain
assigned.

Normally, you use LOB locators to assign and retrieve data from LOB
columns. However, because of compatibility rules, you can also use LOB
locators to assign data to host variables with other data types. For more
information on using locators, see Saving storage when manipulating LOBs
by using LOB locators (DB2 Application programming and SQL).

The default encoding scheme for the data is the value in the bind option
ENCODING, which is the option for application encoding. If this statement
is used with functions such as LENGTH or SUBSTRING that are operating
on LOB locators, and the LOB data that is specifies by the locator is in a
different encoding scheme from the ENCODING bind option, LOB
materialization and character conversion occur. To avoid LOB
materialization and character conversion, select the LOB data from the
SYSIBM.SYSDUMMYA, SYSIBM.SYSDUMMYE, or SYSIBM.SYSDUMMYU
sample table.

Restrictions on using the WITH CONTINUE and CURRENT CONTINUE
clauses:
When using the WITH CONTINUE clause, the DB2 system will only
reserve truncated data for result set columns of the BLOB, CLOB,
DBCLOB, or XML data type, and only when the output host variable data
type is the appropriate LOB data type.

If an application uses FETCH WITH CONTINUE, and truncated data
remains after the FETCH operation, the application cannot perform any
intervening operation on that cursor before performing the FETCH
CURRENT CONTINUE. If intervening operations on that cursor are
performed, the truncated data is lost.

FETCH CURRENT CONTINUE is not supported with multi-row fetch.
Also, FETCH CURRENT CONTINUE is not supported for non-LOB and
non-XML columns that have been truncated. If truncation occurs for these
non-LOB and non-XML columns, the truncated data will be discarded as
usual.
Result column evaluation considerations:

If an error occurs as the result of an arithmetic expression in the SELECT list of an outer SELECT statement (division by zero, or overflow) or a numeric conversion error occurs, the result is the null value. As in any other case of a null value, an indicator variable must be provided and the main variable is unchanged. In this case, however, the indicator variable is set to -2. Processing of the statement continues as if the error had not occurred. (However, this error causes a positive SQLCODE.) If you do not provide an indicator variable, a negative value is returned in the SQLCODE field of the SQLCA. Processing of the statement terminates when the error is encountered. No value is assigned to the host variable or to later variables, though any values that have already been assigned to variables remain assigned.

If the specified host variable is not large enough to contain the result, a warning is returned and W is assigned to SQLWARN1 in the SQLCA. The actual length of the result is returned in the indicator variable associated with the host-variable, if an indicator is provided. It is possible that a warning may not be returned on a FETCH operation. This occurs as a result of optimizations, such as the use of system temporary tables or blocking. It is also possible that the returned warning applies to a previously fetched row. When a datetime value is returned, the length of the variable must be large enough to store the complete value. Otherwise, a warning or an error is returned.

Considerations when using the FETCH statement for a rowset cursor that was passed to an accelerator server for processing:

DB2 provides limited support for rowset queries that are passed to an accelerator server for processing. DB2 supports only high performance access to accelerated query data. The data is pre-fetched in rowsets and returned by using multiple-row-fetch statements, returning multiple rows of data in one FETCH statement. The following restrictions apply to FETCH statements that are executed against a rowset cursor that was accelerated:

- All FETCH requests must be rowset fetches.
- All FETCH requests must specify a FOR n ROWS clause.
- All FETCH requests must specify the same rowset size.
- All FETCH requests must specify target host variables. (The FETCH operation must have a target for positioning.)

Cursor positioning:

An open cursor has three possible positions:

- Before a row
- On a row or rowset
- After the last row

When a scrollable or non-scrollable cursor is opened, it is positioned before the first row in the result table. If a cursor is on a row, that row is called the current row of the cursor. If a cursor is on a rowset, the rows are called the current rowset of the cursor.

A cursor referred to in an UPDATE or DELETE statement must be positioned on a row or rowset. A cursor can only be on a row or rowset as a result of a FETCH statement.

If the cursor was declared SENSITIVE STATIC SCROLL, a row may be a hole, from which no values may be fetched, updated, or deleted. Holes do not exist with sensitive dynamic cursors because there is no temporary
result table. For information about holes in the result table of a cursor, see *DB2 Application Programming and SQL Guide*.

For scrollable cursors, the cursor position after an error varies depending on the type of error:

- When an operation is attempted against an update or delete hole, or when an update or delete hole is detected, the cursor is positioned on the hole.
- When a FETCH operation is attempted past the end of file, the cursor is positioned after the last row.
- When a FETCH operation is attempted before the beginning of file, the cursor is positioned before the first row.
- When an error causes the cursor position to be invalid such as when a single row positioned update or positioned delete error occurs that causes a rollback, the cursor is closed.

**Cursor position after exception condition:**

If an error occurs during the execution of a fetch operation, the position of the cursor and the result of any later fetch is unpredictable. It is possible for an error to occur that makes the position of the cursor invalid, in which case the cursor is closed.

If an individual fetch operation specifies a destination that is outside the range of the cursor, a warning is issued (except for FETCH BEFORE or FETCH AFTER), the cursor is positioned before or after the result table, and values are not assigned to host variables.

**Concurrency and scrollability:**

The current row of a cursor cannot be updated or deleted by another application process if it is locked. Unless it is already locked because it was inserted or updated by the application process during the current unit of work, the current row of a cursor is not locked if:

- The isolation level is UR, or
- The isolation level is CS, and
  - The result table of the cursor is read-only
  - The bind option CURRENTDATA(NO) is in effect

A dynamic scrollable cursor is useful when it is more important to the application to see updated rows and newly inserted rows and there is no need to see deleted rows. The isolation level of CS should be used for maximum concurrency with dynamic scrollable cursors. Specifying an isolation level of RR or RS severely restricts the update of the table, thus defeating the purpose of a SENSITIVE DYNAMIC scrollable cursor. If the application needs a constant result table, a SENSITIVE STATIC scrollable cursor with an isolation level of CS should be used.

**Sensitivity of SENSITIVE STATIC SCROLL cursors to database changes:**

When SENSITIVE STATIC SCROLL has been declared, the following rules apply:

- For the result of an update operation to be visible within a cursor after "open," the update operation must be a positioned update executed against the cursor, or a FETCH SENSITIVE in a STATIC cursor must be executed against a row which has been updated by some other means (that is, a searched update, committed updates of others, or an update with another cursor in the same process).
Another process can update the base table of the SELECT statement so that the current values no longer satisfy the WHERE clause. In this case, an "update hole" effectively exists during the time the values in the base table do not satisfy the WHERE clause, and the row is no longer accessible through the cursor. When an attempt is made to fetch a row that has been identified as an update hole, no values are returned, and a warning is issued.

Under SENSITIVE STATIC SCROLL cursors, update holes are only identified during positioned update, positioned delete, and FETCH SENSITIVE operations. Each positioned update, positioned delete, and FETCH SENSITIVE operation does the necessary tests to determine if an update hole exists.

For the result of a delete operation to be visible within a SENSITIVE STATIC SCROLL cursor, the delete operation must be a positioned delete executed against the cursor or a FETCH SENSITIVE in a STATIC cursor must be executed against a row that has been deleted by some other means (that is, a searched delete, committed deletes of others, or a delete with another cursor in the same process).

Another process, or the even the same process, may delete a row in the base table of the SELECT statement so that a row of the cursor no longer has a corresponding row in the base table. In this case, a "delete hole" effectively exists, and that row is no longer accessible through the cursor. When an attempt is made to fetch a row that has been identified as a delete hole, no values are returned, and a warning is issued.

Under SENSITIVE STATIC SCROLL cursors, delete holes are identified during positioned update, positioned delete, and FETCH SENSITIVE operations.

Inserts into the base table or tables of SENSITIVE STATIC SCROLL cursors are not seen after the cursor is opened.

LOB locators:
When information is retrieved into LOB locators and it is not necessary to retain the locator across FETCH statements, it is a good practice to issue a FREE LOCATOR statement before issuing another FETCH statement because locator resources are limited.

Isolation level considerations:
The isolation level of the statement (specified implicitly or explicitly) can affect the result of a rowset-positioned FETCH statement. This is possible when changes are made to the tables underlying the cursor when isolation level UR is used with a dynamic scrollable cursor, or with other isolation levels when rows have been added by the application fetching from the cursor. These situations can occur with the following fetch orientations:

PRIOR ROWSET
With a dynamic scrollable cursor and isolation level UR, the content of a prior rowset can be affected by other activity within the table. It is possible that a row that previously qualified for the cursor, and was included as a member of the "prior" rowset, has since been deleted or modified before it is actually returned as part of the rowset for the current statement. To avoid this behavior, use an isolation level other than UR.

CURRENT ROWSET
With a dynamic scrollable cursor, additional rows can be added between rows that form the rowset that was returned to the user. With isolation level RR, these rows can only be added by the application
fetching from the cursor. For isolation levels other than RR, other applications can insert rows that can affect the results of a subsequent FETCH CURRENT ROWSET. To avoid this behavior, use a static scrollable cursor instead of a dynamic scrollable cursor.

**LAST ROWSET**

With a dynamic scrollable cursor and isolation level UR, the content of the last rowset can be affected by other activity within the table. It is possible that a row that previously qualified for the cursor, and was included as a member of the "last" rowset, has since been deleted or modified before it is actually returned as part of the rowset for the current statement. To avoid this behavior, use an isolation level other than UR.

**ROWSET STARTING AT RELATIVE -n (where -n is a negative number)**

With a dynamic scrollable cursor and isolation level UR, the content of a prior rowset can be affected by other activity within the table. It is possible that a row that previously qualified for the cursor, and was included as a member of the “prior” rowset, has since been deleted or modified before it is actually returned as part of the rowset for the current statement. To avoid this behavior, use an isolation level other than UR.

**Row positioned and rowset positioned FETCH statement interaction:**

The following table demonstrates the interaction between row positioned and rowset positioned FETCH statements. The table is based on the following assumptions:

- TABLE T1 has 15 rows
- CURSOR CS1 is declared as follows:
  ```sql
  DECLARE CS1 SCROLL CURSOR WITH ROWSET POSITIONING FOR SELECT * FROM T1;
  ```
- An OPEN CURSOR statement has been successfully executed for CURSOR CS1 and the FETCH statements in the table are executed in the order that they appear in the table.

Considerations for using the FOR n ROWS clause with the FETCH FIRST n ROWS ONLY clause:

A clause specifying the number of rows that you want can be specified in the SELECT statement of a cursor, the FETCH statement for a cursor, or both. However, these clauses have different effects:

- In the SELECT statement, a FETCH FIRST n ROWS ONLY clause controls the maximum number of rows that can be accessed with the cursor. When a FETCH statement attempts to retrieve a row beyond the number specified in the FETCH FIRST n ROWS ONLY clause of the SELECT statement, an end-of-data condition occurs.

- In a FETCH statement, a FOR n ROWS clause controls the number of rows that are returned for a single FETCH statement.

Both of these clauses can be specified.

Diagnostics information for rowset positioned FETCH statements:

A single FETCH statement from a rowset cursor might encounter zero, one, or more conditions. If the current cursor position is not valid for the fetch orientation, a warning occurs and the statement terminates. If a warning or non-terminating error (such as a bind out error) occurs during the fetch of a row, processing continues. In this case, a summary message is returned for the FETCH statement, and additional information about each fetched row is available with the GET DIAGNOSTICS statement. Use the GET
DIAGNOSTICS statement to obtain information about all of the conditions that are encountered for one of these FETCH statements. See GET DIAGNOSTICS for more information.

The SQLCA returns some information about errors and warnings that are found while fetching from a rowset cursor. Processing stops when the end of data is encountered, or when a terminating condition occurs. After each FETCH statement from a rowset cursor, information is returned to the program through the SQLCA. The SQLCA is set as follows:

- SQLCODE contains the SQLCODE.
- SQLSTATE contains the SQLSTATE.
- SQLERRD1 and SQLERRD2 contain the number of rows of the result table if the cursor is positioned on the last row of the result table.
- SQLERRD3 contains the actual number of rows returned. If SQLERRD3 is less than the number of rows requested, an error or end-of-data condition occurred.
- SQLWARN flags are set to represent all the warnings that were accumulated while processing the FETCH statement.

Consider the following examples, where 10 rows are fetched with a single FETCH statement.

**Example 1:** Assume that an error is detected on the 5th row. SQLERRD3 is set to 4 for the 4 returned rows, SQLSTATE is set to 22537, and SQLCODE is set to -354. This information is also available from the GET DIAGNOSTICS statement (the information that is returned is generated from connected server, which may differ across different servers). For example:

```sql
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 4 and num_cond = 1 (1 condition)
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 22537, sqlcode = -354, and row_num = 5
```

**Example 2:** Assume that an end-of-data condition is detected on the 6th row and that the cursor does not have immediate sensitivity to updates. SQLERRD3 is set to 5 for the 5 returned rows, SQLSTATE is set to 02000, and SQLCODE is set to +100. This information is also available from the GET DIAGNOSTICS statement. For example:

```sql
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 5 and num_cond = 1 (1 condition)
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 02000, sqlcode = 100, and row_num = 6
```

**Example 3:** Assume that a bind error condition is detected on the 5th row, the condition is recorded, and processing continues. Also, assume that an end-of-data condition is detected on the 8th row. SQLERRD3 is set to 7 for the 7 returned rows, SQLSTATE is set to 02000, and SQLCODE is set to +100. Processing to complete the FETCH statement is performed, and the bind out error that occurred is noted. An additional SQLCODE is recorded for the bind out error. SQLCODE is set to -354, and SQLSTATE is set to 01668. Use the GET DIAGNOSTICS statement to determine what went on. For example:
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 7 and num_cond = 3 (3 conditions)
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 01668, sqlcode = -354, and row_num = 0
GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 02000, sqlcode = 100, and row_num = 0
GET DIAGNOSTICS CONDITION 3 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 22003, sqlcode = -302, and row_num = 5

In some cases, DB2 returns a warning if indicator variables are provided, or an error if indicator variables are not provided. These errors can be thought of as data mapping errors that result in a warning if indicator variables are provided.

- If indicator variables are provided, DB2 returns all rows to the user, marking the errors in the indicator variables. The SQLCODE and SQLSTATE contain the warning from the last data mapping error. The GET DIAGNOSTICS statement can be used to retrieve information about all the data mapping errors that have occurred.
- If some or no indicator variables are provided, all rows are returned as above until the first data mapping error that does not have indicator variables is detected. The rows successfully fetched are returned and the SQLSTATE, SQLCODE, and SQLWARN flags are set, if necessary. (The SQLCODE may be 0 or a positive value).

It is possible, if a data mapping error occurs, for the positioning of the cursor to be successful. In this case, the cursor is positioned on the rowset that encountered the data mapping error.

Consider the following examples, which try to fetch 10 rows with a single FETCH statement.

- **Example 1**: Assume that indicators have been provided for values returned for column 1, but not for column 2. The 5th row has a data mapping error (+802) for column 1, and the 7th row has a data mapping error for column 2 (-802 is returned because an indicator was not provided for column 2). SQLERRD3 is set to 6 for the 6 returned rows, SQLSTATE and SQLCODE are set to the error from the 7th row fetched. The indicator variable for the 5th row column 1 indicates that a data mapping error was found. This information is also available from the GET DIAGNOSTICS statement, for example:

  GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
  -- Results of the statement:
  -- num_rows = 6 and num_cond = 2 (2 conditions)
  GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
  :sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
  -- Results of the statement:
  -- sqlstate = 01519, sqlcode = +802, and row_num = 5
  GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
  :sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
  -- Results of the statement:
  -- sqlstate = 22003, sqlcode = -802, and row_num = 7

  The resulting cursor position is unknown.
• **Example 2:** Assume that null indicators are provided, that rows 3 and 5 are holes, and that data exists for the other requested rows. SQLERRD3 is set to 10 to reflect that 10 fetches were completed and that information has been returned for the 10 requested rows. Eight rows actually contain data. For two rows, indicator variables are set to indicate no data was returned for those rows. SQLSTATE is set to 02502, SQLCODE is set to +222, and all null indicators for rows 3 and 5 are set to -3 to indicate that a hole was detected. This information is also available from the GET DIAGNOSTICS statement, for example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
-- Results of the statement:
-- num_rows = 10 and num_cond = 2 (2 conditions)
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 02502, sqlcode = +222, and row_num = 3
GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
:sqlcode = DB2_RETURNED_SQLCODE, :row_num = DB2_ROW_NUMBER;
-- Results of the statement:
-- sqlstate = 02502, sqlcode = +222, and row_num = 5
```

If a null indicator was not provided for any variable in a row that was a hole, an error occurs.

**SQLCA usage summary:**

For multiple-row-fetch, the fields of the SQLCA are set as follows:

<table>
<thead>
<tr>
<th>Errors</th>
<th>Data</th>
<th>SQLSTATE</th>
<th>SQLCODE</th>
<th>SQLERRD3</th>
</tr>
</thead>
<tbody>
<tr>
<td>No</td>
<td>Return all requested rows</td>
<td>00000</td>
<td>0</td>
<td>Number of rows</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>requested</td>
</tr>
<tr>
<td>No</td>
<td>Return data for subset of</td>
<td>02000</td>
<td>+100</td>
<td>Number of rows</td>
</tr>
<tr>
<td></td>
<td>requested rows, end of data</td>
<td></td>
<td></td>
<td>rows</td>
</tr>
<tr>
<td>No</td>
<td>Return all requested rows</td>
<td>sqlstate(2)</td>
<td>sqlcode(2)</td>
<td>Number of rows</td>
</tr>
<tr>
<td>Yes</td>
<td>Return successfully fetched</td>
<td>sqlstate(3)</td>
<td>sqlcode(3)</td>
<td>Number of rows</td>
</tr>
<tr>
<td></td>
<td>rows</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Yes</td>
<td>Return successfully fetched</td>
<td>sqlstate(4)</td>
<td>sqlcode(4)</td>
<td>Number of rows</td>
</tr>
<tr>
<td></td>
<td>rows</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Notes:**

1. SQLWARN flags may be set in all cases, even if there are no other warnings or errors indicated. The warning flags are an accumulation of all warning flags set while processing the multiple-row-fetch.
2. sqlcode is the last positive SQLCODE, and sqlstate is the corresponding SQLSTATE value.
3. Database Server detected error. sqlcode is the first negative SQLCODE encountered, sqlstate is the corresponding SQLSTATE value.
4. Client detected error. sqlcode is the first negative SQLCODE encountered, sqlstate is one of the following SQLSTATEs: 22002, 22008, 22509, 22518, or 55021.

**Providing indicator variables for error conditions:**

If an error occurs as the result of an arithmetic expression in the SELECT list of an outer SELECT statement (division by zero or overflow) or a numeric conversion error occurs, the result is the null value. As in any
other case of a null value, an indicator variable must be provided and the
main variable is unchanged. In this case, however, the indicator variable is
set to -2. Processing of the statement continues as if the error had not
occurred. (However, this error causes a positive SQLCODE.)

If you do not provide an indicator variable, a negative value is returned in
the SQLCODE field of the SQLCA. Processing of the statement terminates
when the error is encountered. No value is assigned to the host variable or
to later variables, though any values that have already been assigned to
variables remain assigned. Additionally, a -3 is returned in all indicators
provided by the application when a hole was detected for the row on a
rowset positioned FETCH, and values were not returned for the row.
Processing of the statement terminates if a hole is detected and at least one
indicator variable was not provided by the application.

Alternative syntax and synonyms:

USING DESCRIPTOR can be specified as a synonym for INTO
DESCRIPTOR.

Example

Example 1: The FETCH statement fetches the results of the SELECT statement into
the application program variables DNUM, DNAME, and MNUM. When no more
rows remain to be fetched, the not found condition is returned.

```
EXEC SQL DECLARE C1 CURSOR FOR
   SELECT DEPTNO, DEPTNAME, MGRNO FROM DSN8A10.DEPT
   WHERE ADMRDEPT = 'A00';
EXEC SQL OPEN C1;
DO WHILE (SQLCODE = 0);
   EXEC SQL FETCH C1 INTO :DNUM, :DNAME, :MNUM;
END;
EXEC SQL CLOSE C1;
```

Example 2: For an example of FETCH statements with a dynamic scrollable cursor,
see Example 8.

Example 3: Fetch the last 5 rows of the result table C1 using cursor C1:

```
FETCH ROWSET STARTING AT ABSOLUTE -5
   FROM C1 FOR 5 ROWS INTO DESCRIPTOR :MYDESCR;
```

Example 4: Fetch 6 rows starting at row 10 for cursor CURS1, and fetch the data
into three host-variable-arrays:

```
FETCH ROWSET STARTING AT ABSOLUTE 10
   FROM CURS1 FOR 6 ROWS
   INTO :hav1, :hva2, :hva3;
```

Alternatively, a descriptor could have been specified in an INTO DESCRIPTOR
clause where the information in the SQLDA reflects the data types of the
host-variable-arrays:

```
FETCH ROWSET STARTING AT ABSOLUTE 10
   FROM CURS1 FOR 6 ROWS
   INTO DESCRIPTOR :MYDESCR;
```
FREE LOCATOR

The FREE LOCATOR statement removes the association between a LOB locator variable and its value.

Invocation

This statement can only be embedded in an application program. It cannot be issued interactively. It is an executable statement that can be dynamically prepared. However, the EXECUTE statement with the USING clause must be used to execute the prepared statement. FREE LOCATOR cannot be used with the EXECUTE IMMEDIATE statement. It must not be specified in Java.

Authorization

None required.

Syntax

```
FREE LOCATOR host-variable
```

Description

*host-variable, ...*

Identifies one or more locator variables that must be declared in accordance with the rules for declaring locator variables. The locator variable type must be a binary large object locator, a character large object locator, or a double-byte character large object locator.

The *host-variable* must currently have a locator assigned to it. That is, a locator must have been assigned during this unit of work (by a FETCH, SELECT INTO, assignment statement, SET *host-variable* statement, or VALUES INTO statement) and must not subsequently have been freed (by a FREE LOCATOR statement); otherwise, an error is returned.

If more than one locator is specified and an error is returned on one of the locators, it is possible that some locators have been freed and others have not been freed.

Example

Assume that the employee table contains columns RESUME, HISTORY, and PICTURE and that locators have been established in a program to represent the column values. Free the CLOB locator variables LOCRES and LOCHIST, and the BLOB locator variable LOCPIC.

```
EXEC SQL FREE LOCATOR :LOCRES, :LOCHIST, :LOCPIC
```
GET DIAGNOSTICS

The GET DIAGNOSTICS statement provides diagnostic information about the last SQL statement (other than a GET DIAGNOSTICS statement) that was executed. This diagnostic information is gathered as the previous SQL statement is executed. Some of the information available through the GET DIAGNOSTICS statement is also available in the SQLCA.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

None required.

Syntax

```
GET CURRENT DIAGNOSTICS STACKED statement-information condition-information combined-information
```

combined-information:
### Description

Diagnostic information is provided in three main areas: statement information, condition information, and combined information. After the execution of an SQL statement, information about the execution of the statement is provided as statement information, and at least one instance of condition information is provided. The number of instances of the condition information is indicated by the NUMBER item that is available in the statement information. Combined information contains a text representation of all the information gathered about the execution of the SQL statement.

The diagnostic information that is provided is specific to the server. If you are connected to a server other than DB2 for z/OS, see that product's documentation for the diagnostic information that is returned.

**CURRENT**

Specifies that information is to be returned from the first diagnostics area. It corresponds to the previous SQL statement that was executed that was not a GET DIAGNOSTICS or compound statement. **CURRENT** is the default.

**STACKED**

Specifies that information is to be returned from the stacked diagnostics area. The stacked diagnostics area is only available within a handler in a native SQL procedure and compiled SQL functions. The stacked diagnostics area corresponds to the previous SQL statement (that was not a GET DIAGNOSTICS or compound statement) that was executed before the handler was entered. If the GET DIAGNOSTICS statement is the first statement within a handler, the current diagnostics area and the stacked diagnostics area contain the same diagnostics information.

**statement-information**

Provides information about the last SQL statement executed.

**variable1**

Identifies a variable described in the program in accordance with the rules for declaring variables. The data type of the variable must be the data type as specified in [Data types for GET DIAGNOSTICS items](#).

The variable is assigned the value of the specified statement information item. If the value is truncated when assigning it to the variable, a warning is
returned and the GET_DIAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition. If a DIAGNOSTICS item is not set, the variable is set to a default value, based on its data type: 0 for an exact numeric field, an empty string for a VARCHAR field, and blanks for a CHAR field.

**DB2_GET_DIAGNOSTICS_DIAGNOSTICS**
Contains textual information about errors or warnings that might have occurred in the execution of the GET DIAGNOSTICS statement. The format of the information is similar to what would be returned by a GET DIAGNOSTICS :hv = ALL statement.

**DB2_SQL_NESTING_LEVEL**
Identifies the current level of nesting or recursion that is in effect when the GET DIAGNOSTICS statement was executed. Each level of nesting corresponds to a nested or recursive invocation of a compiled SQL function, native SQL procedure, or trigger. If the GET DIAGNOSTICS statement is executed outside of a level of nesting, the value of zero is returned.

**statement-information-item-name:**

**DB2_LAST_ROW**
For a multiple-row FETCH statement, contains a value of +100 if the last row currently in the table is in the set of rows that have been fetched. For cursors that are not sensitive to updates, there would be no need to do a subsequent FETCH, because the result would be an end-of-data indication. For cursors that are sensitive to updates, a subsequent FETCH may return more data if a row had been inserted before the FETCH was executed. For statements other than multiple-row FETCH statements, or for multiple-row FETCH statements that do not contain the last row, this variable contains the value 0.

An end of data warning might not occur and DB2_LAST_ROW might not contain +100 when the number of rows returned is equal to the number of rows requested and the last row of data returned is the last row of data.

**DB2_NUMBER_PARAMETER_MARKERS**
For a PREPARE statement, contains the number of parameter markers in the prepared statement. Otherwise, or if the server only returns an SQLCA, the value zero is returned.

**DB2_NUMBER_RESULT_SETS**
For a CALL statement, contains the actual number of result sets returned by the procedure. Otherwise, or if the server only returns an SQLCA, the value zero is returned.

**DB2_NUMBER_ROWS**
If the previous SQL statement was an OPEN or a FETCH that caused the size of the result table to be known, returns the number of rows in the result table. For SENSITIVE DYNAMIC cursors, this value can be thought of as an approximation because rows that are inserted and deleted will affect the next retrieval of this value. If the previous SQL statement was a PREPARE statement, returns the estimated number of rows in the result table for the prepared statement. Otherwise, or if the server only returns an SQLCA, the value zero is returned.

**DB2_RETURN_STATUS**
Identifies the status value returned from the stored procedure associated with the previously executed SQL statement, provided that the statement
was a CALL statement that invoked a procedure that returns a status. Otherwise, or if the server only returns an SQLCA, the value zero is returned.

**DB2_SQL_ATTR_CURSOR_HOLD**
For an ALLOCATE or OPEN statement, indicates whether a cursor can be held open across multiple units of work.
- N indicates that this cursor does not remain open across multiple units of work.
- Y indicates that this cursor remains open across multiple units of work.
Otherwise, a blank is returned.

**DB2_SQL_ATTR_CURSOR_ROWSET**
For an ALLOCATE or OPEN statement, indicates whether or not a cursor can be accessed using rowset positioning.
- N indicates that this cursor supports only row positioned operations.
- Y indicates that this cursor supports rowset positioned operations.
Otherwise, a blank is returned.

**DB2_SQL_ATTR_CURSOR_SCANNABLE**
For an ALLOCATE or OPEN statement, indicates whether or not a cursor can be scrolled forward and backward.
- N indicates that this cursor is not scrollable.
- Y indicates that this cursor is scrollable.
Otherwise, a blank is returned.

**DB2_SQL_ATTR_CURSOR_SENSITIVITY**
For an ALLOCATE or OPEN statement, indicates whether or not a cursor does or does not show updates to cursor rows made by other connections.
- I indicates insensitive.
- S indicates sensitive.
Otherwise, a blank is returned.

**DB2_SQL_ATTR_CURSOR_TYPE**
For an ALLOCATE or OPEN statement, indicates the type of cursor, whether a cursor type is forward-only, static, or dynamic.
- F indicates a forward cursor.
- D indicates a dynamic cursor.
- S indicates a static cursor.
Otherwise, a blank is returned.

**MORE**
Indicates whether some of the warning and errors from the previous SQL statement were stored or discarded.
- N indicates that all the warnings and errors from the previous SQL statement are stored in the diagnostic area.
- Y indicates that some of the warnings and errors from the previous SQL statement were discarded because the amount of storage needed to record warnings and errors exceeded 65535 bytes.

**NUMBER**
Returns the number of errors and warnings detected by the execution of the previous SQL statement, other than a GET DIAGNOSTICS statement, that have been stored in the diagnostics area. If the previous SQL
statement returned an SQLSTATE of 00000 or no previous SQL statement has been executed, the number returned is one.

The GET DIAGNOSTICS statement itself may return information via the SQLSTATE parameter, but does not modify the previous contents of the diagnostics area, except for the DB2_GET_DIAGNOSTICS_DIAGNOSTICS item.

**ROW_COUNT**

Identifies the number of rows associated with the previous SQL statement that was executed.

If the previous SQL statement is a DELETE, INSERT, UPDATE, or MERGE statement, ROW_COUNT indicates the number of rows that are qualified to be deleted, inserted, or updated by that statement, excluding rows that are affected by triggers or referential integrity constraints. The count does not include rows that are inserted as a result of processing a FOR PORTION OF clause for in an SQL data change statement.

For the OPEN of a cursor for a SELECT with a data change statement, or a SELECT INTO statement, SQLERRD(3) contains the number of rows affected by the embedded data change statement. The value is 0 if the SQL statement fails, indicating that all changes made in executing the statement canceled.

A value of -1 indicates a mass delete from a table in a segmented table space and the DELETE statement did not include selection criteria, or a truncate operation. If the delete was against a view, then neither the DELETE statement nor the definition of the view included selection criteria.

For a REFRESH TABLE statement, SQLERRD(3) contains the number of rows inserted into the materialized query table.

If the previous SQL statement is a multiple-row FETCH, ROW_COUNT identifies the number of rows fetched.

Otherwise, or if the server only returns an SQLCA, the value zero is returned.

**condition-information**

Assigns the values of the specified condition information to the associated variables. The variable specified must be of the data type that is compatible with the data type of the specified diagnostic-ID or an error occurs. If the value of the condition is truncated when assigning it to the variable, an error occurs. If an indicator variable was provided, the length of the value is returned in the indicator variable.

If a DIAGNOSTICS item is not set, then the variable is set to a default value, based on the data type of the item. The specific value will be 0 for a numeric field, an empty string for a VARCHAR field, and blanks for a CHAR field.

**variable2 or integer**

Identifies a variable described in the program in accordance with the rules for declaring variables. The value identifies the diagnostic for which information is requested. Each diagnostic that occurs while executing an SQL statement is assigned an integer. The value 1 indicates the first diagnostic, 2 indicates the second diagnostic, and so on. If the value is 1, the diagnostic information that is retrieved corresponds to the condition that is indicated by the SQLSTATE value actually returned by the execution of the previous SQL statement (other than a GET DIAGNOSTICS statement). The variable specified must be an
integer data type, or an error occurs. An indicator variable is not allowed when this is a host variable; an error occurs. If a value is specified that is less than or equal to zero, or greater than the number of available diagnostics, an error occurs.

`variable3`
Identifies a variable described in the program in accordance with the rules for declaring variables. The data type of the variable must be the data type as specified in [Data types for GET DIAGNOSTICS items](#) for the indicated condition-information item.

`condition-information-item-name`

`CATALOG_NAME`
If the returned SQLSTATE is any one of the following values, the constraint that caused the error is a referential, check, or unique constraint. The location (RDB) name of the server that generated the condition is returned.

- Class 09 (Triggered Action Exception),
- Class 23 (Integrity Constraint Violation)
- Class 27 (Triggered Data Change Violation)
- 40002 (Transaction Rollback - Integrity Constraint Violation)
- 40004 (Transaction Rollback - Triggered Action Exception)

If the returned SQLSTATE is class 42 (Syntax Error or Access Rule Violation), the server name of the table that caused the error is returned.

If the returned SQLSTATE is class 44 (WITH CHECK OPTION Violation), the server name of the view that caused the error is returned.

Otherwise, the empty string is returned.

The actual server name may be different than the server name specified, either implicitly or explicitly, on the CONNECT statement because of the use of aliases or synonyms.

`CONDITION_NUMBER`
Returns the number of the diagnostic returned.

`CURSOR_NAME`
If the returned SQLSTATE is class 24 (Invalid Cursor State), the name of the cursor is returned. Otherwise, the empty string is returned.

`DB2_ERROR_CODE1`
Returns an internal error code. Otherwise, or if the server only returns an SQLCA, the value 0 is returned.

`DB2_ERROR_CODE2`
Returns an internal error code. Otherwise, or if the server only returns an SQLCA, the value 0 is returned.

`DB2_ERROR_CODE3`
Returns an internal error code. Otherwise, or if the server only returns an SQLCA, the value 0 is returned.

`DB2_ERROR_CODE4`
Returns an internal error code. Otherwise, or if the server only returns an SQLCA, the value 0 is returned.

`DB2_INTERNAL_ERROR_POINTER`
For some errors, this is a negative value that is an internal error pointer. Otherwise, the value 0 is returned.
DB2_LINE_NUMBER
Returns the line number where an error is encountered in parsing a dynamic statement. Also returns the line number where an error is encountered in parsing, binding, or executing a CREATE or ALTER statement for a native SQL procedure or compiled SQL function. DB2_LINE_NUMBER also returns the line number when a CALL statement invokes a native SQL procedure and the procedure returns with an error. This information is not returned for an external SQL procedure.

This value will only be meaningful if the statement source contains new line control characters.

DB2_MESSAGE_ID
Corresponds to the message that is contained in the MESSAGE_TEXT diagnostic item (for example, DSNT102I or DSNU180I).

DB2_MODULE_DETECTING_ERROR
Returns an identifier indicating which module detected the error. For a SIGNAL statement that is issued from a routine, the value 'ROUTINE' is returned. Otherwise, the string 'DSN ' is returned.

DB2_ORDINAL_TOKEN_n
Returns the n-th token. n must be a value from 1 to 100. For example, DB2_ORDINAL_TOKEN_1 would return the value of the first token, DB2_ORDINAL_TOKEN_2 the second token, and so on. A numeric value for a token is converted to characters before being returned. If there is no value for the token, or if the server only returns an SQLCA, an empty string is returned.

DB2_REASON_CODE
Contains the reason code for errors that have a reason code token in the message text. Otherwise, the value zero is returned.

DB2_RETURNED_SQLCODE
Returns the SQLCODE for the specified diagnostic.

DB2_ROW_NUMBER
Returns the number of the row where the condition was encountered, when such information is available and applicable. If SQLCODE +1– or +20237 is returned, DB2_ROW_NUMBER returns a value of 0.

DB2_SQLERRD_SET
A value of Y indicates that the DB2_SQLERRD1 through DB2_SQLERRD items might be set. These items are set only when communicating with a server that returns the SQLCA SQL communications area and not the new diagnostics area. Otherwise, a blank is returned.

DB2_SQLERRD1
Returns the value of sqlerrd(1) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

DB2_SQLERRD2
Returns the value of sqlerrd(2) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

DB2_SQLERRD3
Returns the value of sqlerrd(3) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

DB2_SQLERRD4
Returns the value of sqlerrd(4) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.
**DB2_SQLERRD5**
Returns the value of sqlerrd(5) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

**DB2_SQLERRD6**
Returns the value of sqlerrd(6) from the SQLCA that is returned by the server. Otherwise, the value zero is returned.

**DB2_TOKEN_COUNT**
Returns the number of tokens available for the specified diagnostic ID.

**MESSAGE_TEXT**
Returns the message text that is associated with the SQLCODE. This is the short text, including substituted tokens. The message text does not contain the message number. When the SQLCODE is 0, the empty string is returned, even if the RETURNED_SQLSTATE value indicates a warning condition.

**RETURNED_SQLSTATE**
Returns the SQLSTATE for the specified diagnostic.

**SERVER_NAME**
If the previous SQL statement is a CONNECT, DISCONNECT, or SET CONNECTION statement, returns the name of the server specified in the previous statement is returned. Otherwise, the name of the server where the statement executes is returned.

**connection-information-item-name**
Provides information about the last SQL statement executed if it was a CONNECT statement.

**DB2_AUTHENTICATION_TYPE**
Contains an authentication type value of:
- ‘S’ for a server authentication
- ‘C’ for client authentication
- ‘T’ for trusted server authentication
- Otherwise, or if the server only returns an SQLCA, a blank is returned.

**DB2_AUTHORIZATION_ID**
Authorization ID used by connected server. Because of user ID translation and authorization exits, the local user ID may not be the authorized ID used by the server.

**DB2_CONNECTION_STATE**
Contains the connection state:
- -1 if the connection is unconnected
- 1 if the connection is connected
Otherwise, or if the server only returns an SQLCA, the value zero is returned.

**DB2_CONNECTION_STATUS**
Contains a value of:
- 1 if committable updates can be performed on the connection for this unit of work
- 2 if no committable updates can be performed on the connection for this unit of work
Otherwise, or if the server only returns an SQLCA, the value zero is returned.
**DB2_SERVER_CLASS_NAME**

For a CONNECT or SET CONNECTION statement, contains one of the following values:
- QAS for DB2 for i
- QDB2 for DB2 for z/OS
- QDB2/2 for DB2 for OS/2
- QDB2/600 for DB2 for AIX®
- QDB2/6000 PE for DB2 for AIX Parallel Edition
- QDB2/AIX64 for DB2 for AIX 64-bit
- QDB2/HPUX for DB2 for HP-UX
- QDB2/HP64 for DB2 for HP-UX 64-bit
- QDB2/LINUX for DB2 for Linux, UNIX, and Windows
- QDB2/LINUX390 for DB2 for Linux, UNIX, and Windows
- QDB2/LINUXIA64 for DB2 for Linux, UNIX, and Windows
- QDB2/LINUXPPC for DB2 for Linux, UNIX, and Windows
- QDB2/LINUXPPC64 for DB2 for Linux, UNIX, and Windows
- QDB2/LINUXZ64 for DB2 for Linux, UNIX, and Windows
- QDB2/NT for DB2 for Linux, UNIX, and Windows
- QDB2/NT64 for DB2 for Linux, UNIX, and Windows
- QDB2/PTX for DB2 for NUMA-Q®
- QDB2/SCO for DB2 for SCO UnixWare
- QDB2/SGI for DB2 for Silicon Graphics
- QDB2/SNI for DB2 for Siemens Nixdorf
- QDB2/SUN for DB2 for SUN Solaris
- QDB2/SUN64 for DB2 for SUN Solaris 64-bit
- QDB2/Windows 95 for DB2 for Linux, UNIX, and Windows
- QSQLDS/VM for DB2 Server for VSE & VM
- QSQLDS/VSE for DB2 Server for VSE & VM

Otherwise, the empty string is returned.

**DB2_ENCRYPTION_TYPE**

The level of encryption for the connection:
- A indicates only the authentication tokens (authid and password) are encrypted.
- D indicates all data is encrypted for the connection.
- Otherwise, a blank is returned.

**DB2_PRODUCT_ID**

Returns a product signature. If the application server is an IBM relational database product, the form is *pppvvrrm*.

**combined-information**

Provides a text representation of all the information gathered about the execution of the SQL statement.

**ALL**

Indicates that all diagnostic items that are set for the last SQL statement executed are to be combined into one string. The format of the string is a
semicolon separated list of all of the available diagnostic information in the form: item-name[(condition-number)]=value-converted-to-character...; as shown in the following example:

```
NUMBER=1;RETURNED_SQLSTATE=02000;DB2_RETURNED_SQLCODE=+100;
```

**variable4**

Identifies a variable described in the program in accordance with the rules for declaring variables. The data type of the variable must be VARCHAR. If the length of variable4 is not sufficient to hold the full returned diagnostic string, the string is truncated, a warning is returned, and the GET_DiAGNOSTICS_DIAGNOSTICS item of the diagnostics area is updated with the details of this condition.

**STATEMENT**

Indicates that all statement-information-item-name diagnostic items that are set for the last SQL statement executed should be combined into one string. The format is the same as described for the ALL option.

**CONDITION**

Indicates that all condition-information-item-name diagnostic items that are set for the last SQL statement executed should be combined into one string. If variable5 or integer is supplied after CONDITION, the format is the same as described above for the ALL option. If variable5 or integer is not supplied, the format includes a condition number entry at the beginning of the information for that condition in the form:

```
CONDITION_NUMBER=x;item-name=value-converted-to-character;... where X is the number of the condition, as shown in the following example:
CONDITION_NUMBER=1;RETURNED_SQLSTATE=02000;RETURNED_SQLCODE=100;
   CONDITION_NUMBER=2;RETURNED_SQLSTATE=01004;
```

**CONNECTION**

Indicates that all connection-information-item-name diagnostic items that are set for the last SQL statement executed should be combined into one string. If variable5 or integer is supplied after CONNECTION, the format is the same as described for the ALL option. If variable5 or integer is not supplied, then the format includes a condition number entry at the beginning of the information for that condition in the form:

```
CONNECTION_NUMBER=x;item-name=value-converted-to-character;... where X is the number of the condition, as shown in the following example:
CONNECTION_NUMBER=1;CONNECTION_NAME=SVL1;DB2_PRODUCT_ID=DSN10015;
```

**variable5 or integer**

Identifies a variable described in the program in accordance with the rules for declaring variables. The value identifies the diagnostic for which ALL CONDITION or ALL CONNECTION information is requested. The variable specified must be an integer data type or an error occurs. An indicator variable is not allowed when this is a host variable; an error occurs. If a value is specified that is less than or equal to zero or greater than the number of available diagnostics, an error occurs.

**Notes**

**Effect of the statement in a native SQL routine:**

The GET DIAGNOSTICS statement does not change the contents of the diagnostics area except for DB2_GET_DIAGNOSTICS_DIAGNOSTICS.
If you want information about an error, the GET DIAGNOSTICS statement must be the first executable statement specified in the handler that will handle the error condition.

If you want information about a warning and a handler will get control for the warning condition, the GET DIAGNOSTICS statement must be the first executable statement specified in that handler.

If you want information about a warning and a handler will not get control for the warning condition, the GET DIAGNOSTICS statement must be the next statement executed after that previous statement.

**Considerations for the SQLSTATE and SQLCODE SQL variables:**
The GET DIAGNOSTICS statement does not change the value of the SQLSTATE and SQLCODE SQL variables.

**Data types for items:**
When a diagnostic item is assigned to a variable, SQL variable, or SQL parameter, the data type of the target must be compatible with the data type of the requested diagnostic item.

**Data types for GET DIAGNOSTICS items**

DRDA considerations

The GET DIAGNOSTICS statement is supported from a current DB2 for z/OS client, regardless of the level of the server (a DB2 for z/OS Version 7 or a DB2 for Windows Version 7, for example). When the application is connected to servers that do not support the Open Group Version 3 DRDA standard, the diagnostic information that is returned by the servers is available in the condition information.
Alternative syntax and synonyms:
To provide compatibility with previous releases of DB2 or other products
in the DB2 family, DB2 supports the following keywords:
- RETURN_STATUS as a synonym for DB2_RETURN_STATUS
- EXCEPTION as a synonym for CONDITION

Examples

Example 1: In an application, use the GET DIAGNOSTICS statement to determine
how many rows were updated.

```sql
long rcount;
EXEC SQL UPDATE T1 SET C1 = C1 + 1;
EXEC SQL GET DIAGNOSTICS :rcount = ROW_COUNT;
```

After execution of this code segment, rcount will contain the number of rows that
were updated.

Example 2: In an application, use the GET DIAGNOSTICS statement to handle
multiple SQL Errors.

```sql
long numerrors, counter;
char retsqlstate[5];
long hva[5];
EXEC SQL INSERT INTO T1 FOR 5 ROWS VALUES (:hva) NOT ATOMIC
    CONTINUE ON SQL_EXCEPTION;
EXEC SQL GET DIAGNOSTICS :numerrors = NUMBER;
for ( i=1;i < numerrors;i++)
    {
        EXEC SQL GET DIAGNOSTICS CONDITION :i :retsqlstate = RETURNED_SQLSTATE;
        ...
```

Execution of this code segment sets and prints retsqlstate with the SQLSTATE for
each error that was encountered in the previous SQL statement.

Example 3: Retrieve information about a connection.

```sql
EXEC SQL GET DIAGNOSTICS CONDITION :HV_PRODUCT_ID = DB2_PRODUCT_ID;
```

Example 4: Use the GET DIAGNOSTICS statement to retrieve information that is
similar to what is returned in the SQLCA:

```sql
EXEC SQL GET DIAGNOSTICS CONDITION 1
    :dasqlcode = DB2_RETURNED_SQLCODE,
    :datokencnt = DB2_TOKEN_COUNT,
    :datoken1 = DB2_ORDINAL_TOKEN_1,
    :datoken2 = DB2_ORDINAL_TOKEN_2,
    :datoken3 = DB2_ORDINAL_TOKEN_3,
    :datoken4 = DB2_ORDINAL_TOKEN_4,
    :datoken5 = DB2_ORDINAL_TOKEN_5,
    :dasqerrdb1 = DB2_MESSAGE_ID,
    :dmsgtext = MESSAGE_TEXT,
    :dasqerrp = DB2_MODULE_DETECTING_ERROR,
    :dasqlstate = RETURNED_SQLSTATE;
```

Example 5: Specify the STACKED keyword on a GET DIAGNOSTICS statement
that is used within a handler to access information in the diagnostics area that
cause the handler to be activated:

```sql
CREATE PROCEDURE divide2 { IN numerator INTEGER,
    IN denominator INTEGER,
    OUT divide_result INTEGER,
    OUT divide_error VARCHAR(70))
BEGIN
```

2022 SQL Reference
DECLARE msg_text CHAR(70) DEFAULT '';
DECLARE divide_error CHAR(70) DEFAULT '';

DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
BEGIN
    INSERT .....; -- insert row into a log table
    -- get diagnostic information for the INSERT statement
    GET CURRENT DIAGNOSTICS CONDITION 1 msg_text = MESSAGE_TEXT;
    -- get information about condition that activated the handler
    GET STACKED DIAGNOSTICS CONDITION 1 divide_error = MESSAGE_TEXT;
END;

SET divide_result = numerator/denominator;
END;

The first GET DIAGNOSTICS statement obtains diagnostic information about the
INSERT statement.

The second GET DIAGNOSTICS statement specifies the STACKED keyword. The
use of the STACKED keyword allows access the stacked diagnostics area which
contains the diagnostic information for the condition that caused the handler to be
activated. The information about the original condition is still accessible within the
handler even after another statement has been issued, such as the INSERT
statement in the example.

Example 6: The following application logs information whenever a routine is
invoked directly by an application rather than indirectly by another routine. The
application uses the GET DIAGNOSTICS statement that specifies
DB2_SQL_NESTING_LEVEL to obtain the current nesting level, and invokes the
LOG_INVOCATION procedure if the nesting level is 1:

CREATE PROCEDURE TEST
    MODIFIES SQL DATA
    LANGUAGE SQL
BEGIN
    DECLARE NESTING_LEVEL INT DEFAULT 0;

    GET DIAGNOSTICS NESTING_LEVEL = DB2_SQL_NESTING_LEVEL;

    --
    -- If routine is invoked at nesting level 1,
    -- invoke a routine to log the invocation.
    --
    IF (NESTING_LEVEL = 1) THEN
        CALL LOG_INVOCATION();
    END IF;

    --
    -- Remainder of procedure logic
    --
    ...
END
GRANT

The DB2 GRANT statement grants privileges to authorization IDs. There is a separate form of the statement for each of these classes of privilege:

- Collection
- Database
- Distinct type
- Function or stored procedure
- Package
- Plan
- Schema
- Sequence
- System
- Table or view
- Distinct type or JAR file
- Use

The applicable objects are always at the current server. The grants are recorded in the current server’s catalog.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

If the authorization mechanism was not activated when the DB2 subsystem was installed, an error condition occurs.

Authorization

To grant a privilege P, the privilege set must include one of the following:

- The privilege P WITH GRANT OPTION
- Ownership of the object on which P is a privilege
- SECADM authority

**Note:** If installation parameter SEPARATE SECURITY is NO, SYSADM authority has implicit SECADM authority.

- ACCESSCTRL authority
  The presence of ACCESSCTRL authority in the privilege set allows the granting of all authorities except:
  - System DBADM
  - CREATE_SECURE_OBJECT privilege
  - DATAACCESS
  - ACCESSCTRL

**Note:** If installation parameter SEPARATE SECURITY is NO, SYSCTRL authority has implicit ACCESSCTRL authority that allows the granting of all privileges except:
- DBADM on databases
DELETE, INSERT, SELECT, and UPDATE on user tables or views
- EXECUTE on plans, packages, functions, or stored procedures
- PACKADM on collections
- SYSADM authority
- USAGE on distinct types, JARs, and sequences

To grant the CREATE_SECURE_OBJECT system privilege, the privileges that are
held by the authorization ID of the statement must include SECADM authority.

Except for views, the GRANT option for privileges on a table is also inherent in
DBADM authority for its database, provided DBADM authority was acquired with
the GRANT option. See CREATE VIEW for a description of the rules that apply to
views.

If the statement is embedded in an application program, the privilege set is the
privileges that are held by the owner of the plan or package. The owner can be a
role. If the statement is dynamically prepared, the privilege set is the privileges
that are held by the SQL authorization ID of the process. However, if the process is
running in a trusted context that is defined with the ROLE AS OBJECT OWNER
CLAUSE, the privilege set is the privileges that are held by the role in effect.

**Syntax**

```
GRANT authorization-specification TO authorization-name
ROLE role-name
PUBLIC WITH GRANT OPTION
```

**Description**

*authorization-specification*

Specifies one or more privileges for the class of privilege. The same privilege
must not be specified more than once.

*TO*

Specifies to what authorization IDs the privileges are granted.

*authorization-name,...*

Lists one or more authorization IDs.

*ROLE role-name*

Lists one or more role names. Each name must identify a role that exists at
the current server.

The value of the CURRENT RULES special register determines whether
you can use the ID or role of the GRANT statement itself (to grant
privileges to yourself). When CURRENT RULES is:

- **DB2** You cannot use the ID or role of the GRANT statement.
- **STD** You can use the ID or role of the GRANT statement.

*PUBLIC*

Grants the privileges to all users at the current server, including database
requesters using DRDA access.

CREATE_SECURE_OBJECT must not be granted to PUBLIC.
ACCESSCTRL, DATAACCESS and system DBADM authorities cannot be
granted to PUBLIC.

**WITH GRANT OPTION**

Allows the named users to grant the privileges to others. Granting an
administrative authority with this option allows the user to specifically grant
any privilege belonging to that authority. If you omit WITH GRANT OPTION,
the named users cannot grant the privileges to others unless they have that
authority from some other source.

GRANT authority cannot be passed to PUBLIC. When WITH GRANT OPTION
is used with PUBLIC, a warning is issued, and the named privileges are
granted, but without GRANT authority.

If you grant the CREATE_SECURE_OBJECT system privilege, the WITH
GRANT OPTION clause is ignored because the CREATE_SECURE_OBJECT
system privilege cannot be granted to others.

GRANT ACCESSCTRL, DATAACCESS and system DBADM authorities cannot
be passed to others. If WITH GRANT OPTION is used when granting these
authorities, a warning is issued and the named authorities are granted, but
without GRANT authority.

**Notes**

For more on DB2 privileges, read *DB2 Administration Guide*.

A grant is the granting of a specific privilege by a specific grantor to a specific
grantee. The grantor for a given GRANT statement is the authorization ID for the
privilege set; that is, the SQL authorization ID of the process or a role, or the
authorization ID of the owner of the plan or package. Grant statements that are
made in a trusted context that is defined with the ROLE AS OBJECT OWNER
clause result in the grantor being the role that is in effect. If the statement is
prepared dynamically, the grantor is the role that is associated with the ID that is
running the statement. If the statement is embedded in an application program
that was bound in a trusted context that was defined with the ROLE AS OBJECT
OWNER clause the owner of the plan or package is a role which is the grantor. If
the ROLE AS OBJECT OWNER clause is not specified for the trusted context, the
grantor is the authorization ID of the process.

The grantee, as recorded in the catalog, is an authorization ID or PUBLIC.

Duplicate grants from the same grantor are not recorded in the catalog. Otherwise,
the result of executing a GRANT statement is recorded as one or more grants in
the current server's catalog.

If more than one privilege or authority-name is specified after the TO keyword
and one of the grants is in error, execution of the statement is stopped and no
grants are made. The status of the privilege or privileges granted is recorded in the
catalog for each authority-name.

Different grantors can grant the same privilege to a single grantee. The grantee
retains that privilege as long as one or more of those grants are recorded in the
catalog. Privileges that imply other privileges are also termed authorities. Grants are
removed from the catalog by executing SQL REVOKE statements.
Whenever a grant is made for a database, distinct type, package, plan, schema, stored procedure, table, trigger, user-defined function, view, or USE privilege for an object that does not exist, an SQL return code is issued and the grant is not made.

The grantee, as recorded in the catalog for PUBLIC AT ALL LOCATIONS is PUBLIC*.
GRANT (collection privileges)

This form of the GRANT statement grants privileges on collections.

Syntax

\[
\text{GRANT} \quad \text{CREATE IN COLLECTION collection-id, ... TO authorization-name \quad \text{WITH GRANT OPTION}}
\]

Description

CREATE IN
Grants the privilege to use the BIND subcommand to create packages in the designated collections.

The word ON can be used instead of IN.

PACKADM ON
Grants package administrator authority for the designated collections.

The word IN can be used instead of ON.

COLLECTION collection-id, ...
Identifies the collections on which the specified privilege is granted. The collections do not have to exist.

COLLECTION *
Indicates that the specified privilege is granted on all collections including those that do not currently exist.

TO Refer to GRANT for a description of the TO clause.

WITH GRANT OPTION
Refer to GRANT for a description of the WITH GRANT OPTION clause.

Examples

Example 1: Grant the privilege to create new packages in collections QAAACLONE and DSN8CC61 to CLARK.

GRANT CREATE IN COLLECTION QAAACLONE, DSN8CC61 TO CLARK;

Example 2: Grant the privileges to create new packages in collection DSN8CC91 to role ROLE1:

GRANT CREATE IN COLLECTION DSN8CC91 TO ROLE ROLE1;
GRANT (database privileges)

This form of the GRANT statement grants privileges on databases.

Syntax

```
GRANT DBADM, DBCTRL, DBMAINT, CREATETAB, CREATETS, DISPLAYDB, DROP, IMAGCOPY, LOAD, RECOVERDB, REORG, REPAIR, STARTDB, STATS, STOPDB

ON DATABASE database-name

TO authorization-name

ROLE role-name

PUBLIC

WITH GRANT OPTION
```

Description

Each keyword listed grants the privilege described, but only as it applies to or within the databases named in the statement.

**DBADM**
Grants the database administrator authority.

**DBCTRL**
Grants the database control authority.

**DBMAINT**
Grants the database maintenance authority.

**CREATETAB**
Grants the privilege to create new tables. To create tables in an implicitly created database, CREATETAB privileges are needed on the DSNDB04 database. For a work file database, PUBLIC implicitly has the CREATETAB privilege (without GRANT authority) to define declared temporary tables; this privilege is not recorded in the DB2 catalog, and it cannot be revoked.

**CREATETS**
Grants the privilege to create new table spaces.

**DISPLAYDB**
Grants the privilege to issue the DISPLAY DATABASE command.
DROP
Grants the privilege to issue the DROP or ALTER DATABASE statements for the designated databases.

IMAGCOPY
Grants the privilege to run the COPY, MERGECOPY, and QUIESCE utilities against table spaces of the specified databases, and to run the MODIFY RECOVERY utility.

LOAD
Grants the privilege to use the LOAD utility to load tables.

RECOVERDB
Grants the privilege to use the RECOVER and REPORT utilities to recover table spaces and indexes.

REORG
Grants the privilege to use the REORG utility to reorganize table spaces and indexes.

REPAIR
Grants the privilege to use the REPAIR and DIAGNOSE utilities.

STARTDB
Grants the privilege to issue the START DATABASE command.

STATS
Grants the privilege to use the RUNSTATS utility to update statistics, the CHECK utility to test whether indexes are consistent with the data they index, and the MODIFY STATISTICS utility to delete unwanted statistics history records from the corresponding catalog tables.

STOPDB
Grants the privilege to issue the STOP DATABASE command.

ON DATABASE database-name,...
Identifies databases on which privileges are to be granted. For each named database, the grantor must have all the specified privileges with the GRANT option. Each name must identify a database that exists at the current server. DSNDB01 must not be identified; however, a grant of a privilege on DSNDB06 implies the granting of the same privilege on DSNDB01 for utility operations only.

Database privileges granted on DSNDB04 are applicable to all implicitly created databases. This means that a user with the STOPDB privilege on DSNDB04 can also stop database objects in any implicitly created database. Similarly, having DBADM on DSNDB04 allows access to all tables in all implicitly created databases. However, having a database privilege on DSNDB04 does not allow granting of this privilege on an implicitly created database to others.

TO
Refer to GRANT for a description of the TO clause.

WITH GRANT OPTION
Refer to GRANT for a description of the WITH GRANT OPTION clause.

Examples

Example 1: Grant drop privileges on database DSN8D10A to user PEREZ.

GRANT DROP
ON DATABASE DSN8D10A
TO PEREZ;
Example 2: Grant repair privileges on database DSN8D10A to all local users.

```sql
GRANT REPAIR
  ON DATABASE DSN8D10A
  TO PUBLIC;
```

Example 3: Grant authority to create new tables and load tables in database DSN8D10A to users WALKER, PIANKA, and FUJIMOTO, and give them grant privileges.

```sql
GRANT CREATETAB, LOAD
  ON DATABASE DSN8D10A
  TO WALKER, PIANKA, FUJIMOTO
  WITH GRANT OPTION;
```

Example 4: Grant load privileges to database DSN9D91A to role ROLE1:

```sql
GRANT LOAD
  ON DATABASE DSN9D91A
  TO ROLE ROLE1;
```
GRANT (function or procedure privileges)

This form of the GRANT statement grants privileges on user-defined functions, cast functions that are generated for distinct types, and stored procedures.

Syntax

```sql
GRANT EXECUTE ON FUNCTION function-name
  (parameter-type*)
  , SPECIFIC FUNCTION specific-name
  , PROCEDURE procedure-name
  TO authorization-name
    ROLE role-name
    PUBLIC
    WITH GRANT OPTION

AS LOCATOR
```

parameter-type:

```sql
data-type
```

Notes:

1. AS LOCATOR can be specified only for a LOB data type or a distinct type based on a LOB data type.
Description

EXECUTE
Grants the privilege to run the identified user-defined function, cast function that was generated for a distinct type, or stored procedure.

FUNCTION or SPECIFIC FUNCTION
Identifies the function on which the privilege is granted. The function must
exist at the current server, and it must be a function that was defined with the CREATE FUNCTION statement or a cast function that was generated by a CREATE TYPE statement. The function can be identified by name, function signature, or specific name.

If the function was defined with a table parameter (the LIKE TABLE was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to identify the function. Instead, identify the function with its function name, if unique, or with its specific name.

**FUNCTION function-name**

Identifies the function by its name. The *function-name* must identify exactly one function. The function can have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

An asterisk (*) can be specified for an unqualified function name. The function can be identified as a qualified or unqualified *function-name*. For example, * indicates that the privilege is granted on all the functions in the default schema, including those that do not currently exist. *schema-name.* indicates that the privilege is granted on all the functions in the specified schema, including those that do not currently exist. SYSADM authority is required if * or *schema-name.* is specified. Specifying an asterisk does not affect any EXECUTE privileges that are already granted on a function.

**FUNCTION function-name (parameter-type,...)**

Identifies the function by its function signature, which uniquely identifies the function. The *function-name (parameter-type, ...)* must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance on which the privilege is to be granted. Synonyms for data types are considered a match.

If the function was defined with a table parameter (the LIKE TABLE name AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

If *function-name ()* is specified, the function identified must have zero parameters.

**function-name**

Identifies the name of the function. If you do not explicitly qualify the function name with a schema name, the function name is implicitly qualified with a schema name as described in the preceding description for FUNCTION *function-name*.

**(parameter-type,...)**

Identifies the parameters of the function.

If an unqualified distinct type name is specified, DB2 searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:
• Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly, DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).

• If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).

• If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the FOR subtype DATA clause or the CCSID clause is optional. Omission of either clause indicates that DB2 ignores the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR
Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or a distinct type based on a LOB.

SPECIFIC FUNCTION specific-name
Identifies the function by its specific name. The specific-name must identify a specific function that exists at the current server.

PROCEDURE procedure-name
Identifies a stored procedure that is defined at the current server. The name, including the implicit or explicit schema name, must identify a stored procedure that exists at the current server.

An asterisk (*) can be specified for an unqualified procedure name. The procedure can be identified as a qualified or unqualified procedure-name. For example, * indicates that the privilege is granted on all the procedures in the default schema, including those that do not currently exist. schema-name.* indicates that the privilege is granted on all the procedures in the specified schema, including those that do not currently exist. SYSADM authority is required if * or schema-name.* is specified. Specifying an asterisk does not affect any EXECUTE privileges that are already granted on a procedure.

TO Refer to GRANT for a description of the TO clause.

WITH GRANT OPTION
Refer to GRANT for a description of the WITH GRANT OPTION clause.
Examples

Example 1: Grant the EXECUTE privilege on function CALC_SALARY to user JONES. Assume that there is only one function in the schema with function name CALC_SALARY.

GRANT EXECUTE ON FUNCTION CALC_SALARY TO JONES;

Example 2: Grant the EXECUTE privilege on procedure VACATION_ACCR to all users at the current server.

GRANT EXECUTE ON PROCEDURE VACATION_ACCR TO PUBLIC;

Example 3: Grant the EXECUTE privilege on function DEPT_TOTALS to the administrative assistant and give the assistant the ability to grant the EXECUTE privilege on this function to others. The function has the specific name DEPT85_TOT. Assume that the schema has more than one function that is named DEPT_TOTALS.

GRANT EXECUTE ON SPECIFIC FUNCTION DEPT85_TOT TO ADMIN_A
WITH GRANT OPTION;

Example 4: Grant the EXECUTE privilege on function NEW_DEPT_HIRES to HR (Human Resources). The function has two input parameters with data types of INTEGER and CHAR(10), respectively. Assume that the schema has more than one function that is named NEW_DEPT_HIRES.

GRANT EXECUTE ON FUNCTION NEW_DEPT_HIRES (INTEGER, CHAR(10))
TO HR;

You can also code the CHAR(10) data type as CHAR().

Example 5: Grant the EXECUTE privilege on function FIND_EMPDEPT to role ROLE1:

GRANT EXECUTE ON FUNCTION FIND_EMPDEPT TO ROLE ROLE1;
GRANT (package privileges)

This form of the GRANT statement grants privileges on packages.

Syntax

```
GRANT
  ALL,
  BIND COPY EXECUTE RUN
ON PACKAGE collection-id.package-name...
TO authorization-name
  ROLE role-name
  PUBLIC
WITH GRANT OPTION
```

Description

**BIND**

Grants the privilege to use the BIND and REBIND subcommands for the designated packages.

The BIND package privilege can also be used to allow a user to add a new version of an existing package. For details on the authorization required to create new packages and new versions of existing packages, see "Notes" on page 2038.

**COPY**

Grants the privilege to use the COPY option of the BIND subcommand for the designated packages.

**EXECUTE**

Grants the privilege to run application programs that use the designated packages and to specify the packages following PKLIST for the BIND PLAN and REBIND PLAN commands. RUN is an alternate name for the same privilege.

**ALL**

Grants all package privileges for which you have GRANT authority for the packages named in the ON clause.

**ON PACKAGE**

```
ON PACKAGE collection-id.package-name,...
```

Identifies packages for which you are granting privileges. The granting of a package privilege applies to all versions of a package. The list can simultaneously contain items of the following two forms:

- `collection-id.package-name` explicitly identifies a single package. The name must identify a package that exists at the current server.
- `collection-id.*` applies to every package in the indicated collection. This includes packages that currently exist and future packages. The grant applies...
to a collection at the current server, but the *collection-id* does not have to identify a collection that exists when the grant is made.

To grant a privilege in this form requires PACKADM with the WITH GRANT OPTION over the collection or all collections, SYSADM, or SYSCtrl authority. Because of this fact, WITH GRANT OPTION, if included in the statement, is ignored for grants of this form, but not for grants for specific packages.

**TO** Refer to [GRANT](#) for a description of the TO clause.

**WITH GRANT OPTION**

Refer to [GRANT](#) for a description of the WITH GRANT OPTION clause.

**Notes**

The authorization required to add a new package or a new version of an existing package depends on the value of field BIND NEW PACKAGE on installation panel DSNTIPP. The default value is BINDADD.

If the value of BIND NEW PACKAGE is BINDADD, the owner must have one of the following to add a new package or a new version of an existing package to a collection:

- The BINDADD system privilege and either the CREATE IN privilege or PACKADM authority for the collection or for all collections
- SYSADM or SYSCtrl authority

If the value of BIND NEW PACKAGE is BIND, the owner must have one of the following to add a new package or a new version of an existing package to a collection:

- The BINDADD system privilege and either the CREATE IN privilege or PACKADM authority for the collection or for all collections
- SYSADM or SYSCtrl authority
- PACKADM authority for the collection or for all collections
- Users with the BIND package privilege can also add a new version of an existing package

**Alternative syntax and synonyms:** To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports specifying PROGRAM as a synonym for PACKAGE.

**Examples**

*Example 1:* Grant the privilege to copy all packages in collection DSN8CC61 to LEWIS.

```
GRANT COPY ON PACKAGE DSN8CC61.* TO LEWIS;
```

*Example 2:* You have the BIND privilege with GRANT authority over the package CLCT1.PKG1. You have the EXECUTE privilege with GRANT authority over the package CLCT2.PKG2. You have no other privileges with GRANT authority over any package in the collections CLCT1 AND CLCT2. Hence, the following statement, when executed by you, grants LEWIS the BIND privilege on CLCT1.PKG1 and the EXECUTE privilege on CLCT2.PKG2, and makes no other grant. The privileges granted include no GRANT authority.

```
GRANT ALL ON PACKAGE CLCT1.PKG1, CLCT2.PKG2 TO JONES;
```
Example 3: Grant the privileges to run all packages in collection DSN9CC13 to role ROLE1:

```
GRANT EXECUTE ON PACKAGE DSN9CC13.* TO ROLE ROLE1;
```
GRANT (plan privileges)

This form of the GRANT statement grants privileges on plans.

**Syntax**

```
GRANT BIND, EXECUTE
ON PLAN plan-name
TO authorization-name
WITH GRANT OPTION
```

**Description**

**BIND**
Grants the privilege to use the BIND, REBIND, and FREE subcommands for the identified plans. (The authority to create new plans using BIND ADD is a system privilege.)

**EXECUTE**
Grants the privilege to run programs that use the identified plans.

**ON PLAN plan-name,...**
Identifies the application plans on which the privileges are granted. For each identified plan, you must have all specified privileges with the GRANT option.

**TO**
Refer to [GRANT](#) for a description of the TO clause.

**WITH GRANT OPTION**
Refer to [GRANT](#) for a description of the WITH GRANT OPTION clause.

**Examples**

*Example 1:* Grant the privilege to bind plan DSN8IP10 to user JONES.

```
GRANT BIND ON PLAN DSN8IP10 TO JONES;
```

*Example 2:* Grant privileges to bind and execute plan DSN8CP10 to all users at the current server.

```
GRANT BIND, EXECUTE ON PLAN DSN8CP10 TO PUBLIC;
```

*Example 3:* Grant the privilege to execute plan DSN8CP10 to users ADAMSON and BROWN with grant option.

```
GRANT EXECUTE ON PLAN DSN8CP10 TO ADAMSON, BROWN WITH GRANT OPTION;
```

*Example 4:* Grant the privileges to bind the DSN91PLN plan to role ROLE1:

```
GRANT BIND ON PLAN DSN91PLN TO ROLE ROLE1;
```
GRANT (schema privileges)

This form of the GRANT statement grants privileges on schemas.

Syntax

```
GRANT ,

ALTERIN
CREATEIN
DROPIN

ON SCHEMA schema-name

TO authorization-name

* ROLE role-name

PUBLIC

WITH GRANT OPTION
```

Description

**ALTERIN**
Grants the privilege to alter stored procedures and user-defined functions, or specify a comment for distinct types, cast functions that are generated for distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

**CREATEIN**
Grants the privilege to create distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

**DROPIN**
Grants the privilege to drop distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

**SCHEMA schema-name**
Identifies the schemas on which the privilege is granted. The schemas do not need to exist when the privilege is granted.

**SCHEMA ***
Indicates that the specified privilege is granted on all schemas including those that do not currently exist.

**TO**
Refer to **GRANT** for a description of the TO clause.

**WITH GRANT OPTION**
Refer to **GRANT** for a description of the WITH GRANT OPTION clause.

Examples

*Example 1:* Grant the CREATEIN privilege on schema T_SCORES to user JONES.

```
GRANT CREATEIN ON SCHEMA T_SCORES TO JONES;
```

*Example 2:* Grant the CREATEIN privilege on schema VAC to all users at the current server.

```
GRANT CREATEIN ON SCHEMA VAC TO PUBLIC;
```
Example 3: Grant the ALTERIN privilege on schema DEPT to the administrative assistant and give the grantee the ability to grant ALTERIN privileges on this schema to others.

    GRANT ALTERIN ON SCHEMA DEPT TO ADMIN_A
    WITH GRANT OPTION;

Example 4: Grant the CREATEIN, ALTERIN, and DROPIN privileges on schemas NEW_HIRE, PROMO, and RESIGN to HR (Human Resources).

    GRANT CREATEIN, ALTERIN, DROPIN ON SCHEMA NEW_HIRE, PROMO, RESIGN TO HR;

Example 5: Grant the ALTERIN privileges on the EMPLOYEE schema to role ROLE1:

    GRANT ALTERIN ON SCHEMA EMPLOYEE TO ROLE ROLE1;
GRANT (sequence privileges)

This form of the GRANT statement grants privileges on a user-defined sequence.

Syntax

```
GRANT ALTER ON SEQUENCE sequence-name (1)
USAGE TO authorization-name
ROLE role-name
PUBLIC
WITH GRANT OPTION
```

Notes:

1. The keyword SELECT is an alternative keyword for USAGE.

Description

**ALTER**
Grants the privilege to alter a sequence or record a comment on a sequence.

**USAGE**
Grants the USAGE privilege to use a sequence. This privilege is needed when the NEXT VALUE or PREVIOUS VALUE expression is invoked for a sequence name.

**SEQUENCE sequence-name**
Identifies the sequence. The name, including the implicit or explicit schema qualifier, must uniquely identify an existing sequence at the current server. If no sequence by this name exists in the explicitly or implicitly specified schema, an error occurs. `sequence-name` must not be the name of an internal sequence object that is used by DB2.

**TO**
Refer to `GRANT` for a description of the TO clause.

**WITH GRANT OPTION**
Refer to `GRANT` for a description of the WITH GRANT OPTION clause.

Examples

*Example 1:* Grant USAGE privilege on sequence MYNUM to user JONES.
```
GRANT USAGE
ON SEQUENCE MYNUM
TO JONES;
```

*Example 2:* Grant USAGE privileges on sequence ORDER_SEQ to role ROLE1:
```
GRANT USAGE ON SEQUENCE ORDER_SEQ TO ROLE ROLE1;
```
GRANT (system privileges)

This form of the GRANT statement grants system privileges.

Syntax

```sql
GRANT ACCESSCTRL ON SYSTEM
```

- `ACCESSCTRL` grants the `ACCESSCTRL` authority. `ACCESSCTRL` allows the user to grant all authorities and privileges, except system `DBADM`, `DATAACCESS`, `ACCESSCTRL`, and privileges on security related objects.

Notes:

1. The `ACCESSCTRL` and `DATAACCESS` clauses can be specified in any order.
2. The `WITH GRANT OPTION` can be specified but is ignored for `DBADM`, `DATAACCESS`, and `ACCESSCTRL`.

Description

**ACCESSCTRL**

Grants the `ACCESSCTRL` authority. `ACCESSCTRL` allows the user to grant all authorities and privileges, except system `DBADM`, `DATAACCESS`, `ACCESSCTRL`, and privileges on security related objects.
A warning is issued if the WITH GRANT OPTION is specified when granting this authority.

ACCESSCTRL cannot be granted to PUBLIC.

ARCHIVE
Grants the privilege to use the ARCHIVE LOG and SET LOG commands.

BINDADD
Grants the privilege to create plans and packages by using the BIND subcommand with the ADD option.

BINDAGENT
Grants the privilege to issue the BIND, FREE PACKAGE, or REBIND subcommands for plans and packages and the DROP PACKAGE statement on behalf of the grantor. The privilege also allows the holder to copy and replace plans and packages on behalf of the grantor.

A warning is issued if WITH GRANT OPTION is specified when granting this privilege.

BSDS
Grants the privilege to issue the RECOVER BSDS command.

CREATEALIAS
Grants the privilege to use the CREATE ALIAS statement.

CREATEDBA
Grants the privilege to issue the CREATE DATABASE statement and acquire DBADM authority over those databases.

CREATEDBC
Grants the privilege to issue the CREATE DATABASE statement and acquire DBCTRL authority over those databases.

CREATESG
Grants the privilege to create new storage groups.

CREATETMTAB
Grants the privilege to use the CREATE GLOBAL TEMPORARY TABLE statement.

CREATE_SECURE_OBJECT
Grants the privilege to create a secure object.

DATAACCESS
Grants the DATAACCESS authority. DATAACCESS allows the user to access data in all user tables, views, and materialized query tables in a DB2 subsystem and allows the user to execute plans, packages, functions, and procedures.

A warning is issued if the WITH GRANT OPTION is specified when granting this authority.

DATAACCESS cannot be granted to PUBLIC.

DBADM
Grants the DBADM authority. DBADM allows the user to manage all objects in the DB2 subsystem, except security objects.

A warning is issued if the WITH GRANT OPTION is specified when granting this authority.

DBADM cannot be granted to PUBLIC.
WITH ACCESSCTRL
Specifies that the ACCESSCTRL authority is granted along with the system
DBADM authority. ACCESSCTRL allows system DBADM to grant all
authorities and privileges, except system DBADM, DATAACCESS,
ACCESSCTRL authorities and privileges on security related objects.
ACCESSCTRL can be used to REVOKE privileges using the BY clause.
WITH ACCESSCTRL is the default.

WITHOUT ACCESSCTRL
Specifies that system DBADM authority is not granted the ACCESSCTRL
authority.

WITH DATAACCESS
Specifies that the DATAACCESS authority is granted along with the
system DBADM authority. DATAACCESS allows the system DBADM to
access data in all user tables, views, and materialized query tables in a DB2
subsystem and allows the user to execute plans, packages, functions, and
procedures.
WITH DATAACCESS is the default.

WITHOUT DATAACCESS
Specifies that system DBADM authority is not granted the DATAACCESS
authority.

DISPLAY
Grants the privilege to use most of the DISPLAY commands except DISPLAY
PROFILE and DISPLAY RLIMIT. No authorization is required for the DISPLAY
UTILITY command.

DEBUGSESSION
Grants the privilege to attach a debug client to the current application process
connection, which enables client application debugging of native SQL or Java
procedures that are executed within the session.

EXPLAIN
Grants the privilege to issue the following without requiring the privileges
needed to execute the statement:
• EXPLAIN statement with the options:
  – PLAN
  – ALL
• PREPARE statement
• DESCRIBE TABLE statement
• Explain dynamic SQL statements that execute under the special register
  CURRENT EXPLAIN MODE, when CURRENT EXPLAIN MODE =
  EXPLAIN
• BIND options: EXPLAIN(ONLY) and SQLERROR(CHECK)
  EXPLAIN(ONLY) allows to explain the statements.
  SQLERROR(CHECK) performs all syntax and semantic checks on the SQL
  statements that are being bound.

MONITOR1
Grants the privilege to obtain IFC data classified as serviceability data,
statistics, accounting, and other performance data that does not contain
potentially secure data.

MONITOR2
Grants the privilege to obtain IFC data classified as containing potentially
sensitive data such as SQL statement text and audit data. Users with MONITOR2 privileges have MONITOR1 privileges.

**RECOVER**
Grants the privilege to issue the RECOVER INDOUBT command.

**SQLADM**
Grants the authority to perform the following actions without requiring any additional privileges:
- DESCRIBE TABLE statement
- EXPLAIN statement with the following options:
  - PLAN
  - ALL
  - STMTCACHE ALL
  - STMTID
  - STMTTOKEN
  - MONITORED STMTS
- PREPARE statement
- Explain dynamic SQL statements that execute under the special register CURRENT EXPLAIN MODE, when CURRENT EXPLAIN MODE = EXPLAIN
- BIND options: EXPLAIN(ONLY) and SQLERROR(CHECK)
  EXPLAIN(ONLY) allows to explain the statements.
  SQLERROR(CHECK) performs all syntax and semantic checks on the SQL statements that are being bound.
- START command
- STOP command
- DISPLAY PROFILE command
- Execute the RUNSTATS utility and the MODIFY STATISTICS utility in any database.
- MONITOR2 privilege to obtain IFC data classified as containing potentially sensitive data, such as SQL statement text and audit data, as well as IFC data classified as serviceability data, statistics, accounting, and other performance data.

**STOPALL**
Grants the privilege to issue the STOP DB2 command.

**STOSPACE**
Grants the privilege to use the STOSPACE utility.

**SYSADM**
Grants all DB2 privileges except for a few reserved for installation SYSADM authority. The privileges the user possesses are all grantable, including the SYSADM authority itself. The privileges the user lacks restrict what the user can do with the directory and the catalog. Using WITH GRANT OPTION when granting SYSADM is redundant but valid. For more on SYSADM and installation SYSADM authority, see *DB2 Administration Guide*.

**SYSCtrl**
Grants the system control authority, which allows the user to have most of the privileges of a system administrator but excludes the privileges to read or
change user data. Using WITH GRANT OPTION when granting SYSCTRL is redundant but valid. For more information on SYSCTRL authority, see DB2 Administration Guide.

SYSOPR

Grants the privilege to have system operator authority.

TRACE

Grants the privilege to issue the MODIFY TRACE, START TRACE, and STOP TRACE commands.

ON SYSTEM

Identifies that the system privilege is granted for the entire DB2 subsystem.

TO

Refer to GRANT for a description of the TO clause.

WITH GRANT OPTION

If you grant the SYSADM or SYSCTRL system privilege, WITH GRANT OPTION is valid but unnecessary. It is unnecessary because whoever is granted SYSADM or SYSCTRL has that authority and all the privileges it implies, with the GRANT option.

Examples

Example 1: Grant DISPLAY privileges to user LUTZ.

GRANT DISPLAY
TO LUTZ;

Example 2: Grant BSDS and RECOVER privileges to users PARKER and SETRIGHT, with the WITH GRANT OPTION.

GRANT BSDS,RECOVER
TO PARKER,SETRIGHT
WITH GRANT OPTION;

Example 3: Grant TRACE privileges to all local users.

GRANT TRACE
TO PUBLIC;

Example 4: Grant ARCHIVE privileges to role ROLE1:

GRANT ARCHIVE TO ROLE ROLE1;

Example 5: SECADM Linda grants the privilege to Steve to create a secure object:

GRANT CREATE_SECURE_OBJECT
TO STEVE;

Example 6: Grant system DBADM with ACCESSCTRL and with DATAACCESS to role, ADMINROLE and authid, SALLY. Since GRANT system DBADM also grants ACCESSCTRL and DATAACCESS by default, WITH ACCESSCTRL and WITH DATAACCESS clauses need not be specified explicitly.

GRANT DBADM ON SYSTEM
TO ADMINROLE;
GRANT DBADM, ACCESSCTRL, DATAACCESS
ON SYSTEM
TO SALLY;

Example 7: Grant system DBADM without ACCESSCTRL and without DATAACCESS to John. The WITHOUT ACCESSCTRL and WITHOUT DATAACCESS clauses need to be specified explicitly.
GRANT DBADM WITHOUT ACCESSCTRL
    WITHOUT DATAACCESS
    ON SYSTEM
    TO JOHN;

Related tasks:

- Managing explicit privileges (Managing Security)

Related reference:

- Explicit system privileges (Managing Security)
GRANT (table or view privileges)

This form of the GRANT statement grants privileges on tables and views.

Syntax

```
GRANT PRIVILEGES
    ALL, ALTER, DELETE, INDEX, INSERT, REFERENCES,
    SELECT, TRIGGER, UPDATE,
    (column-name),
    TABLE
     ON
    table-name
view-name
    TO
   authorization-name
   ROLE role-name
   PUBLIC
   WITH GRANT OPTION
```

Description

**ALL or ALL PRIVILEGES**

Grants all table or view privileges for which you have GRANT authority, for the tables and views named in the ON clause.

If you do not use ALL, you must use one or more of the keywords in the following list. For each keyword that you use, you must have GRANT authority for that privilege on every table or view identified in the ON clause.

**ALTER**

Grants the privilege to alter the specified table or create a trigger on the specified table. ALTER cannot be used if the statement identifies an auxiliary table or a view.

**DELETE**

Grants the privilege to delete rows in the specified table or view. DELETE cannot be granted on an auxiliary table.

**INDEX**

Grants the privilege to create an index on the specified table. INDEX cannot be granted on a view.
**INSERT**
Grants the privilege to insert rows into the specified table or view. INSERT cannot be granted on an auxiliary table.

**REFERENCES**
Grants the privilege to add a referential constraint in which the specified table is a parent. If a list of column names is not specified or if REFERENCES is granted via the specification of ALL PRIVILEGES, the grantee can define referential constraints using all columns of the table as a parent key, even those added later via the ALTER TABLE statement. This privilege cannot be granted on a view or auxiliary table.

**REFERENCES(column-name,...)**
Grants the privilege to add or drop a referential constraint in which the specified table is a parent using only those columns that are specified in the column list as a parent key. Each column-name must be an unqualified name that identifies a column of the table identified in the ON clause. This privilege cannot be granted on a view or auxiliary table.

**SELECT**
Grants the privilege to create a view or read data from the specified table or view. SELECT cannot be granted on an auxiliary table.

**TRIGGER**
Grants the privilege to create a trigger on the specified table. TRIGGER cannot be granted on an auxiliary table or a view.

**UPDATE**
Grants the privilege to update rows in the specified table or view. UPDATE cannot be granted on an auxiliary table.

**UPDATE(column-name,...)**
Grants the privilege to update only the columns named. Each column-name must be the unqualified name of a column of every table or view identified in the ON clause. Each column-name must not identify a column of an auxiliary table.

**ON table-name or view-name**
Specifies the tables or views on which you are granting the privileges. The list can be a list of table names or view names, or a combination of the two. A declared temporary table and a table that is implicitly created for an XML column must not be identified.

If you use GRANT ALL, then for each named table or view, the privilege set (described in “Authorization” on page 2024 in “GRANT” on page 2024) must include at least one privilege with the GRANT option.

**TO**
Refer to [GRANT](#) for a description of the TO clause.

**WITH GRANT OPTION**
Refer to [GRANT](#) for a description of the WITH GRANT OPTION clause.

**Notes**
The REFERENCES privilege does not replace the ALTER privilege. It was added to conform to the SQL standard. To define a foreign key that references a parent table, you must have either the REFERENCES or the ALTER privilege, or both.

For a created temporary table, only ALL or ALL PRIVILEGES can be granted.
Specific table privileges cannot be granted. In addition, only the ALTER, DELETE, INSERT, and SELECT privileges apply to a created temporary table.
For a view of a created temporary table, either ALL or the specific UPDATE, DELETE, INSERT and SELECT privileges can be granted. When ALL is specified only the UPDATE, DELETE, INSERT, and SELECT privileges apply to a view on created temporary table. However, the UPDATE operation of the view is not allowed.

To grant table privileges on a created temporary table, the privilege set must include one of the following:

- SYSADM
- DBADM on DSNDB06
- Ownership of the created temporary table

To grant table privileges on a view of a created temporary table, the privilege set must include one of the following:

- SYSADM
- ownership of the created temporary table

For a declared temporary table, no privileges can be granted. When a declared temporary table is defined, PUBLIC implicitly receives all table privileges (without GRANT authority) for the table. These privileges are not recorded in the DB2 catalog, and they cannot be revoked.

For an auxiliary table, only the INDEX privilege can be granted. DELETE, INSERT, SELECT, and UPDATE privileges on the base table that is associated with the auxiliary table extend to the auxiliary table.

- ALTER
- INDEX
- REFERENCES
- TRIGGER

**Examples**

**Example 1:** Grant SELECT privileges on table DSN8A10.EMP to user PULASKI.

```sql
GRANT SELECT ON DSN8A10.EMP TO PULASKI;
```

**Example 2:** Grant UPDATE privileges on columns EMPNO and WORKDEPT in table DSN8A10.EMP to all users at the current server.

```sql
GRANT UPDATE (EMPNO,WORKDEPT) ON TABLE DSN8A10.EMP TO PUBLIC;
```

**Example 3:** Grant all privileges on table DSN8A10.EMP to users KWAN and THOMPSON, with the WITH GRANT OPTION.

```sql
GRANT ALL ON TABLE DSN8A10.EMP TO KWAN,THOMPSON WITH GRANT OPTION;
```

**Example 4:** Grant the SELECT and UPDATE privileges on the table DSN8A10.DEPT to every user in the network.

```sql
GRANT SELECT, UPDATE ON TABLE DSN8A10.DEPT TO PUBLIC;
```

Even with this grant, it is possible that some network users do not have access to the table at all, or to any other object at the subsystem where the table exists. Controlling access to the subsystem involves the communications databases at the
subsystems in the network. The tables for the communication databases are described in “DB2 catalog tables” on page 2409. Controlling access is described in DB2 Administration Guide.

Example 5: Grant ALTER privileges on table DSN9910.EMP to role ROLE1:

```
GRANT ALTER ON TABLE DSN9910.EMP TO ROLE ROLE1;
```
GRANT (type or JAR file privileges)

This form of the GRANT statement grants the privilege to use distinct types or JAR files.

Syntax

![Diagram of GRANT statement syntax]

Description

**USAGE**

Grants the privilege to use the distinct type in tables, functions procedures, or the privilege to use the JAR file.

**TYPE distinct-type-name**

Identifies the distinct type. The name, including the implicit or explicit schema name, must identify a unique distinct type that exists at the current server.

**JAR jar-name**

Identifies the JAR file. The name, including the implicit or explicit schema name, must identify a unique JAR file that exists at the current server.

**TO** Refer to [GRANT](#) for a description of the TO clause.

**WITH GRANT OPTION**

Refer to [GRANT](#) for a description of the WITH GRANT OPTION clause.

Notes

*Alternative syntax and synonyms:* To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports DATA TYPE or DISTINCT TYPE as a synonym for TYPE.

Examples

*Example 1:* Grant the USAGE privilege on distinct type SHOE_SIZE to user JONES. This GRANT statement does not give JONES the privilege to execute the cast functions that are associated with the distinct type SHOE_SIZE.

```
GRANT USAGE ON TYPE SHOE_SIZE TO JONES;
```

*Example 2:* Grant the USAGE privilege on distinct type US_DOLLAR to all users at the current server.

```
GRANT USAGE ON TYPE US_DOLLAR TO PUBLIC;
```
Example 3: Grant the USAGE privilege on distinct type CANADIAN_DOLLAR to the administrative assistant (ADMIN_A), and give this user the ability to grant the USAGE privilege on the distinct type to others. The administrative assistant cannot grant the privilege to execute the cast functions that are associated with the distinct type CANADIAN_DOLLAR because WITH GRANT OPTION does not give the administrative assistant the EXECUTE authority on these cast functions.

```
GRANT USAGE ON TYPE CANADIAN_DOLLAR TO ADMIN_A
    WITH GRANT OPTION;
```

Example 4: Grant the USAGE privilege on the distinct type MILES to role ROLE1 at the current server:

```
GRANT USAGE ON TYPE MILES
    TO ROLE ROLE1;
```
GRANT (use privileges)

This form of the GRANT statement grants authority to use particular buffer pools, storage groups, or table spaces.

Syntax

```
GRANT USE OF
  BUFFERPOOL bpname,
  ALL BUFFERPOOLS,
  STOGROUP stogroup-name,
  TABLESPACE database-name.table-space-name,
  TO authorization-name
    ROLE role-name
    PUBLIC
  WITH GRANT OPTION
```

Description

**BUFFERPOOL bpname,...**
Grants the privilege to refer to any of the identified buffer pools in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement. See [Naming conventions](#) for more details about `bpname`.

**ALL BUFFERPOOLS**
Grants the privilege to refer to any buffer pool in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement.

**STOGROUP stogroup-name,...**
Grants the privilege to refer to any of the identified storage groups in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement.

**TABLESPACE database-name.table-space-name,...**
Grants the privilege to refer to any of the identified table spaces in a CREATE TABLE statement. The default for `database-name` is DSNDDB04.

You cannot grant the privilege for table spaces that are for declared temporary tables (table spaces in a work file database). For these table spaces, `PUBLIC` implicitly has the TABLESPACE privilege (without GRANT authority); this privilege is not recorded in the DB2 catalog, and it cannot be revoked.

**TO** Refer to [GRANT](#) for a description of the TO clause.

**WITH GRANT OPTION**
Refer to [GRANT](#) for a description of the WITH GRANT OPTION clause.
Notes

You can grant privileges for only one type of object with each statement. Thus, you can grant the use of several table spaces with one statement, but not the use of a table space and a storage group. For each object you identify, you must have the USE privilege with GRANT authority.

Examples

Example 1: Grant authority to use buffer pools BP1 and BP2 to user MARINO.

```
GRANT USE OF BUFFERPOOL BP1,BP2
TO MARINO;
```

Example 2: Grant to all local users the authority to use table space DSN8S10D in database DSN8D10A.

```
GRANT USE OF TABLESPACE
    DSN8D10A.DSN8S10D
    TO PUBLIC;
```

Example 3: Grant authority to use storage group SG1 to role ROLE1:

```
GRANT USE OF STOGROUP SG1
    TO ROLE ROLE1;
```
The HOLD LOCATOR statement allows a LOB locator variable to retain its association with a value beyond a unit of work.

Invocation

This statement can only be embedded in an application program. It cannot be issued interactively. It is an executable statement that can be dynamically prepared. However, the EXECUTE statement with the USING clause must be used to execute the prepared statement. HOLD LOCATOR cannot be used with the EXECUTE IMMEDIATE statement.

Authorization

None required.

Syntax

```
HOLD LOCATOR host-variable
```

Description

`host-variable, ...`

Identifies one or more locator variables that must be declared in accordance with the rules for declaring locator variables. The locator variable type must be a binary large object locator, a character large object locator, or a double-byte character large object locator.

The `host-variable` must currently have a locator assigned to it. That is, a locator must have been assigned during this unit of work (by a FETCH, SELECT INTO, assignment statement, SET `host-variable` statement, or VALUES INTO statement); otherwise, an error is returned.

If more than one locator is specified and an error is returned on one of the locators, it is possible that some locators have been held and others have not been held.

Notes

A host-variable LOB locator variable that has the hold property is freed (has its association between it and its value removed) when:

- The SQL FREE LOCATOR statement is executed for the locator variable.
- The SQL ROLLBACK statement is executed.
- The SQL session is terminated.

Example

Assume that the employee table contains columns RESUME, HISTORY, and PICTURE and that locators have been established in a program to represent the
values represented by the columns. Give the CLOB locator variables LOCRES and LOCHIST, and the BLOB locator variable LOCPIC the hold property.

EXEC SQL HOLD LOCATOR :LOCRES, :LOCHIST, :LOCPIC
The INCLUDE statement inserts application code, including declarations and statements, into a source program.

**Invocation**

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

**Authorization**

None required.

**Syntax**

```plaintext
►► INCLUDE SQLCA
   SQLDA
   member-name
►◄
```

**Description**

**SQLCA**

Indicates that the description of an SQL communication area (SQLCA) is to be included. INCLUDE SQLCA must not be specified more than once in the same application program. In COBOL, INCLUDE SQLCA must be specified in the Working-Storage Section or the Linkage Section. INCLUDE SQLCA must not be specified if the program is prepared (either with the DB2 precompiler or coprocessor) with the STDSQL(YES) SQL processing option.

For a description of the SQLCA, see [SQL communication area (SQLCA)](#).

**SQLDA**

Indicates that the description of an SQL descriptor area (SQLDA) is to be included. It must not be specified in a Fortran. For a description of the SQLDA, see [SQL descriptor area (SQLDA)](#).

**member-name**

Names a member of the partitioned data set to be the library input when your application program is prepared (either with the DB2 precompiler or coprocessor). It must be an SQL identifier.

The member can contain any host language source statements and any SQL statements other than an INCLUDE statement. In COBOL, INCLUDE `member-name` must not be specified in other than the Data Division or the Procedure Division.

**Notes**

When your application program is prepared (either with the DB2 precompiler or coprocessor), the INCLUDE statement is replaced by source statements. Thus, the INCLUDE statement must be specified at a point in your application program where the resulting source statements are acceptable to the compiler.
The INCLUDE statement cannot refer to source statements that themselves contain INCLUDE statements.

The declarations that are generated by DCLGEN can be used in an application program by specifying the same member in the INCLUDE statement as in the DCLGEN LIBRARY parameter.

**Example**

Include an SQL communications area in a PL/I program.

```sql
EXEC SQL INCLUDE SQLCA;
```
INSERT

The INSERT statement inserts rows into a table or view or activates the INSTEAD OF INSERT trigger. The table or view can be at the current server or any DB2 subsystem with which the current server can establish a connection. Inserting a row into a view inserts the row into the table on which the view is based if no INSTEAD OF INSERT trigger is defined on the specified view. If an INSTEAD OF INSERT trigger is defined, the trigger is activated instead of the INSERT statement.

There are three forms of this statement:

- The INSERT via VALUES form is used to insert a single row into the table or view using the values provided or referenced.
- The INSERT via SELECT form is used to insert one or more rows into the table or view using values from other tables, or views, or both.
- The INSERT via FOR n ROWS form is used to insert multiple rows into the table or view using values provided or referenced. Although not required, the values can come from host-variable arrays. This form of INSERT is supported in SQL procedure applications. However, since host-variable arrays are not supported in SQL procedure applications, the support is limited to insertion of scalar values.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

Authority requirements depend on whether the object identified in the statement is a user-defined table, a catalog table for which inserts are allowed, or a view:

When a user-defined table is identified: The privilege set must include at least one of the following:

- The INSERT privilege on the table
- Ownership of the table
- DBADM authority on the database that contains the table
- SYSADM authority
- DATAACCESS authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

When a catalog table is identified: The privilege set must include at least one of the following:

- ACCESSCTRL authority
- DATAACCESS authority
- DBADM authority on the catalog database
- SQLADM authority
- SYSCTRL authority
- SYSADM authority
- System DBADM authority
When a view is identified: The privilege set must include at least one of the following:

- DATAACCESS authority
- INSERT privilege on the view
- SYSADM authority

The owner of a view, unlike the owner of a table, might not have INSERT authority on the view (or can have INSERT authority without being able to grant it to others). The nature of the view itself can preclude its use for INSERT. For more information, see the discussion of authority in “CREATE VIEW” on page 1862.

If the INSERT statement is embedded in a SELECT statement, the privilege set must include the SELECT privilege on the table or view.

If a fullselect is specified, the privilege set must include authority to execute the fullselect. For more information about the authorization rules, see “Authorization” on page 1098.

If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 152 on page 1171 (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 95.)

Notes:
1 The FOR n ROWS clause must be specified for a static multiple-row-insert. However, this clause is optional for a dynamic INSERT statement. For a dynamic statement, the FOR n ROWS clause is specified on the EXECUTE statement.
2 The ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION clauses can be specified for a static multiple-row-insert. However, this clause must not be specified for a dynamic INSERT statement. For a dynamic statement, the ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION clause is specified as an attribute on the PREPARE statement.

Description

**INTO table-name or view-name**

Identifies the object of the INSERT statement. The name must identify a table or view that exists at the current server. The name must not identify:

- An auxiliary table
- A catalog table
- A directory table
- A read-only view unless an instead of trigger is defined for the insert operation on the view. (For a description of a read-only view, see "CREATE VIEW" on page 1862)
- A view column that is derived from a constant, expression, or scalar function
- A view column that is derived from the base table column as some other column of the view
- A materialized query table
- A table that is implicitly created for an XML column
In an IMS or CICS application, the DB2 subsystem that contains the identified table or view must be a remote server that supports two-phase commit.

column-name,...

Specifies the columns for which insert values are provided. Each name must identify a column of the table or view. The columns can be identified in any order, but the same column must not be identified more than one time. A view column that cannot accept insert values must not be identified. If the object of the INSERT statement is a view with columns that cannot accept insert values, a list of column names must be specified, and the list must not identify these columns. If a qualifier is specified, it must be valid (that is, the table name must be the table or view name specified after the INTO keyword, and if a qualifier is specified for the table name, it must match the default qualifier).

Omission of the column list is an implicit specification of a list in which every column of the table (that is not defined as implicitly hidden) or view is identified in left-to-right order. This list is established when the statement is prepared and therefore does not include columns that were added to the table after the statement was prepared.

The effect of a rebind on INSERT statements that do not include a column list is that the implicit list of names is re-established. Therefore, the number of columns into which data is inserted can change and cause an error.

include-column

Specifies a set of columns that are included, along with the columns of table-name or view-name, in the result table of the INSERT statement when it is nested in the FROM clause of the outer fullselect that is used in a subselect, a SELECT statement, or in a SELECT INTO statement. The included columns are appended to the end of the list of columns that is identified by table-name or view-name.

INCLUDE

Introduces a list of columns that is to be included in the result table of the INSERT statement. The included columns are only available if the INSERT statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement.

column-name

Specifies the name for a column of the result table of the INSERT statement that is not the same name as another included column nor a column in the table or view that is specified in table-name or view-name.

data-type

Specifies the data type of the included column. The included columns are nullable.

built-in-type

Specifies a built-in data type. See "CREATE TABLE" on page 1730 for a description of each built-in type.

distinct-type

Specifies a distinct type. Any length, precision, or scale attributes for the column are those of the source type of the distinct type as specified by using the CREATE TYPE statement.

OVERRIDING USER VALUE

Specifies that the value specified in the VALUES clause or produced by a fullselect for a column that is defined as either GENERATED ALWAYS or GENERATED BY DEFAULT is ignored. Instead, a system-generated value is inserted, overriding the user-specified value.
If OVERRIDING USER VALUE is specified, the implicit or explicit list of column must include a column that is defined as either GENERATED ALWAYS or GENERATED BY DEFAULT. For example, a ROWID column, an identity column, or a row change timestamp column.

VALUES
Specifies one new row in the form of a list of values. The number of values in the VALUES clause must be equal to the number of names in the column list and the columns that are identified in the INCLUDE clause. The first value is inserted in the first column in the list, the second value in the second column, and so on. If more than one value is specified, the list of values must be enclosed in parentheses. Assignments to included columns are only processed when the INSERT statement is nested in the FROM clause in a SELECT statement or a SELECT INTO statement.

expression
Any expression of the type described in “Expressions” on page 246. The expression must not include a column name. If expression is a host variable, the host variable can identify a structure. Any host variable or structure that is specified must be described in the application program according to the rules for declaring host structures and variables.

If expression is a host variable, it can include an indicator variable or an indicator array (in the case of a host structure). When extended indicator variables are enabled, an expression must not be more complex than a reference to a single host variable if the indicator is set to an extended indicator value of default (-5) or unassigned (-7). In addition:

- A CAST specification can be used if either of the following is true:
  - The target column is defined as nullable.
  - The target column is defined as NOT NULL with a non-null default, the source of the CAST specification is a single host variable, and the data attributes (data type, length, precision, and scale) of the host variable are the same as the result of the cast specification.

- A scalar fullselect can be used if either of the following is true for each expression in the select list of the fullselect:
  - The target column that corresponds to the expression is defined as nullable.
  - The expression is not more complex than a reference to a single host variable for which the indicator is set to an extended indicator value of default (-5) or unassigned (-7), or the expression is a CAST specification which would have been valid as a stand-alone expression.

DEFAULT
The default value that is assigned to the column. If the column is a ROWID column, an identity column, a row-begin column, a row-end column, or a transaction-start-ID column, DB2 will generate a value for the column. You can specify DEFAULT only for columns that have an assigned default value, ROWID columns, and identity columns.

For information on default values of data types, see the description of the DEFAULT clause for “CREATE TABLE” on page 1730.

NULL
Specifies the null value as the value of the column. Specify NULL only for nullable columns.
If the implicit or explicit list of columns includes a ROWID, an identity column, or a row change timestamp column that was defined as GENERATED ALWAYS, you must specify DEFAULT unless you specify the OVERRIDING USER VALUE clause to indicate that any user-specified value will be ignored and a unique system-generated value will be inserted.

For a ROWID or identity column that is defined as GENERATED BY DEFAULT, you can specify a value. However, a value can be inserted into ROWID column defined BY DEFAULT only if a single-column unique index is defined on the ROWID column and the specified value is a valid row ID value that was previously generated by DB2. When a value is inserted into an identity column defined BY DEFAULT, DB2 does not verify that the specified value is a unique value for the column unless the identity column has a single-column unique index.

Although an implicitly hidden DOCID column for XML values is defined as GENERATED ALWAYS, you can include the DOCID column in the explicit list of columns and specify a value for it. However, DB2 will ignore the value.

**WITH common-table-expression**

Specifies a common table expression. For an explanation of common table expression, see "common-table-expression" on page 1150.

**fullselect**

Specifies a set of new rows in the form of the result table of a fullselect. If the result table is empty, SQLCODE is set to +100, and SQLSTATE is set to '02000'.

The base object of the INSERT statement and the base object of the fullselect or any subquery of the fullselect can be the same table. In this case, the fullselect is evaluated completely before any rows are inserted.

For an explanation of fullselect, see “fullselect” on page 1141.

The number of columns in the result table must be equal to the number of names in the column list and the columns that are identified in the INCLUDE clause. The value of the first column of the result is inserted in the first column in the list, the second value in the second column, and so on. Any values that are produced for a generated column must conform to the rules that are described for those columns under the VALUES clause. Assignments to included columns are only processed when the INSERT statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement.

If the expression that specifies the value of a result column is a variable, the host variable can include an indicator variable. When extended indicator variables are enabled, the target column that corresponds to an expression in the select list of the fullselect that involves a host variable with an extended indicator value of default (-5) or unassigned (-7), must be defined as nullable and either of the following expressions:

- The expression must not be more complex than a reference to a single host variable.
- The expression must be a CAST specification with the following characteristics:
  - The source of the CAST specification must be a single host variable.
  - The data attributes (data type, length, precision, and scale) of the host variable are the same as the result of the cast specification.

If the object table is self-referencing, the fullselect must not return more than one row.
**isolation-clause**

Specifies the isolation level that is used when the fullselect is executed.

**WITH**

Introduces the isolation level, which can be one of the following values:

- **RR** Repeatable read
- **RS** Read stability
- **CS** Cursor stability

The default isolation level of the statement is the isolation level of the package or plan in which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

**QUERYNO integer**

Specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO column of the plan table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If the clause is omitted, the number that is associated with the SQL statement is the statement number that is assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Using the QUERYNO clause to assign unique numbers to the SQL statements in a program is helpful:

- For simplifying the use of optimization hints for access path selection
- For correlating SQL statement text with EXPLAIN output in the plan table

For information about using optimization hints, such as enabling the system for optimization hints and setting valid hint values, and for information about accessing the plan table, see Managing DB2 Performance.

**multiple-row-insert**

**VALUES**

Specifies the items for the rows to be inserted. The number of items in the VALUES clause must equal the number of names in the implicit or explicit column list. The first item in the list provides the value (or values) for the first column in the list. The second item in the list provides the value (or values) for the second column, and so on.

**expression**

Any expression of the type described in "Expressions" on page 246. The expression must not include a column name. For each row that is inserted, the corresponding column is assigned the value of the expression.

**host-variable-array**

Each host-variable array must be defined in the application program in accordance with the rules for declaring an array. A host-variable array contains the data for a column of table that is a target of the INSERT. The number of rows to be inserted must be less than or equal to the dimension of each of the host-variable arrays.

An optional indicator array can be specified for each host-variable array. It should be specified if the SQLTYPE of any SQLVAR occurrence indicates
that the SQLVAR is nullable. The indicators must be small integers. The indicator array must be large enough to contain an indicator for each row of input data.

If extended indicator variables are enabled, the extended indicator variable values of DEFAULT or UNASSIGNED can be used inside the indicator array.

**DEFAULT**

Specifies that the default value is assigned to the column. For each row inserted, the corresponding column is assigned its default value. DEFAULT can be specified only for columns that have a default value. For information on default values of data types, see the description of the DEFAULT clause for “CREATE TABLE” on page 1730.

**NULL**

Specifies the null value as the value of the column in each row inserted. For each row inserted, the corresponding column is assigned the NULL value. Specify NULL only for nullable columns.

**FOR host-variable or integer-constant ROWS**

Specifies the number of rows to be inserted. For a dynamic INSERT statement, this clause can be specified on the EXECUTE statement. For more information, see the EXECUTE statement. However, this clause is required when a dynamic SELECT statement contains more than one multiple-row INSERT statement.

host-variable or integer-constant is assigned to an integral value k. If host-variable is specified, it must be an exact numeric type with scale zero, and must not include an indicator variable. Furthermore, k must be in the range, 0<k<=32767. k rows are inserted into the target table from the specified source data.

If a parameter marker is specified in this clause, a value must be provided with the USING clause of the associated EXECUTE or OPEN statement.

**ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION**

Specifies whether all of the rows should be inserted as an atomic operation or not.

**ATOMIC**

Specifies that if the insert for any row fails, all changes made to the database by any of the inserts, including changes made by successful inserts, are undone. This is the default.

**NOT ATOMIC CONTINUE ON SQLEXCEPTION**

Specifies that, regardless of the failure of any particular insert of a row, the INSERT statement will not undo any changes made to the database by the successful inserts of other rows, and inserting will be attempted for subsequent rows. However, the minimum level of atomicity is at least that of a single insert (that is, it is not possible for a partial insert to complete), including any triggers that might have been executed as a result of the INSERT statement.

This clause is only valid for a static INSERT statement. This clause must also not be specified if the INSERT statement is contained within a SELECT statement. For a dynamic INSERT statement, specify the clause on the PREPARE statement. For more information, see “PREPARE” on page 2106.
Notes

Insert rules:
Insert values must satisfy the following rules. If they do not, or if any other errors occur during the execution of the INSERT statement, no rows are inserted and the position of the cursors are not changed.

- **Default values.** The value inserted in any column that is not in the column list is the default value of the column. Columns without a default value must be included in the column list. Similarly, if you insert into a view, the default value is inserted into any column of the base table that is not included in the view. Hence, all columns of the base table that are not in the view must have a default value.

- **Length.** If the insert value of a column is a number, the column must be a numeric column with the capacity to represent the integral part of the number. If the insert value of a column is a string, the column must be either a string column with a length attribute at least as great as the length of the string, or a datetime column if the string represents a date, time, or timestamp.

- **Assignment.** Insert values are assigned to columns in accordance with the assignment rules described in [Chapter 2, “Language elements,” on page 75](#).

- **Uniqueness constraints.** If the identified table or the base table of the identified view has one or more unique indexes, each row inserted into the table must conform to the constraints imposed by those indexes.

- **Referential constraints.** Each nonnull insert value of a foreign key must be equal to some value of the parent key of the parent table in the relationship.

- **Check constraints.** The identified table or the base table of the identified view might have one or more check constraints. Each row inserted must conform to the conditions imposed by those constraints. Thus, each check condition must be true or unknown.

- **Field and validation procedures.** If the identified table or the base table of the identified view has a field or validation procedure, each row inserted must conform to the constraints imposed by that procedure.

- **Indexes with VARBINARY columns.** If the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type, that index column cannot specify the DESC attribute. To use the SQL data change operation on the identified table, either drop the index or alter the data type of the column to BINARY and then rebuild the index.

- **Views and the WITH CHECK OPTION.** For views defined with WITH CHECK OPTION, each row you insert into the view must conform to the definition of the view. If the view you name is dependent on other views whose definitions include WITH CHECK OPTION, the inserted rows must also conform to the definitions of those views. For an explanation of the rules governing this situation, see [“CREATE VIEW” on page 1862](#).

For views that are not defined with WITH CHECK OPTION, you can insert rows that do not conform to the definition of the view. Those rows cannot appear in the view but are inserted into the base table of the view.

- **Omitting the column list.** When you omit the column list, you must specify a value for every column that was present in the table when the INSERT statement was bound or (for dynamic execution) prepared.
Triggers. An INSERT statement might cause triggers to be activated. A trigger might cause other statements to be executed or raise error conditions based on the insert values. If an INSERT statement for a view activates an INSTEAD OF trigger, the validity, referential integrity, and check constraints are checked against the data changes that are performed in the trigger, and not against the definition of the view that activates the trigger or the definition of the underlying tables or views.

When triggers are processed for an INSERT statement that inserts multiple rows depends on the atomicity option that is in effect for the INSERT statement:

- **ATOMIC.** The inserts are processed as a single statement. Any statement level triggers are activated one time for the statement, and the transition tables will include all of the rows that were inserted.

- **NOT ATOMIC CONTINUE ON SQLEXCEPTION.** The inserts are processed separately. Any statement level triggers are processed for each row that is inserted, and the transition table includes the individual row that is inserted. When errors are encountered with this option in effect, processing continues, and some of the specified rows will not be inserted. In this case, if an insert trigger is defined on the underlying base table, the statement level triggers will only be activated for rows that were successfully inserted.

Regardless of the failure of any particular source row, the INSERT statement will not undo any changes that are made to the database by the statement. Insert will be attempted for rows that follow the failed row. However, the minimum level of atomicity is at least that of a single source row (that is, it is not possible for a partial insert operation to complete), including any triggers that might have been activated as a result of the INSERT statement.

Inserting XML documents:

When XML documents are inserted into a table that contains an XML index, the XML values that are inserted into the index are cast to the data type that is specified on the CREATE INDEX statement. If the XML value cannot be cast to the specified data type, the XML value is ignored for the XML index but the document is still inserted into the table. If the data type that is specified for casting is DECIMAL, values can be rounded when they are inserted into the index. If the index is unique, the rounding that happens during the cast can result in duplicate values.

Number of rows inserted:

Normally, after an INSERT statement completes execution, the value of SQLERRD(3) in the SQLCA is the number of rows inserted. The value in SQLERRD(3) does not include the number of rows that were inserted as the result of a trigger.

For a complete description of the SQLCA, including exceptions to the above statement, see “SQL communication area (SQLCA)” on page 2377.

Nesting user-defined functions or stored procedures:

An INSERT statement can implicitly or explicitly refer to user-defined functions or stored procedures. This is known as nesting of SQL statements. A user-defined function or stored procedure that is nested within the INSERT must not access the table into which you are inserting values.

Locking:

Unless appropriate locks already exist, one or more exclusive locks are acquired at the execution of a successful insert operation. Until a commit
or rollback operation releases the locks, only the application process that performed the insert can access the inserted row. If LOBs are not inserted into the row, application processes that are running with uncommitted read can also access the inserted row. The locks can also prevent other application processes from performing operations on the table. However, application processes that are running with uncommitted read can access locked pages and rows.

Locks are not acquired on declared temporary tables.

Inserting rows into a table with multilevel security:
When you insert rows into a table with multilevel security, DB2 determines the value for the security label column of the row according to the following rules:

- If the user (the primary authorization ID) has write-down privilege or write-down control is not enabled, the user can set the security label for the row to any valid security label. The value that is specified must be assignable to a column that is defined as CHAR(8) FOR SBCS DATA NOT NULL. If the user does not specify a value for the security label or specifies DEFAULT, the security label of the row becomes the same as the security label of the user.

- If the user does not have write-down privilege and write-down control is enabled, the security label of the row becomes the same as the security label of the user.

Inserting rows into a table for which row or column access control is enforced:
When an INSERT statement is issued for a table for which row or column access control is enforced, the rules specified in the enabled row permissions or column masks determine whether the row can be inserted. Typically those rules are based on the authorization ID or role of the process. The following rules describe how the enabled row permissions and column masks are used during INSERT:

- A row to be inserted must not be effected by enabled column masks whose columns are referenced while deriving the source values for the row.

  When a column is referenced while deriving the values of a new row, if the column has an enabled column mask, the masked value is used to derive the new values. If the object table is also column access control activated, the column mask that is applied to derive the new values must ensure that the evaluation of the access control rules defined in the column mask resolves the column to itself, not to a constant or to an expression. If the column mask does not mask the column to itself, the new value cannot be used for insert and an error is returned at run time.

  If the OVERRIDING USER VALUE clause is specified, the corresponding values in the new row are ignored, and the above rule for column masks is not applicable to those values.

- If the row can be inserted, and there is a BEFORE INSERT trigger for the table, the trigger is activated.

  Within the trigger actions, the new values for insert can be modified in the transition variables. When the values return from the trigger, the final values for the new values are the ones for insert.

- A row to be inserted must conform to the enabled row permissions.

  When multiple enabled row permissions are defined for a table, a row access control search condition is derived by application of the logical OR operator to the search condition in each enabled row permission. A
row that conforms to the enabled row permissions is a row that if the row is inserted it can be retrieved back using the row access control search condition.

Column masks are not applicable in this process.

- If the rows can be inserted, and there is an AFTER INSERT trigger for the table, the trigger is activated.

The preceding rules are not applicable to the include-columns. The include-columns are subject to the rules for the select list because they are not the columns of the object table of the INSERT statement.

Extended indicator variable usage:
When extended indicator variables are enabled, negative indicator values that are outside the range of -1 through -7 must not be specified, and the default and unassigned extended indicator values must not be specified in contexts in which they are not supported.

Extended indicator variables:
In an INSERT statement, a value of unassigned has the effect of setting the column to its default value.

Extended indicator variables and insert triggers:
The activation of insert triggers is not affected by the use of extended indicator variables. If all columns in the implicit or explicit column list have been assigned an extended indicator value of unassigned or default, an insert where all columns have their respective default values is attempted, and, if successful, the insert trigger is activated.

Table space data compression during an insert operation:
If the table space is defined with the COMPRESS YES option, and data is inserted into a table in the table space, the first rows are stored uncompressed. When a DB2-determined amount of data has been inserted into the table, a compression dictionary is created and stored in the table space. The rows that are inserted into the table after the dictionary is created are stored compressed using the compression dictionary.

Generated columns:
A generated column that is defined as GENERATED ALWAYS should not be specified in the column-list unless the corresponding entry in the VALUES list is DEFAULT or an extended indicator that specifies that a default value is to be assigned. Specify the OVERriding user value clause to indicate that any user-specified value should be ignored and DB2 should assign the default value when a row is inserted.

Inserting rows into system-period temporal tables:
When a row is inserted into a system-period temporal table, DB2 assigns values to the following columns as indicated:

- A row-begin column is assigned a value that is generated by reading the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to a row-begin column or a transaction-start-ID column in a table. This also occurs when a row in a system-period temporal table is deleted. DB2 ensures the uniqueness of the generated values for a row-begin column across transactions. If multiple rows are inserted within a single SQL transaction, the values for the row-begin column are the same for all of the rows and are unique from the values that are generated for the column by another transaction.

- A row-end column is assigned a value for the data type of the column.
A transaction-start-ID column is assigned a unique value per unit of work or the null value. The null value is assigned to the transaction-start-ID column if the column is nullable. Otherwise, the value is generated by reading the time-of-day clock during execution of the first data change statement in the unit of work that requires a value to be assigned to a row-begin column or transaction-start-ID column in a table. This also occurs when a row in a system-period temporal table is deleted. If multiple rows are inserted within a single SQL transaction, the values for the transaction-start-ID column are the same for all the rows and are unique from the values that are generated for the column by another unit of work.

Inserting rows into application-period temporal tables:
When a row is inserted into an application-period temporal table, an error is returned if the period that is defined by the begin column and end column of the application period overlap with the period that is defined by the begin column and end column of the application period for another row in the table.

INSERT without a column list:
An INSERT statement without a column list does not include implicitly hidden columns, so columns that are defined as implicitly hidden must have a defined default value.

Inserting a row into catalog table SYSIBM.SYSSTRINGS:
If the object table is SYSIBM.SYSSTRINGS, only certain values can be specified, as described in Specifying conversion procedures (DB2 Administration Guide).

Datetime representation when using datetime registers:
As explained in Datetime special registers when two or more datetime registers are implicitly or explicitly specified in a single SQL statement, they represent the same point in time. This is also true when multiple rows are inserted. When ATOMIC is in effect for the INSERT statement, the special registers are evaluated one time for the processing of the statement. If NOT ATOMIC is in effect, the special registers are evaluated as each row of source data is processed.

Non-atomic processing of an INSERT statement:
When NOT ATOMIC is specified the rows of source data are processed separately. Any references to special registers, sequence expressions, and functions in the INSERT statement are evaluated as each row of source data is processed, Statement level triggers are activated as each row of source data is processed.

If one or more errors occur during the execution of an insert of a row, processing continues. The row that was being inserted at the time of the error is not inserted. Execution continues with the next row to be inserted, and any other changes made during the execution of the multiple-row INSERT statement are not backed out. However, the insert of an individual row is an atomic action.

Diagnostics information for a multiple-row INSERT statement:
A single multiple-row INSERT statement might encounter multiple conditions. These conditions can be errors or warnings. Use the GET DIAGNOSTICS statement to obtain information about all of the conditions that are encountered for one of these INSERT statements. See GET DIAGNOSTICS on page 2008 for more information.
If a warning occurs during the execution of an insert of a row, processing continues.

When multiple errors or warnings occur with a non-atomic INSERT statement, diagnostic information for each row is available using the GET DIAGNOSTICS statement. The SQLSTATE and SQLCODE reflect a summary of what happened during the INSERT statement:

- **SQLSTATE 01659, SQLCODE +252.** All rows were inserted, but one or more warnings occurred.
- **SQLSTATE 22529, SQLCODE -253.** At least one row was successfully inserted, but one or more errors occurred. Some warnings might also have occurred.
- **SQLSTATE 22530, SQLCODE -254.** No row was inserted. One or more errors occurred while trying to insert multiple rows of data.
- **SQLSTATE 429BI, SQLCODE -20252.** More errors occurred that DB2 is capable of recording. Statement processing is terminated.

When ATOMIC is in effect, if an insert value violates any constraints or if any other error occurs during the execution of an insert of a row, all changes made during the execution of the multiple-row INSERT statement are backed out. The SQLCA reflects the last warning encountered.

After an INSERT statement that inserts multiple rows of data, both atomic and non-atomic, information is returned to the program through the SQLCA. The SQLCA is set as follows:

- **SQLCODE** contains the SQLCODE.
- **SQLSTATE** contains the SQLSTATE.
- **SQLERRD3** contains the number of rows actually inserted. SQLERRD3 is the number of rows inserted, if this is less than the number of rows requested, then an error occurred.
- **SQLWARN** flags are set if they were set during any single insert operation.

The SQLCA is used to return information on errors and warnings found during a multiple-row insert. If indicator arrays are provided, the indicator variable values are used to determine if the value from the host-variable array, or NULL, will be used. The SQLSTATE contains the warning from the last data mapping error.

**Specifying the number of rows for a dynamic multiple-row INSERT statement:**

Be aware of these considerations when specifying the number of rows to be inserted with a dynamic multiple-row INSERT statement that uses host-variable arrays:

- The **FOR n ROWS** clause can be specified as part of an INSERT statement or as part of an EXECUTE statement, but not both.
- In the INSERT statement, you can specify a numeric constant in the **FOR n ROWS** clause to indicate the number of rows to be inserted or specify a parameter marker to indicate that the number of rows will be specified with the associated EXECUTE or OPEN statement. A multiple-row INSERT statement that is contained within a SELECT statement must include a **FOR n ROWS** clause.
- In an EXECUTE statement, when a dynamic INSERT statement is not contained within a SELECT statement, the number of rows can be specified with either the **FOR n ROWS** clause or the **USING** clause of the EXECUTE statement.
If the INSERT statement did not contain a FOR n ROWS clause, a value for the number of rows to be inserted can be specified in the FOR n ROWS clause of the EXECUTE statement with a numeric constant or host variable.

If a parameter marker was specified as part of a FOR n ROWS clause in the INSERT statement, a value for the number of rows must be specified with the USING clause of the EXECUTE statement.

In an OPEN statement, when a dynamic SELECT statement contains one or more INSERT statements that have FOR n ROWS clauses with parameter markers, the values for the number of rows to be inserted (that is, the values for the parameter markers) must be specified with the USING clause of the OPEN statement.

DRDA considerations for a multiple-row INSERT statement:
DB2 for z/OS limits the size of user data and control information to 10M (except for LOBs, which are processed in a different data stream) for a single multiple-row INSERT statement using host-variable arrays.

Multiple-row insert and fetch statements are supported by any requester or server that supports the DRDA Version 3 protocols. If an attempt is made to issue a multiple-row INSERT or FETCH statement on a server that does not support DRDA Version 3 protocols, an error occurs.

When a multiple-row INSERT statement is executed at a DB2 for z/OS requester, the number of rows being inserted at the requester might not be known in some cases. These cases include:

- The FOR n ROWS clause contains a constant value for n for either a static or dynamic INSERT statement.
- Host variables are specified on the USING clause of an EXECUTE statement for a dynamic INSERT statement.

In either case, if the number of rows that is being inserted is not known, the requester might flow more data than is required to the server. The number of rows that is actually inserted will be correct because the server knows the correct number of rows to insert. However, performance can be adversely affected. Consider the following scenario:

```c
... long serial_num [10];
struct {
    short len;
    char data [18];
} name [20]
...
EXEC SQL INSERT INTO T1 VALUES (:serial_num, :name) FOR 5 ROWS
```

At the requester, when this statement is executed, the number of rows being inserted, 5, is not known. As a result, the requester will flow 10 values for serial_num and 10 values for name to the server (because the maximum number of rows that can be inserted without error is 10, which is the size of the smallest host-variable array).

Use the following programming techniques to avoid or minimize problems:

- Avoid using constant values for n in the FOR n ROWS clause of INSERT statements. For static INSERT statements, this technique ensures that the value for n will be known at the requester.
- For dynamic INSERT statements, use the USING DESCRIPTOR clause instead of the USING host-variables clause on the EXECUTE statement. If
a USING DESCRIPTOR clause is used on the EXECUTE statement, the value for 'n' must be indicated in the DESCRIPTOR.

• If neither of the above methods can be used:
  – Declare your host-variable arrays as small as possible, or indicate that the size of your host-variable arrays are the size of 'n' in your descriptor. This avoids sending large numbers of host-variable-array entries that will not be used to the server.
  – Ensure that varying length string arrays are initialized to a length of 0 (zero). This minimizes the amount of data that is sent to the server.
  – Ensure that decimal host-variable arrays are initialized to valid values. This avoids a negative SQLCODE from being returned if the requester encounters invalid decimal data.

Other SQL statements in the same unit of work:
The following statements cannot follow an INSERT statement in the same unit of work:

• An ALTER TABLE statement that changes the data type of a column (ALTER COLUMN SET DATA TYPE)
• An ALTER INDEX statement that changes the padding attribute of an index with varying-length columns (PADDED to NOT PADDED or vice versa)
• A CREATE TABLE statement that creates an accelerator-only table.
• An INSERT, UPDATE, or DELETE statement that updates accelerator-only tables from a different accelerator.

Examples

Example 1: Insert values into sample table DSN8A10.EMP.

```sql
INSERT INTO DSN8A10.EMP
    VALUES ('000205', 'MARY', 'T', 'SMITH', 'D11', '2866',
            '1981-08-10', 'ANALYST', '16', 'F', '1956-05-22',
            16345,500,2300);
```

Example 2: Assume that SMITH.TEMPEMPL is a created temporary table. Populate the table with data from sample table DSN8A10.EMP.

```sql
INSERT INTO SMITH.TEMPEMPL
    SELECT * FROM DSN8A10.EMP;
```

Example 3: Assume that SESSION.TEMPEMPL is a declared temporary table. Populate the table with data from department D11 in sample table DSN8A10.EMP.

```sql
INSERT INTO SESSION.TEMPEMPL
    SELECT * FROM DSN8A10.EMP
    WHERE WORKDEPT='D11';
```

Example 4: Insert a row into sample table DSN8A10.EMP_PHOTO_RESUME. Set the value for column EMPNO to the value in host variable HV_ENUM. Let the value for column EMP_ROWID be generated because it was defined with a row ID data type and with clause GENERATED ALWAYS.

```sql
INSERT INTO DSN8A10.EMP_PHOTO_RESUME(EMPNO, EMP_ROWID)
    VALUES (:HV_ENUM, DEFAULT);
```

You can only insert user-specified values into ROWID columns that are defined as GENERATED BY DEFAULT and not as GENERATED ALWAYS. Therefore, in the
above example, if you were to try to insert a value into EMP_ROWID instead of
specifying DEFAULT, the statement would fail unless you also specify
OVERRIDING USER VALUE. For columns that are defined as GENERATED
ALWAYS, the OVERRIDING USER VALUE clause causes DB2 to ignore any
user-specified value and generate a value instead.

For example, assume that you want to copy the rows in
DSN8A10.EMP_PHOTO_RESUME to another table that has a similar definition
(both tables have a ROWID columns defined as GENERATED ALWAYS). For the
following INSERT statement, the OVERRIDING USER VALUE clause causes DB2
to ignore the EMP_ROWID column values from DSN8A10.EMP_PHOTO_RESUME
and generate values for the corresponding ROWID column in
B.EMP_PHOTO_RESUME.

```
INSERT INTO B.EMP_PHOTO_RESUME
    OVERRIDING USER VALUE
SELECT * FROM DSN8A10.EMP_PHOTO_RESUME;
```

*Example 5:* Assume that the T1 table has one column. Insert a variable (:hv) number
of rows of data into the T1 table. The values to be inserted are provided in a
host-variable array (:hva).

```
EXEC SQL INSERT INTO T1 FOR :hv ROWS VALUES (:hva:hvind) ATOMIC;
```

In this example, :hva represents the host-variable array and :hvind represents the
array of indicator variables.

*Example 6:* Assume that the T2 table has 2 columns, C1 is a SMALL INTEGER
column, and C2 is an INTEGER column. Insert 10 rows of data into the T2 table.
The values to be inserted are provided in host-variable arrays :hva1 (an array of
INTEGERS) and :hva2 (an array of DECIMAL(15,0) values). The data values for
:hva1 and :hva2 are represented in Table 205.

**Table 205. Data values for :hva1 and :hva2**

<table>
<thead>
<tr>
<th>Array entry</th>
<th>:hva1</th>
<th>:hva2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>32768</td>
</tr>
<tr>
<td>2</td>
<td>-12</td>
<td>90000</td>
</tr>
<tr>
<td>3</td>
<td>79</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>32768</td>
<td>19</td>
</tr>
<tr>
<td>5</td>
<td>8</td>
<td>36</td>
</tr>
<tr>
<td>6</td>
<td>5</td>
<td>24</td>
</tr>
<tr>
<td>7</td>
<td>400</td>
<td>36</td>
</tr>
<tr>
<td>8</td>
<td>73</td>
<td>4000000000</td>
</tr>
<tr>
<td>9</td>
<td>-200</td>
<td>2000000000</td>
</tr>
<tr>
<td>10</td>
<td>35</td>
<td>88</td>
</tr>
</tbody>
</table>

```
EXEC SQL INSERT INTO T2 (C1, C2)
    FOR 10 ROWS VALUES (:hva1:hvind1, :hva2:hvind2)
    NOT ATOMIC CONTINUE ON SQLEXCEPTION;
```

After execution of the INSERT statement, the following information will be in the
SQLCA:

- SQLCODE = -253
- SQLSTATE = 22529
- SQLERRD3 = 8
Although an attempt was made to insert 10 rows, only 8 rows of data were inserted. Processing continued after the first failed insert because NOT ATOMIC CONTINUE ON SQLEXCEPTION was specified. You can use the GET DIAGNOSTICS statement to find further information, for example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
```

The result of this statement is num_rows = 8 and num_cond = 2 (2 conditions).

```
GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
  :sqlcode = DB2_RETURNED_SQLCODE,
  :row_num = DB2_ROW_NUMBER;
```

The result of this statement is sqlstate = 22003, sqlcode = -302, and row_num = 4.

```
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
  :sqlcode = DB2_RETURNED_SQLCODE,
  :row_num = DB2_ROW_NUMBER;
```

The result of this statement is sqlstate = 22003, sqlcode = -302, and row_num = 8.

**Example 7:** Assume the above table T2 with two columns. C1 is a SMALL INTEGER column, and C2 is an INTEGER column. Insert 8 rows of data into the T2 table. The values to be inserted are provided in host-variable arrays :hva1 (an array of INTEGERS) and :hva2 (an array of DECIMAL(15,0) values.) The data values for :hva1 and :hva2 are represented in Table 205 on page 2079.

```
EXEC SQL INSERT INTO T2 (C1, C2)
  FOR 8 ROWS VALUES (:hva1:hvind1, :hva2:hvind2)
  NOT ATOMIC CONTINUE ON SQLEXCEPTION;
```

After execution of the INSERT statement, the following information will be in the SQLCA:

- SQLCODE = -253
- SQLSTATE = 22529
- SQLERRD3 = 6

Although an attempt was made to insert 8 rows, only 6 rows of data were inserted. Processing continued after the first failed insert because NOT ATOMIC CONTINUE ON SQLEXCEPTION was specified. You can use the GET DIAGNOSTICS statement to find further information, for example:

```
GET DIAGNOSTICS :num_rows = ROW_COUNT, :num_cond = NUMBER;
```

The result of this statement is num_rows = 68 and num_cond = 2 (2 conditions).

```
GET DIAGNOSTICS CONDITION 2 :sqlstate = RETURNED_SQLSTATE,
  :sqlcode = DB2_RETURNED_SQLCODE,
  :row_num = DB2_ROW_NUMBER;
```

The result of this statement is sqlstate = 22003, sqlcode = -302, and row_num = 4.

```
GET DIAGNOSTICS CONDITION 1 :sqlstate = RETURNED_SQLSTATE,
  :sqlcode = DB2_RETURNED_SQLCODE,
  :row_num = DB2_ROW_NUMBER;
```

The result of this statement is sqlstate = 22003, sqlcode = -302, and row_num = 8.

**Example 8:** Assume that table T1 has two columns. Insert a variable number (:hvn) or rows into T1. The values to be inserted are in host-variable arrays :hva and :hvb. In this example, the INSERT statement is contained within the SELECT statement of cursor CS1. The SELECT statement makes use of two other input host variables (:hv1 and :hv2) in the WHERE clause. Either a static or dynamic INSERT statement can be used.
-- Static INSERT statement:
DECLARE CS1 CURSOR WITH ROWSET POSITIONING FOR
    SELECT *
    FROM FINAL TABLE
    (INSERT INTO T1 VALUES (:hva, :hvb) FOR :hvn ROWS)
    WHERE C1 > :hv1 AND C2 < :hv2;
OPEN CS1;
-- Dynamic INSERT statement:
PREPARE INSSTMT FROM
'SELECT *
FROM FINAL TABLE
(INsert INTO T1 VALUES (?, ?) FOR ? ROWS)
WHERE C1 > ? AND C2 < ?';
DECLARE CS1 CURSOR WITH ROWSET POSITIONING FOR :INSSTMT;
OPEN CS1 USING :hva, :hvb, :hvn, :hv1, :hv2; (or OPEN CS1 USING DESCRIPTOR ...)

If the host-variable arrays for the multiple-row INSERT statement were to be specified using a descriptor, that descriptor (SQLDA) would have to describe all input host variables in the statement, and the order of the entries in the SQLDA should be the same as the order of the order of the host variables, host-variable arrays, and values for the FOR n ROWS clauses in the statement. For example, given the statement above, the SQLVAR entries in the descriptor must be assigned in the following order: :hvn, :hva, :hvb, :hv1, hv2. In addition, the SQLVAR entries for host-variable arrays must be tagged in the SQLDA as column arrays (by specifying a special value in part of the SQLNAME field for a host variable), and the SQLVAR entry for the number of rows value must be tagged in the SQLDA (by specifying another special value in part of the SQLNAME field for the host variable).
The LABEL statement adds or replaces labels in the descriptions of tables, views, aliases, or columns in the catalog at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privilege set that is defined below must include at least one of the following:

- Ownership of the table, view, or alias
- DBADM authority for its database (tables only)
- SYSADM or SYSCTRL authority
- System DBADM

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 152 on page 1171 (For more details on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 95).

Syntax

```
LABEL ON TABLE table-name IS string-constant
  view-name
ALIAS alias-name
COLUMN table-name.column-name
  view-name.column-name
  
    table-name
  
    view-name
  
    (column-name IS string-constant)
```

Description

**TABLE table-name or view-name**

Identifies the table or view to which the label applies. The name must identify a table or view that exists at the current server. *table-name* must not identify a declared temporary table. The label is placed into the LABEL column of the SYSIBM.SYSTABLES catalog table for the row that describes the table or view.

**ALIAS alias-name**

Identifies the alias to which the label applies. The name must identify an alias that exists at the current server. The label is placed in the LABEL column of the SYSIBM.SYSTABLES catalog table for the row that describes the alias.
COLUMN table-name.column-name or view-name.column-name
Identifies the column to which the label applies. The name must identify a
column of a table or view that exists at the current server. The name must not
identify a column of a declared temporary table. The label is placed in the
LABEL column of the SYSIBM.SYSCOLUMNS catalog table in the row that
describes the column.

Do not use TABLE or COLUMN to define a label for more than one column
in a table or view. Give the table or view name and then, in parentheses, a list
in the form:

    column-name IS string-constant,
    column-name IS string-constant,...

See Example 2 below.

The column names must not be qualified, each name must identify a column
of the specified table or view, and that table or view must exist at the current
server.

IS   Introduces the label you want to provide.

string-constant
Can be any SQL character string constant of up to 30 bytes in length.

Examples

Example 1: Enter a label on the DEPTNO column of table DSN8A10.DEPT.

    LABEL ON COLUMN DSN8A10.DEPT.DEPTNO
    IS 'DEPARTMENT NUMBER';

Example 2: Enter labels on two columns in table DSN8A10.DEPT.

    LABEL ON DSN8A10.DEPT
    (MGRNO IS 'EMPLOYEE NUMBER FOR THE MANAGER',
    ADMRDEPT IS 'ADMINISTERING DEPARTMENT');
LOCK TABLE

The LOCK TABLE statement requests a lock on a table or table space at the current server. The lock is not acquired if the process already holds an appropriate lock.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privilege set that is defined below must include at least one of the following:

- The SELECT privilege on the identified table (the SELECT privilege does not apply to the auxiliary table)
- Ownership of the table
- DBADM authority for the database
- SYSADM or SYSCTRL authority
- DATAACCESS authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 152 on page 171. (For more details on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see “Authorization IDs and dynamic SQL” on page 95.)

Syntax

```
LOCK TABLE table-name
PARTITION integer
IN SHARE MODE EXCLUSIVE
```

Description

`table-name`

Identifies the table to be locked. The name must identify a table that exists at the current server. It must not identify a view, a temporary table (created or declared), an accelerator-only table, a catalog table, or a directory table. The lock might or might not apply exclusively to the table. The effect of locking an auxiliary table is to lock the LOB table space that contains the auxiliary table.

`PARTITION integer`

Identifies the partition of a partitioned table space to lock. The table identified by `table-name` must belong to a partitioned table space. The value specified for `integer` must be an integer that is no greater than the number of partitions in the table space.
IN SHARE MODE
For a lock on a table that is not an auxiliary table, requests the acquisition of a
lock that prevents other processes from executing anything but read-only
operations on the table. For a lock on a LOB table space, IN SHARE mode
requests a lock that prevents storage from being reallocated. When a LOB table
space is locked, other processes can delete LOBs or update them to a null
value, but they cannot insert LOBs with a nonnull value. The type of lock that
the process holds after execution of the statement depends on what lock, if any,
the process already holds.

IN EXCLUSIVE MODE
Requests the acquisition of an exclusive lock for the application process. Until
the lock is released, it prevents concurrent processes from executing any
operations on the table.

Exception: Unless the lock is on a LOB table space, concurrent processes that
are running at an isolation level of uncommitted read (UR) can execute
read-only operations on the table.

Be aware that an exclusive lock on a table space, table, or partition does not
prevent other transactions from holding claims on the locked object.

Notes
Releasing locks:
If LOCK TABLE is a static SQL statement, the RELEASE option of bind
determines when DB2 releases a lock. For RELEASE(COMMIT), DB2
releases the lock at the next commit point. For RELEASE(DEALLOCATE),
DB2 releases the lock when the plan is deallocated (the application ends).

If LOCK TABLE is a dynamic SQL statement, DB2 uses
RELEASE(COMMIT) and releases the lock at the next commit point, unless
the table or table space is referenced by cached dynamic statements.
Caching allows DB2 to keep prepared statements in memory past commit
points. In this case, DB2 holds the lock until deallocation or until the
commit after the prepared statements are freed from memory. Under some
conditions, if a lock is held past a commit point, DB2 demotes the lock
state of a segmented table or a nonsegmented table space to an intent lock
at the commit point.

When you issue the MODIFY DDF PKGREL(BNDOPT) or MODIFY DDF
PKGREL command, the use of processor resources for package allocation
and deallocation is minimized for packages that use database access
threads and are bound with RELEASE(DEALLOCATE). When the MODIFY
DDF PKGREL(BNDOPT) command has been issued, DB2 honors the
RELEASE bind option even for dynamic SQL statements.

Syntax alternatives and synonyms:
For compatibility with previous releases of DB2, PART can be specified as a
synonym for PARTITION.

Example
Obtain a lock on the sample table named DSN8A10.EMP, which resides in a
partitioned table space. The lock obtained applies to every partition and prevents
other application programs from either reading or updating the table.

LOCK TABLE DSN8A10.EMP IN EXCLUSIVE MODE;

Related reference:
- ISOLATION bind option (DB2 Commands)
- RELEASE bind option (DB2 Commands)
- DYNAMICRULES bind option (DB2 Commands)
The MERGE statement updates a target (a table or view, or the underlying tables or views of a fullselect) using the specified input data. Rows in the target that match the input data are updated as specified, and rows that do not exist in the target are inserted. Updating or inserting a row into a view updates or inserts the row into the tables on which the view is based, if no INSTEAD OF trigger is defined on this view.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

**Authorization**

The privileges that are held by the privilege set that is defined below must include at least one of the following privileges:

- SYSADM authority
- Ownership of the table
- DATAACCESS authority
- If the search condition contains a reference to a column of the table or view, the SELECT privilege for the referenced table or view
- If the delete operation is specified, the DELETE privilege for the table or view
- If the insert operation is specified, the INSERT privilege for the table or view
- If the update operation is specified, at least one of the following privileges is required:
  - the UPDATE privilege for the table or view
  - the UPDATE privilege on each column that is updated
  - If the right side of the assignment clause contains a reference to a column of the table or view, the SELECT privilege for the referenced table or view

If the database is implicitly created, the database privileges must be on the implicit database or on DSND04.

If the insert operation or assignment clause includes a subquery, the privileges that are held by the privilege set must also include at least one of the following privileges:

- SYSADM authority
- The SELECT privilege on every table or view that is identified in the subquery
- Ownership of the tables or views that are identified in the subquery
- DATAACCESS authority

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Table 152 on page 1171. (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see Authorization IDs and dynamic SQL.)
Syntax

MERGE INTO table-name
   view-name
   AS correlation-name
   include-columns

USING source-values
ON search-condition

WHEN matching-condition
THEN modification-operation

NOT ATOMIC CONTINUE ON SQLEXCEPTION
QUERYNO integer

include-columns:

INCLUDE column-name data-type

data-type:

built-in-type distinct-type

built-in-type:
source-values:

\[(VALUES \quad \text{values-single-row} \quad \text{AS} \quad \text{correlation-name} \quad (\text{column-name}) \quad )\]

Notes:
1. The NOT ATOMIC clause must be specified when values-multiple-row is specified.

values-single-row:
values-multiple-row:

```
expression
  NULL
  
( expression
  NULL
)
```

Notes:
1. For a static MERGE statement, if FOR n ROWS is not specified, `values-multiple-row` is treated as `values-single-row`. For a dynamic MERGE statement, FOR n ROWS does not need to be specified in the MERGE statement. It can be specified in the EXECUTE statement, but cannot be specified in both the MERGE and EXECUTE statements.

matching-condition:

```
MATCHED
  NOT
```

modification-operation:

```
UPDATE SET assignment-clause
  insert-operation
```

assignment-clause:
Description

**INTO table-name or view-name**
Identifies the target of the insert or update operations of the MERGE statement. The name must identify a table or view that exists at the current server. The name must not identify:
- A catalog table
- A directory table
- A created global temporary table
- A read-only view
- A system-maintained materialized query table
- A table that is implicitly created for an XML column
- An accelerator-only table

If a view is specified as the target of the MERGE statement, the view must not be defined with any INSTEAD OF triggers.

**AS correlation-name**
correlation-name provides an alternate name that can be used when referencing
columns of the intermediate result table. If no `correlation-name` is specified, the name of the intermediate result table is the name of the target table or view of the MERGE statement. Otherwise, the name is the `correlation-name`.

**include-columns**
Specifies a set of columns that are included, along with the columns of the specified table or view, in the result table of the MERGE statement when it is nested in the FROM clause of the outer fullselect that is used in a SELECT statement, or in a SELECT INTO statement. The included columns are appended to the end of the list of columns that are identified by `table-name` or `view-name`. If a value is not specified for an included column, a null value is returned for that column.

**INCLUDE**
Introduces a list of columns that is to be included in the result table of the MERGE statement. The included columns are only available if the MERGE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement. INCLUDE can only be specified when the MERGE statement is nested in the FROM clause of a SELECT statement.

**column-name**
Specifies the name for a column of the result table of the MERGE statement that is not the same name as another included column or a column in the table or view that is specified in `table-name` or `view-name`.

**data-type**
Specifies the data type of the included column. The included columns are nullable.

Columns with the following data types can not be used as INCLUDE columns:

- LONG VARCHAR,
- LONG VARGRAPHIC,
- XML
- LOBs
- distinct types that are based on any of the listed data types.

**built-in-type**
Specifies a built-in data type. See "CREATE TABLE" on page 1730 for a description of each built-in type.

**distinct-type**
Specifies a distinct type. Any length, precision, or scale attributes for the column are those of the source type of the distinct type as specified by using the CREATE TYPE statement.

**USING source-values**
Specifies the row or rows to be merged into the target table or view. VALUES `values-single-row` specifies a single row of source data. VALUES `values-multiple-row` specifies multiple rows of source data.

**expression**
Specifies an expression of the type that is described in "Expressions" on page 246. The expression must not include a column name. The expression must not reference a NEXT VALUE or PREVIOUS VALUE expression. If the expression is a single host variable, the host variable can identify a structure. Any host variable or structure that is specified must be described in the application program according to the rules for declaring host structures and variables.
If the expression is a host variable, or if a host variable is being explicitly cast, the host variable can include an indicator variable or an indicator array (in the case of a host structure). Either indicator variables or indicator arrays can be enabled for extended indicator variables.

To provide a null value, specify the NULL keyword on a CAST specification.

**NULL**

Specifies a null value.

The column of the source-table corresponding to the NULL keyword is used to determine the data type of the null value. The column of the source-table must be referenced elsewhere in the MERGE statement such that its data type can be determined from the context in which it is used, and all such references must resolve to the same data type. References to date-time data types and CHAR or VARCHAR are considered the same type.

**host-variable-array**

Specifies a host variable array. Each host variable array must be defined in the application program in accordance with the rules for declaring an array. A host variable array contains the data to merge into a target column. The number of rows must be less than or equal to the dimension of each of the host variable arrays. An optional indicator array can be specified for each host variable array. An indicator array should be specified if the SQLTYPE of any SQLVAR occurrence indicates that a column is nullable. The indicator array can be enabled for extended indicator variables. The dimension of the indicator array must be large enough to contain an indicator for each row of input data.

A host structure is not supported in **host-variable-array**. **host-variable-array** is supported in C/C++, COBOL, and PL/I.

**FOR host-variable or integer-constant ROWS**

Specifies the number of rows to merge. For a dynamic MERGE statement, this clause can be specified on the EXECUTE statement. host-variable or integer-constant is assigned to a value k. If host-variable is specified, it must be an exact numeric type with a scale of zero and must not include an indicator variable. k must be in the range of 1 to 32767. k rows are merged into the target from the specified source data.

If a parameter marker is specified in **FOR n ROWS**, a value must be provided with the USING clause of the associated EXECUTE statement.

**AS correlation-name**

Specifies a correlation name for the source-values.

**column-name**

Specifies a column name to associate the input data to the SET assignment-clause for an update operation or the VALUES clause for an insert operation.

**ON search-condition**

Specifies join conditions between the source-values and the target table or view.

Each column-name in the search condition must name a column of the target table, view, or source-values. A subquery is not allowed in the search-condition. If a column-name exists in both the target and the source-values, the column name must be qualified.
For each row of the source-values, the search-condition is applied to each row of the target. If the search-condition is evaluated as true and the target is not empty, the specified WHEN MATCHED clause is used. Otherwise, the specified WHEN NOT MATCHED clause is used.

**WHEN MATCHED or WHEN NOT MATCHED**

Specifies the condition under which the modification-operation is run.

**WHEN MATCHED**

Specifies the operation to perform on the rows where the ON search-condition is true and the target is not empty. Only UPDATE can be specified after the THEN clause. WHEN MATCHED must not be specified more than one time.

**WHEN NOT MATCHED**

Specifies the operation to perform on the rows where the ON search-condition is false or unknown, or the target is empty. Only INSERT can be specified after the THEN clause. WHEN NOT MATCHED must not be specified more than one time.

**THEN update-operation or THEN insert-operation**

Specifies the operation to run when the matching-condition evaluates to true.

**UPDATE SET**

Specifies the update operation to run when the matching-condition evaluates to true.

When extended indicator variables are enabled, a column of the source table must not be referenced multiple times in a single modification-operation. Extended indicator variables are enabled when EXTENDEDINDICATOR(YES) is used, or when the WITH EXTENDED INDICATORS prepare attribute has been specified for the MERGE statement.

The rows that are updated from a source-row are subject to more updates by subsequent source-rows in the same statement. The update is cumulative.

An update-operation in a MERGE statement will not rest the AREO* status on a table.

**assignment-clause**

Specifies a list of column updates.

**column-name**

Identifies a column to update. column-name must identify a column of the specified table or view, and that column must be updatable. The column must not be a generated column, or a column of a view that is derived from a scalar function, a constant, or an expression.

column-name can also identify an included column. The same column-name must not be specified more than one time. A view column that is derived from the same column as another column of the view can be updated, but both columns cannot be updated in the same MERGE statement.

Assignments to included columns are only processed when the MERGE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement. There must be at least one assignment clause that specifies a column-name that is not an included column.

**expression**

Specifies the new value of the column. The expression is any
expression of the type that is described in Expressions. The expression must not include an aggregate function.

An expression can contain references to columns of source-values or target table or view. A column name is first checked as a column of the target, and then checked as a column of the source table. For each row that is updated, the value of a target column in an expression is the value of the column in the row before the row is updated. expression cannot contain references to an included column.

If expression is a reference to a single column of the source-values, the source-values column value might have been specified with an extended indicator variable value. The effects of such indicator variables apply to the corresponding target columns of the assignment-clause.

When extended indicator variables are enabled, an expression must not be more complex than a reference to a single column of the source table, or a single host variable if the indicator is set to an extended indicator value of default (-5) or unassigned (-7). In addition, a CAST specification can be used if either:

- The target column is defined as nullable.
- the target column is defined as NOT NULL with a non-null default, the source of the CAST specification is a single host variable, and the data attributes (data type, length, precision, and scale) of the host variable are the same as the result of the cast specification.

**DEFAULT**

Specifies the default value for the column. DEFAULT can be specified only for columns that have a default value. The value that is assigned depends on how the column is defined. For more information about default values, see the description of the DEFAULT clause in CREATE TABLE on page 1730.

**NULL**

Specifies the null value as the new value of the column. Specify NULL only for nullable columns.

**insert-operation**

Specifies the insert operation that is to be executed for the rows where the matching-condition evaluates to true.

The rows that are inserted from a source-row are immediately subject for update by subsequent source-row in the same statement.

**INSERT**

Specifies a list of column names and row value expressions to use for the insert operation.

The number of values for the row in the row-value expression must be equal to the number of names in the insert column list. The first value is inserted into the first column in the list, the second value into the second column, and so on.

**column-name**

Specifies the columns for which the insert values are provided. Each name must identify a column of the table or view.

If an included column is not specified in the list of column names, the value of the included column is set to null. The column list cannot contain only included columns.
The same column must not be specified more than one time. A view column that cannot accept insert values must not be specified. A view column that cannot accept insert values must not be specified.

If the object of the operation is a view that contains columns that cannot accept insert values, a list of column names must be specified and the list must not specify these columns.

Omission of the column list is an implicit specification of a list in which every column of the table (that is not defined as implicitly hidden) or view is identified in left-to-right order. This list is established when the statement is prepared and therefore does not include columns that were added to the table after the statement was prepared.

VALUES
Introduces one or more rows of values to insert.

expression
Specifies an expression of the type that does not include a column name of the target. If expression is a host variable, the host variable can include an indicator variable, or in the case of a host structure, an indicator array. When extended indicator variables are enabled, an expression must not be more complex than a reference to a single host variable if the indicator is set to an extended indicator value of default (-5) or unassigned (-7).

In addition, a CAST specification can be used if either:
• The target column is defined as nullable.
• the target column is defined as NOT NULL with a non-null default, the source of the CAST specification is a single host variable, and the data attributes (data type, length, precision, and scale) of the host variable are the same as the result of the cast specification.

DEFAULT
Specifies to assign the default value to the column. DEFAULT must only be specified for columns that have a default value. If the column is specified in the INCLUDE column list, the column value is set to null.

DEFAULT must be specified for a column that is defined as GENERATED ALWAYS. A valid value can be specified for a column that is defined as GENERATED BY DEFAULT.

NULL
Specifies the null value as the value of the column. Specify NULL only for nullable columns.

NOT ATOMIC CONTINUE ON SQLEXCEPTION
The rows of input data are processed separately. Any statement level triggers are processed for each row of source data that is processed, and the transition table includes the individual row that was processed. When errors are encountered and this option is in effect, processing continues, and some of the specified rows will not be processed. In this case, if an appropriate trigger is defined on the underlying base table, the statement level trigger will only be activated for rows that were successfully processed.
Regardless of the failure of any particular source row, the MERGE statement will not undo any changes that are made to the database by the statement. Merge will be attempted for rows that follow the failed row. However, the minimum level of atomicity is at least that of a single source row (that is, it is not possible for a partial merge to complete), including any triggers that might have been activated as a result of the MERGE statement.

**QUERYNO integer**

Specifies the number for this SQL statement that is used in EXPLAIN output and trace records. The number is used for the QUERYNO column of the plan table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If QUERYNO is not specified, the number that is associated with the SQL statement is the statement number that is assigned during precompilation. Thus, if the application program is changed and then precompiled, the statement number might change.

**Notes**

**Trigger considerations:**

A MERGE statement might cause triggers to be activated. A trigger might cause other statements to be executed or raise error conditions depending on the source data values. A before-update or before-insert trigger processes immediately before the update or insert operation.

If a source row results in an insert, any after-insert triggers are activated after the insert operation completes.

If a source row results in updates, any after-update triggers are activated after all of the update operations complete.

**SQLCA and GET DIAGNOSTICS considerations:**

The GET DIAGNOSTICS statement can be used immediately after the MERGE statement to check which input rows fail during the merge operation. The GET DIAGNOSTICS statement information item, NUMBER, indicates the number of conditions that are raised. The GET DIAGNOSTICS condition information item, DB2_ROW_NUMBER, indicates the input source rows that cause an error.

**Indexes with VARBINARY columns:**

Suppose that the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type. In that case, that index column cannot specify the DESC attribute. To use the SQL data change operation on the identified table, either drop the index or alter the data type of the column to BINARY and then rebuild the index.

**Considerations for a MERGE without a column list in insert-operation:**

A MERGE statement without a specified column list as part of insert-operation does not include implicitly hidden columns. Therefore, such columns must have a defined default value.

**Considerations for non-atomic processing of a MERGE statement:**

When NOT ATOMIC is specified, the rows of source data are processed separately. Any references to special registers, sequence expressions, and functions in the MERGE statement are evaluated as each row of source data is processed. Statement level triggers are activated as each row of source data is processed.
If one or more errors occur during the operation for a row of source data, processing continues. The row that was being processed at the time of the error is not inserted or updated. Execution continues with the next row to be processed, and any other changes that are made during the execution of the multiple-row MERGE statement are not backed out. However, the processing of an individual row is an atomic action.

**DRDA considerations:**

DB2 Connect™ Version 9.1 and subsequent releases support the MERGE statement. The support is for CLI only, with no embedded static SQL support.

When you run a MERGE statement at a DB2 for z/OS requester, cases might exist where the requestor does not know the number of rows in the source table. This situation includes the following cases:

- For static or dynamic MERGE statements, of the FOR n ROWS clause contains a constant value for n.
- For dynamic MERGE statements, of host variables are specified on the USING clause of an EXECUTE statement.

For both of these cases, if the number of rows in the source table is not known, the requestor might send more data than is required to the server. The number of rows that are processed is correct because the server knows the correct numbers of rows to process. However, performance might be adversely affected. Consider the following example:

```sql
...long serial num [10];
struct { short len;
  char data [18];
} name[20]...
EXEC SQL
MERGE INTO T1
  USING (VALUES (:serial_num, :name))
  FOR 5 ROWS...
```

When this statement is run at the requester, the number of rows to merge (five) is not known. As a result, the requester sends 10 values for serial-name and name to the server because 10 is the size of the smallest host variable array and is, therefore, the maximum number of rows that can merge without causing an error.

Do the following to help minimize performance problems:

- Avoid using numeric constants in the FOR n ROWS clause of the MERGE statement. For static MERGE statements, avoiding numeric constants ensures that the values for n are known at the requester.
- For dynamic MERGE statements, use the USING DESCRIPTOR clause instead of the USING host-variable clause on the EXECUTE statement. If a USING DESCRIPTOR clause is used on the EXECUTE statement, the value for n must be indicated in the descriptor.
- If either of the previous methods cannot be used, perform the following actions:
  - Make your host variable arrays as small as possible, or declare that the size of your host variable arrays are the size of n in the descriptor. This action avoids sending many unused host variable array entries to the server.
- Ensure that varying length string arrays are initialized to a length of 0 (zero). Doing so minimizes the amount of data that is sent to the server.

- Ensure that decimal host variable arrays are initialized to valid values. Doing so causes the requester to avoid sending a negative SQLCODE if the requester encounters invalid decimal data.

**Extended indicator variable usage:**
When extended indicator variables are enabled, negative indicator values outside the range of -1 through -7 must not be specified. Also, the default and unassigned extended indicator values must not be used in contexts in which they are not supported.

**Extended indicator variables in the assignment-clause:**
Assigning the extended indicator a value of unassigned leaves the target column set to its current value, as if it had not been specified in the statement. Assigning the extended indicator a value of default assigns the default value to the column.

The assignment-clause must not assign all target columns to an extended indicator value of unassigned.

**Extended indicator variables in the insert-operation:**
In insert-operation, a value of unassigned sets the column to its default value.

**Extended indicator variables and update triggers:**
If a target column is assigned an extended indicator value of unassigned, that column is not considered to have been updated. That column is treated as if it had not been specified in the OF column-name list of any update trigger that is defined on the target table.

**Extended indicator variables and insert triggers:**
The activation of insert triggers is not affected by the use of extended indicator variables. Suppose that all columns in the implicit or explicit column list are assigned an extended indicator value of unassigned or default. Then, assume that an insert operation where all columns are assigned to the respective default values is attempted. If that operation is successful, the insert trigger is activated.

**Table space data compression during an insert operation:**
If the table space is defined with the COMPRESS YES option, and data is inserted into a table in the table space, the first rows are stored uncompressed. When a amount of data that is determined by DB2 is inserted into the table, a compression dictionary is created and stored in the table space. The rows that are inserted into the table after the dictionary is created are stored compressed by using the compression dictionary.

**System-period temporal tables:**
When a MERGE statement is processed for a system-period temporal table, the rows are affected in the same way as if the specific data change operation was invoked.

**Tables with enforced row and column access controls:**
For information about how enabled row permissions and column masks affect the update and insert operations in the MERGE statement, see the INSERT and UPDATE statement information.
Examples

Example 1: Update the descriptions for activities that exist in the RECORDS table. Otherwise, insert the activity and its description into the RECORDS table.

MERGE INTO RECORDS AS AR
USING (VALUES (:hv_activity, :hv_description)
  FOR :hv_nrows ROWS)
AS AC (ACTIVITY, DESCRIPTION)
on (AR.ACTIVITY = AC.ACTIVITY)
WHEN MATCHED THEN UPDATE SET DESCRIPTION = AC.DESCRIPTION
WHEN NOT MATCHED THEN INSERT (ACTIVITY, DESCRIPTION)
  VALUES (AC.ACTIVITY, AC.DESCRIPTION)
NOT ATOMIC CONTINUE ON SQLEXCEPTION;

Example 2: Use the transaction data to merge rows into the account table. Update the balance from the transaction data against an account ID and insert new accounts from the transaction data where the accounts do not already exist.

MERGE INTO ACCOUNT AS A
USING (VALUES (:hv_id, :hv_amount)
  FOR 3 ROWS)
AS T (ID, AMOUNT)
on (A.ID = T.ID)
WHEN MATCHED THEN UPDATE SET BALANCE = A.BALANCE + T.AMOUNT
WHEN NOT MATCHED THEN INSERT (ID, BALANCE)
  VALUES (T.ID, T.AMOUNT)
NOT ATOMIC CONTINUE ON SQLEXCEPTION;

Example 3: Update the list of activities that are organized by group A in the RECORDS table. Update the activities information (description and date when last modified) in the RECORDS table if the activities exist in the RECORDS table and are also organized by group A. Insert new activities into the RECORDS table.

-- hv_nrows = 3
-- hv_activity(1) = 'D'; hv_description(1) = 'Dance'; hv_date(1) = '03/01/07'
-- hv_activity(2) = 'S'; hv_description(2) = 'Singing'; hv_date(2) = '03/17/07'
-- hv_activity(3) = 'T'; hv_description(3) = 'Tai-chi'; hv_date(3) = '05/01/07'
-- hv_group = 'A';
-- note that hv_group is not an array. All 3 values contain the same values
MERGE INTO RECORDS AS AR
USING (VALUES (:hv_activity, :hv_description, :hv_date, :hv_group)
  FOR :hv_nrows ROWS)
AS AC (ACTIVITY, DESCRIPTION, DATE, GROUP)
on (AR.ACTIVITY = AC.ACTIVITY AND AR.GROUP = AC.GROUP)
WHEN MATCHED
THEN UPDATE SET (DESCRIPTION, DATE, LAST_MODIFIED)
  = (AC.DESCRIPTION, AC.DATE, CURRENT_TIMESTAMP)
WHEN NOT MATCHED
THEN INSERT (GROUP, ACTIVITY, DESCRIPTION, DATE, LAST_MODIFIED)
  VALUES (AC.GROUP, AC.ACTIVITY, AC.DESCRIPTION, AC.DATE, CURRENT_TIMESTAMP)
NOT ATOMIC CONTINUE ON SQLEXCEPTION;
The OPEN statement opens a cursor so that it can be used to process rows from its result table.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

See [DECLARE CURSOR](#) for the authorization required to use a cursor.

Syntax

```
OPEN cursor-name

USING host-variable
USING DESCRIPTOR descriptor-name
```

Description

The `cursor-name` identifies the cursor to be opened. The `cursor-name` must identify a declared cursor as explained in [DECLARE CURSOR](#). When the OPEN statement is executed, the cursor must be in the closed state.

The SELECT statement of the cursor is either one of the following types of SELECT statements:

- The `select-statement` that is specified in the DECLARE CURSOR statement
- The prepared `select-statement` that is identified by the `statement-name` that is specified in the DECLARE CURSOR statement.

If the statement has not been successfully prepared, or is not a `select-statement`, the cursor cannot be successfully opened.

The result table of the cursor is derived by evaluating the SELECT statement. The evaluation uses the current values of any special registers or PREVIOUS VALUE expressions that are specified in the SELECT statement, and the
current values of any host variables that are specified in the SELECT statement or the USING clause of the OPEN statement. The rows of the result table can be derived during the execution of the OPEN statement, and a temporary copy of a result table can be created to hold those rows. They can be derived during the execution of later FETCH statements. In either case, the cursor is placed in the open state and positioned before the first row of its result table.

If the table is empty, the position of the cursor is effectively “after the last row.” The DB2 system does not indicate an empty table when the OPEN statement is executed. A subsequent fetch for the cursor might return the SQLSTATE warning of '02000'.

**USING**

Introduces a list of host variables whose values are substituted for the parameter markers (question marks) or host variables in the statement of the cursor, depending on the declaration of the cursor:

- If the DECLARE CURSOR statement included `statement-name`, the statement was prepared with a PREPARE statement. The host variables specified in the USING clause of the OPEN statement replace any parameter markers in the prepared statement. This reflects the typical use of the USING clause of the OPEN statement. For an explanation of parameter marker replacement, see `PREPARE`.

If the prepared statement includes parameter markers, you must use USING. If the prepared statement does not include parameter markers, USING is ignored.

- If the DECLARE CURSOR statement included `select-statement` and the SELECT statement included host variables, the USING clause of the OPEN statement can be used to specify host variables that are to override the values that were specified when the cursor was defined. In this case, the OPEN statement is executed as if each host variable in the SELECT statement were a parameter marker except that the attributes of the target variable are the same as the host variables in the SELECT statement. The effect is to override the values of the host variables in the SELECT statement of the cursor with the values of the host variables specified in the USING clause. The overriding value is always the value of the main variable because indicator variables are ignored in this context without warning.

The `n`th variable corresponds to the `n`th parameter marker in the prepared statement. Where appropriate, locator variables and file reference variables can be provided as the source of values for parameter markers.

`host-variable,...`

Identifies host structures or variables that must be described in the application program in accordance with the rules for declaring host structures and variables. When the statement is executed, a reference to a structure is replaced by a reference to each of its variables. The number of variables must be the same as the number of parameter markers in the prepared statement.

**DESCRIPTOR** `descriptor-name`

Identifies an SQLDA that contains a valid description of the input host variables.

Before the OPEN statement is processed, the user must set the following fields in the SQLDA:

- `SQLN` to indicate the number of SQLVAR occurrences provided in the SQLDA

  A REXX SQLDA does not contain this field.
- SQLABC to indicate the number of bytes of storage allocated for the SQLDA
- SQLD to indicate the number of variables used in the SQLDA when processing the statement
- SQLVAR occurrences to indicate the attributes of the variables

The SQLDA must have enough storage to contain all SQLVAR occurrences. If LOBs or distinct types are present in the result table, there must be additional SQLVAR entries for each input host variable. For more information on the SQLDA, which includes a description of the SQLVAR and an explanation on how to determine the number of SQLVAR occurrences, see [SQL descriptor area (SQLDA)](#).

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN. It must be the same as the number of parameter markers in the prepared statement.

See [Identifying an SQLDA in C or C++] for how to represent descriptor-name in C.

### Notes

**Errors occurring on OPEN:** In local and remote processing, the DEFER(PREPARE) and REOPT(ALWAYS)/REOPT(ONCE) bind options can cause some SQL statements to receive “delayed” errors. For example, an OPEN statement might receive an SQLCODE that normally occurs during PREPARE processing. Or a FETCH statement might receive an SQLCODE that normally occurs at OPEN time.

**Closed state of cursors:** All cursors in an application process are in the closed state when:

- The application process is started.
- A new unit of work is started for the application process unless the WITH HOLD option has been used in the DECLARE CURSOR statement.
- The application was precompiled with the CONNECT(1) option (which implicitly closes any open cursors).

A cursor can also be in the closed state because:

- A CLOSE statement was executed.
- An error was detected that made the position of the cursor unpredictable.

To retrieve rows from the result table of a cursor, you must execute a FETCH statement when the cursor is open. The only way to change the state of a cursor from closed to open is to execute an OPEN statement.

**Effect of a temporary copy of a result table:** DB2 can process a cursor in two different ways:

- It can create a temporary copy of the result table during the execution of the OPEN statement. You can specify INSENSITIVE SCROLL on the cursor to force the use of a temporary copy of the result table.
- It can derive the result table rows as they are needed during the execution of later FETCH statements.

If the result table is not read-only, DB2 uses the latter method. If the result table is read-only, either method could be used. The results produced by these two methods could differ in the following respects:
When a temporary copy of the result table is used: An error can occur that would otherwise not occur until some later FETCH statement. Insert operations that are executed while the cursor is open cannot affect the result table once all the rows have been materialized in the temporary copy of the result table. For a scrollable insensitive cursor, update and delete operations that are executed while the cursor is open cannot affect the result table. For a scrollable sensitive static cursor, update and delete operations can affect the result table if the rows are subsequently fetched with sensitive FETCH statements.

When a temporary copy of the result table is not used: Insert, update, and delete operations that are executed while the cursor is open can affect the result table. The effect of such operations is not always predictable.

For example, if cursor C is positioned on a row of its result table defined as SELECT * FROM T, and you insert a row into T, the effect of that insert on the result table is not predictable because its rows are not ordered. A later FETCH C might or might not retrieve the new row of T. To avoid these changes, you can specify INSSENSITIVE SCROLL for the cursor to force the use of a temporary copy of the result table.

Parameter marker replacement: Before the OPEN statement is executed, each parameter marker in the query is effectively replaced by its corresponding host variable. The replacement is an assignment operation in which the source is the value of the host variable and the target is a variable within DB2. The assignment rules are those described for assignment to a column in Assignment and comparison. For a typed parameter marker, the attributes of the target variable are those specified by the CAST specification. For an untyped parameter marker, the attributes of the target variable are determined according to the context of the parameter marker. For the rules that affect parameter markers, see Parameter markers.

Let V denote a host variable that corresponds to parameter marker P. The value of V is assigned to the target variable for P in accordance with the rules for assigning a value to a column:

• V must be compatible with the target.
• If V is a string, its length (excluding trailing blanks) must not be greater than the length attribute of the target.
• If V is a number, the absolute value of its integral part must not be greater than the maximum absolute value of the integral part of the target.
• If the attributes of V are not identical to the attributes of the target, the value is converted to conform to the attributes of the target.
• If the target cannot contain nulls, V must not be null.

When the SELECT statement of the cursor is evaluated, each parameter marker in the statement is effectively replaced by the value of its corresponding host variable. For example, if V is CHAR(6) and the target is CHAR(8), the value used in place of P is the value of V padded on the right with two blanks. For more on the process of replacement, see Parameter marker replacement.

Considerations for scrollable cursors: Following an OPEN cursor statement, a GET DIAGNOSTICS statement can be used to get the attributes of the cursor such as the following information (for more information, see GET DIAGNOSTICS):

• DB2_SQL_ATTR_CURSOR_HOLD. Whether the cursor was defined with the WITH HOLD attribute.
• **DB2_SQL_ATTR_CURSOR_SCROLLABLE.** Scrollability of the cursor.

• **DB2_SQL_ATTR_CURSOR_SENSITIVITY.** Effective sensitivity of the cursor.

  The sensitivity information can be used by applications (such as an ODBC driver) to determine what type of FETCH (INSENSITIVE or SENSITIVE) to issue for a cursor defined as ASENSITIVE.

• **DB2_SQL_ATTR_CURSOR_ROWSET.** Whether the cursor can be used to access rowsets.

• **DB2_SQL_ATTR_CURSOR_TYPE.** Whether a cursor type is forward-only, static, or dynamic.

In addition, if subsystem parameter DISABSCL is set to NO, a subset of the above information is returned in the SQLCA:

• The scrollability of the cursor is in SQLWARN1.

• The sensitivity of the cursor is in SQLWARN4.

• The effective capability of the cursor is in SQLWARN5.

**Number of rows inserted:** SQL data change statements and routines that modify SQL data embedded in the cursor definition are completely executed, and the result table is stored in a temporary table when the cursor opens. If statement execution is successful, the SQLERRD(3) field contains the sum of the number of rows that qualified for insert, update, and delete operations. If an error occurs during execution of an OPEN statement that involves a cursor that contains a data change statement within a fullselect, the results of that data change statement are rolled back.

**Materialization of the rows of the result table and NEXT VALUE expressions:** If the rows of the result table of a cursor are materialized when the cursor is opened and the SELECT statement of the cursor contains NEXT VALUE expressions, the expressions are processed when the cursor is opened. Otherwise, the NEXT VALUE expressions are evaluated as the rows of the result table are retrieved.

**Opening the same cursor multiple times:** A cursor in an SQL procedure that is declared as WITH RETURN TO CLIENT can be opened even when a cursor with the same name is already in the open state. In this case, the existing open cursor becomes a result set cursor and is no longer accessible by its cursor name. A new cursor is opened and becomes accessible by the cursor name. Closing the new cursor does not make the cursor that was previously accessible by that name accessible by the cursor name again. Cursors that become result set cursors in this way cannot be accessed at the server and can be processed only at the client.

**Examples**

**Example 1:** Execute an OPEN statement, which places the cursor at the beginning of the rows to be fetched.

```sql
EXEC SQL DECLARE C1 CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO FROM DSN8A10.DEPT
  WHERE ADMRDEPT = 'A00';
EXEC SQL OPEN C1;
DO WHILE (SQLCODE = 0);
  EXEC SQL FETCH C1 INTO :DNUM, :DNAME, :MNUM;
END;
EXEC SQL CLOSE C1;
```
The PREPARE statement creates an executable SQL statement from a string form of the statement. The character-string form is called a *statement string*. The executable form is called a *prepared statement*.

**Invocation**

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

**Authorization**

The authorization rules are those defined for the dynamic preparation of the SQL statement specified by the PREPARE statement. For example, see [Queries](#) for the authorization rules that apply when a SELECT statement is prepared.

The statement that is prepared using only the EXPLAIN privilege cannot be executed, and only the descriptive information can be obtained for that statement.

**Syntax**

```
PREPARE statement-name INTO descriptor-name

USING NAMES USING LABELS ANY BOTH

FROM host-variable

ATTRIBUTES attr-host-variable

FROM string-expression
```

Notes:

1. *attr-host-variable* must be a string host variable and the content must conform to the rules for attribute-string. The ATTRIBUTES clause can only be specified before *host-variable*.
2. *string-expression* is only supported for PLI.

attribute-string
Notes:

1. The same clause must not be specified more than one time. If the options are not specified, their defaults are whatever was specified for the corresponding option in an associated statement.

2. The FOR SINGLE ROW or FOR MULTIPLE ROWS clause must only be specified for an INSERT or a MERGE statement.

3. The ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION clause must only be specified for an INSERT statement.

holdability:

returnability:
Description

`statement-name`  
Names the prepared statement. If the name identifies an existing prepared statement, that prepared statement is destroyed. The name must not identify a prepared statement that is the SELECT statement of an open cursor.

`INTO`  
If you use INTO, and the PREPARE statement is successfully executed, information about the prepared statement is placed in the SQLDA specified by the descriptor name. Thus, the PREPARE statement:

```sql
EXEC SQL PREPARE S1 INTO :SQLDA FROM :V1;
```

is equivalent to:

```sql
EXEC SQL PREPARE S1 FROM :V1;
EXEC SQL DESCRIBE S1 INTO :SQLDA;
```

`descriptor-name`  
Identifies the SQLDA. For languages other than REXX, SQLN must be set to indicate the number of SQLVAR occurrences. See [DESCRIBE](#) for information about how to determine the number of SQLVAR occurrences to use and for an explanation of the information that is placed in the SQLDA.

See [Identifying an SQLDA in C or C++](#) for how to represent `descriptor-name` in C.

`USING`  
Indicates what value to assign to each SQLNAME variable in the SQLDA when INTO is used. If the requested value does not exist, SQLNAME is set to length 0.

`NAMES`  
Assigns the name of the column. This is the default.
LABELS
Assigns the label of the column. (Column labels are defined by the LABEL statement.)

ANY
Assigns the column label, and, if the column has no label, the column name.

BOTH
Assigns both the label and name of the column. In this case, two or three occurrences of SQLVAR per column, depending on whether the result table contains distinct types, are needed to accommodate the additional information. To specify this expansion of the SQLVAR array, set SQLN to 2n or 3n, where n is the number of columns in the object being described. For each of the columns, the first n occurrences of SQLVAR, which are the base SQLVAR entries, contain the column names. Either the second or third n occurrences of SQLVAR, which are the extended SQLVAR entries, contain the column labels. If there are no distinct types, the labels are returned in the second set of SQLVAR entries. Otherwise, the labels are returned in the third set of SQLVAR entries.

A REXX SQLDA does not include the SQLN field, so you do not need to set SQLN for REXX programs.

ATTRIBUTES attr-host-variable
Specifies the attributes that are in effect if a corresponding attribute has not been specified as part of the associated statement. If attributes are specified as part of the associated statement, they are used instead of the corresponding attributes specified on the PREPARE statement. In turn, if attributes are specified in the PREPARE of a SELECT statement, they are used instead of the corresponding attributes specified on a DECLARE CURSOR statement.

attr-host-variable must identify a host variable that is described in the program in accordance with the rules for declaring string variables. attr-host-variable must be a string variable (either fixed-length or varying-length) that has a length attribute that does not exceed 32758 bytes. Leading and trailing blanks are removed from the value of the host variable. The host variable must contain a valid attribute-string.

An indicator variable can be used to indicate whether or not attributes are actually provided on the PREPARE statement. Thus, applications can use the same PREPARE statement regardless of whether attributes need to be specified or not.

The options that can be specified as part of the attribute-string are as follows:

ASENSITIVE, INSENSITIVE, SENSITIVE STATIC, or SENSITIVE DYNAMIC
Specifies the sensitivity of the cursor to inserts, updates, or deletes that made to the rows underlying the result table. The sensitivity of the cursor determines whether DB2 can materialize the rows of the result into a temporary table. The default is ASENSITIVE.

ASENSITIVE
Specifies that the cursor should be as sensitive as possible. A cursor that defined as ASENSITIVE will be either insensitive or sensitive

38. The scrollability and sensitivity of the cursor are independent and do not have to be specified together. Thus, the cursor might be defined as SCROLL INSENSITIVE, but the PREPARE statement might specify SENSITIVE STATIC as an override for the sensitivity.
dynamic; it will not be sensitive static. For information about how the
effective sensitivity of the cursor is returned to the application with the
GET DIAGNOSTICS statement or in the SQLCA, see OPEN.

The sensitivity of a cursor is a factor in the choice of access path.
Explicitly specify the sensitivity level that you need, instead of
specifying ASENSITIVE.

**INSENSITIVE**

Specifies that the cursor does not have sensitivity to inserts, updates,
or deletes that are made to the rows underlying the result table. As a
result, the size of the result table, the order of the rows, and the values
for each row do not change after the cursor is opened. In addition, the
cursor is read-only. The SELECT statement or attribute-string of the
PREPARE statement cannot contain a FOR UPDATE clause, and the
cursor cannot be used for positioned updates or deletes.

**SENSITIVE**

Specifies that the cursor has sensitivity to changes made to the
database after the result table is materialized. The cursor is always
sensitive to positioned updates and deletes that are made using the
same cursor. However, the select-statement of the cursor must not
contain an SQL data change statement if the cursor is defined as either
SENSITIVE DYNAMIC or SENSITIVE STATIC. When the current value
of a row no longer satisfies the select-statement or statement-name, that
row is no longer visible through the cursor. When a row of the result
table is deleted from the underlying base table, the row is no longer
visible through the cursor.

In addition, the cursor has sensitivity to changes made to values
outside the cursor (that is, by other cursors or committed changes by
other application processes). If DB2 can not make changes made
outside the cursor visible to the cursor, an error is issued at OPEN
CURSOR. Whether the cursor is sensitive to changes made outside this
cursor depends on whether DYNAMIC or STATIC is in effect for the
cursor and whether SENSITIVE or INSENSITIVE FETCH statements
are used.

Whether the cursor is sensitive to newly inserted rows depends on
whether DYNAMIC or STATIC is in effect for the cursor. The default is
DYNAMIC.

**DYNAMIC**

Specifies that the result table of the cursor is dynamic in that the
size of the result table can change after the cursor is opened as
rows are inserted into or deleted from the underlying table, and
the order of the rows can change. Inserts, deletes, and updates that
are made by the same application process are immediately visible.
Inserts, deletes, and updates that are made by other application
processes are visible after they are committed.

All FETCH statements for sensitive dynamic cursors are sensitive
to changes made by this cursor, changes made by other cursors in
the same application process, and committed changes made by
other application processes.

If a SENSITIVE DYNAMIC cursor is not possible, an error is
returned. The FETCH FIRST n ROWS ONLY clause must not be
specified for the outermost fullselect for a sensitive dynamic cursor.
**STATIC**
Specifies that the order of the rows and size of the result table is static. The size of the result table does not grow after the cursor is opened and the rows are materialized. The order of the rows is established as the result table is materialized. Rows that are inserted into the underlying table are not added to the result table of the cursor regardless of how the rows were inserted. Rows in the result table do not move if columns in the ORDER BY clause are updated in rows that have already been materialized.

Whether the changes that are made outside the cursor are visible to the cursor depends on the type of FETCH that is used with a SENSITIVE STATIC cursor. For more information, see **Considerations for FETCH statements used with a sensitive static cursor**.

Using a function that is not deterministic (built-in or user-defined) in the WHERE clause of select-statement or statement-name of a SENSITIVE STATIC cursor can cause misleading results. This occurs because DB2 constructs a temporary result table and retrieves rows from this table for INSENSITIVE FETCH statements. When DB2 processes a SENSITIVE FETCH statement, rows are fetched from the underlying table and predicates are re-evaluated if they contain non-correlated subqueries. Using a function that is not deterministic can yield a different result for the re-evaluated query causing the row to no longer be considered a match.

If SENSITIVE STATIC is specified and a sensitive static cursor is not possible, then an error is returned.

If ASENSITIVE, INSENSITIVE, SENSITIVE DYNAMIC, or SENSITIVE STATIC is specified as part of the ATTRIBUTES clause, SCROLL must be specified.

**SCROLL or NO SCROLL**
Specifies whether the cursor is scrollable.

**SCROLL**
Specifies that the cursor is scrollable.

**NO SCROLL**
Specifies that the cursor is not scrollable.

**WITHOUT RETURN or WITH RETURN**
Specifies whether the result table of the cursor is intended to be used as a result set that will be returned from a procedure. If statement-name is specified, the default is the corresponding prepare attribute of the statement. Otherwise, the default is WITHOUT RETURN.

**WITHOUT RETURN**
Specifies that the result table of the cursor is not intended to be used as a result set that will be returned from a procedure.

**WITH RETURN**
Specifies that the result table of the cursor is intended to be used as a result set that will be returned from a procedure. WITH RETURN is relevant only if the PREPARE statement is contained within the source code for a procedure. In other cases, the precompiler might accept the clause, but it has not effect.
When a cursor that is declared using the WITH RETURN TO CALLER clause remains open at the end of a program or routine, that cursor defines a result set from the program or routine. Use the CLOSE statement to close a cursor that is not intended to be a result set from the program or routine. Although DB2 will automatically close any cursors that are not declared using with a WITH RETURN clause, the use of the CLOSE statement is recommended to increase the portability of applications.

For non-scrollable cursors, the result set consists of all rows from the current cursor position to the end of the result table. For scrollable cursors, the result set consists of all rows of the result table.

**TO CALLER**

Specifies that the cursor can return a result set to the caller of the procedure. The caller is the program or routine that executed the SQL CALL statement that invokes the procedure that contains the PREPARE statement. For example, if the caller is a procedure, the result set, is returned to the procedure. If the caller is a client application, the result set is returned to the client application.

If the statement is contained within the source code for a procedure, WITH RETURN TO CALLER specifies that the cursor can be used as a result set cursor. A result set cursor is used when the result table of a cursor is to be returned from a procedure. Specifying TO CALLER is optional.

In other cases, the clause is ignored and the cursor cannot be used as a result set cursor.

**TO CLIENT**

Specifies that the cursor can return a result set to the client application. This cursor is invisible to any intermediate nested procedures. If a function or trigger calls the procedure (either directly or indirectly), the result set cannot be returned to the client and the cursor will be closed after the procedure finishes.

**rowset-positioning**

Specifies whether rows of data can be accessed as a rowset on a single FETCH statement for this cursor.

**WITHOUT ROWSET POSITIONING**

Specifies that the cursor can only be used with row positioned FETCH statements.

**WITH ROWSET POSITIONING**

Specifies that this cursor can be used with rowset positioned or row positioned FETCH statements.

**fetch-first-clause**

Limits the number of rows that can be fetched. It improves the performance of queries with potentially large result sets when only a limited number of rows are needed. If the clause is specified, the number of rows retrieved will not exceed \( n \), where \( n \) is the value of the integer. An attempt to fetch \( n+1 \) rows is handled the same way as normal end of date. The value of integer must be positive and non-zero. The default is 1.

If the OPTIMIZE FOR clause is not specified, a default of OPTIMIZE FOR integer ROWS is assumed. If both the FETCH FIRST and OPTIMIZE FOR clauses are specified, the lower of the integer values from these clauses is used to influence optimization and the communications buffer size.
The FETCH FIRST clause must not be specified for the outermost fullselect for a sensitive dynamic cursor.

**read-only-clause**
Declarations that the result table is read-only and therefore the cursor cannot be referred to in positioned UPDATE and DELETE statements.

**update-clause**
Identifies the columns that can updated in a later positioned UPDATE statement. Each column must be unqualified and must identify a column of the table or view identified in the first FROM clause of the fullselect. The clause must not be specified if the result table of the fullselect is read-only. The clause must also not be specified if a created temporary table is referenced in the first FROM clause of the select-statement.

If the clause is specified without a list of columns, the columns that can be updated include all the updatable columns of the table or view that is identified in the first FROM clause of the fullselect.

**optimize-clause**
Requests special optimization of the select-statement. If the clause is omitted, optimization is based on the assumption that all rows of the result table will be retrieved. If the clause is specified, optimization is based on the assumption that the number of rows retrieved will not exceed $n$, where $n$ is the value of the integer. The clause does not limit the number of rows that can be fetched or affect the result in any way other than performance.

**isolation-clause**
Specifies the isolation level at which the select statement is executed. See [isolation-clause](#).

**concurrent-access-resolution**
Specifies the type concurrent access resolution to use for the select statement. Each clause in `concurrent-access-resolution` can only be specified one time. Only one of the clauses can be specified for each PREPARE statement. If none of the clauses is specified, the locking semantic depends on other attributes of the statement.

**SKIP LOCKED DATA**
Specifies to skip data on which incompatible locks are held by other transactions. See [SKIP LOCKED DATA](#).

**USE CURRENTLY COMMITTED**
Specifies that DB2 can use the currently committed version of the data when the data is in the process of being updated. USE CURRENTLY COMMITTED only applies in the following cases:

- The table that is being accessed is defined in a universal table space
- The access is for a select-statement with an isolation level of cursor stability (CS) or read stability (RS) specified in the isolation-clause:
  - When a read transaction accesses a record that is locked by an insert transaction, both ISOLATION(CS) and ISOLATION(RS) are applicable.
  - When a read transaction accesses a record that is locked by a delete transaction only ISOLATION(CS) is applicable and only when CURRENTDATA(NO) is in effect.

USE CURRENTLY COMMITTED is ignored if used in any other context.
When this clause is specified, the setting of the subsystem parameter EVALUNC applies. If the row qualifies, this clause determines if the row is accessed or skipped.

When this clause is specified and the subsystem parameter SKIPUNCI is in effect, PREPARE uses the specification of this clause. See the Notes section for more information.

When this clause is specified and XML data that does not support multiple XML versions is being selected, DB2 cannot determine whether the data has been committed. In this case, DB2 uses WAIT FOR OUTCOME behavior when accessing the data.

**WAIT FOR OUTCOME**

Specifies that DB2 waits for the commit or rollback when encountering data that is in the process of being updated or deleted. Rows that are in the process of being inserted are not skipped.

**FOR MULTIPLE ROWS or FOR SINGLE ROW**

Specifies if a variable number of rows will be provided for a dynamic INSERT or MERGE statement.

**FOR MULTIPLE ROWS**

Specifies that multiple rows can be provided with host variable arrays on an EXECUTE statement for the statement that is being prepared. FOR MULTIPLE ROWS must only be specified for an INSERT or a MERGE statement.

**FOR SINGLE ROW**

Specifies that multiple rows must not be provided with host variable arrays on an EXECUTE statement for the statement that is being prepared. FOR SINGLE ROW must only be specified for an INSERT or a MERGE statement.

**ATOMIC or NOT ATOMIC CONTINUE ON SQLEXCEPTION**

Specifies if all rows are inserted as an atomic operation. This clause can only be specified for dynamic INSERT statements.

**ATOMIC**

Specifies that if the insert for any row fails, all changes that are made to the database by any of the inserts, including changes that are made by successful inserts, are undone. This is the default.

**NOT ATOMIC CONTINUE ON SQLEXCEPTION**

Specifies that, regardless of the failure of any particular insert of a row, the INSERT statement will not undo any changes that are made to the database by the successful inserts of other rows, and inserting will be attempted for subsequent rows. However, the minimum level of atomicity is at least that of a single insert (that is, it is not possible for a partial insert operation to complete), including any triggers that might have been activated as a result of the INSERT statement.

This clause must not be specified if the INSERT statement is contained within a SELECT statement.

For preparing the MERGE statement, atomicity is specified only on the MERGE statement itself.

**WITHOUT EXTENDED INDICATORS or WITH EXTENDED INDICATORS**

Specifies whether the values that are provided for indicator variables during the execution of the statement follow standard SQL semantics for indicating NULL values, or if the values can use extended indicator
variables to indicate a DEFAULT or UNASSIGNED value. WITHOUT EXTENDED INDICATORS is the default.

CONCENTRATE STATEMENTS OFF or CONCENTRATE STATEMENTS WITH LITERALS
Specifies whether a dynamic SQL statement that specifies literal constants will be cached as a separate unique statement entry in the dynamic statement cache instead of sharing an existing statement in the cache. Dynamic SQL statements are eligible to share an existing statement in the cache if the new statement meets all of the conditions for sharing a cached version of the same dynamic statement except that the new statement specifies one or more literal constants that are different than the cached statement.

CONCENTRATE STATEMENTS OFF
Specifies that the dynamic SQL statement that specifies literal constants will be cached as a unique statement entry if it specifies one or more constants that are different than the cached version of the same dynamic statement. CONCENTRATE STATEMENTS OFF is the default dynamic statement caching behavior.

CONCENTRATE STATEMENTS WITH LITERALS
Specifies that the dynamic SQL statement that specifies literal constants will share a cached version of the same dynamic statement that is also prepared using the CONCENTRATE STATEMENTS WITH LITERALS option if the new dynamic statement meets all of the conditions for sharing the cached statement and the constants that are specified can be reused in place of the constants in the cached statement.

FROM
Specifies the statement string. The statement string is the value of the specified string-expression or the identified variable.

host-variable
Must identify a host variable that is described in the application program in accordance with the rules for declaring string variables. If the source string is over 32KB in length, the host-variable must be a CLOB or DBCLOB variable. The maximum source string length is 2MB although the host variable can be declared larger than 2MB. An indicator variable must not be specified. In PL/I, COBOL and Assembler language, the host variable must be a varying-length string variable. In C, the host variable must not be a NUL-terminated string. In SQL PL, an SQL variable is used in place of a host variable and the value must not be null.

string-expression
string-expression is any PL/I expression that yields a string. string-expression cannot be preceded by a colon. Variables that are within string-expression that include operators or functions should not be preceded by a colon. When string-expression is specified, the precompiler-generated structures for string-expression use an EBCDIC CCSID and an informational message is returned.

Notes

Rules for statement strings:
The value of the specified statement-name is called the statement string. The statement string must be one of the following SQL statements:
The statement string must not:
• Begin with EXEC SQL
• End with END-EXEC or a semicolon
• Include references to variables

Parameter markers:
Although a statement string cannot include references to variables, it can include parameter markers. The parameter markers are replaced by the values of variables when the prepared statement is executed. A parameter marker is a question mark (?) that appears where a variable could appear if the statement string were a static SQL statement.

For an explanation of how parameter markers are replaced by values, see the EXECUTE statement, OPEN, and Dynamically executing a data change statement (DB2 Application programming and SQL).

The two types of parameter markers are typed and untyped:

Typed parameter marker
A parameter marker that is specified with its target data type. A typed parameter marker has the general form:

CAST(? AS data-type)

This invocation of a CAST specification is a “promise” that the data type of the parameter at run time will be of the data type that is specified or some data type that is assignable to the specified data type. For example, in the following UPDATE statement, the value of the argument of the TRANSLATE function will be provided at run time:
UPDATE EMPLOYEE
  SET LASTNAME = TRANSLATE(CAST(?) AS VARCHAR(12))
WHERE EMPNO = ?

The data type of the value that is provided for the TRANSLATE function will either be VARCHAR(12), or some data type that can be converted to VARCHAR(12). For more information, refer to [Assignment and comparison](#).

Typed parameter markers can be used in dynamic SQL statements wherever a host variable is supported and the data type is based on the promise made in the CAST specification.

**Untyped parameter marker**

A parameter marker that is specified without its target data type. An untyped parameter marker has the form of a single question mark. The context in which the parameter marker appears determines its data type. For example, in the above UPDATE statement, the data type of the untyped parameter marker in the predicate is the same as the data type of the EMPNO column.

Untyped parameters markers can be used in dynamic SQL statements in selected locations where host variables are supported. [Table 206](#), [Table 207 on page 2119](#), [Table 208 on page 2120](#), and [Table 209 on page 2121](#) show these locations and the resulting data type of the parameter. The tables group the locations into expressions, predicates, functions, and other statements to help show where untyped parameter markers are allowed.

**Table 206. Untyped parameter marker usage in expressions (including select list, CASE, and VALUES)**

<table>
<thead>
<tr>
<th>Location of untyped parameter marker</th>
<th>Data type (or error if not supported)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alone in a select list. For example: SELECT ?</td>
<td>Error</td>
</tr>
<tr>
<td>Both operands of a single arithmetic operator, after considering operator precedence and the order of operation rules. Includes cases such as: ? + ? + 10</td>
<td>DECFLOAT(34)</td>
</tr>
<tr>
<td>One operand of a single operator in an arithmetic expression (except datetime arithmetic expressions). Includes cases such as: ? + ? * 10</td>
<td>The data type of the other operand</td>
</tr>
<tr>
<td>Any operand of a datetime expression. For example: 'timecol + ?' or '? - datecol'</td>
<td>Error</td>
</tr>
<tr>
<td>A labeled duration in a datetime expression with a type unit other than SECONDS (the portion of a labeled duration that indicates the type of units cannot be a parameter marker).</td>
<td>DECIMAL(15,0)</td>
</tr>
<tr>
<td>A labeled duration in a datetime expression with a type unit of SECONDS (the portion of a labeled duration that indicates the type of units cannot be a parameter marker).</td>
<td>DECIMAL(27,12)</td>
</tr>
</tbody>
</table>
### Table 206. Untyped parameter marker usage in expressions (including select list, CASE, and VALUES) (continued)

<table>
<thead>
<tr>
<th>Location of untyped parameter marker</th>
<th>Data type (or error if not supported)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Both operands of a CONCAT operator</td>
<td>Error</td>
</tr>
<tr>
<td>One operand of a CONCAT operator when the other operand is any character data type except CLOB</td>
<td>If the other operand is CHAR(n) or VARCHAR(n), where n is less than 128, the data type is VARCHAR(254 - n). In all other cases, the data type is VARCHAR(254).</td>
</tr>
<tr>
<td>One operand of a CONCAT operator when the other operand is any graphic data type except DBCLOB</td>
<td>If the other operand is GRAPHIC(n) or VARGRAPHIC(n), where n is less than 64, the data type is VARGRAPHIC(127 - n). In all other cases, the data type is VARGRAPHIC(127).</td>
</tr>
<tr>
<td>One operand of a CONCAT operator when the other operand is any binary type except BLOB</td>
<td>If the other operand is BINARY(n) or VARBINARY(n) where n is less than 128, the data type is VARBINARY(255-n). In all other cases, the data type is VARBINARY(255)</td>
</tr>
<tr>
<td>One operand of a CONCAT operator when the other operand is a LOB string</td>
<td>The data type of the other operand (the LOB string)</td>

</tbody>
</table>

Considerations for FETCH statements used with a sensitive static cursor:

Whether changes made outside the cursor are visible to the cursor depends on the type of FETCH that is used with a SENSITIVE STATIC cursor:

- A SENSITIVE FETCH is sensitive to all updates and deletes that are made by this cursor (including changes made by triggers) and committed updates and deletes by all other application processes because every fetched row is retrieved from the underlying base table and not a temporary table. This is the default type of FETCH statement for a SENSITIVE cursor.
Changes that are made to the underlying data using this cursor result in an automatic refresh of the row. The changes that are made using this type of cursor can result in holes in the result table of the cursor. In addition, re-fetching rows (fetching rows that have already been retrieved) can result in holes in the result table. If a sensitive FETCH is issued to re-fetch a row and the row no longer qualifies for the search condition of the query, it results in a "delete hole" or an "update hole". In this case, no data is returned, and the cursor is left positioned on the hole.

- An INSENSITIVE FETCH is not sensitive to updates and deletes that are made outside this cursor; however, it is sensitive to all updates and deletes that are made by this cursor. Changes that made with triggers are not visible with an INSENSITIVE FETCH until the content of the rows are updated in the result table with a SENSITIVE FETCH statement. If an application does not want to be sensitive to changes that are made outside this cursor (that is, the application does not want to see changes made either with another cursor or by another application process), INSENSITIVE can be explicitly specified as part of the FETCH statement for a SENSITIVE STATIC cursor. This type of FETCH is useful for refreshing data in user data buffers. For more information, see INSENSITIVE.

**Error checking:**

When a PREPARE statement is executed, the statement string is parsed and checked for errors. If the statement string is invalid, a prepared statement is not created and the error condition that prevents its creation is reported in the SQLCA.

In local and remote processing, the DEFER(PREPARE) and REOPT(ALWAYS)/REOPT(ONCE) bind options can cause some SQL statements to receive "delayed" errors. For example, DESCRIBE, EXECUTE, and OPEN might receive an SQLCODE that normally occurs during PREPARE processing.

**Reference and execution rules:**

Prepared statements can be referred to in the following kinds of statements, with the following restrictions:

<table>
<thead>
<tr>
<th>Type of statement</th>
<th>Restriction for prepared statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>DESCRIBE</td>
<td>no restriction</td>
</tr>
<tr>
<td>DECLARE CURSOR</td>
<td>Statement must be SELECT when the cursor is opened</td>
</tr>
<tr>
<td>EXECUTE</td>
<td>Statement must not be SELECT</td>
</tr>
</tbody>
</table>

A prepared statement can be executed many times. Indeed, if a prepared statement is not executed more than once and does not contain parameter markers, it is more efficient to use the EXECUTE IMMEDIATE statement rather than the PREPARE and EXECUTE statements.

**Prepared statement persistence:**

All prepared statements created by a unit of work are destroyed when the unit of work is terminated, with the following exceptions:

- A SELECT statement whose cursor is declared with the option WITH HOLD persists over the execution of a commit operation if the cursor is open when the commit operation is executed.
• SELECT, INSERT, UPDATE, MERGE, and DELETE statements that are bound with KEEPDYNAMIC(YES) are kept past the commit point if your system is enabled for dynamic statement caching, and none of the following are true:
  - SQL RELEASE has been issued for the site
  - Bind option DISCONNECT(AUTOMATIC) was used
  - Bind option DISCONNECT(CONDITIONAL) was used and there are no hold cursors for the site

**Scope of a statement name:**
The scope of a statement-name is the same as the scope of a cursor-name. See DECLARE CURSOR for more information about the scope of a cursor-name.

**Preparation with PREPARE INTO and REOPT bind option:**
If bind option REOPT(ALWAYS) or REOPT(ONCE) is in effect, PREPARE INTO is equivalent to a PREPARE and a DESCRIBE being performed. If a statement has input variables, the DESCRIBE causes the statement to be prepared with default values, and the statement must be prepared again when it is opened or executed. When REOPT(ONCE) is in effect, the statement is always prepared twice even if there are no input variables. Therefore, to avoid having a statement prepared twice, avoid using PREPARE INTO when REOPT(ALWAYS) or REOPT(ONCE) is in effect.

**Relationship of cursor attributes on PREPARE statements and SELECT or DECLARE CURSOR statements:**
Cursor attributes that are specified as part of the select-statement are used instead of any corresponding options that specified with the ATTRIBUTES clause on PREPARE. Attributes that are specified as part of the ATTRIBUTES clause of PREPARE take precedence over any corresponding option that is specified with the DECLARE CURSOR statement. The order for using cursor attributes is as follows:

- SELECT (highest priority)
- PREPARE statement ATTRIBUTES clause
- DECLARE CURSOR (lowest priority)

For example, assume that host variable MYQ has been set to the following SELECT statement:

```
SELECT WORKDEPT, EMPNO, SALARY, BONUS, COMM
FROM EMP
WHERE WORKDEPT IN ('D11', 'D21')
FOR UPDATE OF SALARY, BONUS, COMM
```

If the following PREPARE statement were issued, then the FOR UPDATE clause specified as part of the SELECT statement would be used instead of the FOR READ ONLY clause specified with the ATTRIBUTES clause as part of the PREPARE statement. Thus, the cursor would be updatable.

```
attrstring = 'FOR READ ONLY';
EXEC SQL PREPARE stmt1 ATTRIBUTES :attrstring FROM :MYQ;
```
Precedence of attributes for SELECT and UPDATE WHERE CURRENT OF for positioned updates:

If an UPDATE WHERE CURRENT OF statement and the associated SELECT statement are both prepared and both statements have the same PREPARE attributes, the values of the PREPARE attributes for the UPDATE WHERE CURRENT OF statement override the values of the PREPARE attributes for the SELECT statement.

Effect of extended indicator PREPARE attributes on dynamically executed positioned updates:

If an UPDATE statement with the WHERE CURRENT OF clause and the associated SELECT statement are both prepared, if extended indicator variables are used depends on the WITH EXTENDED INDICATORS or WITHOUT EXTENDED INDICATORS attributes in each of the PREPARE statements.

Table 210. Interaction between EXTENDED INDICATOR attributes of PREPARE statements for SELECT and UPDATE statements

<table>
<thead>
<tr>
<th>Extended indicator attribute of PREPARE for SELECT statement</th>
<th>Extended indicator attribute of PREPARE for UPDATE statement with WHERE CURRENT OF clause</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>WITH EXTENDED INDICATORS</td>
<td>WITH EXTENDED INDICATORS</td>
<td>The PREPARE attributes of the UPDATE statement override the PREPARE attributes of the SELECT statement. Non-updatable columns can be in the select-list.</td>
</tr>
<tr>
<td>WITH EXTENDED INDICATORS</td>
<td>WITHOUT EXTENDED INDICATORS</td>
<td>The UPDATE statement is executed without extended indicator parameters.</td>
</tr>
<tr>
<td>WITH EXTENDED INDICATORS</td>
<td>Default (without attribute specified)</td>
<td>The PREPARE attributes of the SELECT statement override the default PREPARE attributes for the UPDATE statement. Non-updatable columns can be in the select-list.</td>
</tr>
<tr>
<td>WITHOUT EXTENDED INDICATORS</td>
<td>WITH EXTENDED INDICATORS</td>
<td>The PREPARE attributes of the UPDATE statement override the PREPARE attributes of the SELECT statement. Non-updatable columns are not in the implicit or explicit select-list.</td>
</tr>
<tr>
<td>WITHOUT EXTENDED INDICATORS</td>
<td>WITHOUT EXTENDED INDICATORS</td>
<td>The UPDATE statement is executed without extended indicator parameters.</td>
</tr>

<td>The UPDATE statement is executed without extended indicator parameters.</td>
</tr>
</tbody>
</table>

Interactions between the SKIPUNCI subsystem parameter and the PREPARE statement:

When the PREPARE statement is specified with either the CURRENTLY COMMITTED or WAIT FOR OUTCOME clauses and the subsystem parameter SKIPUNCI is in effect, the following table describes whether uncommitted inserts are skipped, or if the transaction will wait until a commit or rollback before completing:

Table 211. Interaction between SKIPUNCI subsystem parameter and PREPARE statement

<table>
<thead>
<tr>
<th>Value of SKIPUNCI subsystem parameter</th>
<th>PREPARE statement attribute working</th>
<th>Skip uncommitted inserts, or wait for commit or rollback</th>
</tr>
</thead>
<tbody>
<tr>
<td>YES</td>
<td>CURRENTLY COMMITTED</td>
<td>Skip</td>
</tr>
<tr>
<td>YES</td>
<td>WAIT FOR OUTCOME</td>
<td>Wait</td>
</tr>
<tr>
<td>YES</td>

<td>Skip</td>
</tr>
<tr>
<td>NO</td>
<td>WAIT FOR OUTCOME</td>
<td>Wait</td>
</tr>
<tr>
<td>NO</td>
<td>Not specified</td>
<td>Wait</td>
</tr>
</tbody>
</table>

Extended indicator variables and deferred error checks:

When extended indicator variables are enabled, the indicator value of unassigned causes the associated target column to be omitted from the statement. Because of that, validation that is normally done in statement preparation (to recognize an INSERT into, or UPDATE of, a non-updatable column) is deferred until statement execution. If statement validation fails, an error is returned when the statement is run, not when the statement is prepared.
Reuse of prepared statements in the dynamic statement cache with
**CONCENTRATE STATEMENTS WITH LITERALS**

To be eligible for reuse of constants, the constants in both the new
statement and the cached statement must have the same:

1. immediate usage context
2. data type
3. data type length and size

If DB2 determines that both instances of the constant meet the criteria for
reuse, a cached statement that is prepared using the **CONCENTRATE STATEMENTS WITH LITERALS** option can be shared by the same SQL
statement with different constants. Even though the new dynamic SQL
statement will share the cached statement, the new statement will use its
own literal constants when the statement is run, not the constants of the
cached statement.

There are some exceptions. For example, the built-in function SUBSTR, for
which, because of the immediate usage context, constant reuse in the
cached statement that uses a different constant value can not be done
without the risk of returning incorrect output or results. In such cases, only
an SQL statement instance with the exact same constant value as the
cached version of the statement is eligible for reuse. DB2 determines when
and where this immediate usage context restriction applies.

When the **CONCENTRATE STATEMENTS WITH LITERALS** option is
specified, DB2 considers the values of the literal constants for access path
selection only for statements that are bound with the REOPT(ONCE) or
REOPT(AUTO) bind options.

The DECIMAL defined constants NAN, SNAN, and INFINITY can
qualify for literal constant reuse.

The following examples show how PREPARE is used with
**CONCENTRATE STATEMENTS WITH LITERALS**. X, Y, and Z are
columns of defined as DECIMAL data type:

```sql
DECLARE C1 CURSOR
   FOR DYNSQL_WITH_LITERAL;

DYNSQL_SELECT = 'SELECT X, Y, Z
                   FROM TABLE1
                   WHERE X < 9';

attrstring = 'CONCENTRATE STATEMENTS WITH LITERALS';

EXEC SQL PREPARE DYNSQL_WITH_LITERAL
   ATTRIBUTES :attrstring
   FROM :DYNSQL_SELECT;

EXEC SQL OPEN C1;

DYNSQL_INSERT = 'INSERT INTO
                 TABLE1 (X, Y, Z)
                 VALUES (8,109,29)';

attrstring = 'CONCENTRATE STATEMENTS WITH LITERALS';

EXEC SQL PREPARE DYNSQL_INSERT_WITH_LITERAL
   ATTRIBUTES :attrstring
   FROM :DYNSQL_INSERT;

EXEC SQL EXECUTE DYNSQL_INSERT_WITH_LITERAL;
```
Examples

Example 1: In this PL/I example, an INSERT statement with parameter markers is prepared and executed. Before execution, values for the parameter markers are read into the host variables S1, S2, S3, S4, and S5.

```pli
EXEC SQL PREPARE DEPT_INSERT FROM
  'INSERT INTO DSN8A10.DEPT VALUES(?,?,?,?,?)';
-- Check for successful execution and read values into host variables
EXEC SQL EXECUTE DEPT_INSERT USING :S1, :S2, :S3, :S4, :S5;
```

Example 2: Prepare a dynamic SELECT statement specifying the attributes of the cursor with a host variable on the PREPARE statement. Assume that the text of the SELECT statement is in a variable named stmttxt, and that the attributes of the cursor are in a variable named attrvar.

```pli
EXEC SQL DECLARE mycursor CURSOR FOR mystmt;
EXEC SQL PREPARE mystmt ATTRIBUTES :attrvar
FROM :stmttxt;
EXEC SQL DESCRIBE mystmt INTO :mysqlda;
EXEC SQL OPEN mycursor;
EXEC SQL FETCH FROM mycursor USING DESCRIPTOR :mysqlda;
```
The REFRESH TABLE statement refreshes the data in a materialized query table. The statement deletes all rows in the materialized query table, executes the fullselect in the table definition to recalculates the data from the tables specified in the fullselect, inserts the calculated result into the materialized query table, and updates the catalog for the refresh timestamp and cardinality of the table. The table can exist at the current server or at any DB2 subsystem with which the current server can establish a connection.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privilege set for REFRESH TABLE must include at least one of the following authorities:

- Ownership of the materialized query table
- DBADM or DBCTRL authority on the database that contains the materialized query table
- SYSADM or SYSCTRL authority
- DATAACCESS authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statements dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke). For more information on these behaviors, including a list of the DYNAMICRULES bind option values, see Authorization IDs and dynamic SQL.

Syntax

```
REFRESH TABLE table-name [QUERYNO integer]
```

Description

table-name

Identifies the table to be refreshed. The name must identify a materialized query table. REFRESH TABLE evaluates the fullselect in the materialized-query-definition clause to refresh the table. The isolation level for the fullselect is the isolation level of the materialized query table recorded when CREATE TABLE or ALTER TABLE was issued.

QUERYNO integer

Specifies the number to be used for this SQL statement in EXPLAIN output
and trace records. The number is used for the QUERYNO column of the plan table for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSTSTMT and SYSIBM.SYSPACKSTMT catalog tables.

If the clause is omitted, the number associated with the SQL statement is the statement number assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Notes

Automatic query rewrite using materialized query tables is not attempted for the fullselect in the materialized query table definition during the processing of REFRESH TABLE statement.

After successful execution of a REFRESH TABLE statement, the SQLCA field SQLERRD(3) will contain the number of rows inserted into the materialized query table.

The EXPLAIN output for REFRESH TABLE table-name is the same as the EXPLAIN output for INSERT INTO table-name fullselect where fullselect is from the materialized query table definition.

If the materialized query table has a security label column, the REFRESH TABLE statement does not do any checking for multilevel security with row-level granularity when it deletes and repopulates the data in the table by executing the fullselect. Instead, DB2 performs the checking for multilevel security with row-level granularity when the materialized query table is exploited in automatic query rewrite or is used directly.

The REFRESH TABLE statement can be used to remove a table space from the logical page list and reset recover-pending status. This can only be done by using REFRESH TABLE to repopulate a materialized query table where the materialized query table is the only table in the table space.

Example

Issue a statement to refresh the content of a materialized query table that is named SALESCOUNT. The statement recalculates the data from the fullselect that was used to define SALESCOUNT and refreshes the content of SALESCOUNT with the recalculated results.

REFRESH TABLE SALESCOUNT;
RELEASE (connection)

The RELEASE (connection) statement places one or more connections in the release pending state.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

None required.

Syntax

```
RELEASE location-name host-variable
CURRENT
ALL SQL
```

Description

`location-name` or `host-variable`

Identifies an SQL connection by the specified location name or the location name contained in the host variable. If a host variable is specified:

- It must be a character string variable with a length attribute that is not greater than 16. (A C NUL-terminated character string can be up to 17 bytes.)
- It must not be followed by an indicator variable.
- The location name must be left-justified within the host variable and must conform to the rules for forming an ordinary location identifier.
- If the length of the location name is less than the length of the host variable, it must be padded on the right with blanks.

The specified location name or the location name contained in the host variable must identify an existing SQL connection of the application process.

`CURRENT`

Identifies the current SQL connection of the application process. The application process must be in the connected state.

`ALL` or `ALL SQL`

Identifies all existing connections (including local, and SQL) of the application process. An error or warning does not occur if no connections exist when the statement is executed.

If the RELEASE (connection) statement is successful, each identified connection is placed in the release-pending state and, therefore, will be ended during the next commit operation. If the RELEASE (connection) statement is unsuccessful, the
connection state of the application process and the states of its connections are unchanged.

Notes

**RELEASE and CONNECT (Type 1):** Using CONNECT (Type 1) semantics does not prevent using RELEASE (connection).

**Scope of RELEASE:** RELEASE (connection) does not close cursors, does not release any resources, and does not prevent further use of the connection.

**Resource considerations for remote connections:** Resources are required to create and maintain remote connections. Thus, a remote connection that is not going to be reused should be in the release pending status and one that is going to be reused should not be in the release pending status. Remote connections can also be ended during a commit operation as a result of the DISCONNECT(AUTOMATIC) or DISCONNECT(CONDITIONAL) bind option.

If the current SQL connection is in the release pending status when a commit operation is performed, the connection is ended and the application process is in the unconnected state. In this case, the next executed SQL statement should be CONNECT or SET CONNECTION.

**Connection states:** ROLLBACK does not reset the state of a connection from release pending to held.

If the current SQL connection is in the release pending state when a commit operation is performed, the connection is ended and the application process is in the unconnected state. In this case, the next executed SQL statement must be CONNECT or SET CONNECTION.

For further information, see [“Application process connection states” on page 71](#).

**Location names CURRENT and ALL:** A database server named CURRENT or ALL can only be identified by a host variable or a delimited identifier. A connection in the release pending state is ended during a commit operation even though it has an open cursor defined with WITH HOLD.

**Encoding scheme of a host variable:** If the RELEASE statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

Examples

**Example 1:** The SQL connection to TOROLAB1 is not needed in the next unit of work. The following statement causes it to be ended during the next commit operation:

```sql
EXEC SQL RELEASE TOROLAB1;
```

**Example 2:** The current SQL connection is not needed in the next unit of work. The following statement causes it to be ended during the next commit operation:

```sql
EXEC SQL RELEASE CURRENT;
```
RELEASE SAVEPOINT

The RELEASE SAVEPOINT statement releases the identified savepoint and any subsequently established savepoints within a unit of recovery.

Invocation

This statement can be imbedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
RELEASE SAVEPOINT savepoint-name
```

Description

`savepoint-name`

Identifies the savepoint to release. If the named savepoint does not exist, an error occurs. The name must identify a savepoint that exists at the current server. After a savepoint is released, it is no longer maintained and rollback to the savepoint is no longer possible.

Notes

`Savepoint names`: The name of the savepoint that was released can be reused in another SAVEPOINT statement, regardless of whether the UNIQUE keyword was specified on an earlier SAVEPOINT statement that specified this same savepoint name.

Example

Assume that a main routine sets savepoint A and then invokes a subroutine that sets savepoints B and C. When control returns to the main routine, release savepoint A and any subsequently set savepoints. Savepoints B and C, which were set by the subroutine, are released in addition to A.

```sql
RELEASE SAVEPOINT A;
```
The RENAME statement renames an existing table or index. An accelerator-only table cannot be renamed.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

To rename a table, the privilege set that is defined below must include at least one of the following privileges:

- Ownership of the table
- DBADM, DBCTRL, or DBMAINT authority for the database that contains the table
- SYSADM or SYSCTRL authority
- System DBADM

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

To rename an index, the privilege set that is defined below must include at least one of the following privileges:

- Ownership of the table for which the index is defined
- Ownership of the index that is being renamed
- DBADM, DBCTRL, or DBMAINT authority for the database that contains the index
- SYSADM or SYSCTRL authority
- System DBADM

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is the union of the privilege sets that are held by each authorization ID of the process.

Syntax

```
RENAME
   TABLE source-table-name TO new-table-identifier
   INDEX source-index-name TO new-index-identifier
```
Description

*source-table-name*

Identifies the existing table that is to be renamed. The name, including the implicit or explicit qualifier, must identify a table that exists at the current server. The name must not identify any of the following types of tables:

- A declared temporary table
- A catalog table
- A directory table
- An active resource limit specification table
- A materialized query table
- A clone table
- A system-period temporal table
- A history table for a system-period temporal table
- A table with a trigger defined on it
- A table that is referenced in the definition of a row permission
- A table that is referenced in the definition of a column mask
- A view
- A synonym
- An SQL table function

If you specify a three-part name or alias for the source table, the source table must exist at the current server. If any view definitions or materialized query table definitions currently reference the source table, an error occurs.

*new-table-identifier*

Specifies the new name for the table without a qualifier. The qualifier of the *source-table-name* is used to qualify the new name for the table. The qualified name must not identify a table, view, alias, or synonym that exists at the current server, or a table that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table.

*source-index-name*

Identifies the existing index that is to be renamed. The name, including an implicit or explicit qualifier, must identify an index that exists at the current server. The name must not identify a system defined catalog index, a directory index, an index on a declared temporary table, or an index on an active resource limit specification table.

*new-index-identifier*

Specifies that new name for the index without a qualifier. The qualifier of the *source-index-name* is used to qualify the new name for the index. The qualified name must not identify an index that exists at the current server or an index that exists in the SYSIBM.SYSPENDINGOBJECTS catalog table.

Notes

*Effects of the statement:* The specified table or index is renamed to the new name. For a renamed table, all privileges and indexes on the table are preserved. For a renamed index, all privileges are preserved.

*Invalidation of packages:* When any table except an auxiliary table is renamed, packages that refer to that table are invalidated. When an auxiliary table is renamed, packages that refer to the auxiliary table are not invalidated.
Restriction when there are pending changes to the definition: A RENAME INDEX statement is not allowed if there are pending changes to the definition of the index.

Considerations for aliases: If an alias name is specified for table-name, the table must exist at the current server, and the table that is identified by the alias is renamed. The name of the alias is not changed and continues to refer to the old table name after the rename.

Changing the name of an alias with the RENAME statement is not supported. To change the name to which an alias refers, you must drop the alias and then re-create it.

Considerations for plan tables: The RENAME INDEX statement does not update the contents of a plan table. Rows that exist in a plan table that are generated from an EXPLAIN statement can contain the name of an index in the access path selections. When an index is renamed, any entries in existing plan tables that refer to the old index name are not updated.

Transfer of authorization, referential integrity constraints, and indexes: All authorizations associated with the source table name are transferred to the new (target) table name. The authorization catalog tables are updated appropriately.

Referential integrity constraints involving the source table are updated to refer to the new table. The catalog tables are updated appropriately.

Indexes that are defined for the source table are transferred to the new table. The index catalog tables are updated appropriately.

Object identifier: Renamed tables and indexes keep the same object identifier as the original table or index.

Renaming registration tables: If an application registration table (ART) or object registration table (ORT) or an index of an ART or ORT is specified as the source table for RENAME, when RENAME completes, it is as if that table had been dropped. There is no ART or ORT once the ART or ORT table has been renamed.

Catalog table updates: Entries in the following catalog tables are updated to reflect the new table:
- SYSAUXRELS
- SYSCHECKS
- SYSCHECKS2
- SYSCHECKDEP
- SYSCOLAUTH
- SYSCOLDIST
- SYSCOLDIST_HIST
- SYSCOLDISTSTATS
- SYSCOLSTATS
- SYSCOLUMNS
- SYSCOLUMNS_HIST
- SYSCONSTDEP
- SYSFIELDS
- SYSFOREIGNKEYS
Entries in SYSSTMT and SYSPACKSTMT are not updated.

Entries in the following catalog tables are updated to reflect the new index:
- SYSDEPENDENCIES
- SYSINDEXES
- SYSINDEXES_HIST
- SYSINDEXESPART
- SYSINDEXESPART_HIST
- SYSINDEXSPACESTATS
- SYSINDEXSTATS
- SYSINDEXSTATS_HIST
- SYSKEYS
- SYSKEYTARGETS
- SYSKEYTARGETS_HIST
- SYSKEYTARGETSTATS
- SYSKEYTGTDIST
- SYSKEYTGTDIST_HIST
- SYSKEYTGTDISTSTATS
- SYSOBJROLEDEP
- SYSPACKDEP
- SYSPLANDEP
- SYSRELS
- SYSTABCONST
- SYSTABLEHISTORY
- SYSTABLEPART

**Examples**

*Example 1:* Change the name of the EMP table to EMPLOYEE:

```sql
RENAME TABLE EMP TO EMPLOYEE;
```

*Example 2:* Change the name of the EMP_USA_HIS2002:

```sql
RENAME TABLE EMP_USA_HIS2002 TO EMPLOYEE_UNITEDSTATES_HISTORY2002;
```
Example 3: Change the name of the EMPINDEX1 to EMPLOYEE_INDEX:

RENAME INDEX COMPANY.EMPINDEX1 TO EMPLOYEE_INDEX;
REVOKE

The REVOKE statement revokes privileges from authorization IDs. There is a separate form of the statement for each of these classes of privilege:

- Collection
- Database
- Distinct type
- Function or stored procedure
- Package
- Plan
- Schema
- Sequence
- System
- Table or view
- Use

The applicable objects are always at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

If the authorization mechanism was not activated when the DB2 subsystem was installed, an error condition occurs.

Authorization

If the BY clause is not specified, the authorization ID of the statement must have granted at least one of the specified privileges to every authorization-name specified in the FROM clause (including PUBLIC, if specified). If the BY clause is specified, the authorization ID of the statement must have SECADM or ACCESSCTRL authority.

Note: If installation parameter SEPARATE SECURITY is NO, SYSADM authority has implicit SECADM authority and SYSCTRL authority has implicit ACCESSCTRL authority.

If the BY clause is specified and the privilege set includes ACCESSCTRL, all privileges and authorities can be revoked except for the following:

- System DBADM
- ACCESSCTRL
- DATAACCESS
- CREATE_SECURE_OBJECT privilege

To revoke the CREATE_SECURE_OBJECT privilege, with or without the BY clause, the privilege set must include SECADM authority.

If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. The owner can be a role. If the statement is dynamically prepared, the privilege set is the privileges
that are held by the SQL authorization ID of the process. However, if the process is running in a trusted context that is defined with the ROLE AS OBJECT OWNER AND QUALIFIER CLAUSE, the privilege set is the privileges that are held by the role that is in effect.

### Syntax

```plaintext
REVOKE authorization-specification FROM authorization-name

- ROLE role-name
- PUBLIC

BY authorization-name

- ROLE role-name
- ALL

INCLUDING DEPENDENT PRIVILEGES

NOT INCLUDING DEPENDENT PRIVILEGES

(1)

RESTRICT
```

### Notes:

1. The RESTRICT clause is the default only for the forms of the REVOKE statement that allow it.

### Description

**authorization-specification**

Specifies one or more privileges for the class of privilege. The same privilege must not be specified more than once.

**FROM**

Specifies from what authorization IDs the privileges are revoked.

```plaintext
authorization-name,...
```

Lists one or more authorization IDs. Do not use the same authorization ID more than one time. If the `authorization-name` is specified in lowercase, it must be delimited using double quotes.

The value of CURRENT RULES determines if you can use the ID of the REVOKE statement itself (to revoke privileges from yourself). When CURRENT RULES is:

- **DB2** You cannot use the ID of the REVOKE statement.
- **STD**

  You can use the ID of the REVOKE statement.

**ROLE role-name**

Lists one or more roles. Do not specify the same role more than one time.

**PUBLIC**

Revoke a grant of privileges to PUBLIC.

**BY** Lists grantors who have granted privileges and revokes each named privilege
that was explicitly granted to some named user by one of the named grantors. Only an authorization ID or role with SYSADM or SYSCTRL authority can use BY, even if the authorization ID or role names only itself in the BY clause.

authorization-name,...

Lists one or more authorization IDs of users who were the grantors of the privileges named. Do not use the same authorization ID more than once. Each grantor that is listed must have explicitly granted some named privilege to all of the named users or roles.

ROLE role-name

Lists one or more roles that were the grantors of the privileges named. Do not specify the same role more than one time. Each grantor that is listed must have explicitly granted some named privilege to all of the named users or roles.

ALL

Revolves each named privilege from all named users who were explicitly granted the privilege, regardless of who granted it.

INCLUDING DEPENDENT PRIVILEGES or NOT INCLUDING DEPENDENT PRIVILEGES

Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and an error is returned if the statement includes INCLUDING DEPENDENT PRIVILEGES.
- Otherwise, INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.

INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

INCLUDING DEPENDENT PRIVILEGES cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

NOT INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

NOT INCLUDING DEPENDENT PRIVILEGES must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.
NOT INCLUDING DEPENDENT PRIVILEGES cannot be specified if the
system parameter REVOKE_DEP_PRIVILEGES is set to YES, which enforces
the behavior to include dependent privileges in the revoke.

RESTRICT
Prevents the named privilege from being revoked when certain conditions
apply. RESTRICT is the default only for the forms of the REVOKE statement
that allow it. These forms are revoking the USAGE privilege on distinct types,
the EXECUTE privilege on user-defined functions and stored procedures, and
the USAGE privilege on sequences.

Notes

Revoked privileges: The privileges revoked from an authorization ID or a role are
those that are identified in the statement and which were granted to the user by
the grantor. Other privileges can be revoked as the result of revoking dependent
privileges. For more on DB2 privileges, see DB2 Administration Guide.

Revoked dependent privileges: Revoking a privilege from a user can also cause that
privilege to be revoked from other users. This was previously known as cascade
revoke. When revoking a privilege from an authorization ID or a role, DB2 looks for
and revokes any grants of the privilege where the grantor is the same as the
authorization ID or role of the original revoke. The following rules must be true
for privilege P' to be revoked from U3 when U1 revokes privilege P from U2:
- P and P' are the same privilege.
- U2 granted privilege P' to U3.
- No one granted privilege P to U2 prior to the grant by U1.
- U2 does not have installation SYSADM authority.

The rules also apply to the implicit grants that are made as a result of a CREATE VIEW statement.

Revoking dependent privileges does not occur under any of the following
conditions:
- The privilege was granted by a current installation SYSADM user.
- The privilege is the USAGE privilege on a distinct type and the revokee owns
  any of these items:
  - A user-defined function or stored procedure that uses the distinct type
  - A table that has a column that uses the distinct type
  - A sequence whose data type is the distinct type
- The privilege is the USAGE privilege on a sequence and the revokee owns any
  of these items:
  - A trigger that has a NEXT VALUE or PREVIOUS VALUE expression that
    specifies the sequence
  - An inline SQL function that has a NEXT VALUE or PREVIOUS VALUE
    expression in the function body that specifies the sequence
- The privilege is the EXECUTE privilege on a user-defined function and the
  revokee owns any of these items:
  - A user-defined function that is sourced on the function
  - A view that uses the function
  - A trigger package that uses the function
A table that uses the function in a check constraint or a user-defined default type

- The privilege is the EXECUTE privilege on a stored procedure and the revokee owns any of these items:
  - A trigger package that refers to the stored procedure in a CALL statement.

- If the ACCESSCTRL administrative authority is revoked from a user, grants that are made by this ACCESSCTRL user are not revoked.
  If this user revoked grants made by it, those revokes will continue to revoke the dependent privileges, unless the behavior to not include the dependent privileges was specified either by using the system parameter REVOKE_DEP_PRIVILEGES or by using the REVOKE statement if REVOKE_DEP_PRIVILEGES is set to SQLSTMT.

- If SECADM is removed from a user, grants that are made by this SECADM user are not revoked.
  If this user revoked grants made by it, those revokes will continue to revoke the dependent privileges, unless the behavior to not include the dependent privileges was specified either by using the system parameter REVOKE_DEP_PRIVILEGES or by using the REVOKE statement if REVOKE_DEP_PRIVILEGES is set to SQLSTMT.

- If NOT INCLUDING DEPENDENT PRIVILEGES option is specified, the grants made by this user are not revoked.

Refer to the diagrams for the following example:
1. Suppose BOB grants SYSADM authority to WADE. Later, CLAIRE grants the SELECT privilege on a table with the WITH GRANT OPTION to WADE.

   ![Diagram 1]

   BOB grants SYSADM to WADE

   CLAIRE grants SELECT WITH GRANT OPTION to WADE

2. WADE grants the SELECT privilege to JOHN on the same table.

   ![Diagram 2]

   WADE grants SELECT to JOHN

3. When CLAIRE revokes the SELECT privilege on the table from WADE, the SELECT privilege on that table is also revoked from JOHN.
The grant from WADE to JOHN is removed because WADE had not been granted the SELECT privilege from any other source before CLAIRE made the grant. The SYSADM authority granted to WADE from BOB does not affect the cascade revoke. For more on SYSADM and installation SYSADM authority, see DB2 Administration Guide. For another example of cascading revokes, see DB2 Administration Guide.

Revoking a SELECT privilege that was exercised to create a view or materialized query table causes the view to be dropped, unless the owner of the view was directly granted the SELECT privilege from another source before the view was created. Revoking a SYSADM privilege that was required to create a view causes the view to be dropped. For details on when SYSADM authority is required to create a view, see Authorization in "CREATE VIEW" on page 1862.

Invalidation of packages: A revoke or cascaded revoke of any privilege or role that was exercised to create a package makes the package invalid when the revokee no longer holds the privilege from any other source. Corresponding authorization caches are cleared even if the revokee has the privilege from any other source. 39

Inoperative packages: A revoke or cascaded revoke of the EXECUTE privilege on a user-defined function that was exercised to create a package makes the package inoperative and causes the corresponding authorization caches to be cleared when the revokee no longer holds the privilege from any other source. 39

Privileges belonging to an authority: You can revoke an administrative authority, but you cannot separately revoke the specific privileges inherent in that administrative authority.

Let P be a privilege inherent in authority X. A user with authority X can also have privilege P as a result of an explicit grant of P. In this case:

- If X is revoked, the user still has privilege P.
- If P is revoked, the user still has the privilege because it is inherent in X.

Revoking of privileges in a trusted context: Revokes that are made in a trusted context that is defined with the ROLE AS OBJECT OWNER clause result in the revoker being the role in effect. If the statement is prepared dynamically, the revoker is the role that is associated with the user that is running the statement. If the statement is embedded in a program, the revoker is the owner of the plan or

39. Dependencies on stored procedures can be checked only if the procedure name is specified as a constant and not via a host variable in the CALL statement.
package. If the ROLE AS OBJECT OWNER clause is not specified for the trusted context, the revoker is the authorization ID of the process.

Ownership privileges: The privileges inherent in the ownership of an object cannot be revoked.

Revoke not including dependent privileges: When a privilege is revoked from a user by specifying NOT INCLUDING DEPENDENT PRIVILEGES, the grants that were made by this user are not revoked and the grantor remains unchanged. If that user is later granted the same privilege and then this privilege is revoked by specifying INCLUDING DEPENDENT PRIVILEGES, that would also revoke all the grants that were previously made by this user. Refer to the following examples:

User U1 is granted SELECT on table T1 with GRANT OPTION:
1. U1 grants this privilege to U2.
2. SELECT privilege is revoked from U1 without including dependent privileges.
   As a result, the grant from U1 to U2 is not revoked.
3. U1 is again granted SELECT on T1.
4. SELECT is now revoked from U1 with including dependent privileges and the grant from U1 to U2 is now revoked.

User U1 is granted SYSADM authority:
1. U1 grants privilege P1 to U2 and privilege P2 to U3.
2. SYSADM is revoked from U1 without including dependent privileges. The grants of privileges P1 and P2 to U2 and U3 are not revoked.
3. U1 is again granted SYSADM. U1 grants privilege P3 to U3.
4. SYSADM is now revoked from U1 including dependent privileges. Now, P1 granted to U2 and P2 and P3 granted to U3 are also revoked.

REVOKE (collection privileges)

This form of the REVOKE statement revokes privileges on collections.

Syntax

```sql
REVOKE CREATE PACKADM IN COLLECTION collection-id FROM

| authorization-name |
| ROLE role-name |
| PUBLIC |
| BY authorization-name |
| ROLE role-name |
| ALL |

INCLUDING DEPENDENT PRIVILEGES or NOT INCLUDING DEPENDENT PRIVILEGES
```

Description

**CREATE IN**
Reverses the privilege to use the BIND subcommand to create packages in the designated collections.

The word ON can be used instead of IN.

**PACKADM ON**
Reverses the package administrator authority for the designated collections.

The word IN can be used instead of ON.

**COLLECTION collection-id,...**
Identifies the collections on which the specified privilege is revoked. For each identified collection, you (or the indicated grantors) must have granted the specified privilege on that collection to all identified users (including PUBLIC if specified). The same collection must not be identified more than once.

**COLLECTION * **
Indicates that the specified privilege on COLLECTION * is revoked. You (or the indicated grantors) must have granted the specified privilege on COLLECTION * to all identified users (including PUBLIC if specified).

Privileges granted on specific collections are not affected.

**FROM**
Refer to REVOKE for a description of the FROM clause.

**BY**
Refer to REVOKE for a description of the BY clause.

**INCLUDING DEPENDENT PRIVILEGES or NOT INCLUDING DEPENDENT PRIVILEGES**
Specifies whether revoking a privilege or an authority from an authorization
ID or a role also results in revoking the grants that were made by that user.
The default value is based on the authority that is being revoked and the
REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and an error is returned if the statement includes INCLUDING DEPENDENT PRIVILEGES.
- Otherwise, INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.

INCLUDING DEPENDENT PRIVILEGES
Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

INCLUDING DEPENDENT PRIVILEGES cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

NOT INCLUDING DEPENDENT PRIVILEGES
Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

NOT INCLUDING DEPENDENT PRIVILEGES must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

NOT INCLUDING DEPENDENT PRIVILEGES cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to YES, which enforces the behavior to include dependent privileges in the revoke.

Examples

Example 1: Revoke the privilege to create new packages in collections QAACLONE and DSN8CC61 from CLARK.

REVOKE CREATE IN COLLECTION QAACLONE, DSN8CC61 FROM CLARK;

Example 2: Revoke the privilege to create new packages in collections DSN8CC91 from role ROLE1:

REVOKE CREATE IN COLLECTION DSN8CC91 FROM ROLE ROLE1;
REVOKE (database privileges)

This form of the REVOKE statement revokes database privileges.

Syntax

```
REVOKE [DBADM] [DBCTRL] [DBMAINT] [CREATETAB] [CREATETS] [DISPLAYDB] [DROP] [IMAGCOPY] [LOAD] [RECOVERDB] [REORG] [REPAIR] [STARTDB] [STATS] [STOPDB] ON DATABASE specified-database FROM [PUBLIC] [ROLE role-name] 
```

Description

Each keyword listed revokes the privilege described, but only as it applies to or within the databases named in the statement.

**DBADM**
Revokes the database administrator authority.

**DBCTRL**
Revokes the database control authority.

**DBMAINT**
Revokes the database maintenance authority.

**CREATETAB**
Revokes the privilege to create new tables. If CREATETAB privilege is revoked from DSNDB04, tables cannot be created in implicitly created databases. For a work file database, you cannot revoke the privilege from PUBLIC. When a work file database is created, PUBLIC implicitly receives the CREATETAB privilege (without GRANT authority); this privilege is not recorded in the DB2 catalog, and it cannot be revoked.

**CREATETS**
Revokes the privilege to create new table spaces.
DISPLAYDB
Revokes the privilege to issue the DISPLAY DATABASE command.

DROP
Revokes the privilege to issue the DROP or ALTER statements in the specified databases.

IMAGCOPY
Revokes the privilege to run the COPY, MERGECOPY, and QUIESCE utilities against table spaces of the specified databases, and to run the MODIFY RECOVERY utility.

LOAD
Revokes the privilege to use the LOAD utility to load tables.

RECOVERDB
Revokes the privilege to use the RECOVER and REPORT utilities to recover table spaces and indexes.

REORG
Revokes the privilege to use the REORG utility to reorganize table spaces and indexes.

REPAIR
Revokes the privilege to use the REPAIR and DIAGNOSE utilities.

STARTDB
Revokes the privilege to issue the START DATABASE command.

STATS
Revokes the privilege to use the RUNSTATS utility to update statistics, and the CHECK utility to test whether indexes are consistent with the data they index, and the MODIFY STATISTICS utility to delete unwanted statistics history records from the corresponding catalog tables.

STOPDB
Revokes the privilege to issue the STOP DATABASE command.

ON DATABASE database-name,...
Identifies databases on which you are revoking the privileges. For each database you identify, you (or the indicated grantors) must have granted at least one of the specified privileges on that database to all identified users (including PUBLIC, if specified). The same database must not be identified more than once.

FROM
Refer to REVOKE for a description of the FROM clause.

BY
Refer to REVOKE for a description of the BY clause.

INCLUDING DEPENDENT PRIVILEGES or NOT INCLUDING DEPENDENT PRIVILEGES
Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user.
The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and an error is returned if the statement includes INCLUDING DEPENDENT PRIVILEGES.
• Otherwise, **INCLUDING DEPENDENT PRIVILEGES** is assumed and the clause must be specified on the REVOKE statement.

**INCLUDING DEPENDENT PRIVILEGES**

Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

**INCLUDING DEPENDENT PRIVILEGES** cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

**NOT INCLUDING DEPENDENT PRIVILEGES**

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

**NOT INCLUDING DEPENDENT PRIVILEGES** must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

**NOT INCLUDING DEPENDENT PRIVILEGES** cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to YES, which enforces the behavior to include dependent privileges in the revoke.

**Examples**

*Example 1:* Revoke drop privileges on database DSN8D10A from user PEREZ.

```sql
REVOKE DROP ON DATABASE DSN8D10A FROM PEREZ;
```

*Example 2:* Revoke repair privileges on database DSN8D10A from all local users. (Grants to specific users will not be affected.)

```sql
REVOKE REPAIR ON DATABASE DSN8D10A FROM PUBLIC;
```

*Example 3:* Revoke authority to create new tables and load tables in database DSN8D10A from users WALKER, PIANKA, and FUJIMOTO.

```sql
REVOKE CREATETAB,LOAD ON DATABASE DSN8D10A FROM WALKER,PIANKA,FUJIMOTO;
```

*Example 4:* Revoke load privileges on database DSN8D10A from role ROLE1:

```sql
REVOKE LOAD ON DATABASE DSN8D10A FROM ROLE ROLE1;
```
REVOKE (function or procedure privileges)

This form of the REVOKE statement revokes privileges on user-defined functions, cast functions that were generated for distinct types, and stored procedures.

Syntax

```
REVOKE EXECUTE ON FUNCTION function-name,
FUNCTION function-name (parameter-type),
SPECIFIC FUNCTION specific-name,
PROCEDURE procedure-name *
FROM authorization-name
ROLE role-name
PUBLIC
BY authorization-name
ROLE role-name
ALL
INCLUDING DEPENDENT PRIVILEGES
NOT INCLUDING DEPENDENT PRIVILEGES
```

parameter-type:
Notes:
1. AS LOCATOR can be specified only for a LOB data type or a distinct type that is based on a LOB data type.
**Description**

**EXECUTE**

Revokes the privilege to run the identified user-defined function, cast function that was generated for a distinct type, or stored procedure.

**FUNCTION or SPECIFIC FUNCTION**

Identifies the function from which the privilege is revoked. The function must exist at the current server, and it must be a function that was defined with the CREATE FUNCTION statement or a cast function that was generated by a CREATE TYPE statement. The function can be identified by name, function signature, or specific name.

If the function was defined with a table parameter (the LIKE TABLE was specified in the CREATE FUNCTION statement to indicate that one of the
input parameters is a transition table), the function signature cannot be used to identify the function. Instead, identify the function with its function name, if unique, or with its specific name.

**FUNCTION** *function-name*

Identifies the function by its name. The *function-name* must identify exactly one function. The function can have any number of parameters defined for it. If there is more than one function of the specified name in the specified or implicit schema, an error is returned.

An * can be specified for a qualified or unqualified *function-name*. An * (or *schema-name.*) indicates that the privilege is revoked for all the functions in the schema. You (or the indicated grantors) must have granted the privilege on FUNCTION * to all identified users (including PUBLIC if specified). Privileges granted on specific functions are not affected.

**FUNCTION** *function-name* (parameter-type,...)

Identifies the function by its function signature, which uniquely identifies the function. The *function-name* (parameter-type, ...) must identify a function with the specified function signature. The specified parameters must match the data types in the corresponding position that were specified when the function was created. The number of data types, and the logical concatenation of the data types is used to identify the specific function instance on which the privilege is to be granted. Synonyms for data types are considered a match.

If the function was defined with a table parameter (the LIKE TABLE *name* AS LOCATOR clause was specified in the CREATE FUNCTION statement to indicate that one of the input parameters is a transition table), the function signature cannot be used to uniquely identify the function. Instead, use one of the other syntax variations to identify the function with its function name, if unique, or its specific name.

If *function-name ()* is specified, the function identified must have zero parameters.

*function-name*

Identifies the name of the function. If you do not explicitly qualify the function name with a schema name, the function name is implicitly qualified with a schema name as described in the preceding description for FUNCTION *function-name*.

*(parameter-type,...)*

Identifies the parameters of the function.

If an unqualified distinct type name is specified, DB2 searches the SQL path to resolve the schema name for the distinct type.

For data types that have a length, precision, or scale attribute, use one of the following:

- Empty parentheses indicate that the database manager ignores the attribute when determining whether the data types match. For example, DEC() will be considered a match for a parameter of a function defined with a data type of DEC(7,2). Similarly DECFLOAT() will be considered a match for DECFLOAT(16) or DECFLOAT(34). However, FLOAT cannot be specified with empty parenthesis because its parameter value indicates a specific data type (REAL or DOUBLE).
- If a specific value for a length, precision, or scale attribute is specified, the value must exactly match the value that was specified
(implicitly or explicitly) in the CREATE FUNCTION statement. If the data type is FLOAT, the precision does not have to exactly match the value that was specified because matching is based on the data type (REAL or DOUBLE).

- If length, precision, or scale is not explicitly specified, and empty parentheses are not specified, the default attributes of the data type are implied. The implicit length must exactly match the value that was specified (implicitly or explicitly) in the CREATE FUNCTION statement.

For data types with a subtype or encoding scheme attribute, specifying the FOR subtype DATA clause or the CCSID clause is optional. Omission of either clause indicates that DB2 ignores the attribute when determining whether the data types match. If you specify either clause, it must match the value that was implicitly or explicitly specified in the CREATE FUNCTION statement.

AS LOCATOR
Specifies that the function is defined to receive a locator for this parameter. If AS LOCATOR is specified, the data type must be a LOB or a distinct type based on a LOB.

SPECIFIC FUNCTION specific-name
Identifies the function by its specific name. The specific-name must identify a specific function that exists at the current server.

PROCEDURE procedure-name
Identifies a stored procedure that is defined at the current server.

An * can be specified for a qualified or unqualified procedure-name. An * (or schema-name.*) indicates that the privilege is revoked for all the procedures in the schema. You (or the indicated grantors) must have granted the privilege on PROCEDURE * to all identified users (including PUBLIC if specified). Privileges granted on specific procedures are not affected.

FROM
Refer to REVOKE for a description of the FROM clause.

BY
Refer to REVOKE for a description of the BY clause.

INCLUDING DEPENDENT PRIVILEGES or NOT INCLUDING DEPENDENT PRIVILEGES
Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and an error is returned if the statement includes INCLUDING DEPENDENT PRIVILEGES.
- Otherwise, INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.

INCLUDING DEPENDENT PRIVILEGES
Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any
grants that were made by the user will continue to be revoked, until all
grants in the chain have been revoked.

**INCLUDING DEPENDENT PRIVILEGES** cannot be specified if the
system parameter REVOKE_DEP_PRIVILEGES is set to NO, which
enforces the behavior to not include the dependent privileges.

**NOT INCLUDING DEPENDENT PRIVILEGES**
Specifies that revoking a privilege or an authority from an authorization ID
or a role does not cause the grants that were made by the user to be
revoked. However, for the revoked privileges, all implications of the
privilege being revoked are applied. For example, if the revoked privileges
were required to bind a package successfully, that package would continue
to be invalidated as a result of the package owner losing these privileges.
An object might be dropped if a privilege is revoked that was used to
create the object.

**NOT INCLUDING DEPENDENT PRIVILEGES** must be specified when
ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

**NOT INCLUDING DEPENDENT PRIVILEGES** cannot be specified if the
system parameter REVOKE_DEP_PRIVILEGES is set to YES, which enforces
the behavior to include dependent privileges in the revoke.

**RESTRICT**
Prevents the EXECUTE privilege from being revoked on a user-defined
function or stored procedure if the revokee owns any of the following objects
and does not have the EXECUTE privilege from another source:

- A function that is sourced on the function
- A view that uses the function
- A trigger package that uses the function or stored procedure
- A table that uses the function in a check constraint or user-defined default
  clause
- A materialized query table whose fullselect uses the function
- An extended index that uses the function

**Examples**

**Example 1:** Revoke the EXECUTE privilege on function CALC_SALARY for user
JONES. Assume that there is only one function in the schema with function
CALC_SALARY.

```sql
REVOKE EXECUTE ON FUNCTION CALC_SALARY FROM JONES;
```

**Example 2:** Revoke the EXECUTE privilege on procedure VACATION_ACCR from
all users at the current server.

```sql
REVOKE EXECUTE ON PROCEDURE VACATION_ACCR FROM PUBLIC;
```

**Example 3:** Revoke the privilege of the administrative assistant to grant EXECUTE
privileges on function DEPT_TOTALS to other users. The administrative assistant
will still have the EXECUTE privilege on function DEPT_TOTALS.

```sql
REVOKE EXECUTE ON FUNCTION DEPT_TOTALS
FROM ADMIN_A;
```

**Example 4:** Revoke the EXECUTE privilege on function NEW_DEPT_HIRES for HR
(Human Resources). The function has two input parameters with data types of
INTEGER and CHAR(10), respectively. Assume that the schema has more than one
function that is named NEW_DEPT_HIRES.
REVOKE EXECUTE ON FUNCTION NEW_DEPT_HIRES (INTEGER, CHAR(10))
FROM HR;

You can also code the CHAR(10) data type as CHAR().

Example 5: Revoke the EXECUTE privilege on function FIND_EMPDEPT from role ROLE1:

REVOKE EXECUTE ON FUNCTION FIND_EMPDEPT
FROM ROLE ROLE1;
REVOKE (package privileges)

This form of the REVOKE statement revokes privileges on packages.

Syntax

```
REVOKE ALL
ON PACKAGE collection-id.package-name
FROM

BIND
COPY
EXECUTE
RUN

authorization-name
ROLE role-name
PUBLIC

BY

authorization-name
ROLE role-name
ALL

INCLUDING DEPENDENT PRIVILEGES
NOT INCLUDING DEPENDENT PRIVILEGES
```

Description

**BIND**

Revokes the privilege to use the BIND and REBIND subcommands for the designated packages. In addition, if the value of field BIND NEW PACKAGE on installation panel DSNTIPP is BIND, the additional BIND privilege of adding new versions of packages is revoked. (For details, see `GRANT (package privileges)`)

**COPY**

Revokes the privilege to use the COPY option of the BIND subcommand for the designated packages.

**EXECUTE**

Revokes the privilege to run application programs that use the designated packages and to specify the packages following PKLIST for the BIND PLAN and REBIND PLAN commands. RUN is an alternate name for the same privilege.

**ALL**

Revokes all package privileges for which you have authority for the packages named in the ON clause.
ON PACKAGE `collection-id.package-name`...

Identifies packages for which you are revoking privileges. The revoking of a package privilege applies to all versions of that package. For each package that you identify, you (or the indicated grantors) must have granted at least one of the specified privileges on that package to all identified users (including PUBLIC, if specified). An authorization ID with PACKADM authority over the collection or all collections, SYSADM, or SYSCTRL authority can specify all packages in the collection by using * for `package-name`. The same package must not be specified more than once.

FROM

Refer to `REVOKE` for a description of the FROM clause.

BY

Refer to `REVOKE` for a description of the BY clause.

INCLUDING DEPENDENT PRIVILEGES or NOT INCLUDING DEPENDENT PRIVILEGES

Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and an error is returned if the statement includes INCLUDING DEPENDENT PRIVILEGES.
- Otherwise, INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.

INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

INCLUDING DEPENDENT PRIVILEGES cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

NOT INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

NOT INCLUDING DEPENDENT PRIVILEGES must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

NOT INCLUDING DEPENDENT PRIVILEGES cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to YES, which enforces the behavior to include dependent privileges in the revoke.
Notes

*Alternative syntax and synonyms:* To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports specifying PROGRAM as a synonym for PACKAGE.

Examples

*Example 1:* Revoke the privilege to copy all packages in collection DSN8CC61 from LEWIS.

```
REVOKE COPY ON PACKAGE DSN8CC61.* FROM LEWIS;
```

*Example 2:* Revoke the privilege to run all packages in collection DSN9CC13 from role ROLE1:

```
REVOKE EXECUTE ON PACKAGE DSN9CC13.* FROM ROLE ROLE1;
```
REVOKE (plan privileges)

This form of the REVOKE statement revokes privileges on application plans.

Syntax

```
REVOKE
    BIND
    EXECUTE
ON PLAN
 plan-name
    FROM
 authorization-name
    ROLE role-name
    PUBLIC
    BY
 authorization-name
    ROLE role-name
    ALL
    INCLUDING DEPENDENT PRIVILEGES
    NOT INCLUDING DEPENDENT PRIVILEGES
```

Description

BIND
Revolves the privilege to use the BIND, REBIND, and FREE subcommands for the identified plans.

EXECUTE
Revolves the privilege to run application programs that use the identified plans.

ON PLAN plan-name,...
Identifies application plans for which you are revoking privileges. For each plan that you identify, you (or the indicated grantors) must have granted at least one of the specified privileges on that plan to all identified users (including PUBLIC, if specified). The same plan must not be specified more than once.

FROM
Refer to REVOKE for a description of the FROM clause.

BY
Refer to REVOKE for a description of the BY clause.

INCLUDING DEPENDENT PRIVILEGES or NOT INCLUDING DEPENDENT PRIVILEGES
Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and an error is returned if the statement includes INCLUDING DEPENDENT PRIVILEGES.
• Otherwise, INCLUDING DEPENDENT PRIVILEGES is assumed and the
  clause must be specified on the REVOKE statement.

INCLUDING DEPENDENT PRIVILEGES
  Specifies that revoking a privilege or an authority from an authorization ID
  or a role also results in revoking dependent privileges. This means that any
  grants that were made by the user will continue to be revoked, until all
  grants in the chain have been revoked.

INCLUDING DEPENDENT PRIVILEGES cannot be specified if the
  system parameter REVOKE_DEP_PRIVILEGES is set to NO, which
  enforces the behavior to not include the dependent privileges.

NOT INCLUDING DEPENDENT PRIVILEGES
  Specifies that revoking a privilege or an authority from an authorization ID
  or a role does not cause the grants that were made by the user to be
  revoked. However, for the revoked privileges, all implications of the
  privilege being revoked are applied. For example, if the revoked privileges
  were required to bind a package successfully, that package would continue
  to be invalidated as a result of the package owner losing these privileges.
  An object might be dropped if a privilege is revoked that was used to
  create the object.

NOT INCLUDING DEPENDENT PRIVILEGES must be specified when
  ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

NOT INCLUDING DEPENDENT PRIVILEGES cannot be specified if the
  system parameter REVOKE_DEP_PRIVILEGES is set to YES, which enforces
  the behavior to include dependent privileges in the revoke.

Examples

Example 1: Revoke authority to bind plan DSN8IP10 from user JONES.
  REVOKE BIND ON PLAN DSN8IP10 FROM JONES;

Example 2: Revoke authority previously granted to all users at the current server to
  bind and execute plan DSN8CP10. (Grants to specific users will not be affected.)
  REVOKE BIND, EXECUTE ON PLAN DSN8CP10 FROM PUBLIC;

Example 3: Revoke authority to execute plan DSN8CP10 from users ADAMSON
  and BROWN.
  REVOKE EXECUTE ON PLAN DSN8CP10 FROM ADAMSON, BROWN;

Example 4: Revoke authority to bind plan DSN91PLN from role ROLE1:
  REVOKE BIND ON PLAN DSN91PLN FROM ROLE ROLE1;
REVOKE (schema privileges)

This form of the REVOKE statement revokes privileges on schemas.

Syntax

```
REVOKE
  ALTERIN
  CREATEIN
  DROPIN
  ON SCHEMA
    schema-name
  FROM
    authorization-name
    ROLE role-name
    PUBLIC
    ALL
    BY
      authorization-name
      ROLE role-name
      ALL
  INCLUDING DEPENDENT PRIVILEGES
  NOT INCLUDING DEPENDENT PRIVILEGES
```

Description

**ALTERIN**
Revolves the privilege to alter sequences, stored procedures, and user-defined functions, or specify a comment for distinct types, cast functions that are generated for distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

**CREATEIN**
Revolves the privilege to create distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

**DROPIN**
Revolves the privilege to drop distinct types, sequences, stored procedures, triggers, and user-defined functions in the designated schemas.

**SCHEMA schema-name**
Identifies the schema on which the privilege is revoked.

**SCHEMA ***
Indicates that the specified privilege on all schemas is revoked. You (or the indicated grantors) must have previously granted the specified privilege on SCHEMA * to all identified users (including PUBLIC if specified). Privileges granted on specific schemas are not affected.

**FROM**
Refer to REVOKE for a description of the FROM clause.

**BY**
Refer to REVOKE for a description of the BY clause.

**INCLUDING DEPENDENT PRIVILEGES or NOT INCLUDING DEPENDENT PRIVILEGES**
Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter.
When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, **NOT INCLUDING DEPENDENT PRIVILEGES** is assumed and the clause must be specified on the REVOKE statement.

When the REVOKE DEP_PRIVILEGES system parameter is set to NO, **NOT INCLUDING DEPENDENT PRIVILEGES** is assumed and an error is returned if the statement includes **INCLUDING DEPENDENT PRIVILEGES**.

Otherwise, **INCLUDING DEPENDENT PRIVILEGES** is assumed and the clause must be specified on the REVOKE statement.

**INCLUDING DEPENDENT PRIVILEGES**

Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

**INCLUDING DEPENDENT PRIVILEGES** cannot be specified if the system parameter REVOKE DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

**NOT INCLUDING DEPENDENT PRIVILEGES**

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

**NOT INCLUDING DEPENDENT PRIVILEGES** must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

**NOT INCLUDING DEPENDENT PRIVILEGES** cannot be specified if the system parameter REVOKE DEP_PRIVILEGES is set to YES, which enforces the behavior to include dependent privileges in the revoke.

**Examples**

**Example 1:** Revoke the CREATEIN privilege on schema T_SCORES from user JONES.

```
REVOKE CREATEIN ON SCHEMA T_SCORES FROM JONES;
```

**Example 2:** Revoke the CREATEIN privilege on schema VAC from all users at the current server.

```
REVOKE CREATEIN ON SCHEMA VAC FROM PUBLIC;
```

**Example 3:** Revoke the ALTERIN privilege on schema DEPT from the administrative assistant.

```
REVOKE ALTERIN ON SCHEMA DEPT FROM ADMIN_A;
```

**Example 4:** Revoke the ALTERIN and DROPIN privileges on schemas NEW_HIRE, PROMO, and RESIGN from HR (Human Resources).

```
REVOKE ALTERIN, DROPIN ON SCHEMA NEW_HIRE, PROMO, RESIGN FROM HR;
```

**Example 5:** Revoke the ALTERIN privilege on schemas EMPLOYEE from role ROLE1:
REVOKE ALTER ON SCHEMA EMPLOYEE FROM ROLE ROLE1;
REVOKE (sequence privileges)

This form of the REVOKE statement revokes the privileges on a user-defined sequence.

Syntax

```
REVOKE ALTER, USAGE ON SEQUENCE sequence-name FROM authorization-name
ROLE role-name PUBLIC

REVOKE USAGE ON SEQUENCE sequence-name FROM authorization-name
ROLE role-name PUBLIC

REVOKE INCLUDING DEPENDENT PRIVILEGES
REVOKE NOT INCLUDING DEPENDENT PRIVILEGES

BY authorization-name
role-name
ALL

Restrict
```

Notes:
1. The keyword SELECT is an alternative keyword for USAGE.

Description

**ALTER**
Revoke the privilege to alter a sequence or record a comment on a sequence.

**USAGE**
Revoke the USAGE privilege to use a sequence. This privilege is needed when the NEXT VALUE or PREVIOUS VALUE expression is invoked for a sequence name.

**SEQUENCE sequence-name**
Identifies the sequence. The name, including the implicit or explicit schema qualifier, must uniquely identify an existing sequence at the current server. If no sequence by this name exists in the explicitly or implicitly specified schema, an error occurs. `sequence-name` must not be the name of an internal sequence object that is generated by the system for an identity column.

**FROM**
Refer to [REVOKE](#) for a description of the FROM clause.

**BY**
Refer to [REVOKE](#) for a description of the BY clause.

**INCLUDING DEPENDENT PRIVILEGES** or **NOT INCLUDING DEPENDENT PRIVILEGES**
Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user.
The default value is based on the authority that is being revoked and the `REVOKE_DEP_PRIVILEGES` system parameter:

- When `ACCESSCTRL`, `DATAACCESS`, or system `DBADM` authority is revoked, **NOT INCLUDING DEPENDENT PRIVILEGES** is assumed and the clause must be specified on the REVOKE statement.
• When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, **NOT INCLUDING DEPENDENT PRIVILEGES** is assumed and an error is returned if the statement includes **INCLUDING DEPENDENT PRIVILEGES**.

• Otherwise, **INCLUDING DEPENDENT PRIVILEGES** is assumed and the clause must be specified on the REVOKE statement.

**INCLUDING DEPENDENT PRIVILEGES**

  Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

**INCLUDING DEPENDENT PRIVILEGES** cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

**NOT INCLUDING DEPENDENT PRIVILEGES**

  Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

**NOT INCLUDING DEPENDENT PRIVILEGES** must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

**NOT INCLUDING DEPENDENT PRIVILEGES** cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to YES, which enforces the behavior to include dependent privileges in the revoke.

**RESTRICT**

  Prevents the USAGE privilege from being revoked on a sequence if the revokee owns one of the following objects and does not have the USAGE privilege from another source:

  • A trigger that specifies the sequence in a NEXT VALUE or PREVIOUS VALUE expression
  • An inline SQL function that specifies the sequence in a NEXT VALUE or PREVIOUS VALUE expression

**Examples**

*Example 1*: Revoke USAGE privilege on sequence MYNUM to user JONES.

```sql
REVOKE USAGE
  ON SEQUENCE MYNUM
  FROM JONES;
```

*Example 2*: Revoke the USAGE privilege on sequence ORDER_SEQ from role ROLE1:

```sql
REVOKE USAGE
  ON SEQUENCE ORDER_SEQ
  FROM ROLE ROLE1;
```
REVOKE (system privileges)

This form of the REVOKE statement revokes system privileges.

Syntax

```
REVOKE ACCESSCTRL
     ARCHIVE
     BINDADD
     BINDAGENT
     BSDS
     CREATEALIAS
     CREATEDBA
     CREATEDBC
     CREATESG
     CREATETTAB
     CREATE_SECURE_OBJECT
     DATAACCESS
     DBADM
     DEBUGSESSION
     DISPLAY
     EXPLAIN
     MONITOR1
     MONITOR2
     RECOVER
     SQLADM
     STOPALL
     STOSPACE
     SYSADM
     SYSCtrl
     SYSOPR
     TRACE
ON SYSTEM
FROM authorization-name
   ROLE role-name
   PUBLIC
```

Notes:

1. INCLUDING DEPENDENT PRIVILEGES must not be specified when ACCESSCTRL, DATAACCESS, or DBADM is specified.
2. NOT INCLUDING DEPENDENT PRIVILEGES must be specified when ACCESSCTRL, DATAACCESS, or DBADM is specified.

Description

ACCESSCTRL

Reovkes the ACCESSCTRL authority, but does not revoke any privileges that are dependent on it.
ARCHIVE
Revokes the privilege to use the ARCHIVE LOG command.

BINDADD
Revokes the privilege to create plans and packages using the BIND subcommand with the ADD option.

BINDAGENT
Revokes the privilege to issue the BIND, FREE PACKAGE, or REBIND subcommands for plans and packages and the DROP PACKAGE statement on behalf of the grantor. The privilege also allows the holder to copy and replace plans and packages on behalf of the grantor.

A revoke of this privilege does not cascade.

BSDS
Revokes the privilege to issue the RECOVER BSDS command.

CREATEALIAS
Revokes the privilege to use the CREATE ALIAS statement.

CREATEDBA
Revokes the privilege to issue the CREATE DATABASE statement and acquire DBADM authority over those databases.

CREATEDBC
Revokes the privilege to issue the CREATE DATABASE statement and acquire DBCTRL authority over those databases.

CREATESG
Revokes the privilege to create new storage groups.

CREATETMTAB
Revokes the privilege to use the CREATE GLOBAL TEMPORARY TABLE statement.

CREATE_SECURE_OBJECT
Revokes the privilege to create a secure object.

DATAACCESS
Revokes the DATAACCESS authority, but does not revoke any privileges that are dependent on it. Revoking DATAACCESS can result in authorization cache entries (plan, package, routine, and dynamic statement) being updated if they were dependent on it. The RESTRICT semantics on objects prevents the DATAACCESS authority from being revoked if the revokee owns an object that was created with dependencies on the authority to be revoked.

Revoking DATAACCESS is similar to revoking the individual privileges that DATAACCESS includes. For example, if a view was created based on the view owner having the SELECT privilege as acquired through the DATAACCESS authority, revoking DATAACCESS would be the equivalent of revoking the SELECT privilege and the view would be dropped.

DBADM
Revokes the DBADM authority from the user. If this user was also granted DATAACCESS or ACCESSCTRL authority along with DBADM authority, DATAACCESS or ACCESSCTRL would not be revoked.

DISPLAY
Revokes the privilege to use the following commands:
- The DISPLAY ARCHIVE command for archive log information
- The DISPLAY BUFFERPOOL command for the status of buffer pools
• The DISPLAY DATABASE command for the status of all databases
• The DISPLAY FUNCTION SPECIFIC command for statistics about accessed external user-defined functions
• The DISPLAY LOCATION command for statistics about threads with a distributed relationship
• The DISPLAY PROCEDURE command for statistics about accessed stored procedures
• The DISPLAY THREAD command for information on active threads with in DB2
• The DISPLAY TRACE command for a list of active traces

**DEBUGSESSION**
Revokes the privilege to create a debug session, which prevents client application debugging of native SQL or Java procedures that are executed within the session.

**EXPLAIN**
Revokes the privilege to issue the following:

• The EXPLAIN statement with the following options:
  – PLAN
  – ALL
• The PREPARE statement
• The DESCRIBE TABLE statement
• The ability to explain dynamic SQL statements that are executing with the special register CURRENT EXPLAIN MODE = EXPLAIN
• The BIND options EXPLAIN(ONLY) and SQLERROR(CHECK)
  EXPLAIN(ONLY) allows to explain the statements. SQLERROR(CHECK) performs all syntax and semantic checks on the SQL statements being bound.

**MONITOR1**
Revokes the privilege to obtain IFC data classified as serviceability data, statistics, accounting, and other performance data that does not contain potentially secure data.

**MONITOR2**
Revokes the privilege to obtain IFC data classified as containing potentially sensitive data such as SQL statement text and audit data. (Having the MONITOR2 privilege also implies having MONITOR1 privileges, however, revoking the MONITOR2 privilege does not cause the revoke of an explicitly granted MONITOR1 privilege.)

**RECOVER**
Revokes the privilege to issue the RECOVER INDOUBT command.

**SQLADM**
Revokes the privilege to issue the following:

• The DESCRIBE TABLE statement
• The EXPLAIN statement with the following options:
  – PLAN
  – ALL
  – STMTCACHE ALL
  – STMTID
  – STMTTOKEN
MONITORED STMTS

- The PREPARE statement
- The ability to explain dynamic SQL statements that are executing with the special register CURRENT EXPLAIN MODE = EXPLAIN
- The BIND options EXPLAIN(ONLY) and SQLERROR(CHECK)
  EXPLAIN(ONLY) allows to explain the statements. SQLERROR(CHECK) performs all syntax and semantic checks on the SQL statements being bound.
- The START command
- The STOP command
- The DISPLAY PROFILE command
- The ability to execute the RUNSTATS utility and the MODIFY STATISTICS utility in any database
- MONITOR2 privilege, which allows users to obtain IFC data that is classified as containing potentially sensitive data, such as SQL statement text and audit data, as well as IFC data that is classified as serviceability data, statistics, accounting, and other performance data.

STOPALL
Revoke the privilege to use the STOP DB2 command.

STOSPACE
Revoke the privilege to use the STOSPACE utility.

SYSADM
Revoke the system administrator authority.

SYSCTRL
Revoke the system control authority.

SYSOPR
Revoke the system operator authority.

TRACE
Revoke the privilege to use the MODIFY TRACE, START TRACE, and STOP TRACE commands.

ON SYSTEM
Identifies that the system privilege is revoked for the entire DB2 subsystem.

FROM
Refer to REVOKE for a description of the FROM clause.

BY
Refer to REVOKE for a description of the BY clause.

INCLUDING DEPENDENT PRIVILEGES or NOT INCLUDING DEPENDENT PRIVILEGES
Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE DEP_PRIVILEGES system parameter:
- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE DEP_PRIVILEGES system parameter is set to NO, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and an error is returned if the statement includes INCLUDING DEPENDENT PRIVILEGES.
• Otherwise, **INCLUDING DEPENDENT PRIVILEGES** is assumed and the clause must be specified on the REVOKE statement.

**INCLUDING DEPENDENT PRIVILEGES**

Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

**INCLUDING DEPENDENT PRIVILEGES** cannot be specified if the system parameter `REVOKE_DEP_PRIVILEGES` is set to NO, which enforces the behavior to not include the dependent privileges.

**NOT INCLUDING DEPENDENT PRIVILEGES**

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

**NOT INCLUDING DEPENDENT PRIVILEGES** must be specified when `ACCESSCTRL`, `DATAACCESS`, or system `DBADM` authority is revoked.

**NOT INCLUDING DEPENDENT PRIVILEGES** cannot be specified if the system parameter `REVOKE_DEP_PRIVILEGES` is set to YES, which enforces the behavior to include dependent privileges in the revoke.

**Examples**

**Example 1:** Revoke DISPLAY privileges from user LUTZ.

```
REVOKE DISPLAY
   FROM LUTZ;
```

**Example 2:** Revoke BSDS and RECOVER privileges from users PARKER and SETRIGHT.

```
REVOKE BSDS,RECOVER
   FROM PARKER,SETRIGHT;
```

**Example 3:** Revoke TRACE privileges previously granted to all local users. (Grants to specific users will not be affected.)

```
REVOKE TRACE
   FROM PUBLIC;
```

**Example 4:** Revoke ARCHIVE privileges from role ROLE1:

```
REVOKE ARCHIVE
   FROM ROLE ROLE1;
```

**Example 5:** SECADM Mary revokes the privilege to create a secure object from Steve that was granted by another SECADM.

```
REVOKE CREATE_SECURE_OBJECT
   FROM STEVE BY MARY;
```
Example 6: Revoke system DBADM from the role, ADMINROLE. This only revokes system DBADM authority from the role. If DATAACCESS and ACCESSCTRL authorities were granted during GRANT DBADM, those authorities are not revoked.

    REVOKE DBADM ON SYSTEM
    FROM ROLE ADMINROLE
    NOT INCLUDING DEPENDENT PRIVILEGES;

Example 7: Revoke system DBADM, DATAACCESS, and ACCESSCTRL authorities from the role, ADMINROLE.

    REVOKE DBADM, DATAACCESS, ACCESSCTRL ON SYSTEM
    FROM ROLE ADMINROLE
    NOT INCLUDING DEPENDENT PRIVILEGES;
REVOKE (table or view privileges)

This form of the REVOKE statement revokes privileges on one or more tables or views.

Syntax

```
REVOKE PRIVILEGES ALL
     , ALTER
     , DELETE
     , INDEX
     , INSERT
     , REFERENCES
     , SELECT
     , TRIGGER
     , UPDATE
     TABLE ON
     , table-name
     view-name FROM
     , authorization-name
     ROLE role-name
     PUBLIC
     BY
     , authorization-name
     ROLE role-name
     ALL

INCLUDING DEPENDENT PRIVILEGES
NOT INCLUDING DEPENDENT PRIVILEGES
```

Description

**ALL or ALL PRIVILEGES**

If you specify ALL, the authorization ID of the statement must have granted at least one privilege on each identified table or view to each `authorization-name`. The privilege revoked from an authorization ID are those privileges on the table or view that the authorization ID of the statement granted to the authorization ID.

If you do not use ALL, you must use one or more of the keywords listed below. Each keyword revokes the privilege described, but only as it applies to the tables or views named in the ON clause.

**ALTER**

Revokes the privilege to alter the specified table or create a trigger on the specified table.

**DELETE**

Revokes the privilege to delete rows in the specified table or view.
INDEX
Revokes the privilege to create an index on the specified table.

INSERT
Revokes the privilege to insert rows into the specified table or view.

REFERENCES
Revokes the privilege to define and drop referential constraints. Although you can use a list of column names with the GRANT statement, you cannot use a list of column names with REVOKE; the privilege is revoked for all columns.

SELECT
Revokes the privilege to create a view or read data from the specified table or view. A view or a materialized query table is dropped when the SELECT privilege that was used to create it is revoked, unless the owner of the view or materialized query table was directly granted the SELECT privilege from another source before the view or materialized query table was created.

TRIGGER
Revokes the privilege to create a trigger on the specified table.

UPDATE
Revokes the privilege to update rows in the specified table or view. A list of column names can be used only with GRANT, not with REVOKE.

ON table-name or view-name
Names one or more tables or views on which you are revoking the privileges. The list can consist of table names, view names, or a combination of the two. A table or view must not be identified more than one time, and a declared temporary table and a table that is implicitly created for an XML column must not be identified.

FROM
Refer to REVOKE for a description of the FROM clause.

BY
If you omit BY, you must have granted each named privilege to each of the named users. More precisely, each privilege must have been granted to each user by a GRANT statement whose authorization ID is also the authorization ID of your REVOKE statement. Each of these grants is then revoked. (No single privilege need be granted on all tables and views.)

If BY is specified, each named grantor must satisfy the above requirement. In that case, the authorization ID of the statement need not satisfy the requirement unless it is one of the named grantors.

Refer to “REVOKE” on page 2138 for a description of the BY clause.

INCLUDING DEPENDENT PRIVILEGES or NOT INCLUDING DEPENDENT PRIVILEGES
Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

• When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.
• When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and an error is returned if the statement includes INCLUDING DEPENDENT PRIVILEGES.
• Otherwise, INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.
INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

INCLUDING DEPENDENT PRIVILEGES cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

NOT INCLUDING DEPENDENT PRIVILEGES

Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

NOT INCLUDING DEPENDENT PRIVILEGES must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

NOT INCLUDING DEPENDENT PRIVILEGES cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to YES, which enforces the behavior to include dependent privileges in the revoke.

Notes

For a created temporary table, only ALL or ALL PRIVILEGES can be revoked. Specific table privileges cannot be revoked.

For a view of a created temporary table, either ALL or the specific UPDATE, DELETE, INSERT and SELECT privileges can be revoked.

For a declared temporary table, no privileges can be revoked because none can be granted. When a declared temporary table is defined, PUBLIC implicitly receives all table privileges (without GRANT authority) for the table. These privileges are not recorded in the DB2 catalog.

Examples

Example 1: Revoke SELECT privileges on table DSN8A10.EMP from user PULASKI.

REVOKE SELECT ON TABLE DSN8A10.EMP FROM PULASKI;

Example 2: Revoke update privileges on table DSN8A10.EMP previously granted to all local DB2 users. (Grants to specific users are not affected.)

REVOKE UPDATE ON TABLE DSN8A10.EMP FROM PUBLIC;

Example 3: Revoke all privileges on table DSN8A10.EMP from users KWAN and THOMPSON.

REVOKE ALL ON TABLE DSN8A10.EMP FROM KWAN, THOMPSON;

Example 4: Revoke the grant of SELECT and UPDATE privileges on the table DSN8A10.DEP on to every user in the network. Doing so does not affect users who obtained these privileges from some other grant.
REVOKE SELECT, UPDATE ON TABLE DSN8A10.DEPT
FROM PUBLIC;

Example 5: Revoke the ALTER privileges on the table DSN8A10.EMP that were previously granted to role ROLE1:

REVOKE ALTER ON TABLE DSN8A10.EMP
FROM ROLE ROLE1;
REVOKE (type or JAR file privileges)

This form of the REVOKE statement revokes the privilege to use distinct types or JAR files.

Syntax

```
REVOKE USAGE ON TYPE distinct-type-name FROM authorization-name
| JAR jar-name | ROLE role-name | PUBLIC |
| BY authorization-name | ROLE role-name | ALL |
| INCLUDING DEPENDENT PRIVILEGES | NOT INCLUDING DEPENDENT PRIVILEGES |
| RESTRICT |
```

Description

 USAGE
 Revokes the privilege to use the distinct type in tables, functions procedures, or the privilege to use the JAR file.

 TYPE distinct-type-name
 Identifies the distinct type. The name, including the implicit or explicit schema name, must identify a unique distinct type that exists at the current server.

 JAR jar-name
 Identifies the JAR file. The name, including the implicit or explicit schema name, must identify a unique JAR file that exists at the current server.

 FROM
 Refer to REVOKE for a description of the FROM clause.

 BY
 Refer to REVOKE for a description of the BY clause.

 INCLUDING DEPENDENT PRIVILEGES or NOT INCLUDING DEPENDENT PRIVILEGES
 Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:

 - When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.
 - When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and an error is returned if the statement includes INCLUDING DEPENDENT PRIVILEGES.
• Otherwise, **INCLUDING DEPENDENT PRIVILEGES** is assumed and the clause must be specified on the REVOKE statement.

**INCLUDING DEPENDENT PRIVILEGES**
- Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.
- **INCLUDING DEPENDENT PRIVILEGES** cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

**NOT INCLUDING DEPENDENT PRIVILEGES**
- Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.
- **NOT INCLUDING DEPENDENT PRIVILEGES** must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.
- **NOT INCLUDING DEPENDENT PRIVILEGES** cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to YES, which enforces the behavior to include dependent privileges in the revoke.

**RESTRICT**
- Prevents the USAGE privilege from being revoked on a distinct type or JAR file if any of the following conditions exist and the revokee does not have the USAGE privilege from another source:
  - The revokee owns a function or stored procedure that uses the distinct type or references the JAR file.
  - The revokee owns a JAR file whose path references the JAR file for which USAGE is being revoked.
  - The revokee owns a table that has a column that uses the distinct type.
  - A sequence exists for which the data type of the sequence is the distinct type.

**Notes**

*Alternative syntax and synonyms:* To provide compatibility with previous releases of DB2 or other products in the DB2 family, DB2 supports DATA TYPE or DISTINCT TYPE as a synonym for TYPE.

**Examples**

*Example 1:* Revoke the USAGE privilege on distinct type SHOESIZE from user JONES.

```sql
REVOKE USAGE ON TYPE SHOESIZE FROM JONES;
```

*Example 2:* Revoke the USAGE privilege on distinct type US_DOLLAR from all users at the current server except for those who have been specifically granted USAGE and not through PUBLIC.

```sql
REVOKE USAGE ON TYPE US_DOLLAR FROM PUBLIC;
```
Example 3: Revoke the USAGE privilege on distinct type CANADIAN_DOLLARS from the administrative assistant (ADMIN_A).

    REVOKE USAGE ON TYPE CANADIAN_DOLLARS
    FROM ADMIN_A;

Example 4: Revoke the USAGE privilege on distinct type MILES from the role ROLE1:

    REVOKE USAGE ON TYPE MILES
    FROM ROLE ROLE1;
REVOKE (use privileges)

This form of the REVOKE statement revokes authority to use particular buffer pools, storage groups, or table spaces.

Syntax

```
REVOKE USE OF BUFFERPOOL bpname,
ALL BUFFERPOOLS,
STOGROUP stogroup-name,
TABLESPACE database-name.table-space-name
FROM
authorization-name
ROLE role-name
PUBLIC
BY
authorization-name
ROLE role-name
ALL
INCCLUDING DEPENDENT PRIVILEGES
NOT INCLUDING DEPENDENT PRIVILEGES
```

Description

**BUFFERPOOL bpname,...**
Revolves the privilege to refer to any of the identified buffer pools in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement. See **Naming conventions** for more details about `bpname`.

**ALL BUFFERPOOLS**
Revolves the privilege to refer to any buffer pool in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement.

**STOGROUP stogroup-name,...**
Revolves the privilege to refer to any of the identified storage groups in a CREATE INDEX, CREATE TABLESPACE, ALTER INDEX, or ALTER TABLESPACE statement.

**TABLESPACE database-name.table-space-name,...**
Revolves the privilege to refer to any of the specified table spaces in a CREATE TABLE statement. The default `database-name` is DSNDDB04.

For table spaces in a work file database you cannot revoke the privilege from PUBLIC. When a table space is created in a work file database, PUBLIC
implicitly receives the TABLESPACE privilege (without GRANT authority); this privilege is not recorded in the DB2 catalog, and it cannot be revoked.

FROM
Refer to REVOKE for a description of the FROM clause.

BY Refer to REVOKE for a description of the BY clause.

INCLUDING DEPENDENT PRIVILEGES or NOT INCLUDING DEPENDENT PRIVILEGES
Specifies whether revoking a privilege or an authority from an authorization ID or a role also results in revoking the grants that were made by that user. The default value is based on the authority that is being revoked and the REVOKE_DEP_PRIVILEGES system parameter:
- When ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.
- When the REVOKE_DEP_PRIVILEGES system parameter is set to NO, NOT INCLUDING DEPENDENT PRIVILEGES is assumed and an error is returned if the statement includes INCLUDING DEPENDENT PRIVILEGES.
- Otherwise, INCLUDING DEPENDENT PRIVILEGES is assumed and the clause must be specified on the REVOKE statement.

INCLUDING DEPENDENT PRIVILEGES
Specifies that revoking a privilege or an authority from an authorization ID or a role also results in revoking dependent privileges. This means that any grants that were made by the user will continue to be revoked, until all grants in the chain have been revoked.

INCLUDING DEPENDENT PRIVILEGES cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to NO, which enforces the behavior to not include the dependent privileges.

NOT INCLUDING DEPENDENT PRIVILEGES
Specifies that revoking a privilege or an authority from an authorization ID or a role does not cause the grants that were made by the user to be revoked. However, for the revoked privileges, all implications of the privilege being revoked are applied. For example, if the revoked privileges were required to bind a package successfully, that package would continue to be invalidated as a result of the package owner losing these privileges. An object might be dropped if a privilege is revoked that was used to create the object.

NOT INCLUDING DEPENDENT PRIVILEGES must be specified when ACCESSCTRL, DATAACCESS, or system DBADM authority is revoked.

NOT INCLUDING DEPENDENT PRIVILEGES cannot be specified if the system parameter REVOKE_DEP_PRIVILEGES is set to YES, which enforces the behavior to include dependent privileges in the revoke.

Notes
You can revoke privileges for only one type of object with each statement. Thus you can revoke the use of several table spaces with one statement, but not the use of a table space and a storage group.

For each object you name, you (or the indicated grantors) must have granted the USE privilege on that object to all identified users (including PUBLIC, if specified). The same object must not be identified more than once.
Revoking the privilege USE OF ALL BUFFERPOOLS does not cascade to all other privileges that can be granted under that privilege. A user with the privilege USE OF ALL BUFFERPOOLS WITH GRANT OPTION can make two types of grants:

- **GRANT USE OF ALL BUFFERPOOLS TO user.** This privilege is revoked when the original user's privilege is revoked.
- **GRANT USE OF BUFFERPOOL BPn TO user.** This privilege is *not revoked* when the original user's privilege is revoked.

**Examples**

*Example 1:* Revoke authority to use buffer pool BP2 from user MARINO.

```
REVOKE USE OF BUFFERPOOL BP2
   FROM MARINO;
```

*Example 2:* Revoke a grant of the USE privilege on the table space DSN8S10D in the database DSN8D10A. The grant is to PUBLIC, that is, to everyone at the local DB2 subsystem. (Grants to specific users are not affected.)

```
REVOKE USE OF TABLESPACE DSN8D10A.DSN8S10D
   FROM PUBLIC;
```

*Example 3:* Revoke the authority to use storage group SG1 from role ROLE1:

```
REVOKE USE OF STOGROUP SG1
   FROM ROLE ROLE1;
```
**ROLLBACK**

The ROLLBACK statement can be used to end a unit of recovery and back out all the relational database changes that were made by that unit of recovery. If relational databases are the only recoverable resources used by the application process, ROLLBACK also ends the unit of work. ROLLBACK can also be used to back out only the changes made after a savepoint was set within the unit of recovery without ending the unit of recovery. Rolling back to a savepoint enables selected changes to be undone.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared. It can be used in the IMS or CICS environment only if the TO SAVEPOINT clause is specified.

**Authorization**

None required.

**Syntax**

```
ROLLBACK WORK TO SAVEPOINT savepoint-name
```

**Description**

When ROLLBACK is used without the SAVEPOINT clause, the unit of recovery in which the ROLLBACK statement is executed is ended and a new unit of recovery is started.

All changes that are made by the following statements during the unit of recovery are backed out:

- ALTER
- COMMENT
- CREATE
- DELETE
- DROP
- EXPLAIN
- GRANT
- INSERT
- LABEL
- MERGE
- REFRESH TABLE
- RENAME
- REVOKE
- SELECT INTO with an SQL data change statement
• select-statement with an SQL data change statement
• TRUNCATE when the IMMEDIATE clause is not specified
• UPDATE

ROLLBACK without the TO SAVEPOINT clause also causes the following actions to occur:
• All locks that are implicitly acquired during the unit of recovery are released. See [LOCK TABLE] for an explanation of the duration of explicitly acquired locks.
• All cursors are closed, all prepared statements are destroyed, and any cursors that are associated with the prepared statements are invalidated.
• All rows and all logical work files of every created temporary table of the application process are deleted. (All the rows of a declared temporary table are not implicitly deleted. As with base tables, any changes that are made to a declared temporary table during the unit of recovery are undone to restore the table to its state at the last commit point.)
• All LOB locators, including those that are held, are freed.

TO SAVEPOINT
Specifies that the unit of recovery is not to be ended and that only a partial rollback (to a savepoint) is to be performed. If a savepoint name is not specified, rollback is to the last active savepoint. For example, if in a unit of recovery, savepoints A, B, and C are set in that order and then C is released, ROLLBACK TO SAVEPOINT causes a rollback to savepoint B.

savepoint-name
Identifies the savepoint to which to roll back. The name must identify a savepoint that exists at the current server.

All database changes (including changes made to a declared temporary tables but excluding changes made to created temporary tables) that were made after the savepoint was set are backed out. Changes that are made to created temporary tables are not logged and are not backed out; a warning is issued instead. (A warning is also issued when a created temporary table is changed and there is an active savepoint.)

In addition, none of the following items are backed out:
• The opening or closing of cursors
• Changes in cursor positioning
• The acquisition and release of locks
• The caching of the rolled back statements

Any savepoints that are set after the one to which rollback is performed are released. The savepoint to which rollback is performed is not released.

ROLLBACK with or without the TO SAVEPOINT clause has no effect on connections.

Notes

The following information applies only to rolling back all changes in the unit of recovery (the ROLLBACK statement without the TO SAVEPOINT clause):
• Stored procedures. The ROLLBACK statement cannot be used if the procedure is in the calling chain of a user-defined function or a trigger or if DB2 is not the commit coordinator.
• **IMS or CICS.** Using a ROLLBACK to SAVEPOINT statement in an IMS or CICS environment only rolls back DB2 resources. Any other recoverable resources updated in the environment are not rolled back. To do a rollback operation in these environments, SQL programs must use the call prescribed by their transaction manager. The effect of these rollback operations on DB2 data is the same as that of the SQL ROLLBACK statement.

A rollback operation in an IMS or CICS environment might handle the closing of cursors that were declared with the WITH hold option differently than the SQL ROLLBACK statement does. If an application requests a rollback operation from CICS or IMS, but no work has been performed in DB2 since the last commit point, the rollback request will not be broadcast to DB2. If the application had opened cursors using the WITH HOLD option in a previous unit of work, the cursors will not be closed, and any prepared statements associated with those cursors will not be destroyed.

• **Implicit rollback operations:** In all DB2 environments, the abend of a process is an implicit rollback operation.

**ROLLBACK and non-LOB table spaces that are not logged:** If ROLLBACK is executed for a unit of work that includes changes to a non-LOB table space that is not logged (specifies the NOT LOGGED attribute), that table space is marked RECOVER-pending and the table space is placed in the logical page list. The table space is therefore not available after the rollback operation completes. For more information about the RECOVER utility, see [RECOVER (DB2 Utilities)](#).

**Effect of ROLLBACK on insert operations:** If execution of an INSERT statement results in creation of a data set in a table space, and the INSERT operation is rolled back, the inserted data is deleted, but the data set is not deleted.

**Examples**

*Example 1:* Roll back all DB2 database changes made since the unit of recovery was started.

```
ROLLBACK WORK;
```

*Example 2:* After a unit of recovery started, assume that three savepoints A, B, and C were set and that C was released:

```
...  
SAVEPOINT A ON ROLLBACK RETAIN CURSORS;
...  
SAVEPOINT B ON ROLLBACK RETAIN CURSORS;
...  
SAVEPOINT C ON ROLLBACK RETAIN CURSORS;
...  
RELEASE SAVEPOINT C;
...  
```

Roll back all DB2 database changes only to savepoint A:

```
ROLLBACK WORK TO SAVEPOINT A;
```

If a savepoint name was not specified (that is, ROLLBACK WORK TO SAVEPOINT), the rollback would be to the last active savepoint that was set, which is B.
SAVEPOINT

The SAVEPOINT statement sets a savepoint within a unit of recovery to identify a point in time within the unit of recovery to which relational database changes can be rolled back.

Invocation

This statement can be imbedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SAVEPOINT savepoint-name
[ UNIQUE ]
ON ROLLBACK RETAIN CURSORS

(1)
```

```
(1)
```

ON ROLLBACK RETAIN LOCKS

Notes:
1 These clauses can be specified in either order.

Description

`savepoint-name`

Names the savepoint. `savepoint-name` must not begin with 'SYS'.

`UNIQUE`

Specifies that the application program cannot reuse the savepoint name within the unit of recovery. An error occurs if a savepoint with the same name as `savepoint-name` already exists within the unit of recovery.

Omitting **UNIQUE** indicates that the application can reuse the savepoint name within the unit of recovery. If `svpt-name` identifies a savepoint that already exists within the unit of recovery and the savepoint was not created with the **UNIQUE** option, the existing savepoint is destroyed and a new savepoint is created. Destroying a savepoint to reuse its name for another savepoint is not the same as releasing the savepoint. Reusing a savepoint name destroys only one savepoint. Releasing a savepoint with the **RELEASE SAVEPOINT** statement releases the savepoint and all savepoints that have been subsequently set.

`ON ROLLBACK RETAIN CURSORS`

Specifies that any cursors that are opened after the savepoint is set are not tracked, and thus, are not closed upon rollback to the savepoint. Although these cursors remain open after rollback to the savepoint, they might not be usable. For example, if rolling back to the savepoint causes the insertion of a
row on which the cursor is positioned to be rolled back, using the cursor to update or delete the row results in an error.

**ON ROLLBACK RETAIN LOCKS**

Specifies that any locks that are acquired after the savepoint is set are not tracked, and thus, are not released on rollback to the savepoint. ON ROLLBACK RETAIN LOCKS is the default behavior.

**Example**

Assume that you want to set three savepoints at various points in a unit of recovery. Name the first savepoint A and allow the savepoint name to be reused. Name the second savepoint B and do not allow the name to be reused. Because you no longer need savepoint A when you are ready to set the third savepoint, reuse A as the name of the savepoint.

```
SAVEPOINT A ON ROLLBACK RETAIN CURSORS;

SAVEPOINT B UNIQUE ON ROLLBACK RETAIN CURSORS;

SAVEPOINT A ON ROLLBACK RETAIN CURSORS;
```
SELECT

The *select-statement* is the form of a query that can be directly specified in a DECLARE CURSOR statement, or prepared and then referenced in a DECLARE CURSOR statement. It can also be issued interactively using SPUFI or the command line processor which causes a result table to be displayed at your terminal. In any case, the table specified by *select-statement* is the result of the fullselect.

For a description of the SELECT statement, see [select-statement](#).
SELECT INTO

The SELECT INTO statement produces a result table that contains at most one row. The statement assigns the values in that row to host variables. If the table is empty, the statement does not assign values to the host variables.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

The privileges that are held by the authorization ID of the owner of the plan or package must include at least one of the following for every table and view identified in the statement:

- The SELECT privilege on the table or view
- Ownership of the table or view
- DBADM authority for the database (tables only)
- DATAACCESS authority
- SYSADM authority
- SYSCTRL authority (catalog tables only)

If the SELECT INTO statement includes an SQL data change statement, the privilege set must also include at least the privileges (INSERT, UPDATE, or DELETE) that are associated with that SQL data change statement on the table or view.

Syntax

```sql
WITH common-table-expression
select-clause INTO host-variable from-clause
where-clause group-by-clause having-clause order-by-clause
isolation-clause
(1)
QUERYNO integer
FETCH FIRST ROWS ONLY
SKIP LOCKED DATA
```

Notes:

1. The same clause must not be specified more than once.
Description

The result table is derived by logically evaluating the isolation-clause, from-clause, where-clause, group-by-clause, having-clause, order-by-clause, and the select-clause, in this order. See [Queries](#) for a description of these clauses.

The tables or views identified in the statement can exist at the current server or at any DB2 subsystem with which the current server can establish a connection.

**WITH common-table-expression**

Refer to [common-table-expression](#) for information about specifying a common-table-expression.

**INTO host-variable,...**

Each host-variable must identify a structure or variable that is described in the program in accordance with the rules for declaring host structures and variables. In the operational form of the INTO clause, a reference to a structure is replaced by a reference to each of its host variables.

The first value in the result row is assigned to the first variable in the list, the second value to the second variable, and so on. If the number of host variables is less than the number of column values, the value W is assigned to the SQLWARN3 field of the SQLCA. (See [SQL communication area (SQLCA)](#))

The data type of a variable must be compatible with the value assigned to it. If the value is numeric, the variable must have the capacity to represent the integral part of the value. For a date or time value, the variable must be a character string variable of a minimum length as defined in [Datetime assignments](#). If the value is null, an indicator variable must be specified.

Each assignment to a variable is made according to the rules described in [Language elements](#). Assignments are made in sequence through the list.

If an error occurs as the result of an arithmetic expression in the SELECT list of a SELECT INTO statement (division by zero or overflow) or a numeric conversion error occurs, the result is the null value. As in any other case of a null value, an indicator variable must be provided and the main variable is unchanged. In this case, however, the indicator variable is set to -2. Processing of the statement continues as if the error had not occurred. (However, this error causes a positive SQLCODE.) If you do not provide an indicator variable, a negative value is returned in the SQLCODE field of the SQLCA. Processing of the statement terminates when the error is encountered.

If an error occurs, no value is assigned to the host variable or to later variables, though any values that have already been assigned to variables remain assigned.

If an error occurs because the result table has more than one row, values may or may not be assigned to the host variables. If values are assigned to the host variables, the row that is the source of the values is undefined and not predictable.

**isolation-clause**

Specifies the isolation level at which the statement is executed and, optionally, the type of locks that are acquired.

**SKIP LOCKED DATA**

Specifies that rows are skipped when incompatible locks are held on the row by other transactions. These rows can belong to any accessed table that is specified in the statement. SKIP LOCKED DATA can be used only when isolation CS or RS is in effect and applies only to row level or page level locks.
SKIP LOCKED DATA is ignored if it is specified when the isolation level that is in effect is repeatable read (WITH RR) or uncommitted read (WITH UR).

**QUERYNO integer**

Specifies the number to be used for this SQL statement in EXPLAIN output and trace records. The number is used for the QUERYNO columns of the plan tables for the rows that contain information about this SQL statement. This number is also used in the QUERYNO column of the SYSIBM.SYSTMT and SYSIBM.SYSPACKSTM T catalog tables.

If the clause is omitted, the number associated with the SQL statement is the statement number assigned during precompilation. Thus, if the application program is changed and then precompiled, that statement number might change.

Using the QUERYNO clause to assign unique numbers to the SQL statements in a program is helpful:

- For simplifying the use of optimization hints for access path selection
- For correlating SQL statement text with EXPLAIN output in the plan table

For information on using optimization hints, such as enabling the system for optimization hints and setting valid hint values, and for information on accessing the plan table, see *Managing DB2 Performance*.

**FETCH FIRST ROW ONLY integer**

The FETCH FIRST ROW ONLY clause can be used in the SELECT INTO statement when the query can result in more than a single row. The clause indicates that only one row should be retrieved regardless of how many rows might be in the result table. When a number is explicitly specified, it must be 1.

Using the FETCH FIRST ROW ONLY clause to explicitly limit the result table to a single row provides a way for the SELECT INTO statement to be used with a query that returns more than a single row. Using the clause helps you to avoid using a cursor when you know that you want to retrieve only one row. To influence which row is returned, you can use the *order-by-clause*. When you specify *order-by-clause*, the rows of the result are ordered and then the first row is returned. If the FETCH FIRST ROW ONLY clause is not specified and the result table contains more than a single row, an error occurs.

**Notes**

**Default encoding scheme:**

The default encoding scheme for the data is the value in the bind option ENCODING, which is the option for application encoding. If this statement is used with functions such as LENGTH or SUBSTRING that are operating on LOB locators, and the LOB data that is specified by the locator is in a different encoding scheme from the ENCODING bind option, LOB materialization and character conversion occur. To avoid LOB materialization and character conversion, select the LOB data from the SYSIBM.SYSDUMMYA, SYSIBM.SYSDUMMYE, or SYSIBM.SYSDUMMYU sample table.

**If the result table is empty:**

If the table is empty, the statement assigns +100 to SQLCODE, '02000' to SQLSTATE, and does not assign values to the host variables.
Number of rows inserted:
If the SELECT INTO statement of the cursor contains an SQL data change statement, the SELECT INTO operation sets SQLERRD(3) to the number of rows inserted.

Using locators:
Normally, you use LOB locators to assign and retrieve data from LOB columns. However, because of compatibility rules, you can also use LOB locators to assign data to host variables with CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data types.

Examples

Example 1: Put the maximum salary in DSN8A10.EMP into the host variable MAXSALRY.

EXEC SQL SELECT MAX(SALARY) INTO :MAXSALRY
FROM DSN8A10.EMP;

Example 2: Put the row for employee 528671, from DSN8A10.EMP, into the host structure EMPREC.

EXEC SQL SELECT * INTO :EMPREC
FROM DSN8A10.EMP
WHERE EMPNO = '528671'
END-EXEC.

Example 3: Put the row for employee 528671, from DSN8A10.EMP, into the host structure EMPREC. Assume that the row will be updated later and should be locked when the query executes.

EXEC SQL SELECT * INTO :EMPREC
FROM DSN8A10.EMP
WHERE EMPNO = '528671'
WITH RS USE AND KEEP EXCLUSIVE LOCKS
END-EXEC.
SET CONNECTION

The SET CONNECTION statement establishes the database server of the process by identifying one of its existing connections.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared. It must not be specified in Java.

Authorization

None required.

Syntax

\[
\text{SET CONNECTION} \quad \text{location-name or host-variable}
\]

Description

\text{location-name or host-variable}

Identifies the SQL connection by the specified location name or the location name contained in the host variable. If a host variable is specified:

- It must be a character string variable with a length attribute that is not greater than 16. (A C NUL-terminated character string can be up to 17 bytes.)
- It must not be followed by an indicator variable.
- The location name must be left-justified within the host variable and must conform to the rules for forming an ordinary location identifier.
- If the length of the location name is less than the length of the host variable, it must be padded on the right with blanks.

Let S denote the specified location name or the location name contained in the host variable. S must identify an existing SQL connection of the application process. If S identifies the current SQL connection, the state of S and all other connections of the application process are unchanged. The following rules apply when S identifies a dormant SQL connection.

If the SET CONNECTION statement is successful:

- SQL connection S is placed in the current state.
- S is placed in the CURRENT SERVER special register.
- Information about server S is placed in the SQLERRP field of the SQLCA. If the server is an IBM product, the information has the form \text{pppwwrrm}.

The format of product identifier values is \text{pppwwrrm}, where \text{ppp} is a 3-letter product code (such as DSN for DB2), \text{ww} is the version, \text{rr} is the release, and \text{m} is the modification level. For example, DSN10015 identifies DB2 10 in new-function mode, the value is ‘DSN10015’. The product code (\text{ppp}) is one of the following values:

- \text{AQT} for IBM DB2 Analytics Accelerator for z/OS
Modification \(m\) values have the following meanings:

- **0 - 1** Modification levels in conversion and enabling-new-function mode from DB2 Version 8 (CM8, CM8*, ENFM8, and ENFM8*)
- **2 - 3** Modification levels in conversion and enabling-new-function mode from DB2 9 (CM9, CM9*, ENFM9, and ENFM9*)
- **4** Not used.
- **5 - 9** Modification levels in new-function mode.

- Any previously current SQL connection is placed in the dormant state.

If the SET CONNECTION statement is unsuccessful, the connection state of the application process and the states of its SQL connections are unchanged.

**Notes**

*SET CONNECTION after CONNECT (Type 1):* The use of CONNECT (Type 1) statements does not prevent the use of SET CONNECTION, but the statement either fails or does nothing because dormant SQL connections do not exist. The SQLRULES(DB2) bind option does not prevent the use of SET CONNECTION, but the statement is unnecessary because CONNECT (Type 2) statements can be used instead. Use the SET CONNECTION statement to conform to the SQL standard.

*Status of locks, cursors, and prepared statements:* When an SQL connection is used, made dormant, and then restored to the current state in the same unit of work, the status of locks, cursors, and prepared statements for that SQL connection reflects its last use by the application process.

*Host variables:* If the SET CONNECTION statement contains host variables, the contents of the host variables are assumed to be in the encoding scheme that was specified in the ENCODING parameter when the package or plan that contains the statement was bound.

**Example**

Execute SQL statements at TOROLAB1, execute SQL statements at TOROLAB2, and then execute more SQL statements at TOROLAB1.

```sql
EXEC SQL CONNECT TO TOROLAB1;

-- execute statements referencing objects at TOROLAB1

EXEC SQL CONNECT TO TOROLAB2;

-- execute statements referencing objects at TOROLAB2

EXEC SQL SET CONNECTION TOROLAB1;

-- execute statements referencing objects at TOROLAB1
```

The first CONNECT statement creates the TOROLAB1 connection, the second CONNECT statement places it in the dormant state, and the SET CONNECTION
statement returns it to the current state.
SET CURRENT APPLICATION ENCODING SCHEME

The SET CURRENT APPLICATION ENCODING SCHEME statement assigns a value to the CURRENT APPLICATION ENCODING SCHEME special register. This special register allows users to control which encoding scheme will be used for dynamic SQL statements after the SET statement has been executed.

Invocation

This statement can be embedded only in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT APPLICATION ENCODING SCHEME = string-constant
```

Description

`string-constant`

A character string constant that represents a valid encoding scheme (ASCII, EBCDIC, UNICODE, or a character representation of a number between 1 and 65533).

`host-variable`

A variable with a data type of CHAR or VARCHAR. The value of `host-variable` must not be null and must represent a valid encoding scheme or a character representation of a number between 1 and 65533). An associated indicator variable must not be provided.

The value must:

- Be left justified within the host variable
- Be padded on the right with blanks if its length is less than that of the host variable

Examples

The following examples set the CURRENT APPLICATION ENCODING SCHEME special register to 'EBCDIC' (in the second example, Host variable HV1 = 'EBCDIC').

```
EXEC SQL SET CURRENT APPLICATION ENCODING SCHEME = 'EBCDIC';
EXEC SQL SET CURRENT ENCODING SCHEME = :HV1;
```

Related reference:

CURRENT APPLICATION ENCODING SCHEME
SET CURRENT DEBUG MODE

The SET CURRENT DEBUG MODE statement assigns a value to the CURRENT DEBUG MODE special register.

The special register sets the default value for the DEBUG MODE option for the following statements:

- CREATE FUNCTION statements that define an SQL scalar function
- ALTER FUNCTION statements that create or replace a version of an SQL scalar function
- CREATE PROCEDURE statements that define a native SQL or Java procedure
- ALTER PROCEDURE statements that create or replace a version of a native SQL procedure

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT DEBUG MODE = host-variable
```

Description

*host-variable*

Specifies a host variable that contains the debugging option. The host variable must conform to the following rules:

- Be a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC variable. The actual length of the contents of the host variable must not exceed the length of the special register.
- Include a keyword value of DISALLOW, ALLOW, or DISABLE that is left justified
- Be padded on the right with blanks if the host variable is a fixed length character
- Not contain lowercase letters or characters that cannot be specified in an ordinary identifier
- Not be empty or contain only blanks
- Not be the null value

DISALLOW

Specifies that DISALLOW DEBUG MODE is the default option for CREATE statements when defining an SQL scalar function, a native SQL procedure, or a
Java procedure, or ALTER statements that create or replace a version of an SQL scalar function or a native SQL procedure.

ALLOW
Specifies that ALLOW DEBUG MODE is the default option for CREATE statements when defining an SQL scalar function, a native SQL procedure, a Java procedure, or ALTER statements that create or replace a version of an SQL scalar function or a native SQL procedure.

DISABLE
Specifies that DISABLE DEBUG MODE is the default option for CREATE statements when defining an SQL scalar function, a native SQL procedure, a Java procedure, or ALTER statements that create or replace a version of an SQL scalar function or a native SQL procedure.

Examples

Example: The following statement sets the CURRENT DEBUG MODE special register so that the default option for CREATE PROCEDURE statements will be ALLOW DEBUG MODE:

```
SET CURRENT DEBUG MODE = ALLOW;
```

Related reference:

CURRENT DEBUG MODE
SET CURRENT DECFLOAT Rounding Mode

The SET CURRENT DECFLOAT Rounding Mode statement assigns a value to the CURRENT DECFLOAT Rounding Mode special register. The special register sets the default rounding mode that is used with decimal floating point values (DECFLOAT).

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT DECFLOAT Rounding MODE
  ROUND_CEILING
  ROUND_DOWN
  ROUND_FLOOR
  ROUND_HALF_DOWN
  ROUND_HALF_EVEN
  ROUND_HALF_UP
  ROUND_UP
  string-constant
  host-variable
```

Description

ROUND_CEILING
Round towards positive infinity. If all of the discarded digits are zero or if the sign is negative, the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by 1 (round up).

ROUND_DOWN
Round towards 0 (truncation). The discarded digits are ignored.

ROUND_FLOOR
Round towards negative infinity. If all of the discarded digits are zero or if the sign is positive, the result is unchanged other than the removal of discarded digits. Otherwise, the sign is negative and the result coefficient is incremented by 1 (round down).

ROUND_HALF_DOWN
Round to nearest value; if values are equidistant, rounds down. If the discarded digits represent greater than half (0.5) of the value of a number in the next left position, the result coefficient is incremented by 1 (round up). Otherwise, the discarded digits are ignored. This rounding mode is not recommended when creating a portable application because it is not supported by the IEEE draft standard for floating-point arithmetic.

ROUND_HALF_EVEN
Round to nearest value; if values are equidistant, round so that the final digit
is even. If the discarded digits represent greater than half (0.5) of the value of a number in the next left position, the result coefficient is incremented by 1 (round up). If the discarded digits represent less than half of the value, the result coefficient is not adjusted (that is, the discarded digits are ignored). Otherwise, the result coefficient is unaltered if its rightmost digit is even, or is incremented by 1 (round up) if its rightmost digit is odd (to make an even digit).

**ROUND_HALF_UP**
Round to nearest value; if values are equidistant, round up. If the discarded digits represent greater than or equal to half (0.5) of the value of a number in the next left position, the result coefficient is incremented by 1 (round up). Otherwise the discarded digits are ignored.

**ROUND_UP**
Round away from 0. If all of the discarded digits are zero, the result is unchanged other than the removal of discarded digits. Otherwise, the result coefficient is incremented by 1 (round up). This rounding mode is not recommended when creating a portable application because it is not supported by the IEEE draft standard for floating-point arithmetic.

**string-constant**
Specifies a string constant that contains a specification of the rounding mode. The string-constant must have the following characteristics:

- Must be a string constant. The actual length of the contents of the string constant, after trailing blanks have been removed, must not exceed 19 characters.
- Must not be the null value.
- Must not contain lower case letters or characters that cannot be specified in an ordinary identifier.
- Must specify one of the seven rounding mode keywords as a string constant.

**host-variable**
Specifies a variable that contains a specification of the rounding mode. The variable must have the following characteristics:

- Must have a length, after trailing blanks have been removed, that does not exceed 19 bytes.
- Must not be followed by an indicator variable.
- Must not be a CLOB or DBCLOB.
- Must include a rounding mode that is left justified and conforms to the rules for forming an ordinary identifier.
- Must not contain lower case letters or characters that cannot be specified in an ordinary identifier.
- Must be padded on the right with blanks if the variable is a fixed length string.
- Must contain one of the seven rounding mode keywords.

**Examples**

*Example:* The following statement sets the CURRENT DECFLOAT ROUNDING MODE to ROUND_CEILING, using a string constant and a keyword.

```
SET CURRENT DECFLOAT ROUNDING MODE = ROUND_CEILING;
```

Related reference:

[SQL Reference](#)
SET CURRENT DEGREE

The SET CURRENT DEGREE statement assigns a value to the CURRENT DEGREE special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT DEGREE = string-constant | host-variable
```

Description

The value of CURRENT DEGREE is replaced by the value of the string constant or host variable. The value must be a character string that is not longer than 3 bytes and the value must be 'ANY', '1', or '1 '.

Notes

If the value of CURRENT DEGREE is '1' when a query is dynamically prepared, the execution of that query will not use parallel operations. If the value of CURRENT DEGREE is 'ANY' when a query is dynamically prepared, the execution of that query can involve parallel operations.

For distributed applications, the default value at the server is used unless the requesting application issues the SQL statement SET CURRENT DEGREE. For requests using DRDA, the SET CURRENT DEGREE statement must be within the scope of the CONNECT statement.

The value specified in the SET CURRENT DEGREE statement remains in effect until it is changed by the execution of another SET CURRENT DEGREE statement or until deallocation of the application process. For applications that connect to DB2 using the call attachment facility, the value of register CURRENT DEGREE can be requested to remain in effect for a longer duration. For more information, see the description of the call attachment facility CONNECT statement in DB2 Application Programming and SQL Guide.

Examples

Example 1: The following statement inhibits parallel operations:

```
SET CURRENT DEGREE = '1';
```

Example 2: The following statement allows parallel operations:

```
SET CURRENT DEGREE = 'ANY';
```
Related concepts:

- Parallel processing (DB2 Performance)
- Call attachment facility (DB2 Application programming and SQL)

Related tasks:

- Enabling parallel processing (DB2 Performance)
- Disabling query parallelism (DB2 Performance)

- CURRENT DEGREE field (CDSSRDEF subsystem parameter) (DB2 Installation and Migration)

CONNECT
SET CURRENT EXPLAIN MODE

The SET CURRENT EXPLAIN MODE statement assigns a value to the CURRENT EXPLAIN MODE special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT EXPLAIN MODE 

NO
YES
EXPLAIN

host-variable
```

Description

This statement replaces the value of the CURRENT EXPLAIN MODE special register with the value of the specified keyword or host variable.

**NO**  
Specifies that no EXPLAIN information is captured. NO is the initial value of the EXPLAIN MODE special register.

**YES**  
Enables the EXPLAIN facility and causes EXPLAIN information to be inserted into the EXPLAIN tables for eligible dynamic SQL statements after the statement is prepared and executed. All dynamic SQL statements are compiled and executed normally.

**EXPLAIN**  
Enables the EXPLAIN facility and causes EXPLAIN information to be captured for any eligible dynamic SQL statement after the statement is prepared. This setting behaves similarly to YES, however, dynamic statements, except for SET statements, are not executed.

**host-variable**  
host-variable must be a CHAR or VARCHAR value and must be NO, YES, or EXPLAIN. Leading blanks are not allowed. All input values must be uppercase, must be left justified within the host variable, and must be padded on the right with blanks if the length of the value is less than the length of the host variable.

For values YES and EXPLAIN, prepared statements are not saved into the dynamic statement cache.
Examples

Example 1: The following statement sets the CURRENT EXPLAIN MODE special register, so that EXPLAIN information will be captured for any subsequent eligible dynamic SQL statements during execution.

```
SET CURRENT EXPLAIN MODE = YES;
```

Related reference:

CURRENT EXPLAIN MODE
SET CURRENT GET_ACCEL_ARCHIVE

The SET CURRENT GET_ACCEL_ARCHIVE statement changes the value of the CURRENT GET_ACCEL_ARCHIVE special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT GET_ACCEL_ARCHIVE = NO
```

Description

**NO**  Specifies that if a table is archived in an accelerator server, and a query references that table, the query does not use the data that is archived.

**YES**  Specifies that if a table is archived in an accelerator server, and a query references that table, the query uses the data that is archived.

**host-variable**  A variable with a data type of CHAR or VARCHAR. The length must not exceed 255 bytes. Valid values are YES or NO. If host-variable has an associated indicator variable, the value of that indicator variable must not indicate a null value. The value of host-variable must be left justified and must be padded on the right with blanks.

Examples

The following statement sets the CURRENT GET_ACCEL_ARCHIVE special register to NO to indicate that when a table is archived in an accelerator server, the table reference does not include the archived data.

```
SET CURRENT GET_ACCEL_ARCHIVE=NO;
```

Related reference:

[CURRENT GET_ACCEL_ARCHIVE]
SET CURRENT LOCALE LC_CTYPE

The SET CURRENT LOCALE LC_CTYPE statement assigns a value to the CURRENT LOCALE LC_CTYPE special register. The special register allows control over the LC_CTYPE locale for statements that use a built-in function that refers to a locale, such as LCASE, UCASE, and TRANSLATE (with a single argument).

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT LC_CTYPE = string-constant
```

Description

The value of CURRENT LOCALE LC_CTYPE is replaced by the value specified.

**string-constant**

A character string constant that must not be longer than 50 bytes and must represent a valid locale.

**host-variable**

A variable with a data type of CHAR or VARCHAR and a length that is not longer than 50 bytes. The value of host-variable must not be null and must represent a valid locale. If the host variable has an associated indicator variable, the value of the indicator variable must not indicate a null value.

The locale must:

- Be left justified within the host variable
- Be padded on the right with blanks if its length is less than that of the host variable

A locale can be specified in uppercase characters, lowercase characters, or a combination of the two. For more information, see [CURRENT LOCALE LC_CTYPE](#).

**Note:** The existence of a locale is not validated when the CURRENT LOCALE LC_CTYPE special register is set. For example, a locale name that is misspelled is not detected, which could affect the way subsequent SQL operates. When the special register value is used at execution time, an error is returned if the locale does not exist. For example, if the LOWER function is invoked without specifying a locale name, the special register determines the locale that is used.
Examples

Example 1: Set the CURRENT LOCALE LC_CTYPE special register to the locale 'En_US'.

EXEC SQL SET CURRENT LOCALE LC_CTYPE = 'En_US';

Example 2: Set the CURRENT LOCALE LC_CTYPE special register to the value of host variable HV1, which contains 'Fr_FR@EURO'.

EXEC SQL SET CURRENT LOCALE LC_CTYPE = :HV1;

Related concepts:

Related reference:

CURRENT LOCALE LC_CTYPE
SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION

The SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION statement changes the value of the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION = ALL NONE SYSTEM SESSION_USER USER host-variable
```

Description

The value indicates which materialized query tables that are enabled for optimization are considered when optimizing the processing of dynamic SQL queries.

**ALL**

Indicates that all materialized query tables will be considered.

**NONE**

Indicates that no materialized query tables will be considered.

**SYSTEM**

Indicates that only system-maintained materialized query tables that are refresh deferred will be considered.

**SESSION_USER** or **USER**

Indicates that only user-maintained materialized query tables that are refresh deferred will be considered.

**host-variable**

A variable of type CHAR or VARCHAR. The length of the contents of **host-variable** must not exceed 255 bytes. It cannot be set to null. If **host-variable** has an associated indicator variable, the value of that indicator variable must not indicate a null value.

The characters of **host-variable** must be left justified. The content of the host variable must be a string that would match what can be specified as keywords for the special register in the exact case intended as there is no conversion to uppercase characters.
Notes

The CURRENT REFRESH AGE special register needs to be set to a value other than zero in order for the specified types of objects to be considered for optimizing the processing of dynamic SQL queries.

The CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register affects dynamic statement cache matching.

Examples

Example 1: The following statement sets the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register:

```sql
SET CURRENT MAINTAINED TABLE TYPES ALL;
```

Example 2: The following example retrieves the current value of the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register into the host variable called CURMAINTYPES.

```sql
EXEC SQL VALUES (CURRENT MAINTAINED TABLE TYPES) INTO :CURMAINTYPES;
```

The value would be ALL if set by the previous example.

Example 3: The following example resets the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register so that no materialized query tables can be considered to optimize the processing of dynamic SQL queries.

```sql
SET CURRENT MAINTAINED TABLE TYPES NONE;
```

Related reference:

CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION
SET CURRENT OPTIMIZATION HINT

The SET CURRENT OPTIMIZATION HINT statement assigns a value to the CURRENT OPTIMIZATION HINT special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT OPTIMIZATION HINT = string-constant
```

Description

The value of special register CURRENT OPTIMIZATION HINT is replaced by the value of the string constant or host variable. The value must be a character string that is not longer than 128 bytes.

Notes

*Using the OPTIMIZATION HINT special register:* The CURRENT OPTIMIZATION HINT special register specifies whether optimization hints are used in determining the access path of dynamic statements. An empty string or all blanks indicates that DB2 uses normal optimization techniques and ignores optimization hints.

Example

*Example 1:* Assume that string constant 'NOHYB' identifies a user-defined optimization hint in owner.PLAN_TABLE. Set the CURRENT OPTIMIZATION HINT special register so that DB2 uses this optimization hint to generate the access path for dynamic statements.

```
SET CURRENT OPTIMIZATION HINT = 'NOHYB';
```

If you set the register this way, DB2 validates and considers information in the rows in owner.PLAN_TABLE where the value in the OPTHINT column matches 'NOHYB' for dynamic SQL statements.

*Example 2:* Clear the CURRENT OPTIMIZATION HINT special register by specifying an empty string.

```
SET CURRENT OPTIMIZATION HINT = '';
```

Related reference:

CURRENT OPTIMIZATION HINT
SET CURRENT PACKAGE PATH

The SET CURRENT PACKAGE PATH statement assigns a value to the CURRENT PACKAGE PATH special register.

Invocation

This statement can be embedded only in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT PACKAGE PATH (collection-id)
```

Notes:
1. SESSION_USER (or USER), CURRENT PACKAGE PATH, and CURRENT PATH can each be specified only once on the right side of the statement.

Description

The value of CURRENT PACKAGE PATH is replaced by the values specified.

collection-id
Identifies a collection. collection-id must not be a delimited identifier that is empty or contains only blanks.

SESSION_USER or USER
Specifies the value of the SESSION_USER (USER) special register.

CURRENT PACKAGE PATH
Specifies the value of the CURRENT PACKAGE PATH special register before the execution of the SET CURRENT PACKAGE PATH statement.

CURRENT PATH
Specifies the value of the CURRENT PATH special register.

host-variable
Specifies a host variable that contains one or more collection IDs, separated by commas. The host variable must:
- Have a data type of CHAR or VARCHAR. The actual length of the contents of the host variable must not exceed the maximum length of the CURRENT PACKAGE PATH special register.
- Not be the null value if an indicator variable is provided.
• Contain an empty or blank string, or one or more collection IDs that are separated by commas.
• Be padded on the right with blanks if the host variable is fixed-length, or if the actual length of the host variable is longer than the content.
• Not contain a delimited identifier that is empty or contains only blanks.

string-constant
Specifies a string constant that contains one or more collection IDs, separated by commas. The string constant must:
• Have a length that does not exceed the maximum length of the CURRENT PACKAGE PATH special register.
• Contain an empty or blank string, or one or more collection IDs separated by commas.
• Not contain a delimited identifier that is empty or contains only blanks.

Notes

Contents of host variable or string constant: The contents of a host variable or string constant are interpreted as a list of collection IDs if the value contains at least one comma. If multiple collection IDs are specified, they must be separated by commas. Each collection ID in the list must conform to the rules for forming an ordinary identifier or be specified as a delimited identifier.

Checking for the existence of collections: No validation that the collections exist is made at the time that the CURRENT PACKAGE PATH special register is set. For example, a collection ID that is misspelled is not detected, which could affect the way subsequent SQL operates. At package execution time, authorization to the specific package is checked, and if this authorization check fails, an error is issued.

Resulting contents of the special register: The special register string is built by taking each collection ID specified and removing trailing blanks, delimiting with double quotation marks, doubling any double quotation marks within the collection ID as necessary, and then separating each collection ID by a comma. If the same collection ID appears more than once in the list, the first occurrence of the collection is used, and a warning is issued. The length of the resulting list cannot exceed the length of the special register. For example, assume that the following statements are issued:

SET CURRENT PACKAGE PATH = MYPKGS, "ABC E", SYSIBM
SET :HVPKLIST = CURRENT PACKAGE PATH

These statements result in the value of the host variable being set to: "MYPKGS", "ABC E", "SYSIBM".

A collection ID that does not conform to the rules for an ordinary identifier must be specified as a delimited collection ID and must not be specified within a host variable or string constant.

Considerations for keywords: A difference exists between specifying a single keyword, such as SESSION_USER, as a single keyword or as a delimited identifier. To indicate that the current value of a special register that is specified as a single keyword should be used in the package path, specify the name of the special register as a keyword. If you specify the name of the special register as a delimited identifier, it is interpreted as a collection ID of that value. For example, assume that the current value of the SESSION_USER special register is SMITH and that the following statement is issued:
SET CURRENT PACKAGE PATH = SYSIBM, SESSION_USER, "USER"

The result is that the value of the CURRENT PACKAGE PATH special register is set to: "SYSIBM, "SMITH", "USER".

Specifying a collection ID in an SQL procedure: Because a host variable (SQL variable) in an SQL procedure does not begin with a colon, DB2 uses the following rules to determine whether a value that is specified in a SET PACKAGE PATH = name statement is a variable or a collection ID:

- If name is the same as a parameter or SQL variable in the SQL procedure, DB2 uses name as a parameter or SQL variable and assigns the value in name to the package path.
- If name is not the same as a parameter or SQL variable in the SQL procedure, DB2 uses name as a collection ID and assigns the value in name is the package path.

DRDA classification: The SET CURRENT PACKAGE PATH statement is executed by the database server and, therefore, is classified as a non-local SET statement in DRDA. The SET CURRENT PACKAGE PATH statement requires a new level of DRDA support. If SET CURRENT PACKAGE PATH is issued when connected to the local server, the SET CURRENT PACKAGE PATH special register at the local server is set. Otherwise, when SET CURRENT PACKAGE PATH is issued when connected to a remote server, the SET CURRENT PACKAGE PATH special register at the remote server is set.

Examples

Example 1: Set the CURRENT PACKAGE PATH special register to the list of collections COLL4 and COLL5, where :hvar1 contains the value COLL4,COLL5:

```sql
SET CURRENT PACKAGE PATH :hvar1;
```

The value of CURRENT PACKAGE PATH is set to the following two collection IDs: "COLL4","COLL5".

Example 2: Set the CURRENT PACKAGE PATH special register to the list of collections: COLL1, COLL#2, COLL3, COLL4, and COLL5, where :hvar1 contains the value COLL4,COLL5:

```sql
SET CURRENT PACKAGE PATH = "COLL1","COLL#2","COLL3", :hvar1;
```

The value of CURRENT PACKAGE PATH is set to the following five collection IDs: "COLL1","COLL#2","COLL3","COLL4","COLL5".

Example 3: Clear the CURRENT PACKAGE PATH special register.

```sql
SET CURRENT PACKAGE PATH = ' ';
```

Example 4: In preparation of calling a stored procedure that is named SUMARIZE, temporarily add two collections, COLL_PROD1" and "COLL_PROD2, to the end of the CURRENT PACKAGE PATH special register (the values of the collections are in host variables :prodcoll1 and prodcoll2, respectively). Because the stored procedure SUMARIZE is not defined with a COLLID value and is defined with INHERIT SPECIAL REGISTERS, the stored procedure will inherit the value of CURRENT PACKAGE PATH. When the stored procedure returns, set the value of the CURRENT PACKAGE PATH special register back to its original value.
SET :oldCPP = CURRENT PACKAGE PATH;
SET CURRENT PACKAGE PATH = CURRENT PACKAGE PATH, :prodcoll1, :prodcoll2;
CALL SUMARIZE(:V1,:V2);
SET CURRENT PACKAGE PATH = :oldCPP;

Related reference:

CURRENT PACKAGE PATH
SET CURRENT PACKAGESET

The SET CURRENT PACKAGESET statement assigns a value to the CURRENT PACKAGESET special register.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT PACKAGESET = SESSION_USER
```

Description

The value of CURRENT PACKAGESET is replaced by the value of the SESSION_USER special register, string-constant, or host-variable. The value specified by string-constant or host-variable must be a character string that is not longer than 128 bytes.

Notes

Selection of plan elements: A plan element is a DBRM that has been bound into the plan or a package that is implicitly or explicitly identified in the package list of the plan. Plan elements contain the control structures used to execute certain SQL statements.

Since a plan can have many elements, one of the first steps involved in the execution of an SQL statement that requires a control structure is the selection of the plan element that contains its control structure. The information used by DB2 to select plan elements includes the value of CURRENT PACKAGESET.

SET CURRENT PACKAGESET is used to specify the collection ID of a package that exists at the current server. SET CURRENT PACKAGESET is optional and should not be used without an understanding of the following rules for selecting a plan element.

If the CURRENT PACKAGESET special register is an empty string, DB2 searches for a DBRM or a package in one of these sequences:

At the local location (if CURRENT SERVER is blank or explicitly names that location), the order is:
1. All DBRMs bound directly to the plan
2. All packages that have already been allocated for the application process
3. All unallocated packages explicitly named in, and all collections completely included in, the package list of the plan. The order of search is the order those packages are named in the package list.

At a remote location, the order is:
1. All packages that have already been allocated for the application process at that location
2. All unallocated packages explicitly named in, and all collections completely included in, the package list of the plan, whose locations match the value of CURRENT SERVER. The order of search is the order those packages are named in the package list.

If the special register CURRENT PACKAGESET is set, DB2 skips the check for programs that are part of the plan and uses the value of CURRENT PACKAGESET as the collection. For example, if CURRENT PACKAGESET contains COL5, then DB2 uses COL5.PROG1.timestamp for the search. For additional information, see DB2 Application Programming and SQL Guide.

DRDA classification: SET CURRENT PACKAGESET is executed by the requester and is therefore classified as a local SET statement in DRDA.

CURRENT PACKAGESET special register with stored procedures and user-defined functions: The initial value of the CURRENT PACKAGESET special register in a stored procedure or user-defined function is the value of the COLLID parameter with which the stored procedure or user-defined function was defined. If the routine was defined without a value for the COLLID parameter, the value of the special register is inherited from the calling program. A stored procedure or user-defined function can use the SET CURRENT PACKAGESET statement to change the value of the special register. This allows the routine to select the version of the DB2 package that is used to process the SQL statements in a called routine that is not defined with a COLLID value.

When control returns from the stored procedure to the calling program, the special register CURRENT PACKAGESET is restored to the value it contained before the stored procedure was called.

Examples

Example 1: Limit the plan element selection to packages in the PERSONNEL collection at the current server.
   EXEC SQL SET CURRENT PACKAGESET = 'PERSONNEL';

Example 2: Eliminate collections as a factor in plan element selection.
   EXEC SQL SET CURRENT PACKAGESET = '';

Related reference: CURRENT PACKAGESET
SET CURRENT PRECISION

The SET CURRENT PRECISION statement assigns a value to the CURRENT PRECISION special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT PRECISION = string-constant
                     host-variable
```

Description

This statement replaces the value of the CURRENT PRECISION special register with the value of the string constant or host variable. The value must be a character string 5 bytes in length. The value must be 'DEC15,' 'DEC31,' or 'Dpp.s', where 'pp' is either 15 or 31 and 's' is a number between 1 and 9. If the form 'Dpp.s' is used, 'pp' represents the precision that will be used with the rules that are used for DEC15 or DEC31, and 's' represents the minimum divide scale to use for division operations. The separator used in the form 'Dpp.s' can be either the '.' or the ',' character, regardless of the setting of the default decimal point.

Example

Set the CURRENT PRECISION special register so that subsequent statements that are prepared use DEC15 rules for decimal arithmetic.

```
EXEC SQL SET CURRENT PRECISION = 'DEC15';
```

Related reference:

- CURRENT PRECISION

---

Chapter 7. Statements 2217
SET CURRENT QUERY ACCELERATION

The SET CURRENT QUERY ACCELERATION statement changes the value of the CURRENT QUERY ACCELERATION special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT QUERY ACCELERATION [NONE | ENABLE | ENABLE WITH FAILBACK | ELIGIBLE | ALL | host-variable]
```

Description

NONE

Specifies that no query acceleration is done.

ENABLE

Specifies that queries are accelerated only if DB2 determines that it is advantageous to do so. If an accelerator failure occurs while a query is running or if the accelerator returns an error, DB2 returns a negative SQLCODE to the application.

ENABLE WITH FAILBACK

Specifies that queries are accelerated only if DB2 determines that it is advantageous to do so. If the accelerator returns an error during the PREPARE or first OPEN for the query, DB2 executes the query without the accelerator. If the accelerator returns an error during a FETCH or a subsequent OPEN, DB2 returns the error to the user and does not execute the query.

ELIGIBLE

Specifies that queries are accelerated if they are eligible for acceleration. DB2 does not use cost information to determine whether to accelerate the queries. Queries that are not eligible for acceleration are executed by DB2. If an accelerator failure occurs while a query is running or if the accelerator returns an error, DB2 returns a negative SQLCODE to the application.

ALL

Specifies that queries are accelerated if they are eligible for acceleration. DB2 does not use cost information to determine whether to accelerate the queries. Queries that are not eligible for acceleration are not executed by DB2, and an
SQL error is returned. If an accelerator failure occurs while a query is running or if the accelerator returns an error, DB2 returns a negative SQLCODE to the application.

**host-variable**
A variable with a data type of CHAR or VARCHAR. The length must not exceed 255 bytes. Valid values are NONE, ENABLE, ENABLE WITH FAILBACK, ELIGIBLE, or ALL. If `host-variable` has an associated indicator variable, the value of that indicator variable must not indicate a null value. The value of `host-variable` must be left justified and must be padded on the right with blanks.

**Examples**
The following statement sets the CURRENT QUERY ACCELERATION special register to NONE to indicate that no acceleration is done.

```sql
SET CURRENT QUERY ACCELERATION NONE;
```

**Related reference:**
[CURRENT QUERY ACCELERATION](#)
SET CURRENT REFRESH AGE

The SET CURRENT REFRESH AGE statement changes the value of the CURRENT REFRESH AGE special register.

The CURRENT REFRESH AGE value corresponding to ANY (99 999 999 999 999) cannot be used in timestamp arithmetic operations because the result would be outside the valid range of dates.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT REFRESH AGE numeric-constant
```

Description

**numeric-constant**

A DECIMAL(20,6) value representing a timestamp duration. The value must be 0 or 99 999 999 999 999, the partial seconds of which is ignored and thus can be any value.

0 Indicates that query optimization using materialized query tables will not be attempted.

99999999999999 Indicates that any materialized query tables identified by the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register may be used to optimize the processing of a query. This value represents 9999 years, 99 months, 99 days, 99 hours, 99 minutes, and 99 seconds.

**ANY**

Shorthand for 99999999999999.

**host-variable**

A variable of type DECIMAL(20,6) or other type that is assignable to DECIMAL(20,6). It cannot be set to null. If **host-variable** has an associated indicator variable, the value of that indicator variable must not indicate a null value. The value of **host-variable** must be 0 or 99 999 999 999 999, the partial seconds of which is ignored and thus can be any value.
Notes

Materialized query tables created or altered with DISABLE QUERY OPTIMIZATION specified are not eligible for automatic query rewrite. Thus, they are not affected by the setting of this special register.

Setting the CURRENT REFRESH AGE special register to a value other than zero should be done with caution. Allowing a materialized query table that may not represent the values of the underlying base table to be used to optimize the processing of a query may produce results that do not accurately represent the data in the underlying table. This situation may be acceptable when you know the underlying data has not changed or you are willing to accept the degree of error in the results based on your knowledge of the data.

Examples

Example: Set the CURRENT REFRESH AGE special register to 99 999 999 999 999 to indicate that any materialized query tables identified by the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register can be used to optimize the processing of a query.

    SET CURRENT REFRESH AGE ANY;

Related reference:

CURRENT REFRESH AGE
SET CURRENT ROUTINE VERSION

The SET CURRENT ROUTINE VERSION statement assigns a value to the CURRENT ROUTINE VERSION special register. The special register sets the override value for the version identifier of native SQL procedures when they are invoked.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT ROUTINE VERSION = routine-version-id
               host-variable
               string-constant
```

Description

`routine-version-id`
- Specifies a routine version identifier.

`host-variable`
- Specifies a host variable that contains a version identifier. The host variable must conform to the following rules:
  - Be a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC variable. The actual length of the contents of the host variable must not exceed the length of a version identifier.
  - Include a routine version identifier that is left justified and conforms to the rules for forming an ordinary identifier or a delimited identifier, or must be blank or empty.
  - Be padded on the right with blanks if the host variable is a fixed length character.
  - Not be empty or contain only blanks if the identifier is delimited.
  - Not be the null value.

`string-constant`
- Specifies a string constant that contains a version identifier. The string constant must conform to the following rules:
  - Have a length that does not exceed the length of a `routine-version-id`.
  - Include a routine version identifier that is left justified and conforms to the rules for forming an ordinary identifier or a delimited identifier, or must be blank or an empty string
  - Not be empty or contain only blanks if the identifier is delimited.
Notes

Resetting the special register: To reset the special register, specify an empty string constant, a string of blanks, or a host variable that is empty or contains only blanks. A routine version override is not in effect when the special register is reset.

Implications of using the special register: Setting the CURRENT ROUTINE VERSION special register to a version identifier will affect all SQL procedures that are subsequently invoked using CALL statements that specify the name of the procedure using a host variable, until the value of CURRENT ROUTINE VERSION is changed. If a version of the procedure that is identified by the version identifier in the special register exists for an SQL procedure that is being invoked, that version of the procedure is used. Otherwise, the currently active version of the procedure (as noted in the catalog) is used.

When you use the CURRENT ROUTINE VERSION special register to test a version of one or more native SQL procedures, you should use a routine version identifier that is a value other than the default value (V1) on the CREATE PROCEDURE statement. This will avoid having the special register affect more procedures that you intend when testing a new version of a procedure. For example, assume that you want to run version VER2 of procedure P1, and procedure P1 invokes another procedure, P2. If a version exists for both procedures P1 and P2 with the routine version identifier VER2, that version will be used for both procedures.

Examples

Example: The following statement sets the CURRENT ROUTINE VERSION special register so that the override value for the version identifier of native SQL procedures will be the value that is specified in the host variable rvid:

SET CURRENT ROUTINE VERSION = :rvid;

Related reference:

CURRENT ROUTINE VERSION
SET CURRENT RULES

The SET CURRENT RULES statement assigns a value to the CURRENT RULES special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT RULES = string-constant
```

Description

This statement replaces the value of the CURRENT RULES special register with the value of the string constant or host variable. The value must be a character string that is 3 bytes in length, and the value must be 'DB2' or 'STD'.

Notes

For the effect of the values 'DB2' and 'STD' on the execution of certain SQL statements, see CURRENT RULES.

Example

Set the SQL rules to be followed to DB2.

```
EXEC SQL SET CURRENT RULES = 'DB2';
```

Related reference:

CURRENT RULES
**SET CURRENT SQLID**

The SET CURRENT SQLID statement assigns a value to the CURRENT SQLID special register.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared. The value to which special register CURRENT SQLID is set is used as the SQL authorization ID for dynamic SQL statements only if DYNAMICRULES run behavior is in effect. The CURRENT SQLID value is ignored for the other DYNAMICRULES behaviors.

**Authorization**

The specified value must be equal to one of the authorization IDs of the application process. This rule always applies, even when SET CURRENT SQLID is a static statement.

**Exception:** If any of the authorization IDs of the process has SYSADM authority, CURRENT SQLID can be set to any value when the SEPARATE SECURITY system parameter is set to NO. Note that the SEPARATE_SECURITY subsystem parameter does not apply to or affect users with installation SYSADM authority.

CURRENT SQLID cannot be set to the name of a role.

**Syntax**

```
SET CURRENT SQLID = SESSION_USER
  USER
string-constant
host-variable
```

**Description**

The value of CURRENT SQLID is replaced by the value of SESSION_USER, string-constant, or host-variable. The value specified by a string-constant or host-variable must be a character string that contains 8 characters or less. Unless some authorization ID of the process has SYSADM authority, the value must be equal to one of the authorization IDs of the process.

**Notes**

*Effect on authorization IDs:* SET CURRENT SQLID does not change the primary authorization ID of the process.

If the SET CURRENT SQLID statement is executed in a stored procedure or user-defined function package that has a dynamic SQL behavior other than run behavior, the SET CURRENT SQLID statement does not affect the authorization ID that is used for dynamic SQL statements in the package. The dynamic SQL behavior determines the authorization ID. For more information, see [DYNAMICRULES bind option (DB2 Commands)](chapter_7_statements/2225)
Effect on special register CURRENT PATH: When the value of the PATH special register depends on the value of the CURRENT SQLID special register, any changes to the CURRENT SQLID special register are not reflected in the value of the PATH special register until a commit operation is performed or a SET PATH statement is issued to change the SQL path to use the new value of the CURRENT SQLID.

DRDA classification: SET CURRENT SQLID is executed by the database server and is therefore classified as a non-local SET statement in DRDA.

Examples

Example 1: Set the CURRENT SQLID to the primary authorization ID.

SET CURRENT SQLID = SESSION_USER;
SET ENCRYPTION PASSWORD

The SET ENCRYPTION PASSWORD statement sets the value of the encryption password and, optionally, the password hint. The encryption and decryption built-in functions use this password and password hint for data encryption unless the functions are invoked with an explicitly specified password and hint. The password is not tied to DB2 authentication and is used only for data encryption.

Invocation

The statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET ENCRYPTION PASSWORD = password-variable
password-string-constant
WITH HINT hint-variable
hint-string-constant
```

Description

password-variable

Specifies a variable that contains an encryption password. The variable:

- Must be a CHAR or VARCHAR variable. The actual length of the contents of the variable must be between 6 and 127 inclusive or must be an empty string. If an empty string is specified, the default encryption password is set to no value.
- Must not be the null value.
- All characters are case-sensitive and are not converted to uppercase characters.

password-string-constant

A character constant that contains an encryption password. The length of the constant must be between 6 and 127 inclusive or must be an empty string. If an empty string is specified, the default encryption password is set to no value. All characters are case-sensitive and are not converted to uppercase characters.

WITH HINT

Indicates that a value is specified that will help you remember passwords (for example, 'Ocean' as a hint to remember 'Pacific'). If a hint value is specified, the hint is used as the default for encryption functions. The hint can subsequently be retrieved for an encrypted value using the GETHINT function.
If this clause is not specified and a hint is not explicitly specified on the encryption function, no hint will be embedded in encrypted data result.

**hint-variable**

Specifies a variable that contains an encryption password hint. The variable:

- Must be a CHAR or VARCHAR variable. The actual length of the contents of the variable must not be greater than 32. If an empty string is specified, the default encryption password hint is set to an empty string.
- Must not be the null value.
- All characters are case-sensitive and are not converted to uppercase characters.

**hint-string-constant**

A character string constant that contains an encryption password hint. The length of the constant must not be greater than 32. If the value is an empty string, the default encryption password hint is set to an empty string.

**Notes**

Normal DB2 mechanisms are used to transmit the host variable or constant to the database server.

**Examples**

*Example 1:* Set the ENCRYPTION PASSWORD to the value in :hv1. Do not specify a hint for the password.

```
SET ENCRYPTION PASSWORD = :hv1
```

*Example 2:* Set the ENCRYPTION PASSWORD to the value in :hv1. Specify the value in :hv2 as the hint for the password.

```
SET ENCRYPTION PASSWORD = :hv1 WITH HINT :hv2
```

**Related reference:**

- ENCRYPTION PASSWORD
- ENCRYPT_TDES
- DECRYPT_BINARY, DECRYPT_BIT, DECRYPT_CHAR, and DECRYPT_DB
**SET host-variable assignment**

The SET host-variable assignment statement assigns values, either of expressions or NULL values, to host variables.

**Invocation**

This statement can be embedded only in an application program. It is an executable statement that cannot be dynamically prepared.

**Authorization**

The privileges that are held by the current authorization ID must include those required to execute any of the expressions.

**Syntax**

```
SET host-variable= CURRENT SERVER
          CURRENT PACKAGESET
          CURRENT PACKAGE PATH

host-variable= expression

NULL

VALUES expression

NULL

( host-variable, host-variable ) = ( expression, expression )
```

**Notes:**

1. The number of expressions and NULL keywords must match the number of host-variables.

**Description**

**host-variable**

Identifies one or more host variables or transition variables that are used to receive the corresponding expression or NULL value on the right side of the statement.

For the triggered action of a CREATE TRIGGER statement, use the SET transition-variable instead.

The value to be assigned to each host-variable can be specified immediately following the item reference, for example, **host-variable = expression**, **host-variable=expression**. Or, sets of parentheses can be used to specify all the host-variables and then all the values, for example, **(host-variable, host-variable) = (expression, expression)**.
**host-variable**

Identifies one or more host variables that are used to receive the corresponding expression or NULL value on the right side of the statement. Each host variable must be defined in the program as described under the rules for declaring host variables. A parameter marker must not be specified in place of host-variable.

The value to be assigned to each host-variable can be specified immediately following the host variable, for example, host-variable = expression, host-variable = expression. Or, sets of parentheses can be used to specify all the host-variables and then all the values, for example, (host-variable, host-variable) = (expression, expression).

**expression**

Specifies the value to be assigned to the corresponding host-variable. The expression is any expression of the type described in Expressions except it cannot contain a reference to CURRENT PACKAGE PATH or to local special registers (CURRENT SERVER or CURRENT PACKAGESET).

Each assignment to a host variable is made according to the assignment rules described in Assignment and comparison. Assignments are made in sequence through the list. When the host-variables are enclosed within parentheses, for example, (host-variable, host-variable, ...) = (expression, expression, ...), the first value is assigned to the first host variable in the list, the second value to the second host variable in the list, and so on.

**NULL**

Specifies the null value and can only be specified for host variables that have an associated indicator variable.

**VALUES**

Specifies the value to be assigned to the corresponding host variable. When more than one value is specified, the values must be enclosed in parentheses. Each value can be an expression or NULL, as described above. The following syntax is equivalent:

- (host-variable, host-variable) = (VALUES(expression, NULL))
- (host-variable, host-variable) = (expression, NULL)

Local special registers and the CURRENT PACKAGE PATH special register can be referenced only in a VALUES host-variable statement that results in the assignment of a single host variable and not those that result in setting more than one value.

**Notes**

**Multiple assignments:**

If more than one assignment is included in the same SET statement, all expressions are completely evaluated before the assignments are performed. Thus, references to a target host variable in an expression are always the value of the target host variable prior to any assignment in the SET statement.

**LOB assignments:**

Normally, you use LOB locators to assign and retrieve data from LOB columns. However, because of compatibility rules, you can also use LOB locators to assign data to host variables with other data types. For more information on using locators, see DB2 Application Programming and SQL Guide.
Default encoding scheme:
The default encoding scheme for the data is the value in the bind option ENCODING, which is the option for application encoding. If this statement is used with functions such as LENGTH or SUBSTRING that are operating on LOB locators, and the LOB data that is specified by the locator is in a different encoding scheme from the ENCODING bind option, LOB materialization and character conversion occur. To avoid LOB materialization and character conversion, select the LOB data from the SYSIBM.SYSDUMMYA, SYSIBM.SYSDUMMYE, or SYSIBM.SYSDUMMYU sample table.

Examples

Example 1: Set the host variable HVL to the value of the CURRENT PATH special register.

```
SET :HVL = CURRENT PATH;
```

Example 2: Set the host variable PATH to the contents of the SQL PATH special register, the host variable XTIME to the local time at the current server, and the host variable MEM to the current member of the data sharing environment.

```
SET :SERVER = CURRENT PATH,
     :XTIME = CURRENT TIME,
     :MEM = CURRENT MEMBER;
```

Example 3: Set the host variable DETAILS to a portion of a LOB value, using a LOB expression with a LOB locator to refer the extracted portion of the value.

```
SET :DETAILS = SUBSTR(:LOCATOR,1,35);
```

If the LOB data that is specified by the LOB locator LOCATOR is in a different encoding scheme from the value of the ENCODING bind option, and you want to avoid LOB materialization and character conversion, use the following statement instead of the SET statement:

```
SELECT SUBSTR(:LOCATOR,1,35)
  INTO :DETAILS
  FROM SYSIBM.SYSDUMMYU;
```

Example 4: Set host variable HV1 to the results of external function CALC_SALARY and host variable HV2 to the value of special register CURRENT PATH. Use an indicator value with HV1 in case CALC_SALARY returns a null value.

```
SET (:HV1:IND1, :HV2) =
  (CALC_SALARY(:HV3, :HF4), CURRENT PATH);
```
SET PATH

The SET PATH statement assigns a value to the CURRENT PATH special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET CURRENT PATH = (1)
```

Notes:

1. SYSTEM PATH, SESSION_USER or USER, and CURRENT PATH can be specified only once each.

Description

The value of PATH is replaced by the values specified.

```
schema-name
```

Identifies a schema. DB2 does not verify that the schema exists. For example, a schema name that is misspelled is not detected, which could affect the way subsequent SQL operates.

```
SYSTEM PATH
```

Specifies the schema names "SYSIBM", "SYSFUN", "SYSPROC".

```
SESSION_USER or USER
```

Specifies the value of the SESSION_USER (USER) special register.

```
PATH
```

Specifies the value of the CURRENT PATH special register before the execution of this statement.

```
CURRENT PACKAGE PATH
```

Specifies the value of the CURRENT PACKAGE PATH special register.

```
host-variable
```

A variable with a data type of CHAR or VARCHAR. The value of host-variable must not be null and must represent a valid schema name.
The schema name must:
• Be left justified within the host variable
• Be padded on the right with blanks if its length is less than that of the host variable

*string-constant*
A character string constant that represents a valid schema name.

If the schema name specified in *string-constant* will also be specified in other SQL statements and the schema name does not conform to the rules for ordinary identifiers, the schema name must be specified as a delimited identifier in the other SQL statements.

**Notes**

**Restrictions on SET PATH:**
These restrictions apply to the SET PATH statement:

• If the same schema name appears more than one time in the path, the first occurrence of the name is used and a warning is issued.

• The length of the CURRENT PATH special register limits the number of schema names that can be specified. The special register string is built by taking each schema name that is specified and removing trailing blanks, delimiting with double quotes, changing each double quote character to two double quote characters within the schema name as necessary, and then separating each schema name with a comma. The length of the resulting string cannot exceed 2048 bytes.

**Specifying "SYSIBM", "SYSFUN", "SYSPROC":**
Schemas "SYSIBM", "SYSFUN", "SYSPROC" do not need to be specified in the special register. If these schemas are not explicitly specified in the CURRENT PATH special register, each schema is implicitly assumed at the front of the SQL path; if any of these schemas are not specified, they are assumed in the order of "SYSIBM", "SYSFUN", "SYSPROC" (see *"SQL path"* on page 85 for an example). Only the schemas that are explicitly specified in the CURRENT PATH register are included in the 2048 byte limit.

To avoid having "SYSIBM", "SYSFUN", "SYSPROC" implicitly added to the front of the SQL path, explicitly specify them in the path when setting the value of the register. If you specify them at the end of the path, DB2 will check all the other schemas in the path first.

**Specifying keywords versus delimited identifiers:**
There is a difference between specifying a keyword and specifying a delimited identifier. For example, specifying SESSION_USER with and without escape characters. To indicate that the value of the SESSION_USER special register should be used in the SQL path, specify the keyword SESSION_USER. If you specify SESSION_USER as a delimited identifier instead (for example, "SESSION_USER"), it is interpreted as a schema name of 'SESSION_USER'. For example, assume that the current value of the SESSION_USER special register is SMITH and that the following statement is issued:

`SET PATH = SYSIBM, SYSPROC, SESSION_USER, "SESSION_USER"`

The result is that the value of the SQL path is set to: "SYSIBM","SYSPROC","SMITH","SESSION_USER".

**Specifying a schema name in an SQL procedure:**
Because a host variable (SQL variable) in an SQL procedure does not begin
with a colon, DB2 uses the following rules to determine whether a value
that is specified in a SET PATH=name statement is a variable or a
schema-name:

- If name is the same as a parameter or SQL variable in the SQL
  procedure, DB2 uses name as a parameter or SQL variable and assigns
  the value in name to PATH.

- If name is not the same as a parameter or SQL variable in the SQL
  procedure, DB2 uses name as a schema-name and assigns the value name
to PATH.

The use of the path to resolve object names:
For information on when the SQL path is used to resolve unqualified data
type, function, and procedure names and when the CURRENT PATH
special register provides the SQL path, see sql path.

DRDA classification:
The SET PATH statement is executed by the database server and, therefore,
is classified as a non-local SET statement in DRDA.

Alternative syntax and synonyms:
For compatibility with previous releases of DB2 or other products in the
DB2 family, DB2 supports CURRENT FUNCTION PATH or
CURRENT_PATH as a synonym for CURRENT PATH. CURRENT_PATH is
consistent with the SQL standard name of the special register.

Examples

Example 1: Set the CURRENT PATH special register to the list of schemas:
"SCHEMA1", "SCHEMA#2", "SYSIBM".

    SET PATH = SCHEMA1,"SCHEMA#2", SYSIBM;

When the SQL path specified in the special register is used for name resolution the
system schemas which were not explicitly specified in the special register are
implicitly assumed at the front of the SQL path, making the effective value of the
path:
    SYSFUN, SYSPROC, SCHEMA1, SCHEMA#2, SYSIBM

Example 2: Add schema SMITH and SYSPROC to the value of the CURRENT
PATH special register that was set in Example 1.

    SET PATH = CURRENT PATH, SMITH, SYSPROC;

The effective value of the SQL path specified by the special register becomes:
    SYSFUN, SCHEMA1, SCHEMA#2, SYSIBM, SMITH, SYSPROC

Related reference:
CURRENT PATH
SET SCHEMA

The SET SCHEMA statement assigns a value to the CURRENT SCHEMA special register. If the package is bound with the DYNAMICRULES BIND option, this statement does not affect the qualifier that is used for unqualified database object references.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```sql
SET CURRENT_SCHEMA = schema-name
```

Description

- **schema-name**
  Identifies a schema. No validation that the schema exists is made at the time the CURRENT SCHEMA is set. For example, if a schema name is misspelled, it could affect the way subsequent SQL operates.

- **SESSION_USER** or **USER**
  Specifies the value of the SESSION_USER (USER) special register.

- **host-variable**
  Specifies a host variable that contains a schema name. The content is not folded to uppercase.

  The host variable must:
  - Be a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC variable. The actual length of the contents of the `host-variable` must not exceed the length of a schema name.
  - Not be set to null. If `host-variable` has an associated indicator variable, the value of that indicator variable must not indicate a null value.
  - Include a schema name that is left justified and conforms to the rules for forming an ordinary identifier or delimited identifier. If the identifier is delimited, it must not be empty or contain only blanks.
  - Be padded on the right with blanks if the host variable is fixed length.
  - Not contain SESSION_USER, USER, or DEFAULT.
**string-constant**

Specifies a string constant that contains a schema name. The content is not folded to uppercase.

The string constant must:

- Have a length that does not exceed the maximum length of a schema name.
- Include a schema name that is left justified and conforms to the rules for forming an ordinary identifier or delimited identifier. If the identifier is delimited, it must not be empty or contain only blanks.
- Not contain SESSION_USER, USER, or DEFAULT.

**DEFAULT**

Specifies that CURRENT SCHEMA is to be set to its initial value, as if it had never been explicitly set during the application process. For information about the initial value of CURRENT SCHEMA, see “CURRENT SCHEMA” on page 207.

**Notes**

**Considerations for keywords:**

There is a difference between specifying a single keyword (such as SESSION_USER or DEFAULT) as a single keyword or as a delimited identifier. To indicate that the current value of the SESSION_USER special register should be used for setting the current schema, specify SESSION_USER as a keyword. To indicate that the special register should be set to its default value, specify DEFAULT as a keyword. If SESSION_USER or DEFAULT is specified as a delimited identifier instead (for example, "SESSION_USER"), it is interpreted as a schema name of that value ("SESSION_USER").

**Transaction considerations:**

The SET SCHEMA statement is not a committable operation. ROLLBACK has no effect on CURRENT SCHEMA.

**Usage of the assigned value:**

The value of the CURRENT SCHEMA special register, as set by this statement, is used as the schema name in all dynamic SQL statements. The QUALIFIER bind option specifies the schema name for use as the qualifier for unqualified database object names in static SQL statements.

**Impact on other special registers:**

Setting the CURRENT SCHEMA special register does not affect any other special register. Therefore, the CURRENT SCHEMA is not be included in the SQL path that is used to resolve the schema name for unqualified references to function, procedures and user-defined types in dynamic SQL statements. To include the current schema value in the SQL path, whenever the SET SCHEMA statement is issued, also issue the SET PATH statement including the schema name from the SET SCHEMA statement.

**Examples**

*Example 1:* The following statement sets the CURRENT SCHEMA special register.

```sql
EXEC SQL SET SCHEMA RICK;
```

*Example 2:* The following example retrieves the current value of the CURRENT SCHEMA special register into the host variable called CURSCHEMA.

```sql
EXEC SQL SELECT CURRENT SCHEMA INTO :CURSCHEMA FROM SYSIBM.SYSDUMMY1;
```
The value of the host variable is RICK.

*Example 3:* Assume that the following statements are issued:

```
SET CURRENT SQLID = 'USR001';
SET CURRENT SCHEMA = 'USR002';
```

At this point, the two special registers contain different values. Any subsequent CREATE statements will use USR002 as the implicit qualifier, but the owner of the newly created objects is USR001.

*Example 4:* Assume that the value of CURRENT SCHEMA is 'Jane' and that the default value of the PATH special register was established using that value (that is, the value of PATH is "SYSIBM", "SYSFUN", "SYSPROC", "JANE"). Change the value of the CURRENT SCHEMA special register to 'John'.

```
SET CURRENT SCHEMA = 'JOHN';
```

To change the SQL path to use the updated CURRENT SCHEMA value of "JOHN", issue a SET PATH statement to change the value of the PATH special register to specify "JOHN" as the first schema to check:

```
SET PATH = 'JOHN', CURRENT PATH;
```

Alternatively, a commit would cause PATH to be re-initialized. Otherwise, the path remains "SYSIBM", "SYSFUN", "SYSPROC", "JANE"), which might cause unqualified object names to resolve to "JANE" when you want them to resolve to "JOHN".
SET SESSION TIME ZONE

The SET SESSION TIME ZONE statement assigns a value to the SESSION TIME ZONE special register.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

```
SET SESSION TIME ZONE string-constant
```

Description

`string-constant`

Identifies a time zone with a value of the form `±th:tm`, where `th` represents the time zone hour between -12 and +14, and `tm` represents the time zone minutes between 0 and 59, with values ranging from -12:59 to +14:00.

`variable`

Specifies a variable that contains a time zone. The variable must be a CHAR or VARCHAR variable that is not followed by an indicator variable. The variable must not be the null value. The value must be left justified and be of the form `±th:tm`, where `th` represents the time zone hour between -12 and +14, and `tm` represents the time zone minutes between 0 and 59, with values ranging from -12:59 to +14:00.

Notes

Impact on other special registers:

Setting the SESSION TIME ZONE special register does not affect the CURRENT TIMEZONE special register.

Syntax alternatives:

SESSIONTIMEZONE, SESSION TIMEZONE, and TIMEZONE can be specified as an alternative to SESSION TIME ZONE or TIME ZONE.

Example

Set the SESSION TIME ZONE as -8:00:

```
SET SESSION TIME ZONE = '-8:00';
```

Related reference:

SESSION TIME ZONE
SET transition-variable assignment

The SET transition-variable assignment statement assigns values, either of
expressions or NULL values, to transition variables.

Invocation

This statement can be used as a triggered SQL statement in the triggered action of
a before trigger whose granularity is FOR EACH ROW.

Authorization

The privileges that are held by the current authorization ID must include those
required to execute any of the expressions or assignments to transition variables.

Syntax

Notes:
1. The number of expressions, DEFAULT, and NULL keywords must match the number of
   transition-variables.

transition-variable:

Description

transition-variable
Identifies a column in the set of affected rows for the trigger that is used to
used to receive the corresponding expression, default value, or NULL value on
the right side of the statement.
transition-variable must not correspond to a begin column or end column of a BUSINESS_TIME period.

The value to be assigned to each transition-variable can be specified immediately following the transition variable, for example, transition-variable = expression, transition-variable=expression. Or, sets of parentheses can be used to specify all the transition-variables and then all the values, for example, (transition-variable, transition-variable) = (expression, expression).

correlation-name
Identifies the correlation name given for referencing the NEW transition variables. The name must match the correlation name specified following NEW in the REFERENCING clause of the CREATE TRIGGER statement.

If OLD is not specified in the REFERENCING clause, correlation-name defaults to the correlation name following NEW.

column-name
Identifies the column to be updated. The name must identify a column of the subject table. The name can identify a column that is defined as GENERATED BY DEFAULT but not one defined as GENERATED ALWAYS, unless the DEFAULT keyword is specified on the right side of the statement. You must not specify the same column more than once.

The effect of a SET transition-variable statement is equivalent to the effect of an SQL UPDATE statement.

expression
Specifies the value to be assigned to the corresponding transition-variable. The expression is any expression of the type described in “Expressions” on page 246. A reference to a local special register is the value of that special register at the server when the trigger body is activated. If the expression contains a scalar fullselect, the scalar fullselect cannot reference columns of the triggering table. The expression cannot include a aggregate function except when it occurs within a scalar fullselect.

An expression can contain references to OLD and NEW transition variables that are qualified with a correlation name.

All expressions are evaluated before any result is assigned to a transition variable. If an expression refers to a transition variable that is used in the list of transition variables, the value of the variable in the expression is the value of the variable prior to any assignments.

Each assignment to a transition variable column is made according to the assignment rules described in “Assignment and comparison” on page 138. Assignments are made in sequence through the list. When the transition-variables are enclosed within parentheses, for example, (transition-variable, transition-variable, ...) = (expression, expression, ...), the first value is assigned to the first transition variable in the list, the second value to the second transition variable in the list, and so on.

DEFAULT
Specifies that the default value is used based on how the corresponding column is defined in the table. The value that is assigned depends on how the column is defined.
• If the column is defined using the IDENTITY clause, the column is generated by the DB2 system.
• If the column is defined as a row change timestamp column, the column value is generated by the DB2 system.
• If the column is defined using the WITH DEFAULT clause, the value is set to the default that is defined for the column.
• If the column is defined without specifying the WITH DEFAULT clause, the GENERATED clause, or the NOT NULL clause, the value is NULL.
• If the column is specified in the INCLUDE column list, the column value is set to null.

A ROWID column must not be set to the DEFAULT keyword.

An identity column or a row change timestamp column that is defined as GENERATED ALWAYS can be set only to the DEFAULT keyword.

If the column is defined using the NOT NULL clause and the GENERATED clause is not used, or the WITH DEFAULT clause is not used, the DEFAULT keyword cannot be specified for that column.

NULL
Specifies the null value and can only be specified for nullable transition variables.

VALUES
Specifies the value to be assigned to the corresponding transition variable. When more than one value is specified, the values must be enclosed in parentheses. Each value can be an expression or NULL, as described above. The following syntax is equivalent:

• \((transition-variable, transition-variable) = (VALUES(expression, NULL))\)
• \((transition-variable, transition-variable) = (expression, NULL)\)

Examples

Example 1: Assume that you want to create a before trigger that sets the salary and commission columns to default values for newly inserted rows in the EMPLOYEE table and that you will define the trigger only with NEW in the REFERENCING clause. Write the SET transition-variable statement that assigns the default values to the SALARY and COMMISSION columns.

\[
\text{SET (SALARY, COMMISSION) = (50000, 8000);}
\]

Example 2: Assume that you want to create a before trigger that detects any commission increases greater than 10% for updated rows in the EMPLOYEE table and limits the commission increase to 10%. You will define the trigger with both OLD and NEW in the REFERENCING clause. Write the SET transition-variable statement that limits an increase to the COMMISSION column to 10%.

\[
\text{SET NEWROW.COMMISSION = 1.1 * OLDROW.COMMISSION;}
\]
The SIGNAL statement is used to signal an error. It causes an error to be returned with the specified SQLSTATE and error description.

For a description of the statement, see SIGNAL statement.
The DB2 TRUNCATE statement deletes all rows for either base tables or declared global temporary tables. The base table can be in a simple table space, a segmented table space, a partitioned table space, or a universal table space. If the table contains LOB or XML columns, the corresponding table spaces and indexes are also truncated.

**Invocation**

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

**Authorization**

The privilege set that is defined below must include at least one of the following privileges:
- The DELETE privilege for the table
- Ownership of the table
- DBADM authority for the database
- DATAACCESS authority
- SYSADM authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

If the IGNORE DELETE TRIGGERS option is in effect, the privilege set must include at least one of the following privileges:
- The ALTER privilege for the table
- Ownership of the table
- DBADM authority for the database
- System DBADM authority
- SYSADM authority

If row access control is activated for the table, the privilege set must include at least one of the following privileges or authorities:
- Ownership of the table
- DBADM authority
- SYSADM authority
- SYSCTRL authority
- System DBADM authority

**Privilege set:** If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in Dynamic preparation and execution. (For more details on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see Authorization IDs and dynamic SQL.)
### Syntax

```
TRUNCATE TABLE table_name
  DROP STORAGE | REUSE STORAGE
  IGNORE DELETE TRIGGERS
IMMEDIATE
```

### Description

**table-name**

Identifies the table that is to be truncated. The name must identify a table that exists at the current server. The name must not identify the following objects:

- a view
- an auxiliary table
- an XML table
- a catalog table
- a system-period temporal table
- an accelerator-only table

If `table-name` is a base table of a table space, all tables that are defined under the table will also be truncated (for example: auxiliary LOB table spaces and XML table spaces), and all of its associated indexes will also be truncated.

**DROP STORAGE or REUSE STORAGE**

Specifies whether to drop or reuse the existing storage that is allocated for the table.

**DROP STORAGE**

Specifies that all storage that is allocated for the table is released and made available for use for the same table or any other table that resides in the table space. The scope of `DROP STORAGE` is always at the table space level and the deallocated space is always available for reuse by all tables in the table space.

`DROP STORAGE` is the default.

**REUSE STORAGE**

Specifies that all storage that is allocated for the table will be emptied, but will continue to be allocated for the table. `REUSE STORAGE` is ignored for a table in a simple table space and the statement is processed as if `DROP STORAGE` is specified.

**RESTRICT WHEN DELETE TRIGGERS or IGNORE DELETE TRIGGERS**

Specifies what to do when delete triggers are defined on the table.

**RESTRICT WHEN DELETE TRIGGERS**

Specifies that an error is returned if delete triggers are defined on the table.

**IGNORE DELETE TRIGGERS**

Specifies that any delete triggers that are defined for the table are not activated by the truncate operation. Additional authorization is required for this option; see “Authorization” on page 2243.
**IGNORE DELETE TRIGGERS** is the default.

**IMMEDIATE**

Specifies that the truncate operation is processed immediately and cannot be undone. If the IMMEDIATE option is specified, the table must not contain any uncommitted updates. In the case of a table in a multi-table table space, if there are any uncommitted updates to any table in the table space, the truncate operation will fail. Also, if there are any uncommitted CREATE, ALTER or DROP statements for any table in the table space, the truncate operation will fail.

The truncated table is immediately available for use in the same unit of work. Although a ROLLBACK statement is allowed to execute after a TRUNCATE statement, the truncate operation is not undone, and the table remains in a truncated state. For example, if another data change operation is done on the table after the TRUNCATE IMMEDIATE statement and then the ROLLBACK statement is executed, the truncate operation will not be undone, but all other data change operations are undone.

If IMMEDIATE is not specified, a ROLLBACK statement can undo the truncate operation.

The IMMEDIATE option can be specified for a table in a segmented table space or a universal table space which allows deallocated spaces to be reclaimed immediately for subsequent insert operations in the same unit of work without committing the truncate operation.

**Notes**

**Rules and restrictions:**

- The truncate operation cannot be executed if the table is a parent table in an enforced referential constraint. The DB2 subsystem issues an error when it detects the existence of rule violations. Therefore, if the referential integrity constraint exists, the TRUNCATE statement will be restricted regardless of whether the child table contains rows.

- The TRUNCATE statement cannot be used if the table is a system-maintained temporal table.

- If the TRUNCATE statement is used on a tables where any of the following conditions is true, the truncate operation will perform in a similar way to a mass delete operation:
  - Tables with Change Data Capture (CDC) attribute
    The DB2 subsystem allows a table with the CDC-enabled attribute to be truncated without imposing any new restrictions.
  - Tables with multi-level security
    If the table contains a column that is defined as a security label, the truncate operation needs to examine each row to determine if the security label of the authorization ID or role has the authority to delete that row. However, if the primary authorization ID or role has write-down privilege, verification of each row in the table is not necessary.
  - Tables with a VALIDPROC attribute
    If a VALIDPROC is defined for the table, the truncate operation needs to verify the validity of each row in the table.

**TRUNCATE and table spaces that are not logged:**

The TRUNCATE TABLE statement can be used to remove a table space.
from the logical page list and to reset recover-pending status. When the table space is segmented or universal, the table is the only table in the table space, and the table does not have a VALIDPROC, referential constraints, delete triggers, or a SECURITY LABEL column, use the TRUNCATE TABLE statement to empty the table and the table space will be removed from the LPL and recover-pending status will be reset.

Truncating rows from a table with activated row permissions or column access control:

Row permissions and column access control is not enforced for the TRUNCATE statement.

Examples

Example 1: Empty an unused inventory table regardless of any existing triggers and return its allocated space.

```
TRUNCATE TABLE INVENTORY
DROP STORAGE
IGNORE DELETE TRIGGERS;
```

Example 2: Empty an unused inventory table regardless of any existing delete triggers but preserve its allocated space for later reuse.

```
TRUNCATE TABLE INVENTORY
REUSE STORAGE
IGNORE DELETE TRIGGERS;
```

Example 3: Empty an unused inventory table permanently (a ROLLBACK statement cannot undo the truncate operation when the IMMEDIATE option is specified) regardless of any existing delete triggers and preserve its allocated space for immediate use.

```
TRUNCATE TABLE INVENTORY
REUSE STORAGE
IGNORE DELETE TRIGGERS
IMMEDIATE;
```
The UPDATE statement updates the values of specified columns in rows of a table or view or activates an instead of update trigger. Updating a row of a view updates a row of the table on which the view is based if no instead of update trigger is defined for the update operation on the view. If such a trigger is defined, the trigger is activated instead of the UPDATE statement. The table or view can exist at the current server or at any DB2 subsystem with which the current server can establish a connection.

There are two forms of this statement:

- The *searched* UPDATE form is used to update one or more rows optionally determined by a search condition.
- The *positioned* UPDATE form specifies that one or more rows corresponding to the current cursor position are to be updated.

**Invocation**

This statement can be embedded in an application program or issued interactively. A positioned UPDATE can be embedded in an application program. Both forms are executable statements that can be dynamically prepared.

**Authorization**

Authority requirements depend on whether the object identified in the statement is a user-defined table, a catalog table for which updates are allowed, or a view, and whether SQL standard rules are in effect:

**When a user-defined table is identified:** The privilege set must include at least one of the following:

- DATAACCESS authority
- The UPDATE privilege on the table
- The UPDATE privilege on each column to be updated
- Ownership of the table
- DBADM authority on the database that contains the table
- SYSADM authority

If the database is implicitly created, the database privileges must be on the implicit database or on DSNDB04.

**When a catalog table is identified:** The privilege set must include at least one of the following:

- ACCESSCTRL authority
- DATAACCESS authority
- The UPDATE privilege on each column to be updated
- DBADM authority on the catalog database
- SYSCTRL authority
- SYSADM authority
- SYSADM authority
- System DBADM authority
When a view is identified: The privilege set must include at least one of the following:
  • DATAACCESS authority
  • SYSADM authority
  • UPDATE privilege on the view
  • UPDATE privilege on each column to be updated

If the expression in the assignment-clause contains a reference to a column of the table or view, or if the search-condition in a searched UPDATE contains a reference to a column of the table or view, the privilege set must include at least one of the following:
  • The SELECT privilege on the table or view
  • Ownership of the table or view
  • DBADM authority on the database that contains the table, if the target is a table and that table that is not a catalog table
  • DATAACCESS
  • SYSADM authority

When FOR PORTION OF BUSINESS_TIME is specified: The privilege set must include at least one of the following:
  • The UPDATE privilege on the columns of the BUSINESS_TIME period
  • The UPDATE privilege on the table
  • Ownership of the table or view
  • DBADM authority on the database that contains the table, if the target is a table and that table that is not a catalog table
  • DATAACCESS
  • SYSADM authority

If the search-condition in a searched UPDATE includes a subquery, or if the assignment-clause includes a scalar-fullselect or a row-fullselect, see [Authorization] for an explanation of the authorization required.

The owner of a view, unlike the owner of a table, might not have UPDATE authority on the view (or might have UPDATE authority without being able to grant it to others). The nature of the view itself can preclude its use for UPDATE. For more information, see the discussion of authority in [“CREATE VIEW” on page 1862].

Privilege set: If the statement is embedded in an application program, the privilege set is the privileges that are held by the owner of the plan or package. If the statement is dynamically prepared, the privilege set is determined by the DYNAMICRULES behavior in effect (run, bind, define, or invoke) and is summarized in [Table 152 on page 1171] (For more information on these behaviors, including a list of the DYNAMICRULES bind option values that determine them, see [“Authorization IDs and dynamic SQL” on page 95].)
Notes:
1. The same clause must not be specified more than one time.

positioned update:

period-clause:

include-column:

data-type:
built-in-type:

assignment clause:
column-name = expression
column-name = expression
column-name = expression

Notes:
1 The number of expressions, DEFAULT, and NULL keywords must match the number of column-names.
2 The number of columns in the select list must match the number of column-names.

isolation-clause:

Description

table-name or view-name
Identifies the object of the UPDATE statement. The name must identify a table or view that exists at the DB2 subsystem that is identified by the implicitly or explicitly specified location name. The name must not identify one of the following tables:

- An auxiliary table
- A created temporary table or a view of a created temporary table
- A catalog table with no updatable columns or a view of a catalog table with no updatable columns
- A directory table
- A read-only view that has no INSTEAD OF trigger defined for its update operations. (For a description of a read-only view, see “CREATE VIEW” on page 1862)
- A system-maintained materialized query table
- A table that is implicitly created for an XML column

In an IMS or CICS application, the DB2 subsystem that contains the identified table or view must be a remote server that supports two-phase commit.

A catalog table or a view of a catalog table can be identified if every column identified in the SET clause is an updatable column. If a column of a catalog table is updatable, its description in “DB2 catalog tables” on page 2409 indicates that the column can be updated. If the object table is SYSIBM.SYSSTRINGS, any column other than IBMREQD can be updated, but
the rows that are selected for update must be rows that are provided by the
user (the value of the IBMREQD column is N) and only certain values can be
specified as explained in [How an entry in SYSIBM.SYSSTRINGS works with
character conversion (DB2 Installation and Migration)]

period-clause

Specifies that a period clause applies to the target of the update operation. The
same period name must not be specified more than one time. The object of the
UPDATE statement must not be a view.

FOR PORTION OF BUSINESS_TIME

Specifies that the update only applies to row values for the portion of the
BUSINESS_TIME period in the row that is specified by the period clause.
BUSINESS_TIME must be a period that is defined on the table.

FOR PORTION OF BUSINESS_TIME must not be specified if the value of
the CURRENT TEMPORAL BUSINESS_TIME special register is not NULL
when the BUSTIMESENSITIVE bind option is set to YES.

FROM value1 TO value2

Specifies that the update applies to rows for the period that is specified
from value1 to value2. No rows are updated if value1 is greater than or
equal to value2 or if value1 or value2 is the null value.

For the period condition that is specified with FROM value1 TO value2, the
period that is specified with period-name in a row of the target update:
- Overlaps the beginning of the specified period if the value of the begin
column is less than value1 and the value of the end column is greater
than value1.
- Overlaps the end of the specified period if the value of the end column
is greater than or equal to value2 and the value of the begin column is
less than value2.
- Is fully contained within the specified period if the value for the begin
column is greater than or equal to value1 and the value for the end
column is less than or equal to value2.
- Is not contained in the period if both columns of period-name are less
than value1 or greater than or equal to value2.
- Is partially contained in the specified period if the period in the row
overlaps the beginning of the specified period or the end of the specified
period, but not both.
- Fully overlaps the specified period if the period in the row overlaps both
the beginning and the end of the specified period.

If the period, period-name in a row is not contained in the specified period,
the row is not updated. Otherwise, the update is applied based on the
specification of PORTION OF and how the values in the columns of
period-name overlap the specified period as follows:
- If the period, period-name in a row is fully contained within the specified
period, the row is updated and the values of the begin column and end
column of period-name are unchanged.
- If the period, period-name in a row is partially contained in the specified
period and overlaps the beginning of the specified period:
  - The row is updated. In the updated row, the value of the begin
column is set to value1 and the value of the end column is the original
value of the end column.
An additional row is inserted using the original values from the row, except that the end column is set to \texttt{value1}, and new values are used for other generated columns.

- If the period, \texttt{period-name} in a row is partially contained in the specified period and overlaps the end of the specified period:
  - The row is updated. In the updated row, the value of the begin column is the original value of the begin column and the end column is set to \texttt{value2}.
  - An additional row is inserted using the original values from the row, except that the begin column is set to \texttt{value2}, and new values are used for other generated columns.

- If the period, \texttt{period-name} in a row fully overlaps the specified period:
  - The row is updated. In the updated row, the value of the begin column is set to \texttt{value1} and the value of the end column is set to \texttt{value2}.
  - An additional row is inserted using the original values from the row, except that the end column is set to \texttt{value1}, and new values are used for other generated columns.
  - An additional row is inserted using the original values from the row, except that the begin column is set to \texttt{value2}, and new values are used for other generated columns.

Any existing update triggers are activated for the updated rows and any existing insert triggers are activated for rows that are implicitly inserted.

\texttt{value1}, \texttt{value2}

Specifies expressions that return a value of a built-in data type. The result of each expression must be comparable to the data type of the columns of the specified period. See the comparison rules described in Assignment and comparison. Each expression can contain any of the following supported operands:

- A constant
- A special register
- A variable (host variable, SQL variable, SQL parameter, or transition variable)
- A built-in scalar function whose arguments are supported operands
- A CAST specification where the cast operand is a supported operand
- An expression that uses arithmetic operators and operands

Each expression must not have a timestamp precision that is greater than the precision of the columns for the period.

If the begin and end columns of the period are defined as \texttt{TIMESTAMP WITHOUT TIME ZONE}, each expression must not return a value of a timestamp with a time zone.

\texttt{correlation-name}

Can be used within search-condition or assignment-clause to designate the table or view. (For an explanation of \texttt{correlation-name}, see \texttt{"Correlation names" on} page 220.)

\texttt{include-column}

Specifies a set of columns that are included, along with the columns of \texttt{table-name} or \texttt{view-name}, in the result table of the UPDATE statement when it is nested in the FROM clause of the outer fullselect that is used in a subselect, SELECT statement, or in a SELECT INTO statement. The included columns are
appended to the end of the list of columns that is identified by table-name or view-name. If no value is assigned to a column that is specified by an include-column, a NULL value is returned for that column.

**INCLUDE**

Introduces a list of columns that are to be included in the result table of the UPDATE statement. The included columns are only available if the UPDATE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement.

*column-name*

Specifies the name for a column of the result table of the UPDATE statement that is not the same name as another included column nor a column in the table or view that is specified in table-name or view-name.

*data-type*

Specifies the data type of the included column. The included columns are nullable.

*built-in-type*

Specifies a built-in data type. See "CREATE TABLE" on page 1730 for a description of each built-in type.

*distinct-type*

Specifies a distinct type. Any length, precision, or scale attributes for the column are those of the source type of the distinct type as specified by using the CREATE TYPE statement.

**SET**

Introduces the assignment of values to column names.

*assignment-clause*

If row-fullselect is specified, the number of columns in the result of row-fullselect must match the number of column-names that are specified. If row-fullselect is not specified, the number of expressions, and NULL and DEFAULT keywords must match the number of column-names that are specified.

*column-name*

Identifies a column that is to be updated. column-name must identify a column of the specified table or view, and that column must be updatable if extended indicator variables are not enabled. The column must not identify a generated column or a view column where the column is derived from a scalar function, constant, or expression. column-name can also identify an INCLUDE column that must not be qualified. The same column must not be specified more than one time.

A column that is defined as part of a BUSINESS_TIME period must not be specified if the UPDATE statement contains a period-clause.

Assignments to included columns are only processed when the UPDATE statement is nested in the FROM clause of a SELECT statement or a SELECT INTO statement. There must be at least one assignment clause that specifies a column-name that is not an INCLUDE column. The null value is returned for an included column that is not set by using an explicit SET clause.

For a positioned update, allowable column names can be further restricted to those in a certain list. This list appears in the FOR UPDATE clause of
the SELECT statement for the associated cursor. The clause can be omitted
by using the conditions that are described in “Positioned updates of
columns” on page 331.

A view column that is derived from the same column as another column of
the view can be updated, but both columns cannot be updated in the same
UPDATE statement.

expression
Indicates the new value of the column. The expression is any expression of
the type described in “Expressions” on page 246. It must not include an
aggregate function.

If expression is a host variable, the host variable can include an indicator
variable. When extended indicator variables are enabled, an expression
must not be more complex than a reference to a single host variable if the
indicator is set to an extended indicator value of default (-5) or unassigned
(-7). In addition, a CAST specification can be used if either of the following
is true:

- The target column is defined as nullable.
- the target column is defined as NOT NULL with a non-null default, the
  source of the CAST specification is a single host variable, and the data
  attributes (data type, length, precision, and scale) of the host variable are
  the same as the result of the cast specification.

A column-name in an expression must identify a column of the table or
view. For each row that is updated, the value of the column in the
expression is the value of the column in the row before the row is updated.

DEFAULT
Specifies that the default value is used based on how the corresponding
column is defined in the table. The value that is assigned depends on how
the column is defined.

- If the column is defined using the IDENTITY clause, the column is
  generated by the DB2 system.
- If the column is defined as a row change timestamp column, the column
  value is generated by the DB2 system.
- If the column is defined using the WITH DEFAULT clause, the value is
  set to the default that is defined for the column.
- If the column is defined without specifying the WITH DEFAULT clause,
  the GENERATED clause, or the NOT NULL clause, the value is NULL.
- If the column is specified in the INCLUDE column list, the column
  value is set to null.

A ROWID column must not be set to the DEFAULT keyword.

An identity column or a row change timestamp column that is defined as
GENERATED ALWAYS can be set only to the DEFAULT keyword.

If the column is defined using the NOT NULL clause and the
GENERATED clause is not used, or the WITH DEFAULT clause is not
used, the DEFAULT keyword cannot be specified for that column.

NULL
Specifies the null value as the new value of the column. Specify NULL
only for nullable columns.

row-fullselect
Specifies a fullselect that returns a single row. The column values are
assigned to each of the corresponding column-names. If the fullselect returns no rows, the null value is assigned to each column; an error occurs if any column to be updated is not nullable. An error also occurs if there is more than one row in the result.

For a positioned update, if the table or view that is the object of the UPDATE statement is used in the fullselect, a column from the instance of the table or view in the fullselect cannot be the same as column-name, a column being updated.

If the fullselect refers to columns to be updated, the value of such a column in the fullselect is the value of the column in the row before the row is updated.

WHERE

Specifies the rows to be updated. You can omit the clause, give a search condition, or specify a cursor. If you omit the clause, all rows of the table or view are updated.

search-condition

Specifies any search condition described in Chapter 2, “Language elements,” on page 75. Each column-name in the search condition, other than in a subquery, must identify a column of the table or view.

The search-condition is applied to each row of the table or view and the updated rows are those for which the result of the search-condition is true. If the unique key or primary key is a parent key, the constraints are effectively checked at the end of the operation.

If the search condition contains a subquery, the subquery can be thought of as being executed each time the search condition is applied to a row, and the results used in applying the search condition. In actuality, a subquery with no correlated references is executed just once, whereas it is possible that a subquery with a correlated reference must be executed once for each row.

WHERE CURRENT OF cursor-name

Identifies the cursor to be used in the update operation. cursor-name must identify a declared cursor as explained in the description of the DECLARE CURSOR statement in “DECLARE CURSOR” on page 1870. If the UPDATE statement is embedded in a program, the DECLARE CURSOR statement must include select-statement rather than statement-name.

The object of the UPDATE statement must also be identified in the FROM clause of the SELECT statement of the cursor. The columns to be updated can be identified in the FOR UPDATE clause of that SELECT statement though they do not have to be identified. If the columns are not specified, the columns that can be updated include all the updatable columns of the table or view that is identified in the first FROM clause of the fullselect.

The result table of the cursor must not be read-only. For an explanation of read-only result tables, see [Read-only cursors]. Note that the object of the UPDATE statement must not be identified as the object of the subquery in the WHERE clause of the SELECT statement of the cursor.

When the UPDATE statement is executed, the cursor must be open and positioned on a row or rowset of the result table.

• If the cursor is positioned on a single row, that row is the one updated.
• If the cursor is positioned on a rowset, all rows corresponding to the rows of the current rowset are updated.
A positioned UPDATE must not be specified for a cursor that references a view on which an instead of update trigger is defined, even if the view is an updatable view.

**FOR ROW n OF ROWSET**

Specifies which row of the current rowset is to be updated. The corresponding row of the rowset is updated, and the cursor remains positioned on the current rowset.

*host-variable* or *integer-constant* is assigned to an integral value *k*. If *host-variable* is specified, it must be an exact numeric type with scale zero, must not include an indicator variable, and *k* must be in the range of 1 to 32767.

The cursor must be positioned on a rowset, and the specified value must be a valid value for the set of rows most recently retrieved for the cursor. If the specified row cannot be updated, an error is returned. It is possible that the specified row is within the bounds of the rowset most recently requested, but the current rowset contains less than the number of rows that were implicitly or explicitly requested when that rowset was established.

If this clause is not specified, the cursor position determines the rows that will be affected. If the cursor is positioned on a single row, that row is the one updated. In the case where the most recent FETCH statement returned multiple rows of data (but not as a rowset), this position would be on the last row of data that was returned. If the cursor is positioned on a rowset, all rows corresponding to the current rowset are updated. The cursor position remains unchanged.

It is possible for another application process to update a row in the base table of the SELECT statement so that the specified row of the cursor no longer has a corresponding row in the base table. An attempt to update such a row results in an error.

**isolation-clause**

Specifies the isolation level used when locating the rows to be updated by the statement.

**WITH**

Introduces the isolation level, which may be one of the following:

RR    Repeatable read
RS    Read stability
CS    Cursor stability

The default isolation level of the statement is the isolation level of the package or plan in which the statement is bound, with the package isolation taking precedence over the plan isolation. When a package isolation is not specified, the plan isolation is the default.

**SKIP LOCKED DATA**

Specifies that rows are skipped when incompatible locks are held on the row by other transactions. These rows can belong to any accessed table that is specified in the statement. **SKIP LOCKED DATA** can be used only when isolation CS or RS is in effect and applies only to row level or page level locks.

**SKIP LOCKED DATA** can be specified only in the searched UPDATE statement (or the searched update operation of a MERGE statement). **SKIP LOCKED DATA** is ignored if it is specified when the isolation level that is in effect is repeatable read (WITH RR) or uncommitted read (WITH UR). The default isolation level of the statement depends on the isolation level of the package or plan with which the statement is bound, with the package isolation
taking precedence over the plan isolation. When a package isolation is not
specified, the plan isolation is the default.

**QUERYNO** *integer*

Specifies the number to be used for this SQL statement in EXPLAIN output
and trace records. The number is used for the QUERYNO column of the plan
table for the rows that contain information about this SQL statement. This
number is also used in the QUERYNO column of the SYSIBM.SYSSTMT and
SYSIBM.SYSPACKSTMT catalog tables.

If the clause is omitted, the number associated with the SQL statement is the
statement number assigned during precompilation. Thus, if the application
program is changed and then precompiled, that statement number might
change.

Using the **QUERYNO** clause to assign unique numbers to the SQL statements
in a program is helpful:

- For simplifying the use of optimization hints for access path selection
- For correlating SQL statement text with EXPLAIN output in the plan table

For information on using optimization hints, such as enabling the system for
optimization hints and setting valid hint values, and for information on
accessing the plan table, see *Managing DB2 Performance*.

**Notes**

**Update rules:**

Update values must satisfy the following rules. If they do not, or if other
errors occur during the execution of the UPDATE statement, no rows are
updated and the position of the cursors are not changed.

- **Assignment.** Update values are assigned to columns using the assignment
  rules described in Chapter 2, “Language elements;” on page 75.
- **Validity.** Updates must obey the following rules. If they do not, or if any
  other errors occur during the execution of the UPDATE statement, no
  rows are updated.
  - **Fullselects:** The row-fullselect and expressions that contain a
    *scalar-fullselect* must return no more than one row.
  - **Unique constraints and unique indexes:** If the identified table (or base
    table of the identified view) has any unique indexes or unique
    constraints, each row that is updated in the table must conform to the
    limitations that are imposed by those indexes and constraints.
    All uniqueness checks are effectively made at the end of the
    statement. In the case of a multi-row update, this validation occurs
    after all the rows are updated.
  - **Check constraints:** If the identified table (or base table of the identified
    view) has any check constraints, each check constraint must be true or
    unknown for each row that is updated in the table.
    All checks constraints are effectively validated at the end of the
    statement. In the case of a multi-row update, this validation occurs
    after all the rows are updated.
  - **Views and the WITH CHECK OPTION.** For views defined with WITH
    CHECK OPTION, an updated row must conform to the definition of
    the view. If the view you name is dependent on other views whose
    definitions include WITH CHECK OPTION, the updated rows must
    also conform to the definitions of those views. For an explanation of
    the rules governing this situation, see “CREATE VIEW” on page 1862.
For views that are not defined with WITH CHECK OPTION, you can change the rows so that they no longer conform to the definition of the view. Such rows are updated in the base table of the view and no longer appear in the view.

- **Field and validation procedures.** The updated rows must conform to any constraints imposed by any field or validation procedures on the identified table (or on the base table of the identified view).

  - **Referential constraints.** The value of the parent key in a parent row must not be changed. If the update value produces a foreign key that is nonnull, the foreign key must be equal to some value of the parent key of the parent table of the relationship.

  All referential constraints are effectively checked at the end of the statement. In the case of a multi-row update, this validation occurs after all the rows are updated.

  - **Indexes with VARBINARY columns.** If the identified table has an index on a VARBINARY column or a column that is a distinct type that is based on VARBINARY data type, that index column cannot specify the DESC attribute. To use the SQL data change operation on the identified table, either drop the index or alter the data type of the column to BINARY and then rebuild the index.

  - **Triggers.** An UPDATE statement might cause triggers to activate. A trigger might cause other statements to be executed or raise error conditions based on the update values. If an UPDATE statement for a view causes an instead of trigger to activate, validity, referential integrity, and check constraints are checked against the data changes that are performed in the trigger and not against the view that causes the trigger to activate or its underlying base tables.

**Number of rows updated:**

Normally, after an UPDATE statement completes execution, the value of SQLERRD(3) in the SQLCA is the number of rows updated. (For a complete description of the SQLCA, including exceptions to the preceding sentence, see “SQL communication area (SQLCA)” on page 2377.)

**Nesting user-defined functions or stored procedures:**

An UPDATE statement can implicitly or explicitly refer to user-defined functions or stored procedures. This is known as nesting of SQL statements. A user-defined function or stored procedure that is nested within the UPDATE must not access the table being updated.

**Locking:**

Unless appropriate locks already exist, one or more exclusive locks are acquired by the execution of a successful update operation. Until a commit or rollback operation releases the locks, only the application process that performed the insert can access the updated row. If LOBs are not updated, application processes that are running with uncommitted read can also access the updated row. The locks can also prevent other application processes from performing operations on the table. However, application processes that are running with uncommitted read can access locked pages and rows.

Locks are not acquired on declared temporary tables.

**Datetime representation when using datetime registers:**

As explained under Datetime special registers when two or more datetime
registers are implicitly or explicitly specified in a single SQL statement, they represent the same point in time. This is also true when multiple rows are updated.

Rules for positioned UPDATE with a SENSITIVE STATIC scorable cursor:
When a SENSITIVE STATIC scorable cursor has been declared, the following rules apply:

- Update attempt of delete holes. If, with a positioned update against a SENSITIVE STATIC scorable cursor, an attempt is made to update a row that has been identified as a delete hole, an error occurs.

- Update operations. Positioned update operations with SENSITIVE STATIC scorable cursors perform as follows:
  1. The SELECT list items in the target row of the base table of the cursor are compared with the values in the corresponding row of the result table (that is, the result table must still agree with the base table). If the values are not identical, then the update operation is rejected, and an error occurs. The operation may be attempted again after a successful FETCH SENSITIVE has occurred for the target row.
  2. The WHERE clause of the SELECT statement is re-evaluated to determine whether the current values in the base table still satisfy the search criteria. The values in the SELECT list are compared to determine that these values have not changed. If the WHERE clause evaluates as true, and the values in the SELECT have not changed, the update operation is allowed to proceed. Otherwise, the update operation is rejected, an error occurs, and an update hole appears in the cursor.

- Update of update holes. Update holes are not permanent. It is possible for another process, or a searched update in the same process, to update an update hole row so that it is no longer an update hole. Update holes become visible with a FETCH SENSITIVE for positioned updates and positioned deletes.

- Result table. After the base table is updated, the row is re-evaluated and updated in the temporary result table. At this time, it is possible that the positioned update changed the data such that the row does not qualify the search condition, in which case the row is marked as an update hole for subsequent FETCH operations.

Updating rows in a table with multilevel security:
When you update rows in a table with multilevel security, DB2 compares the security label of the user (the primary authorization ID) to the security label of the row. The update proceeds according to the following rules:

- If the security label of the user and the security label of the row are equivalent, the row is updated and the value of the security label is determined by whether the user has write-down privilege:
  - If the user has write-down privilege or write-down control is not enabled, the user can set the security label of the row to any valid security label. The value that is specified for the security label column must be assignable to a column that is defined as CHAR(8) FOR SBCS DATA NOT NULL.
  - If the user does not have write-down privilege and write-down control is enabled, the security label of the row is set to the value of the security label of the user.

2260  SQL Reference
• If the security label of the user dominates the security label of the row, the result of the UPDATE statement is determined by whether the user has write-down privilege:
  – If the user has write-down privilege or write-down control is not enabled, the row is updated and the user can set the security label of the row to any valid security label.
  – If the user does not have write-down privilege and write-down control is enabled, the row is not updated.
• If the security label of the row dominates the security label of the user, the row is not updated.

**Updating rows in a table for which row or column access control is enforced:**
When an UPDATE statement is issued for a table for which row or column access control is enforced, the rules specified in the enabled row permissions or column masks determine whether the row can be updated. Typically those rules are based on the authorization ID or role of the process. The following describes how enabled row permissions and column masks are used during UPDATE:

• Row permissions are used to identify the set of rows to be updated.
  When multiple enabled row permissions are defined for a table, a row access control search condition is derived by application of the logical OR operator to the search condition in each enabled permission. This row access control search condition is applied to the table to determine which rows are accessible to the authorization ID or role of the UPDATE statement. If the WHERE clause is specified in the UPDATE statement, the user-specified predicates are applied on the accessible rows to determine the rows to be updated. If there is no WHERE clause, the accessible rows are the rows to be updated.
  Column masks are not applicable in this step.
  If the table is not enforced by row access control, the WHERE clause determines the rows to be updated, otherwise all rows in the table are to be updated.

• If there are rows to be updated, the following rules determine whether those rows can be updated:
  – For every column to be updated, the new value of the column must not be affected by enabled column masks whose columns are referenced when deriving the new value.
    When a column is referenced while deriving the values of a new row, if the column has an enabled column mask, the masked value is used to derive the new values. If the object table is also column access control activated, the column mask applied to derive the new values must ensure the evaluation of the access control rules defined in the column mask resolves the column to itself, not to a constant or an expression. If the column mask does not mask the column to itself, the new value cannot be used for update and an error is returned at run time.
    – If the rows are updatable, and there is a BEFORE UPDATE trigger for the table, the trigger is activated.
      Within the trigger actions, the new values for update might be modified in transition variables. When the final values are returned from the trigger, the new values are used for the update.
    – The rows that are to be updated must conform to the enabled row permissions:
For each row that is to be updated, the old values are replaced with the new values that were specified in the UPDATE statement. A row that conforms to the enabled row permissions is a row that, if updated, can be retrieved using the derived row access control search condition.

- If the rows are updatable, and there is an AFTER UPDATE trigger for the table, the trigger is activated.

The above rules are not applicable to the included columns. The included columns are subject to the rules for the select list because they are not the columns of the object table of the UPDATE statement.

**Extended indicator variable usage:**

When extended indicator variables are enabled, negative indicator values that are outside the range of -1 through -7 must not be specified, and the default and unassigned extended indicator values must not appear in contexts in which they are not supported.

**Extended indicator variables:**

Assigning an extended indicator value of unassigned has the effect of leaving the target column set to its current value, as if it had not been specified in the statement. Assigning an extended indicator value of default assigns the default value to the column.

The UPDATE statement must not assign all target columns to the extended indicator value of unassigned.

**Extended indicator variables and update triggers:**

If a target column has been assigned an extended indicator value of unassigned, the column is not considered to have been updated. The column is treated as if it had not been specified in the OF column-name list of any update trigger that is defined on the target table.

**Considerations for a generated column:**

A generated column that is defined as GENERATED ALWAYS should not be specified as the target of an assignment clause unless the value that is to be assigned is specified with the DEFAULT keyword or an extended indicator that specifies that a default value is to be assigned.

**Considerations for a system-period temporal table:**

When a row of a system-period temporal table is updated, DB2 updates the values of the row-begin and transaction-start-ID columns as follows:

- A row-begin column is assigned a value that is generated by using the time-of-day clock during the execution of the first data change statement in the transaction that requires a value to be assigned to a row-begin column or transaction-start-ID column in a table. This also occurs when a row in a system-period temporal table is deleted. DB2 ensures the uniqueness of the generated values for a row-begin column across transactions. If multiple rows are updated within a single SQL transaction, the values for the row-begin column are the same for all the rows and are unique from the values that are generated for the column for another transaction.

- A transaction-start-ID column is assigned a unique timestamp value per unit of work or the null value. The null value is assigned to the transaction-start-ID column if the column is nullable. Otherwise, the value is generated by using the time-of-day clock during execution of the first data change statement in the unit of work that requires a value to be assigned to a row-begin column or transaction-start-ID column in a table. This also occurs when a row in a system-period temporal table is
deleted. If multiple rows are updated within a single SQL unit of work, the values for the transaction-start-ID column are the same for all the rows and are unique from the values that are generated for the column for another unit of work.

If the UPDATE statement has a search condition that contains a correlated subquery that references historical rows (explicitly referencing the name of the history table or implicitly referenced through the use of a period specification in the FROM clause), the old version of the updated rows that are inserted as historical rows (into the history table) are potentially visible to update operations for the rows that are subsequently processed for the statement.

Considerations for a history table:
When a row of a system-period temporal table is updated, a historical copy of the row is inserted into the corresponding history table and the end timestamp of the historical row is captured in the form of a system determined value that corresponds to the time of the data change operation. DB2 generates the value by using the time-of-day clock during the execution of the first data change statement in the transaction that requires a value to be assigned to a row-begin or transaction-start-ID column in a table. This also occurs when a row in a system-period temporal table is deleted. DB2 ensures uniqueness of the generated values for an end column in a history table across transactions. If a conflicting transaction is updating the same row in the system-period temporal table and the row that is to be inserted into the associated history table would have an end timestamp value that is greater than the begin timestamp value, an error is returned.

Considerations for an application-period temporal table:
An UPDATE statement that contains a FOR PORTION OF BUSINESS_TIME clause for an application-period temporal table indicates the two points in time between which the specified updates are effective.

Suppose that FOR PORTION OF BUSINESS_TIME is specified, and the period value for a row is only partially contained in the period that is specified from value1 up to value2. (The period value for a row is specified by the values of the begin column and end column for the BUSINESS_TIME period.) In this case, the row is updated and one or two rows are automatically inserted to represent the portion of the row that is not changed. For each row that is automatically inserted as a result of an update operation on the table, new values are generated for each generated column in the application-period temporal table. If a generated column is defined as part of a unique or primary key, parent key in a referential constraint, or unique index, an automatic insert might violate a constraint or index. In this case, an error is returned.

Other SQL statements in the same unit of work:
The following statements cannot follow an UPDATE statement in the same unit of work:

- An ALTER TABLE statement that changes the data type of a column (ALTER COLUMN SET DATA TYPE)
- An ALTER INDEX statement that changes the padding attribute of an index with varying-length columns (PADDED to NOT PADDED or vice versa)
- A CREATE TABLE statement that creates an accelerator-only table.
• An INSERT, UPDATE, or DELETE statement that updates accelerator-only tables from a different accelerator.

**Using UPDATE to reset AREO* status on a table:**
An UPDATE statement will reset the AREO* state of a table if all conditions are true:
• The statement is a searched UPDATE statement. An UPDATE statement within a SELECT statement will not reset the AREO* state.
• The expression in the SET clause is not a *scalar-fullselect* or *row-fullselect*
• The update operation is against a table in a universal table space
• The table does not have row access control activated
• The SKIP LOCKED DATA clause is not specified
• The WHERE clause is not specified
• A resource unavailable condition is not encountered.

No error or warning SQLCODE is returned if a resource unavailable condition is encountered. Only a resource unavailable console message will be displayed.

A DISPLAY DATABASE command can be used to determine if AREO* is reset.

**Examples**

**Example 1**
Change employee 000190’s telephone number to 3565 in DSN8A10.EMP.

```
UPDATE DSN8A10.EMP
SET PHONENO='3565'
WHERE EMPNO='000190';
```

**Example 2**
Give each member of department D11 a 100-dollar raise.

```
UPDATE DSN8A10.EMP
SET SALARY = SALARY + 100
WHERE WORKDEPT = 'D11';
```

**Example 3**
Employee 000250 is going on a leave of absence. Set the employee's pay values (SALARY, BONUS, and COMMISSION) to null.

```
UPDATE DSN8A10.EMP
SET SALARY = NULL, BONUS = NULL, COMM = NULL
WHERE EMPNO='000250';
```

Alternatively, the statement could also be written as follows:

```
UPDATE DSN8A10.EMP
SET (SALARY, BONUS, COMM) = (NULL, NULL, NULL)
WHERE EMPNO='000250';
```

**Example 4**
Assume that a column named PROJSIZE has been added to DSN8A10.EMP. The column records the number of projects for which the employee’s department has responsibility. For each employee in department E21, update PROJSIZE with the number of projects for which the department is responsible.

```
UPDATE DSN8A10.EMP
SET PROJSIZE = (SELECT COUNT(*)
               FROM DSN8A10.PROJ
               WHERE DEPTNO = 'E21')
WHERE WORKDEPT = 'E21';
```
Example 5

Double the salary of the employee represented by the row on which the cursor C1 is positioned.

EXEC SQL UPDATE DSN8A10.EMP
   SET SALARY = 2 * SALARY
   WHERE CURRENT OF C1;

Example 6

Assume that employee table EMP1 was created with the following statement:

CREATE TABLE EMP1
   (EMP_ROWID ROWID GENERATED ALWAYS,
    EMPNO CHAR(6),
    NAME CHAR(30),
    SALARY DECIMAL(9,2),
    PICTURE BLOB(250K),
    RESUME CLOB(32K));

Assume that host variable HV_EMP_ROWID contains the value of the ROWID column for employee with employee number '350000'. Using that ROWID value to identify the employee and user-defined function UPDATE_RESUME, increase the employee's salary by $1000 and update that employee's resume.

EXEC SQL UPDATE EMP1
   SET SALARY = SALARY + 1000,
          RESUME = UPDATE_RESUME(:HV_RESUME)
   WHERE EMP_ROWID = :HV_EMP_ROWID;

Example 7

In employee table X, give each employee whose salary is below average a salary increase of 10%.

EXEC SQL UPDATE EMP X
   SET SALARY = 1.10 * SALARY
   WHERE SALARY < (SELECT AVG(SALARY) FROM EMP Y
                   WHERE X.JOBCODE = Y.JOBCODE);

Example 8

Raise the salary of the employees in department 'E11' whose salary is below average to the average salary.

EXEC SQL UPDATE EMP T1
   SET SALARY = (SELECT AVG(T2.SALARY) FROM EMP T2)
   WHERE WORKDEPT = 'E11' AND
         SALARY < (SELECT AVG(T3.SALARY) FROM EMP T3);

Example 9

Give the employees in department 'E11' a bonus equal to 10% of their salary.

EXEC SQL
   DECLARE C1 CURSOR FOR
      SELECT BONUS
         FROM DSN8710.EMP
         WHERE WORKDEPT = 'E12'
         FOR UPDATE OF BONUS;
   EXEC SQL
      UPDATE DSN8710.EMP
         SET BONUS = ( SELECT .10 * SALARY FROM DSN8710.EMP Y
                        WHERE EMPNO = Y.EMPNO )
         WHERE CURRENT OF C1;

Example 10

Assuming that cursor CS1 is positioned on a rowset consisting of 10 rows in table T1, update all 10 rows in the rowset.
EXEC SQL UPDATE T1 SET C1 = 5 WHERE CURRENT OF CS1;

Example 11
Assuming that cursor CS1 is positioned on a rowset consisting of 10 rows in table T1, update the fourth row of the rowset.

short ind1, ind2;
int n, upd_value;

stmt = 'UPDATE T1 SET C1 = ? WHERE CURRENT OF CS1 FOR ROW ? OF ROWSET'

ind1 = 0;
ind2 = 0;
n = 4;
upd_value = 5;
...
strcpy(my_sqlda.sqlaid,"SQLDA");
my_sqlda.sqln = 2;
my_sqlda.sqlid = 2;

my_sqlda.sqlvar[0].sqltype = 497;
my_sqlda.sqlvar[0].sqllen = 4;
my_sqlda.sqlvar[0].sqldata = (int *) &upd_value;
my_sqlda.sqlvar[0].sqlind = (short *) &ind1;

my_sqlda.sqlvar[1].sqltype = 497;
my_sqlda.sqlvar[1].sqllen = 4;
my_sqlda.sqlvar[1].sqldata = (int *) &n;
my_sqlda.sqlvar[1].sqlind = (short *) &ind2;

EXEC SQL PREPARE S1 FROM :stmt;

EXEC SQL EXECUTE S1 USING DESCRIPTOR :my_sqlda;

Example 12
Assume that table POLICY exists and that it is defined with a single period, BUSINESS_TIME. The table contains a row where column BK has a value of 'P138', column CLIENT has a value of 'C882', column TYPE has a value of 'PPO', and the period has value ('2013-01-01', '2020-12-31'). Update the portion of the row beginning from '2014-01-01' to set the TYPE column to 'HMO':

UPDATE POLICY
  FOR PORTION OF BUSINESS_TIME
  FROM '2014-01-01' TO '9999-12-31'
  SET TYPE='HMO'
  WHERE BK='P138', CLIENT='C882';

After the UPDATE statement is processed, the table contains 2 rows in place of the original row. One row with period value ('2013-01-01', '2014-01-01') represents a value of 'PPO' for the TYPE column (the value before the update) and the other row with period value ('2014-01-01', '2020-12-31') represents a value of 'HMO' for the TYPE column (that began with the UPDATE statement).
VALUES

The VALUES statement provides a method for invoking a user-defined function from a trigger. Transition variables and transition tables can be passed to the user-defined function.

Invocation

This statement can only be used in the triggered action of a trigger.

Authorization

Authorization is required for any expressions that are used in the statement. For more information, see [Expressions](#).

Syntax

```
VALUES expression
(expression)
```

Description

VALUES

Specifies one or more expressions. If more than one expression is specified, the expressions must be enclosed within parentheses.

expression

Any expression of the type described in [Expressions](#). The expression must not contain a host variable.

The expressions are evaluated, but the resulting values are discarded and are not assigned to any output variables.

If a user-defined function is specified as part of an expression, the user-defined function is invoked. If a negative SQLCODE is returned when the function is invoked, DB2 stops executing the trigger and rolls back any triggered actions that were performed.

Example

Example: Create an after trigger EMPISRT1 that invokes user-defined function NEWEMP when the trigger is activated. An insert operation on table EMP activates the trigger. Pass transition variables for the new employee number, last name, and first name to the user-defined function.

```
CREATE TRIGGER EMPISRT1
AFTER INSERT ON EMP
REFERENCING NEW AS N
FOR EACH ROW
MODE DB2SQL
BEGIN ATOMIC
  VALUES(NEWEMP(N.EMPNO, N.LASTNAME, N.FIRSTNAME));
END
```
VALUES INTO

The VALUES INTO statement assigns one or more values to host variables.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

The privileges that are held by the authorization ID of the owner of the plan or package must include at least one of the following for every table and view identified in the statement:

- The SELECT privilege on the table or view
- Ownership of the table or view
- DBADM authority for the database (tables only)
- DATAACCESS authority
- SYSADM authority
- SYSCTRL authority (catalog tables only)

Authorization is required for any expressions that are used in the statement. For more information, see "Expressions" on page 246.

Syntax

```
VALUES CURRENT PACKAGESET INTO target-variable
expression
expression
NULL,
NULL
(NULL,
(NULL,
expression
expression
(NULL,
expression
expression
(NULL,
NULL
)
)

Description

VALUES

Introduces a single row that consists of one or more columns. If more than one value is specified, the list of values must be enclosed within parentheses.

expression

The expression is any expression of the type described in "Expressions" on page 246.
In a native SQL routine, the expression can contain a reference to the CURRENT PACKAGESET, CURRENT PACKAGE PATH, or CURRENT SERVER special registers if target-variable is an SQL parameter or SQL variable. The expression must not include a column name.

**NULL**

The null value. NULL can only be specified for host variables that have an associated indicator variable.

**INTO**

Identifies one or more targets for the assignment of output values. The number of targets in the INTO clause must equal the number of values that are to be assigned. The first value in the result row is assigned to the first target in the list, the second value to the second target, and so on. A target variable must not be specified more than once in the INTO clause. Each assignment to a target is made in sequence through the list, according to the rules described in “Assignment and comparison” on page 138.

The value 'W' is assigned to the SQLWARN3 field of the SQLCA if the number of targets is less than the number of result column values.

If an error occurs on any assignment, the value is not assigned to the target, and no more values are assigned to the specified targets. Any values that have already been assigned remain assigned.

- **host-variable-name**
  Identifies the host variable that is the assignment target. For LOB output values, the target can be a regular host variable (if it is large enough), a LOB locator variable, or a LOB file reference variable.

- **SQL-parameter-name**
  Identifies the parameter that is the assignment target.

- **SQL-variable-name**
  Identifies the SQL variable that is the assignment target. SQL variables must be declared before they are used.

**Notes**

**Default encoding scheme:**

The default encoding scheme for the data is the value in the bind option ENCODING, which is the option for application encoding. If this statement is used with functions such as LENGTH or SUBSTRING that are operating on LOB locators, and the LOB data that is specifies by the locator is in a different encoding scheme from the ENCODING bind option, LOB materialization and character conversion occur. To avoid LOB materialization and character conversion, select the LOB data from the SYSIBM.SYSDUMMYA, SYSIBM.SYSDUMMYE, or SYSIBM.SYSDUMMYU sample table.

**Examples**

**Example 1:** Assign the value of the CURRENT PATH special register to host variable HV1.

```sql
EXEC SQL VALUES(CURRENT PATH)
INTO :HV1;
```

**Example 2:** Assign the value of the CURRENT MEMBER special register to host variable MEM.
EXEC SQL VALUES (CURRENT MEMBER)
   INTO :MEM;

Example 3: Assume that LOB locator LOB1 is associated with a CLOB value. Assign a portion of the CLOB value to host variable DETAILS using the LOB locator.

   EXEC SQL VALUES (SUBSTR (:LOB1, 1, 35))
       INTO :DETAILS;

If the LOB data that is specified by the LOB locator LOB1 is in a different encoding scheme from the value of the ENCODING bind option, and you want to avoid LOB materialization and character conversion, use the following statement instead of the VALUES INTO statement:

   EXEC SQL SELECT SUBSTR (:LOB1, 1, 35)
       INTO :DETAILS
       FROM SYSIBM.SYSDUMMYU;
WHENEVER

The WHENEVER statement specifies the host language statement to be executed when a specified exception condition occurs.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in Java or REXX.

Authorization

None required.

Syntax

```
WHENEVER NOT FOUND CONTINUE SQLERROR GOTO host-label
```

Description

The NOT FOUND, SQLERROR, or SQLWARNING clause is used to identify the type of exception condition.

**NOT FOUND**

Identifies any condition that results in an SQLCODE of +100 (equivalently, an SQLSTATE code of '02000').

**SQLERROR**

Identifies any condition that results in a negative SQLCODE.

**SQLWARNING**

Identifies any condition that results in a warning condition (SQLWARN0 is W), or that results in a positive SQLCODE other than +100.

The CONTINUE or GO TO clause specifies the next statement to be executed when the identified type of exception condition exists.

**CONTINUE**

Specifies the next sequential statement of the source program.

**GOTO or GOTO host-label**

Specifies the statement identified by host-label. For host-label, substitute a single token, optionally preceded by a colon. The form of the token depends on the host language. In COBOL, for example, it can be section-name or an unqualified paragraph-name.

Notes

There are three types of WHENEVER statements:

- WHENEVER NOT FOUND
- WHENEVER SQLERROR
- WHENEVER SQLWARNING
Every executable SQL statement in an application program is within the scope of one implicit or explicit WHENEVER statement of each type. The scope of a WHENEVER statement is related to the listing sequence of the statements in the application program, not their execution sequence.

An SQL statement is within the scope of the last WHENEVER statement of each type that is specified before that SQL statement in the source program. If a WHENEVER statement of some type is not specified before an SQL statement, that SQL statement is within the scope of an implicit WHENEVER statement of that type in which CONTINUE is specified. If a WHENEVER statement is specified in a Fortran subprogram, its scope is that subprogram, not the source program.

The GET DIAGNOSTICS statement can be used to provide additional information.

**Examples**

The following statements can be embedded in a COBOL program.

**Example 1:** Go to the label HANDLER for any statement that produces an error.

```
EXEC SQL WHENEVER SQLERROR GOTO HANDLER END-EXEC.
```

**Example 2:** Continue processing for any statement that produces a warning.

```
EXEC SQL WHENEVER SQLWARNING CONTINUE END-EXEC.
```

**Example 3:** Go to the label ENDDATA for any statement that does not return.

```
EXEC SQL WHENEVER NOT FOUND GO TO ENDDATA END-EXEC.
```
Chapter 8. SQL control statements for SQL routines

SQL control statements for SQL routines can be used in SQL functions and native SQL procedures. SQL control statements provide the capability to control the logic flow, declare and set variables, and handle warnings and exceptions. Some SQL control statements include other nested SQL statements.

SQL-control-statement:

- CALL statement
- CASE statement
- compound-statement
- FOR statement
- GET DIAGNOSTICS statement
- GOTO statement
- IF statement
- ITERATE statement
- LEAVE statement
- LOOP statement
- REPEAT statement
- RESIGNAL statement
- RETURN statement
- SIGNAL statement
- WHILE statement

Control statements are supported in SQL functions and SQL procedures.

- SQL functions are created by specifying LANGUAGE SQL and an SQL routine body in a CREATE FUNCTION (compiled SQL) statement. An SQL function can be changed. A new SQL routine body can be specified in an ALTER FUNCTION (compiled SQL) statement.

- SQL procedures are created by specifying LANGUAGE SQL and an SQL routine body in a CREATE PROCEDURE (native SQL) statement. An SQL procedure can be changed. A new SQL routine body can be specified in an ALTER PROCEDURE (native SQL) statement.

The SQL routine body is the executable part of the function or procedure and is transformed by DB2 into a program.

The remainder of the topics about SQL control statements for SQL routines contain information about references to SQL parameters and variables, SQL condition names, SQL cursor names, labels, and reference information for the use of the statements that constitute the SQL routine body.

The two common elements that are used in describing specific SQL control statements are:

- SQL control statements as described above
- SQL-procedure-statement
References to SQL parameters and SQL variables

SQL parameters and SQL variables can be referenced anywhere in the statement where an expression or a variable can be specified. Host variables cannot be specified in SQL routines. SQL parameters can be referenced anywhere in the routine and can be qualified with the routine name. SQL variables can be referenced anywhere in the compound statement in which they are declared, including any statement that is directly or indirectly nested within that compound statement.

If the compound statement where the variable is declared has a label, references to the variable name can be qualified with that label.

All SQL parameters and SQL variables are considered nullable. The name of an SQL parameter or an SQL variable in an SQL routine can be the same as the name of a column in a table or view that is referenced in the routine. The name of an SQL variable can also be the same as the name of another SQL variable that is declared in the same routine. This can occur when the two SQL variables are declared in different compound-statements. The compound-statement that contains the declaration of an SQL variable determines the scope of that variable. See “compound-statement” on page 2287 for additional information.

The name of an SQL variable or an SQL parameter in an SQL routine can be the name of an identifier that is used in certain SQL statements. If the name is not qualified, the following rules describe whether the name refers to an identifier, an SQL variable, or an SQL parameter:

- In the SET CURRENT PACKAGE PATH, SET PATH and SET SCHEMA statements, the name is checked as an SQL variable name or an SQL parameter name. If an SQL variable or SQL parameter with that name is not found, the name is assumed to be an identifier.
- In the ASSOCIATE LOCATORS, CONNECT, RELEASE (connection), and SET CONNECTION statements, the name is used as an identifier.

Names that are the same should be explicitly qualified. Qualifying a name clearly indicates whether the name refers to a column, an SQL variable, or an SQL parameter. If the name is not qualified or is qualified but is still ambiguous, the following rules describe whether the name refers to a column or to an SQL variable or an SQL parameter in an SQL routine:

- The name is checked to see if it is the name of a column of any existing table or a view that is specified in the SQL routine body at the current server. If the name is found as a column name, but the privilege set that is used to issue the CREATE PROCEDURE or ALTER PROCEDURE statement does not have the proper authority to access the table or view, the VALIDATE option that is in effect for the procedure determines what happens:
  - If VALIDATE BIND is in effect, an error is returned.
  - If VALIDATE RUN is in effect, the name is assumed to be a column name. If the privilege set that is used to issue the CREATE statement does not have the proper authority to access the table or view at run time, an error is returned.
- If the referenced tables or views do not exist at the current server, the name will be checked first as an SQL variable name in the compound statement and then as an SQL parameter name. The variable can be declared within the compound-statement that contains the reference, or within a compound statement.
in which that compound statement is nested. If two SQL variables are within the same scope and have the same name, the SQL variable that is declared in the innermost compound statement is used.

If the name is not found as an SQL parameter or SQL variable, the VALIDATE option that is in effect for the procedure determines what happens:

– If VALIDATE BIND is in effect, an error is returned.
– If VALIDATE RUN is in effect, the name is assumed to be a column name. If a column does not exist with that name at run time, an error is returned.

### References to SQL condition names

A condition name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When there is a reference to a condition name, the condition that is declared in the innermost compound statement is the condition that is used.

The name of an SQL condition can be the same as the name of another SQL condition that is declared in the same routine. This can occur when the two SQL conditions are declared in different compound-statements. The compound-statement that contains the declaration of an SQL condition name determines the scope of that condition name. A condition name must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement. A condition name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When there is a reference to a condition name, the condition that is declared in the innermost compound statement is the condition that is used. See "compound-statement" on page 2287 for additional information.

### References to SQL cursor names

A cursor name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement.

The name of an SQL cursor can not be the same as the name of another SQL cursor that is declared on the same routine. The compound-statement that contains the declaration of an SQL cursor name determines the scope of that cursor name. A cursor name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. See "compound-statement" on page 2287 for additional information.

### References to labels

Labels can be specified on most SQL procedure statements. If a label is specified on an SQL procedure statement, it must be unique from other labels within the same scope. A label must not be the same as any other label within the same compound statement, must not be the same as a label specified on the compound statement itself, and if the compound statement is nested within another compound statement, the label must not be the same as the label specified on any higher level compound statement. The label must not be the same as the name of the SQL function or SQL procedure.
Specifying a label for an SQL procedure statement defines that label and determines the scope of that label. A label name can only be referenced within the compound statement in which it is defined, including a reference from any statement that is directly or indirectly nested within that compound statement. The FOR statement is considered the same as a compound statement with respect to defining and referencing labels. A label can be specified as the target of a GOTO, LEAVE, or ITERATE statement, subject to the rules for the statement that references the label as a target.

**References to SQL statement names**

The name of an SQL statement can be the same as the name of another SQL statement declared in the same routine.

This can occur when the two SQL statements are declared in different compound statements. The compound statement that contains the declaration of an SQL statement name determines the scope of that statement name. A statement name must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement. A statement name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When there is a reference to a statement name, the statement that is declared in the innermost compound statement is the statement that is used.

**Nested compound statements and scope of names**

Nested compound statements can be used within an SQL routine to define the scope of SQL variable declarations, cursors, condition names, and condition handlers.

In addition, labels have a defined scope in the context of nested compound statements. However, the rules for name spaces and how non-unique names can be referenced, differs depending on the type of name. The following table summarizes these differences:

*Table 212. Scope and qualification of names within nested compound statements*

<table>
<thead>
<tr>
<th>Type of name</th>
<th>Name can be qualified</th>
<th>Name must be unique within</th>
<th>Name can be referenced within</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL variable</td>
<td>Yes. The name can be qualified with the label of the compound statement in which the variable is declared</td>
<td>the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement</td>
<td>The compound statement in which it is declared, including any compound statements that are nested within that compound statement. When multiple SQL variables are defined with the same name, a label can be used to explicitly refer to a specific variable that is not the most local in scope</td>
</tr>
<tr>
<td>Type of name</td>
<td>Name can be qualified</td>
<td>Name must be unique within</td>
<td>Name can be referenced within</td>
</tr>
<tr>
<td>-------------</td>
<td>----------------------</td>
<td>----------------------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td>condition name</td>
<td>No</td>
<td>the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement</td>
<td>The compound statement in which it is declared, including any compound statements that are nested within that compound statement. Condition names can be used in the declaration of a condition handler, or in a SIGNAL or RESIGNAL statement. If multiple conditions are defined with the same name, there is no way to explicitly refer to the condition that is not the most local in scope.</td>
</tr>
<tr>
<td>cursor name</td>
<td>No</td>
<td>the routine</td>
<td>The compound statement in which it is declared, including any compound statements that are nested within that compound statement. If the cursor is defined as a result set cursor, the invoking application can access the result set.</td>
</tr>
<tr>
<td>label</td>
<td>No</td>
<td>the compound statement that defined the label, including any definitions in compound statements that are nested within that compound statement</td>
<td>The compound statement in which it is defined, including any compound statements that are nested within that compound statement. Use a label to qualify the name of an SQL variable or as the target of a GOTO, LEAVE, or ITERATE statement, subject to the rules for these statements.</td>
</tr>
</tbody>
</table>
SQL-procedure-statement

An SQL control statement can allow multiple SQL statements to be specified within the SQL control statement. These statements are defined as SQL procedure statements.

Syntax

```
<table>
<thead>
<tr>
<th>SQL-control-statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATE CURSOR statement</td>
</tr>
<tr>
<td>ALTER DATABASE statement</td>
</tr>
<tr>
<td>ALTER FUNCTION statement (external scalar, external table, sourced, SQL scalar, or SQL table)</td>
</tr>
<tr>
<td>ALTER INDEX statement</td>
</tr>
<tr>
<td>ALTER MASK statement</td>
</tr>
<tr>
<td>ALTER PERMISSION statement</td>
</tr>
<tr>
<td>ALTER PROCEDURE statement (external, SQL - external, or SQL - native)</td>
</tr>
<tr>
<td>ALTER SEQUENCE statement</td>
</tr>
<tr>
<td>ALTER STOGROUP statement</td>
</tr>
<tr>
<td>ALTER TABLE statement</td>
</tr>
<tr>
<td>ALTER TABLESPACE statement</td>
</tr>
<tr>
<td>ALTER TRUSTED CONTEXT statement</td>
</tr>
<tr>
<td>CALL statement</td>
</tr>
<tr>
<td>CLOSE statement</td>
</tr>
<tr>
<td>COMMENT statement</td>
</tr>
<tr>
<td>COMMIT statement</td>
</tr>
<tr>
<td>CONNECT statement</td>
</tr>
<tr>
<td>CREATE ALIAS statement</td>
</tr>
<tr>
<td>CREATE DATABASE statement</td>
</tr>
<tr>
<td>CREATE FUNCTION statement (external scalar, external table, or sourced)</td>
</tr>
<tr>
<td>CREATE GLOBAL TEMPORARY TABLE statement</td>
</tr>
<tr>
<td>CREATE INDEX statement</td>
</tr>
<tr>
<td>CREATE PROCEDURE statement (external)</td>
</tr>
<tr>
<td>CREATE ROLE statement</td>
</tr>
<tr>
<td>CREATE SEQUENCE statement</td>
</tr>
<tr>
<td>CREATE STOGROUP statement</td>
</tr>
<tr>
<td>CREATE SYNONYM statement</td>
</tr>
<tr>
<td>CREATE TABLE statement</td>
</tr>
<tr>
<td>CREATE TABLESPACE statement</td>
</tr>
<tr>
<td>CREATE TRUSTED CONTEXT statement</td>
</tr>
<tr>
<td>CREATE TYPE statement</td>
</tr>
<tr>
<td>CREATE VIEW statement</td>
</tr>
</tbody>
</table>
```

Notes:

1. The statement is not allowed in an SQL-routine-body for an SQL function.
2. An ALTER FUNCTION statement (SQL scalar) or an ALTER PROCEDURE statement (SQL - native) with an ADD VERSION or REPLACE clause is not allowed in an SQL-routine-body.
3. The COMMIT, ROLLBACK, CONNECT, RELEASE, and SET CONNECTION statements must only be specified within the body of an SQL procedure. The COMMIT statement and the ROLLBACK
A CREATE TABLE statement must not include a column defined as a LOB or XML.

---

### Notes:

1. The statement is not allowed in an *SQL-routine-body* for an SQL function.
2. A FETCH statement must not specify a *fetch-orientation* clause, *multiple-row-fetch* clause, the WITH CONTINUE or the CURRENT CONTINUE clauses.
3. The COMMIT, ROLLBACK, CONNECT, RELEASE, and SET CONNECTION statements must only be specified within the body of an SQL procedure. The COMMIT statement and the ROLLBACK statement (without the TO SAVEPOINT clause) must not be issued in a routine body if the routine is in the calling chain of an SQL routine, or an external routine.

### Description

**SQL-control-statement**

Specifies an SQL statement that provides the capability to control logic flow, declare and set variables, and handle warnings and exceptions, as defined in this section. Control statements are supported in SQL routines.

**SQL-statement**

Specifies an SQL statement. These statements are described in Chapter 7. "Statements," on page 1163.
Notes

*Comments*: Comments can be included within the body of an SQL routine. In addition to the double-dash form of comments (--), a comment can begin with /* and end with */. The following rules apply to this form of comment:

- The beginning characters /* must be adjacent and on the same line.
- The ending characters */ must be adjacent and on the same line.
- Comments can be started wherever a space is valid.
- Comments can be continued to the next line.

*Detecting and processing error and warning conditions*: As an SQL statement is executed, DB2 stores information about the processing of the statement in a diagnostics area (including the SQLSTATE and SQLCODE), unless otherwise noted in the description of the SQL statement. A completion condition can indicate that the SQL statement completed successfully, completed with a warning condition, or completed with a not found condition. An exception condition indicates that the SQL statement was not successful.

A condition handler can be defined to execute when an exception condition, a warning condition, or a not found condition occurs in a compound statement. The declaration of a condition handler includes the code that is executed when the condition handler is activated. When a condition other than a successful completion occurs in the processing of SQL-procedure-statement and a condition handler that can handle the condition is within scope, one such condition handler will be activated to process the condition. See “compound-statement” on page 2287 for information about defining condition handlers. The code in the condition handler can check for a warning condition, a not found condition, or an exception condition and can take the appropriate action. Use one of the following methods at the beginning of the body of a condition handler to check the condition in the diagnostics area that caused the handler to be activated.

- Issue a GET DIAGNOSTICS statement to request the information from the diagnostics area. See “GET DIAGNOSTICS” on page 2008.
- Test the SQLSTATE and SQLCODE SQL variables.

If the condition is a warning and no handler exists for the condition, the previous two methods can be used outside of the body of a condition handler, if they are used immediately following the statement for which the condition is wanted. If the condition is an error and no handler exists for the condition, the routine terminates with the error condition.
The assignment statement assigns a value to a SQL parameter or to an SQL variable.

**Syntax**

```
label: SET assignment-clause
```

**Description**

*label*

Specifies the label for assignment-statement. The label name cannot be the same as the name of the SQL routine, or another label within the same scope. For additional information, see "References to labels" on page 2275.

*SQL-parameter-name*

Identifies the parameter that is the assignment target. The parameter must be specified in parameter-declaration in the CREATE statement.

*SQL-variable-name*

Identifies the SQL variable that is the assignment target. SQL variables can only be declared in a compound-statement and must be declared before they are used. For information on declaring SQL variables, see "compound-statement" on page 2287.

*expression or NULL*

Specifies the expression or value that is the source for the assignment.

**Notes**

*Assignment rules:* Assignment statements in SQL routines must conform to the SQL assignment rules. For example, the data type of the target and source must be compatible. See " Assignment and comparison" on page 138 for assignment rules.
When a string is assigned to a fixed-length variable and the length of the string is less than the length attribute of the target, the string is padded on the right with the necessary number of single-byte or double-byte blanks. When a string is assigned to a variable and the string is longer than the length attribute of the variable, the value is truncated and a warning is returned.

If truncation of the whole part of a number occurs on assignment to a numeric variable, the value is truncated and a warning is returned.

Assignments involving SQL parameters for SQL procedures: An IN parameter can appear on the left or right side in an assignment statement. When control returns to the caller, the original value of the IN parameter is retained. An OUT parameter can also appear on the left or right side in an assignment statement. If used without first being assigned a value, the value is undefined. When control returns to the caller, the last value that is assigned to an OUT parameter is returned to the caller. For an INOUT parameter, the first value of the parameter is determined by the caller, and the last value that is assigned to the parameter is returned to the caller.

Multiple assignments: If more than one assignment is included in the same SET statement, all expressions are completely evaluated before the assignments are performed. Thus, references to a target variable in an expression are always the value of the target variable prior to any assignment in the SET statement.

Considerations for SQLSTATE and SQLCODE SQL variables: Assignment to these variables is not prohibited. However, it is not recommended as assignment does not affect the diagnostic area or result in the activation of condition handlers. Furthermore, processing an assignment to these SQL variables causes the specified values for the assignment to be overlayed with the SQL return codes returned from executing the statement that does the assignment.

Examples

Example 1: Increase the SQL variable \texttt{p\_salary} by 10 percent.
\footnotesize
\begin{verbatim}
SET p_salary = p_salary + (p_salary * .10)
\end{verbatim}

Example 2: Set SQL variable \texttt{p\_salary} to the null value.
\footnotesize
\begin{verbatim}
SET p_salary = NULL
\end{verbatim}

Example 3: Set SQL variable \texttt{midinit} to the first character of SQL variable \texttt{midname}.
\footnotesize
\begin{verbatim}
SET midinit = SUBSTR(midname,1,1)
\end{verbatim}
CALL statement

The CALL statement invokes a stored procedure.

Syntax

```
label: CALL procedure-name argument-list
```

**Description**

**label**
Specifies the label for the CALL statement. The label name cannot be the same as the name of the SQL routine or another label within the same scope. For additional information, see "References to labels" on page 2275.

**procedure-name**
Identifies the stored procedure to call. The procedure name must identify a stored procedure that exists at the current server.

**argument-list**
Identifies a list of values to be passed as parameters to the stored procedure. The \( n \)th value corresponds to the \( n \)th parameter in the procedure. The number of parameters must be the same as the number of parameters defined for the stored procedure. See CALL for more information.

Control is passed to the stored procedure according to the calling conventions for SQL routines. When execution of the stored procedure is complete, the value of each parameter of the stored procedure is assigned to the corresponding parameter of the CALL statement defined as OUT or INOUT.

**SQL-variable-name**
Specifies an SQL variable as an argument to the stored procedure. For an explanation of references to SQL variables, see References to SQL parameters and SQL variables.

**SQL-parameter-name**
Specifies an SQL parameter as an argument to the stored procedure. For an explanation of references to SQL parameters, see References to SQL parameters and SQL variables.

**expression**
The parameter is the result of the specified expression, which is evaluated.
before the stored procedure is invoked. If expression is a single SQL-parameter-name or SQL-variable-name, the corresponding parameter of the procedure can be defined as IN, INOUT, or OUT. Otherwise, the corresponding parameter of the procedure must be defined as IN. If the result of the expression can be the null value, either the description of the procedure must allow for null parameters or the corresponding parameter of the stored procedure must be defined as OUT.

The following additional rules apply depending on how the corresponding parameter was defined in the CREATE PROCEDURE statement for the procedure:

- IN expression can contain references to multiple SQL parameters or variables. In addition to the rules stated in Expressions for expression, expression cannot include a column name, an aggregate function, or a user-defined function that is sourced on an aggregate function.
- INOUT or OUT expression can only be a single SQL parameter or variable.

**NULL**

The parameter is a null value. The corresponding parameter of the procedure must be defined as IN and the description of the procedure must allow for null parameters.

**Notes**

See CALL for more information on the SQL CALL statement.

**Examples**

Call stored procedure proc1 and pass SQL variables as parameters.

```sql
call proc1(v_empno, v_salary)
```
CASE statement

The CASE statement selects an execution path based on multiple conditions. A CASE statement operates in the same way as a CASE expression.

**Syntax**

```
CASE
  label:
    simple-when-clause
      searched-when-clause
        else-clause
      END CASE
```

**Description**

- **label**
  Specifies the label for the CASE statement. The label name cannot be the same as the name of the SQL routine or another label within the same scope. For additional information, see "References to labels" on page 2275.

- **CASE**
  Begins a case-expression.

- **simple-when-clause**
  The value of the expression prior to the first WHEN keyword is tested for equality with the value of the expression that follows each WHEN keyword. If the comparison is true, the statements in the associated THEN clause are
executed and processing of the CASE statement ends. If the result is unknown or false, processing continues to the next comparison. If the result does not match any of the comparisons, and an ELSE clause is present, the statements in the ELSE clause are executed.

**searched-when-clause**
The *search-condition* following the WHEN keyword is evaluated. If it evaluates to true, the statements in the associated THEN clause are executed and processing of the CASE statement ends. If it evaluates to false, or unknown, the next *search-condition* is evaluated. If no *search-condition* evaluates to true and an ELSE clause is present, the statements in the ELSE clause are executed.

When *searched-when-clause* is used, *search-condition* cannot contain a full select.

**SQL-procedure-statement**
Specifies a statement to execute. See “SQL-procedure-statement” on page 2278.

**search-condition**
Specifies a condition that is true, false, or unknown about a row or group of table data.

**ELSE SQL-procedure-statement**
If none of the conditions specified in the *simple-when-clause* or *searched-when-clause* are true, the statements specified in *SQL-procedure-statement* are executed.

If none of the conditions specified in the WHEN clauses are true and an ELSE is not specified, an error is issued when the statement executes, and the execution of the CASE statement is terminated.

**END CASE**
Ends a *case-statement*.

**Examples**

*Example 1:* Use a simple case statement WHEN clause to update column DEPTNAME in table DEPT, depending on the value of SQL variable `v_workdept`.

```sql
CASE v_workdept
    WHEN 'A00'
        THEN UPDATE DEPT SET DEPTNAME = 'DATA ACCESS 1';
    WHEN 'B01'
        THEN UPDATE DEPT SET DEPTNAME = 'DATA ACCESS 2';
    ELSE UPDATE DEPT SET DEPTNAME = 'DATA ACCESS 3';
END CASE
```

*Example 2:* Use a searched case statement WHEN clause to update column DEPTNAME in table DEPT, depending on the value of SQL variable `v_workdept`.

```sql
CASE
    WHEN v_workdept < 'B01'
        THEN UPDATE DEPT SET DEPTNAME = 'DATA ACCESS 1';
    WHEN v_workdept < 'C01'
        THEN UPDATE DEPT SET DEPTNAME = 'DATA ACCESS 2';
    ELSE UPDATE DEPT SET DEPTNAME = 'DATA ACCESS 3';
END CASE
```
A compound statement groups other statements together in an SQL routine. A compound statement allows the declaration of SQL variables, cursors, and condition handlers.

**Syntax**

- **label**: `BEGIN` not atomic
- `SQL-variable-declaration`;
- `SQL-condition-declaration`;
- `return-codes-declaration`;
- `statement-declaration`;
- `DECLARE-CURSOR-statement`;
- `handler-declaration`;
- `SQL-procedure-statement`;
- `END label`;

**SQL-variable-declaration**:

- `DECLARE SQL-variable-name data-type DEFAULT NULL constant RESULT_SET_LOCATOR VARYING`;

**SQL-condition-declaration**:

- `DECLARE SQL-condition-name CONDITION FOR SQLSTATE VALUE string-constant`;

**return-codes-declaration**:
statement-declaration:

Notes:
1 The statement is not allowed in an SQL-routine-body for an SQL function.

handler-declaration:

specific-condition-value:

general-condition-value:

Description

label
Specifies the label for the compound-statement. If the beginning label is specified, it can be used to qualify SQL variables declared in the compound statement and can also be specified as the target on a LEAVE statement. If the
ending label is specified, it must be the same as beginning label. The label name cannot be the same as the routine name or another label within the same scope.

**NOT ATOMIC**

NOT ATOMIC indicates that an unhandled exception condition within the compound-statement does not cause the compound-statement to be rolled back.

**SQL-variable-declaration**

Declares a variable that is local to the compound statement.

**SQL-variable-name**

Defines the name of a variable. DB2 converts all SBCS SQL variable names that are not delimited to uppercase. **SQL-variable-name** must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement. **SQL-variable-name** must not be the same as a parameter name. See [References to SQL parameters and SQL variables](#) for information about how SQL variable names are resolved when there are columns with the same name as an SQL variable involved in a statement, or when multiple SQL variables exist with the same name in the routine body.

**SQL-variable-name** can only be referenced within the compound statement in which it is declared, including any compound statement that is nested within that compound statement. If the compound statement where the variable is declared has a label, references to the variable name can be qualified with that label. For example, an SQL variable V that is declared in a compound statement that is labeled C can be referenced as C.V.

**data-type**

Specifies the data type and length of the variable. SQL variables follow the same rules for default lengths and maximum lengths as SQL routine parameters. See [CREATE FUNCTION (compiled SQL scalar)](#) for descriptions of SQL data types and lengths.

**DEFAULT constant or NULL**

Defines the default for the SQL variable. The specified constant must represent a value that could be assigned to the variable in accordance with the rules of assignment as described in [Assignment and comparison](#). The variable is initialized when the compound statement begins processing. If a default value is not specified, the SQL variable is initialized to NULL.

**RESULT_SET_LOCATOR VARYING**

Specifies the data type for a result set locator variable.

**SQL-condition-declaration**

Declares a condition name and corresponding SQLSTATE value.

**SQL-condition-name**

Specifies the name of the condition. The condition name must be unique within the compound statement in which it is declared, excluding any declarations that are in compound statements that are nested within that compound statement. A condition name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement.

**FOR SQLSTATE string-constant**

Specifies the SQLSTATE that is associated with the condition. The string
must be specified as five characters enclosed in single quotes, and the SQLSTATE class (the first two characters) must not be '00'.

return-codes-declaration
Declares special variables named SQLSTATE and SQLCODE. These variables are automatically set to the SQLSTATE and SQLCODE values for the first condition in the diagnostics area after executing an SQL statement other than GET DIAGNOSTICS or an empty compound statement.

The SQLSTATE and SQLCODE SQL variables are only intended to be used as a means of obtaining the SQL return codes that resulted from processing the previous SQL statement other than GET DIAGNOSTICS. If there is any intention to use the SQLSTATE and SQLCODE values, save the values immediately to other SQL variables to avoid having the values replaced by the SQL return codes returned after executing the next SQL statement. If a handler is defined that handles an SQLSTATE, you can use an assignment statement to save that SQLSTATE (or the associated SQLCODE) value in another SQL variable, if the assignment is the first statement in the handler.

Assignment to these variables is not prohibited; however, it is not recommended. Assignment to these variables is ignored by condition handlers, and processing an assignment to these special variables causes the specified values for the assignment to be overlayed with the SQL return codes returned from executing the statement that does the assignment. The SQLSTATE and SQLCODE SQL variables cannot be set to NULL.

statement-declaration
Declares a list of one or more names that are local to the compound statement. A statement name cannot be the same as another statement name within the same compound statement.

DECLARE-CURSOR-statement
Declares a cursor in the procedure body. Each cursor must have a unique name within the routine. The cursor can only be referenced from within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. Use an OPEN statement to open the cursor, a FETCH statement to read a row using the cursor, and a CLOSE statement to close the cursor. If the cursor is intended for use as a result set cursor:
- Specify WITH RETURN when the cursor is declared
- Create the procedure using the DYNAMIC RESULT SETS clause with a non-zero value
- Do not specify a CLOSE statement for the cursor in the compound statement

For additional information about declaring a cursor, see DECLARE CURSOR.

handler-declaration
Specifies a condition handler, an SQL-procedure-statement to execute when an exception or completion condition occurs in the compound-statement. The SQL-procedure-statement executes when a condition handler receives control.

A condition handler declaration cannot reference the same condition value or SQLSTATE value more than one time. It cannot reference an SQLSTATE value and a condition name that represent the same SQLSTATE value.

When two or more condition handlers are declared in a compound statement, no two condition handler declarations can specify the same:
- general condition category
specific condition, either as an SQLSTATE value or as a condition name that represents the same value.

A condition handler is active for the set of SQL-procedure-statements that follow the condition handler declarations within the compound statement in which the condition handler is declared, including any nested compound statements.

**CONTINUE**
Specifies that after the condition handler is activated and completes successfully, control is returned to the SQL statement that follows the statement that raised the condition. However, if the condition is an error condition and it was encountered while evaluating a search condition, as in a CASE, FOR, IF, REPEAT or WHILE statement, control returns to the statement that follows the corresponding END CASE, END FOR, END IF, END REPEAT, or END WHILE.

**EXIT**
Specifies that after the condition handler is activated and completes successfully, control is returned to the end of the compound statement that declared the condition handler.

The conditions that can cause the handler to gain control are:

**SQLSTATE** string-constant
Specifies that the handler is invoked when the specific SQLSTATE occurs. The first two characters of the SQLSTATE value must not be '00'.

**SQL-condition-name**
Specifies that the handler is invoked when the specific SQLSTATE that is associated with the condition name occurs. The SQL-condition-name must be declared within the compound statement that contains the handler declarations, or within a compound statement in which that compound statement is nested.

**SQLEXCEPTION**
Specifies that the handler is invoked when an SQLEXCEPTION occurs. An SQLEXCEPTION is an SQLSTATE in which the class code is a value other than '00', '01', or '02'. For more information on SQLSTATE values, see DB2 Codes.

**SQLWARNING**
Specifies that the handler is invoked when an SQLWARNING occurs. An SQLWARNING is an SQLSTATE value with a class code of '01'.

**NOT FOUND**
Specifies that the handler is invoked when a NOT FOUND condition occurs. NOT FOUND corresponds to an SQLSTATE value with a class code of '02'.

**Notes**

Unlike host variables, SQL variables are not preceded by colons when they are used in SQL statements.

**Nesting compound statements:** Compound statements can be nested. Nested compound statements can be used to scope variable definitions, condition names, condition handlers, and cursors to a subset of the statements in a routine. This can simplify the processing that is done for each SQL routine statement. Nested compound statements enable the use of a compound statement within the declaration of a condition handler.
The scope of a cursor: The scope of a cursor name is the compound statement in which it is declared, including any compound statements that are nested within that compound statement. A cursor name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement.

Considerations for statement-name: The scope of a statement-name that is declared in a compound statement is the compound statement and any nested compound statements (unless the same statement-name is declared in a nested compound statement). If a statement-name is used in a DECLARE CURSOR statement or a PREPARE statement and has not been declared in the compound statement where it is used or any outer compound statements in which it is nested, the statement-name is assumed to be declared globally for the routine.

Condition handlers: Condition handlers in SQL routines are similar to WHENEVER statements that are used in external SQL application programs. A condition handler can be defined to automatically get control when an exception, warning, or not found condition occurs. The body of a condition handler contains code that is executed when the condition handler is activated. A condition handler can be activated as the result of an exception, a warning, or a not found condition that is returned by DB2 for the processing of an SQL statement. Or the condition that activates the handler can be the result of a SIGNAL or RESIGNAL statement that is issued within the SQL routine body.

A condition handler is declared within a compound statement, and it is active for the set of SQL-procedure-statements that follow all of the condition handler declarations within the compound statement in which the condition handler is declared. For example, the scope of a condition handler declaration H is the list of SQL-procedure-statements that follow the condition handler declarations that are contained within the compound statement in which H appears. This means that the scope of H does not include the statements that are contained in the body of the condition handler H, implying that a condition handler cannot handle conditions that arise inside its own body. Similarly, for any two condition handlers H1 and H2 that are declared in the same compound statement, H1 will not handle conditions that arise in the body of H2, and H2 will not handle conditions that arise in the body of H1.

The declaration of a condition handler specifies the condition that activates it, the type of condition handler (CONTINUE or EXIT), and the handler action. The type of condition handler determines to where control is returned after the handler action successfully completes.

Condition handler activation: When a condition other than a successful completion occurs in the processing of SQL-procedure-statement, if a condition handler that could handle the condition is within scope, one such condition handler will be activated to process the condition.

In a routine with nested compound statements, condition handlers that could handle a specific condition might exist at several levels of the nested compound statements. The condition handler that is activated is a condition handler that is declared innermost to the scope in which the condition was encountered. If more than one condition handler at the nesting level could handle the condition, the condition handler that is activated is the most appropriate handler that is declared in that compound statement.
The most appropriate handler is the condition handler that most closely matches the SQLSTATE or the exception or completion condition. For a given compound statement, when both a specific handler for a condition and a general handler are declared that address the same condition, the specific handler takes precedence over the general handler.

For example, if the innermost compound statement declares a specific handler for SQLSTATE '22001', as well as a general handler for SQLEXCEPTION, the specific handler for SQLSTATE '22001' is the most appropriate handler when SQLSTATE '22001' is encountered. In this case, the specific handler is activated.

When a condition handler is activated, the condition handler action is executed. If the handler action completes successfully or with an unhandled warning, the diagnostics area is cleared, and the type of the condition handler (CONTINUE or EXIT handler) determines to where control is returned. Additionally, the SQLSTATE and SQLCODE SQL variables are cleared when a handler completes successfully or with an unhandled warning.

If the handler action does not complete successfully and an appropriate handler exists for the condition that is encountered in the handler action, that condition handler is activated. Otherwise, the condition that is encountered within the condition handler is unhandled.

**Unhandled conditions:** If a condition is encountered and an appropriate handler does not exist for that condition, the condition is unhandled.

- If the unhandled condition is an exception, the SQL routine that contains the failing statement is terminated with an unhandled exception condition.
- If the unhandled condition is a warning or is a not found condition, processing continues with the next statement. Note that the processing of the next SQL statement will cause information about the unhandled condition in the diagnostics area to be overwritten, and evidence of the unhandled condition will no longer exist.

**Considerations for using SIGNAL and RESIGNAL statements with nested compound statements:** If an SQL-procedure-statement that is specified in the condition handler is either a SIGNAL or RESIGNAL statement with an exception SQLSTATE, the compound statement terminates with the specified exception. This happens even when this condition handler or another condition handler in the same compound statement specifies CONTINUE, since these condition handlers are not in the scope of this exception. If a compound statement is nested in another compound statement, condition handlers in the higher level compound statement can handle the exception because those condition handlers are within the scope of the exception.

**SQLSTATE and SQLCODE variables in SQL routines:** To help debug your SQL routines, you might find it useful to check the SQLSTATE and SQLCODE value after executing a statement. An SQLCODE or SQLSTATE variable can be declared and subsequently referenced in an SQL routine. You could insert the value of the SQLCODE and SQLSTATE into a table at various points in the SQL routine, or return the SQLCODE and SQLSTATE values in a diagnostics string as an OUT parameter. To use the SQLCODE and SQLSTATE values, you must declare the following SQL variables in the SQL routine body:

```sql
DECLARE SQLCODE INTEGER DEFAULT 0;
DECLARE SQLSTATE CHAR(5) DEFAULT '00000';
```
When you reference the SQLCODE or SQLSTATE variables in an SQL routine, DB2 sets the value of SQLCODE to 0 and SQLSTATE to '00000' for the subsequent statement. You can also use CONTINUE condition handlers to assign the value of the SQLSTATE and SQLCODE variables to variables in your SQL routine body. You can then use these SQL variables to control your routine logic, or pass the value back as an output parameter. In the following example, the SQL routine returns control to the statement following each SQL statement with the SQLCODE set in a SQL variable called RETCODE:

```
DECLARE SQLCODE INTEGER DEFAULT 0;
DECLARE retcode INTEGER DEFAULT 0;
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION SET retcode = SQLCODE;
DECLARE CONTINUE HANDLER FOR SQLWARNING SET retcode = SQLCODE;
DECLARE CONTINUE HANDLER FOR NOT FOUND SET retcode = SQLCODE;
```

The compound statement itself does not affect the SQLSTATE and SQLCODE SQL variables. However, SQL statements contained within the compound statement can affect the SQLSTATE and SQLCODE SQL variables. At the end of the compound statement, the SQLSTATE and SQLCODE SQL variables reflect the result of the last SQL statement executed within the compound statement that caused a change to the SQLSTATE and SQLCODE SQL variables. If the SQLSTATE and SQLCODE SQL variables were not changed within the compound statement, they contain the same values as when the compound statement was entered.

Null values in SQL parameters and SQL variables: If the value of an SQL parameter or SQL variable is null and it is used in an SQL statement that does not allow an indicator variable, an error is returned.

Effect on open cursors: At the end of the compound statement, all open cursors that are declared in that compound statement, except cursors that are used to return result sets, are closed.

Atomic processing of a compound statement: Atomic processing is not supported for a compound statement. If atomic behavior is needed for a block of code in a compound statement, set a savepoint before the nested compound statement is entered. This will allow changes to be undone with a ROLLBACK TO SAVEPOINT statement.

Examples

Example 1: Create a procedure body with a compound statement that performs the following actions:
- Declares SQL variables.
- Declares a cursor to return the salary of employees in a department determined by an IN parameter.
- Declares an EXIT handler for the condition NOT FOUND (end of file) which assigns the value 6666 to the OUT parameter medianSalary.
- Select the number of employees in the given department into the SQL variable v_numRecords.
- Fetch rows from the cursor in a WHILE loop until 50% + 1 of the employees have been retrieved.
- Return the median salary.

```
CREATE PROCEDURE DEPT_MEDIAN
(IN deptNumber SMALLINT,
 OUT medianSalary DOUBLE)
LANGUAGE SQL
```
BEGIN
   DECLARE v_numRecords INTEGER DEFAULT 1;
   DECLARE v_counter INTEGER DEFAULT 0;
   DECLARE c1 CURSOR FOR
      SELECT salary FROM staff
      WHERE DEPT = deptNumber
      ORDER BY salary;
   DECLARE EXIT HANDLER FOR NOT FOUND
      SET medianSalary = 6666;
      /* initialize OUT parameter */
      SET medianSalary = 0;
      SELECT COUNT(*) INTO v_numRecords FROM staff
      WHERE DEPT = deptNumber;
   OPEN c1;
   WHILE v_counter < (v_numRecords / 2 + 1) DO
      FETCH c1 INTO medianSalary;
      SET v_counter = v_counter + 1;
   END WHILE;
   CLOSE c1;
END

Example 2: Define an exit handler for any error, warning, or case of end of data. When this procedure is invoked and it returns to the caller, the value 45000 is returned for the output parameter:
CREATE PROCEDURE JMGLIB.PROCL(OUT MEDIANSALARY INT)
 LANGUAGE SQL
 BEGIN
   DECLARE CHAR1 CHAR;
   DECLARE c1 CURSOR FOR SELECT *
      FROM SYSIBM.SYSDUMMY1;
   DECLARE EXIT HANDLER FOR NOT FOUND,
      SQLEXCEPTION,
      SQLWARNING;
   OPEN c1;
   FETCH c1 INTO CHAR1;
   SET MEDIANSALARY = 45000;
   FETCH c1 INTO CHAR1;
   SET MEDIANSALARY = 50000;
 END
FOR statement

The FOR statement executes a statement for each row of a table. An implicit compound statement is generated to implement the FOR statement.

Syntax

```
label: FOR for-loop-name AS cursor-name CURSOR FOR
      WITHOUT HOLD cursor-name CURSOR FOR
      WITH HOLD FOR
      select-statement DO SQL-procedure-statement END FOR label
```

Description

**label**

Specifies the label for the FOR statement. If the ending label is specified, it must be the same as the beginning label. The label name cannot be the same as the routine name or another label within the same scope. For more information, see “References to labels” on page 2275.

**for-loop-name**

Specifies the label for the implicit compound statement that is generated to implement the FOR statement. **for-loop-name** follows the rules for the label of a compound statement except that it cannot be used with an ITERATE, GOTO, or LEAVE statement within the FOR statement. **for-loop-name** must not be the same as any label within the same scope.

**for-loop-name** can be used to qualify generated SQL variables that correspond to the columns that are returned by **select-statement**.

**cursor-name**

Names a cursor that is generated to select rows from the result table of **select-statement**. If **cursor-name** is not specified, a unique cursor name is generated.

**cursor-name** cannot be referenced outside of the FOR statement and cannot be specified on an OPEN, FETCH, or CLOSE statement.

**WITH HOLD** or **WITHOUT HOLD**

Specifies whether the cursor should be prevented from being closed as a consequence of a commit operation.

**WITHOUT HOLD**

Specifies that the cursor is not prevented from being closed as a consequence of a commit operation. **WITHOUT HOLD** is the default.

**WITH HOLD**

Specifies that the cursor should not be closed as a consequence of a commit operation. A cursor that is declared using the **WITH HOLD** clause is implicitly closed at commit time only if the connection that is associated
with the cursor is ended during the commit operation. For more information, see “DECLARE CURSOR” on page 1870.

select-statement
Specifies the select statement of the cursor. Each expression in the SELECT list must have a name. If an expression is not a simple column name, the AS clause must be used to name the expression. If the AS clause is specified, that name is used for the variable and must be unique.

select-statement must not include a values-clause.

SQL-procedure-statement
Specifies the SQL statements to be executed for each row of the table. The SQL statements must not include an OPEN, FETCH, or CLOSE statement that specifies the cursor name of the FOR statement.

Notes

FOR statement rules: The FOR statement executes one or multiple statements for each row in the result table of the cursor. The cursor is defined by specifying a SELECT list that describes the columns and rows selected. The statements within the FOR statement are executed for each row selected.

The SELECT list must consist of unique column names and the objects referenced in the select-statement must exist when the routine is created. All objects referenced in the select-statement must exist at the current server.

The cursor specified in a FOR statement cannot be referenced outside the FOR statement and cannot be specified on an OPEN, FETCH, or CLOSE statement.

Handler warning: Handlers can be used to handle errors that might occur on the open of the cursor or fetch of a row using the cursor in the FOR statement. Handlers defined to handle these open or fetch conditions should not be CONTINUE handlers as they might cause the FOR statement to loop indefinitely.

Examples

In the following example, the FOR statement is used to specify a cursor that selects three columns from the employee table. For every row selected, SQL variable fullname is set to the last name followed by a comma, the first name, a blank, and the middle initial. Each value for fullname is inserted into table TNAMES.

BEGIN
DECLARE fullname CHAR(40);
FOR v1 AS
  c1 CURSOR FOR
  SELECT firstname, midinit, lastname FROM employee
  DO
    SET fullname =
      lastname CONCAT ' ',
      CONCAT firstname
      CONCAT '
      CONCAT midinit;
    INSERT INTO TNAMES VALUES ( fullname );
  END FOR;
END;
GET DIAGNOSTICS statement

The GET DIAGNOSTICS statement obtains information about the previous SQL statement that was executed.

See "GET DIAGNOSTICS" on page 2008.

When you need to specify a variable in a GET DIAGNOSTICS statement that is used within an SQL routine, you would use either SQL-variable-name or SQL-parameter-name. In an embedded GET DIAGNOSTICS statement, you would use a host-variable. You can replace the instances of host-variable in the description of "GET DIAGNOSTICS" on page 2008 with SQL-variable-name or SQL-parameter-name.

Effects of the statement: The GET DIAGNOSTICS statement does not change the contents of the diagnostics area except for DB2_GET_DIAGNOSTICS.

Considerations for the SQLSTATE and SQLCODE SQL variables: The GET DIAGNOSTICS statement does not change the value of the SQLSTATE and SQLCODE SQL variables.

The stacked diagnostics area: The stacked diagnostics area is only available within a handler in a native SQL procedure and non-inline SQL functions.
GOTO statement

Syntax

\[
\text{label:} \quad \text{GOTO} - \text{target-label}
\]

Description

\textit{label}

Specifies the label for the GOTO statement. The label name cannot be the same as the name of the SQL routine in which the label is used or another label in the same scope.

\textit{target-label}

Specifies a label of the statement where processing is to continue. \textit{target-label} must be defined as a label for an SQL procedure statement. The target label must be accessible to the GOTO statement as defined in References to labels, subject to the following restrictions:

- If the GOTO statement is in a condition handler, \textit{target-label} must be defined in that condition handler.
- If the GOTO statement is not defined in a condition handler, \textit{target-label} must not be defined in a condition handler.

Notes

\textit{Using a GOTO statement:} It is recommended that the GOTO statement be used sparingly. This statement interferes with the normal sequence of processing SQL statements, thus making a routine more difficult to read and maintain. Before using a GOTO statement, determine whether another statement, such as IF or LEAVE, can be used in place, to eliminate the need for a GOTO statement.

\textit{Effect on open cursors:} When a GOTO statement transfers control out of a compound statement, all open cursors that are declared in the compound statement that contains the GOTO statement are closed, except cursors that are used to return result sets.

Examples

\textit{Example 1:} In the following procedure, the GOTO statement branches outside of the current compound statement to a higher level:

```sql
CREATE PROCEDURE TESTGOTO5 ( )
P1: BEGIN
  DECLARE I ,A INTEGER;
  SET I = 1;
  LAB1: SET A = 1;
  BEGIN
    LAB2: SET A = 2;
    BEGIN
      SET I = I+1;
      IF I<3 THEN GOTO LAB1;
    BEGIN
```

Example 2: In the following example, cursors are declared at multiple levels. The GOTO statement that specified TargLabel as the target label, results in the closing of cursors C1, C2, and C3. This is because cursors C1, C2, and C3 are all declared directly or indirectly in the compound statement with the label L1. The GOTO statement causes control to transfer out of the compound statement with label L1, so the cursors that are defined within that compound statement (at any level) are closed.

L0: BEGIN
   DECLARE CURSOR C0 ...
   ...
   TARGLABEL: ...
   ...
L1: BEGIN
   DECLARE CURSOR C1 ...
   ...
L2: BEGIN
   DECLARE CURSOR C2 ...
   ...
   GOTO TARGLABEL;
   ...
L3: BEGIN
   DECLARE CURSOR C3 ...
   ...
END L3;
END L2;
END L1;
END L0
IF statement

The IF statement executes different sets of SQL statements based on the result of search conditions.

Syntax

```
label: IF search-condition THEN SQL-procedure-statement;
ELSEIF search-condition THEN SQL-procedure-statement;
ELSE SQL-procedure-statement;
END IF;
```

Description

`label`

Specifies the label for the IF statement. The label name cannot be the same as the name of the SQL routine or another label name within the same scope. For additional information, see “References to labels” on page 2275.

`search-condition`

Specifies the search-condition for which an SQL statement should be executed. If the condition is unknown or false, processing continues to the next search condition, until either a condition is true or processing reaches the ELSE clause.

`SQL-procedure-statement`

Specifies an SQL statement to be executed if the preceding search-condition is true. See SQL-procedure-statement.

Examples

Assign a value to the SQL variable `new_salary` based on the value of SQL variable rating.

```sql
IF rating = 1
    THEN SET new_salary =
        new_salary + (new_salary * .10);
ELSEIF rating = 2
    THEN SET new_salary =
        new_salary + (new_salary * .05);
ELSE SET new_salary =
    new_salary + (new_salary * .02);
END IF;
```
ITERATE statement

The ITERATE statement causes the flow of control to return to the beginning of a labeled loop.

Syntax

```
label: ITERATE target-label
```

Description

*label*

Specifies the label for the ITERATE statement. The label name cannot be the same as the name of the SQL routine or another label within the same scope. For additional information, see "References to labels" on page 2275.

*target-label*

Specifies the label of the FOR, LOOP, REPEAT, or WHILE statement to which the flow of control is passed. *target-label* must be defined as a label for a FOR, LOOP, REPEAT, or WHILE statement. The ITERATE statement must be in that FOR, LOOP, REPEAT, or WHILE statement, or in the block of code that is directly or indirectly nested within that statement, subject to the following restrictions:

- If the ITERATE statement is in a condition handler, *target-label* must be defined in that condition handler.
- If the ITERATE statement is not in a condition handler, *target-label* must not be defined in a condition handler.

Examples

*Example 1:* This example uses a cursor to return information for a new department. If the not_found condition handler is invoked, the flow of control passes out of the loop. If the value of *v_dept* is 'D11', an ITERATE statement causes the flow of control to be passed back to the top of the LOOP statement. Otherwise, a new row is inserted into the table.

```
CREATE PROCEDURE ITERATOR ()
LANGUAGE SQL
MODIFIES SQL DATA
BEGIN
    DECLARE v_dept CHAR(3);
    DECLARE v_deptname VARCHAR(29);
    DECLARE v_admdept CHAR(3);
    DECLARE at_end INTEGER DEFAULT 0;
    DECLARE not_found CONDITION FOR SQLSTATE '02000';
    DECLARE c1 CURSOR FOR
        SELECT deptno,deptname,admdept
        FROM department
        ORDER BY deptno;
    DECLARE CONTINUE HANDLER FOR not_found
        SET at_end = 1;
    OPEN c1;
    ins_loop:
    LOOP
        FETCH c1 INTO v_dept, v_deptname, v_admdept;
        IF at_end = 1 THEN
```
LEAVE ins_loop;
ELSEIF v_dept = 'D11' THEN
  ITERATE ins_loop;
END IF;
INSERT INTO department (deptno,deptname,admrd dept)
VALUES('NEW', v_deptname, vadmdept);
END LOOP;
CLOSE c1;
END

Example 2: An ITERATE statement can be issued from a nested block to cause that
flow of control to return to the beginning of a loop at a higher level. In the
following example, the ITERATE statement within the LAB2 compound statement
causes the flow of control to return to the beginning of the LAB1 LOOP statement:

LAB1: LOOP
  SET A = 0;
  LAB2: BEGIN
    ...
    LAB3: BEGIN
      ...
      ITERATE LAB1; -- Multilevel ITERATE
      ...
      END LAB3;
    ...
    ITERATE LAB1; -- Multilevel ITERATE
    ...
    END LAB2;
END LOOP;S
LEAVE statement

The LEAVE statement transfers program control out of a FOR, LOOP, REPEAT, WHILE, or compound statement.

Syntax

```sql
label: LEAVE target-label
```

Description

**label**

Specifies the label for the LEAVE statement. The label name cannot be the same as the name of the SQL routine or the same as another label that is within the same scope. For additional information, see [References to labels](#).

**target-label**

Specifies the label of the compound, FOR, LOOP, REPEAT, or WHILE statement to exit. target-label must be defined as a label for a compound, FOR, LOOP, REPEAT, or WHILE statement, or in a block of code that is directly or indirectly nested within that statement, subject to the following rules:

- If the LEAVE statement is in a condition handler, target-label must be defined in that condition handler.
- If the LEAVE statement is not in a condition handler, target-label must not be defined in a condition handler.

Notes

**Effect on open cursors:** When a LEAVE statement transfers control out of a compound statement, all open cursors in the compound statement, except cursors that are used to return result sets, are closed.

Examples

**Example 1:** The example contains a loop that fetches data for cursor c1. If the value of SQL variable `at_end` is not zero, the LEAVE statement transfers control out of the loop.

```sql
CREATE PROCEDURE LEAVE_LOOP (OUT COUNTER INTEGER)
  LANGUAGE SQL
  BEGIN
    DECLARE v_counter INTEGER;
    DECLARE v_firstname VARCHAR(12);
    DECLARE v_midinit CHAR(1);
    DECLARE v_lastname VARCHAR(15);
    DECLARE at_end SMALLINT DEFAULT 0;
    DECLARE not_found CONDITION FOR SQLSTATE '02000';
    DECLARE c1 CURSOR FOR
      SELECT firstname, midinit, lastname
      FROM employee;
    DECLARE CONTINUE HANDLER FOR not_found
      SET at_end = 1;
    SET v_counter = 0;
    OPEN c1;
    fetch_loop:
```

```sql```
LOOP
  FETCH c1 INTO v_firstnme, v_midinit, v_lastname;
  IF at_end <> 0 THEN
    LEAVE fetch_loop;
  END IF;
  SET v_counter = v_counter + 1;
END LOOP fetch_loop;
SET counter = v_counter;
CLOSE c1;
END

Example 2: A LEAVE statement can be issued from a nested block to leave a
statement at a higher level. In the following example, the LEAVE statement within
the LAB2 compound statement causes the LAB1 LOOP statement to terminate:
LAB1: LOOP
  ...
  LAB2: BEGIN
    SET A = 0;
    ...
  LAB3: BEGIN
    ...
    LEAVE LAB1; -- Multilevel LEAVE
    ...
  END LAB3;
  ...
  LEAVE LAB1; -- Multilevel LEAVE
  ...
  END LAB2;
END LOOP;S
The LOOP statement executes a statement or group of statements multiple times.

**Syntax**

```
label: LOOP SQL-procedure-statement ; END LOOP label
```

**Description**

*label*

Specifies the label for the LOOP statement. If the ending label is specified, a matching beginning label must be specified. A label name cannot be the same as the name of the SQL routine or another label within the same scope. For additional information, see [“References to labels” on page 2275](#).  

*SQL-procedure-statement*

Specifies an SQL statement to be executed in the loop. The statement must be one of the statements listed under [SQL-procedure-statement](#).

**Notes**

**Considerations for the diagnostics area:** At the beginning of the first iteration of the LOOP statement, and with every subsequent iteration, the diagnostics area is cleared.

**Considerations for the SQLSTATE and SQLCODE SQL variables:** Prior to executing the first SQL-procedure-statement within that LOOP statement, the SQLSTATE and SQLCODE values reflect the last values that were set prior to the LOOP statement. If the loop is terminated with a GOTO or a LEAVE statement, the SQLSTATE and SQLCODE values reflect successful completion of that statement. When the LOOP statement iterates, the SQLSTATE and SQLCODE values reflect the result of the last SQL statement that is executed within the LOOP statement.

**Examples**

This procedure uses a LOOP statement to fetch values from the employee table. Each time the loop iterates, the OUT parameter counter is incremented and the value of `v_midinit` is checked to ensure that the value is not a single space (' '). If `v_midinit` is a single space, the LEAVE statement passes the flow of control outside of the loop.

```sql
CREATE PROCEDURE LOOP_UNTIL_SPACE (OUT counter INTEGER)
    LANGUAGE SQL
BEGIN
    DECLARE v_counter INTEGER DEFAULT 0;
    DECLARE v_firstname VARCHAR(12);
    DECLARE v_midinit CHAR(1);
    DECLARE v_lastname VARCHAR(15);
    DECLARE c1 CURSOR FOR
        SELECT firstname, midinit, lastname
        FROM employee;
    DECLARE EXIT HANDLER FOR NOT FOUND
```
SET counter = -1;
OPEN c1;
fetch_loop:
LOOP
  FETCH c1 INTO v_firstnme, v_midinit, v_lastname;
  IF v_midinit = '' THEN
    LEAVE fetch_loop;
  END IF;
  SET v_counter = v_counter + 1;
END LOOP fetch_loop;
SET counter = v_counter;
CLOSE c1;
END
The REPEAT statement executes a statement or group of statements until a search condition is true.

**Syntax**

```sql
label: REPEAT SQL-procedure-statement ; UNTIL search-condition END REPEAT
```

**Description**

- **label**
  Specifies the label for the REPEAT statement. If an ending label is specified, a matching beginning label must be specified. A label name cannot be the same as the name of the SQL routine or another label within the same scope. For additional information, see “References to labels” on page 2275.

- **SQL-procedure-statement**
  Specifies an SQL statement to be executed within the REPEAT loop. The statement must be one of the statements listed under **SQL-procedure-statement**.

- **search-condition**
  Specifies a condition that is evaluated after each execution of the REPEAT loop. If the condition is true, the REPEAT loop will exit. If the condition is unknown or false, the looping continues.

**Notes**

- **Considerations for the diagnostics area**: At the beginning of the first iteration of the REPEAT statement, and with every subsequent iteration, the diagnostics area is cleared.

  **Considerations for the SQLSTATE and SQLCODE SQL variables**: At the beginning of the first iteration of the REPEAT statement, the SQLSTATE and SQLCODE values reflect the values that were set prior to the REPEAT statement. At the beginning of iterations 2 through n of the REPEAT statement, the SQLSTATE and SQLCODE SQL values reflect the result of evaluating the search condition in the UNTIL clause of that REPEAT. If the loop is terminated with a GOTO, ITERATE, or LEAVE statement, the SQLSTATE and SQLCODE values reflect the successful completion of that statement. Otherwise, after the END REPEAT of the REPEAT statement completes, the SQLSTATE and SQLCODE reflect the result of evaluating the search condition in the UNTIL clause of that REPEAT statement.

**Examples**

Use a REPEAT statement to fetch rows from a table.
fetch_loop:
REPEAT
  FETCH c1 INTO
    v_firstnme, v_midinit, v_lastname;
UNTIL
  SQLCODE <> 0
END REPEAT fetch_loop
RESIGNAL statement

The RESIGNAL statement is used within a condition handler to resignal the condition that activated the handler, or to raise an alternate condition so that it can be processed at a higher level. It causes an exception, warning, or not found condition to be returned along with optional message text.

Syntax

```
label: RESIGNAL

SQLSTATE VALUE

sqlstate-string-constant

SQL-variable-name

SQL-parameter-name

signal-information
```

```
SET MESSAGE_TEXT = diagnostic-string-expression
```

Description

**label**

Specifies the label for the RESIGNAL statement. A label name cannot be the same as the name of the SQL routine or another label within the same scope. For additional information, see "References to labels" on page 2275.

**SQLSTATE VALUE**

Specifies the SQLSTATE that will be returned. Any valid SQLSTATE value can be used. It must be a character string constant with exactly five characters that follow the rules for SQLSTATE values:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letter ('A' through 'Z').
- The SQLSTATE class (the first two characters) cannot be '00' because it represents successful completion.

If the SQLSTATE does not conform to these rules, an error occurs.

**sqlstate-string-constant**

A character string constant with an actual length of five bytes that is a valid SQLSTATE value.

**SQL-variable-name or SQL-parameter-name**

Specifies an SQL variable or SQL parameter that is defined for the routine.

**SQL-variable-name**

Specifies an SQL variable that is declared within the compound-statement that contains the RESIGNAL statement or within a compound statement in which that compound statement is nested.
**SQL-variable-name** must be defined as CHAR or VARCHAR data type with an actual length of five bytes, must not be null, and must contain a valid SQLSTATE value.

**SQL_parameter-name**

Specifies an SQL parameter that is defined for the routine that contains the SQLSTATE value. The SQL parameter must be defined as CHAR or VARCHAR data type with an actual length of five bytes, must not be null, and must contain a valid SQLSTATE value.

**SQL-condition-name**

Specifies the name of the condition that will be returned. **SQL-condition-name** must be declared within the compound-statement that contains the RESIGNAL statement, or within a compound statement in which that compound statement is nested.

**SET MESSAGE_TEXT**

Specifies a string that describes the error or warning. The string is returned in the SQLERRMC field of the SQLCA or with the GET DIAGNOSTICS statement.

**diagnostic-string-expression**

An expression with a data type of CHAR or VARCHAR that returns a character string of up to 1000 bytes that describes the error or warning condition. For information on how to obtain the complete message text, see [GET DIAGNOSTICS](#).

**Notes**

While any valid SQLSTATE value can be used in the RESIGNAL statement, programmers should define new SQLSTATEs based on ranges reserved for applications. This practice prevents the unintentional use of an SQLSTATE value that might be defined by the database manager in a future release.

If the SQLSTATE or condition indicates that an exception is signaled (SQLSTATE class other than '01' or '02'):

- If a condition handler exists in the same compound statement as the RESIGNAL statement, and the compound statement contains a condition handler for SQLEXCEPTION or the specified SQLSTATE or condition, the exception is handled and control is transferred to that condition handler.
- If the compound statement is nested and an outer level compound statement has a condition handler for SQLEXCEPTION or the specified SQLSTATE or condition, the exception is handled and control is transferred to that condition handler.
- Otherwise, the exception is not handled and control is immediately returned to the end of the compound statement.

If an SQLSTATE or a condition indicates that a warning or a not found condition is signaled:

- If a condition handler exists in the same compound statement as the RESIGNAL statement, and the compound statement contains a condition handler for SQLWARNING, NOT FOUND, or the specified SQLSTATE or condition, the warning or not found condition is handled and control is transferred to that condition handler.
- If the compound statement is nested and an outer level compound statement contains a condition handler for SQLWARNING, NOT FOUND, or the specified
SQLSTATE or condition, the warning or not found condition is handled and control is returned to that condition handler.

- Otherwise, the warning is not handled and processing continues with the next statement.

**Considerations for the diagnostics area:** The RESIGNAL statement might modify the contents of the current diagnostics area. If an SQLSTATE or condition-name is specified as part of the RESIGNAL statement, the RESIGNAL statement starts with a clear diagnostics area and sets the RETURNED_SQLSTATE to reflect the specified SQLSTATE or condition-name. If message text is specified, the MESSAGE_TEXT item of the condition area is assigned the specified value. DB2_RETURNED_SQLCODE is set to +438 or -438 corresponding to the specified SQLSTATE or condition-name.

**Processing a RESIGNAL statement:** If the RESIGNAL statement is specified without an SQLSTATE clause or a condition-name, the SQL routine ressignals the identical condition that invoked the handler and the SQLCODE is not changed.

When a RESIGNAL statement is issued and an SQLSTATE or condition-name is specified, the SQLCODE is based on the SQLSTATE value as follows:

- If the specified SQLSTATE class is either '01' or '02', a warning or not found is signaled and the SQLCODE is set to +438.
- Otherwise, an exception is returned and the SQLCODE is set to -438.

**Examples**

The following example detects a division by zero error. The IF statement uses a SIGNAL statement to invoke the overflow condition handler. The condition handler uses a RESIGNAL statement to return a different SQLSTATE to the client application.

```sql
CREATE PROCEDURE divide (IN numerator INTEGER,
                        IN denominator INTEGER,
                        OUT divide_result INTEGER)
    LANGUAGE SQL
    CONTAINS SQL
BEGIN
    DECLARE overflow CONDITION for SQLSTATE '22003';
    DECLARE CONTINUE HANDLER FOR overflow
        RESIGNAL SQLSTATE '22375';
    IF denominator = 0 THEN
        SIGNAL overflow;
    ELSE
        SET divide_result = numerator / denominator;
    END IF;
END
```
RETURN statement

The RETURN statement is used to return from the routine.

- For an SQL scalar function, the scalar result of the function is returned. The body of an SQL scalar function must contain at least one RETURN statement and a RETURN statement must be executed when the function is invoked.
- For an SQL table function, the result table of the function is returned. A RETURN statement must be specified in the body of an SQL table function.
- For an SQL procedure, the RETURNS statement optionally returns an integer status value.

Syntax

```
label: RETURN expression
NULL
fullselect
```

Description

**label**

Specifies the label for the RETURN statement. A label name cannot be the same as the name of the SQL routine or another label within the same scope.
For additional information, see [References to labels](#).

**expression**

Specifies a value that is returned from the routine.

- If the routine is a scalar function, the data type of the result must be assignable to the data type that is defined for the function result, using the storage assignment rules as described in [Assignment and comparison](#). The RETURN statement must not contain a period specification.

  The body of any SQL function must not contain a reference to an aggregate function, or a reference to a user-defined function that is sourced on an aggregate function, or an OLAP specification.

  In the body of an inlined SQL function, the RETURN statement must not contain a scalar fullselect. If the expression does not conform to this rule, DB2 attempts to define a compiled function. To determine what type of SQL scalar function is created, refer to the INLINE column of the SYSIBM.SYSROUTINES catalog table. For more information about creating the two types of SQL scalar functions, see "CREATE FUNCTION (inlined SQL scalar)" on page 1565 and "CREATE FUNCTION (compiled SQL scalar)" on page 1500.

- If the routine is a table function, a scalar expression (other than a scalar fullselect) cannot be specified. The data type of the result column of the fullselect must be assignable to the data type that is defined for the function result, using the storage assignment rules as described in [Assignment and comparison](#). The RETURN statement must not contain a period specification.

- If the routine is a procedure, the data type of expression must be INTEGER.

**NULL**

The null value is returned from the SQL routine.
• If the routine is a scalar function, the null value is returned.
• If the routine is a table function, NULL must not be specified.
• If the routine is a procedure, NULL must not be specified.

fullselect
   Specifies the row or rows that are returned from the routine.
   • If the routine is a scalar function, the function is a compiled function and the
     fullselect must return one column and, at most, one row. The data type of
     the result column must be assignable to the data type that is defined for the
     function result, using the storage assignment rules as described in
     [Assignment and comparison].
   • If the routine is a table function, the fullselect can return zero or more rows
     with one or more columns. The number of columns in the fullselect must
     match the number of columns in the function result. In addition, the data
     types of the result table columns of the fullselect must be assignable to the
     data types of the columns that are defined for the function result, using the
     storage assignment rules as described in [Assignment and comparison].
   • If the routine is a procedure, fullselect must not be specified.

Notes

Considerations for SQL functions: A RETURN statement in an SQL function must
specify expression, NULL, or fullselect. For an inlined SQL scalar function, only a
single expression can be specified in the RETURN statement, and the expression
must not include a scalar fullselect. Only a single RETURN statement can be
specified in the routine body of an SQL table function. The execution of an SQL
function must end with a RETURN statement.

A data change table reference is not allowed in a RETURN statement in an SQL
function.

Considerations for SQL procedures:
• When a RETURN statement is used within an SQL procedure: If a RETURN
   statement with a specified return value was used to return from a procedure, the
   SQLCODE, SQLSTATE, and message length in the SQLCA are initialized to
   zeros and the message text is set to blanks. An error is not returned to the caller.
• When a RETURN statement is not used within an SQL procedure or when no
   value is specified: If a RETURN statement was not used to return from a
   procedure or if a value is not specified on the RETURN statement, one of the
   following values is set:
   – If the procedure returns with an SQLCODE that is greater or equal to zero,
     the specified target for DB2_RETURN_STATUS in a GET DIAGNOSTICS
     statement will be set to a value of zero.
   – If the procedure returns with an SQLCODE that is less than zero, the
     specified target for DB2_RETURN_STATUS in a GET DIAGNOSTICS
     statement will be set to a value of ’-1’.
• When the value is returned from an SQL procedure: When a value is returned
   from a procedure, the caller may access the value using one of the following
   methods:
   – The GET DIAGNOSTICS statement to retrieve the RETURN_STATUS when
     the SQL procedure was called from another SQL procedure.
   – The parameter bound for the return value parameter marker in the escape
     clause CALL syntax (?=CALL...) in a CLI application.
Directly from the SQLCA returned from processing the CALL of an SQL procedure by retrieving the value of sqlerrd[0]. When the SQLCODE is less than zero, the sqlerrd[0] value is not set. The application should assume a return status value of '-1'.

Examples

Example 1: Use a RETURN statement to return from an SQL procedure with a status value of zero if successful or '-200' if not successful.

```
BEGIN
    ...
    GOTO FAIL;
    ...
SUCCESS: RETURN 0;
FAIL:   RETURN -200;
END
```

Example 2: Define a scalar function that returns the tangent of a value using the existing sine and cosine functions:

```
CREATE FUNCTION TAN (X DOUBLE)
RETURNS DOUBLE
LANGUAGE SQL CONTAINS SQL NO EXTERNAL ACTION
DETERMINISTIC
RETURN SIN(x)/COS(x)
```
**SIGNAL statement**

The SIGNAL statement is used to return an exception or warning condition. It causes an error or warning to be returned with the specified SQLSTATE, along with optional message text. The SIGNAL statement places the specified condition information in the cleared diagnostics area.

**Syntax**

```
label: SIGNAL VALUE SQLSTATE sqlstate-string-constant
      [SQL-variable-name]
      [SQL-parameter-name]
      [SQL-condition-name]
signal-information
```

**signal-information:**

```
SET MESSAGE_TEXT = diagnostic-string-expression
      (diagnostic-string-expression)
```

**Notes:**

1. `(diagnostic-string-expression)` must only be specified within a trigger body.

**Description**

**label**

Specifies the label for the SIGNAL statement. A label name cannot be the same as the name of the SQL routine or another label within the same scope. For additional information, see "References to labels" on page 2275.

**SQLSTATE VALUE**

Specifies the SQLSTATE that will be returned. Any valid SQLSTATE value can be used. It must be a character string constant with exactly five characters that follow the rules for SQLSTATEs:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letter ('A' through 'Z').
- The SQLSTATE class (the first two characters) cannot be '00' because it represents successful completion.

If the SQLSTATE does not conform to these rules, an error occurs.

**sqlstate-string-constant**

A character string constant with an actual length of five bytes that is a valid SQLSTATE value.
SQL-variable-name or SQL-parameter-name
Specifies an SQL variable or SQL parameter that contains a valid SQLSTATE value.

SQL-variable-name
Specifies an SQL variable that is declared within the compound-statement that contains the SIGNAL statement, or within a compound statement in which that compound statement is nested. SQL-variable-name must be defined as a CHAR or VARCHAR data type with an actual length of five bytes, must not be null, and must contain a valid SQLSTATE value.

SQL-parameter-name
Specifies an SQL parameter that is defined for the routine and contains the SQLSTATE value. The SQL parameter must be defined as a CHAR or VARCHAR data type with an actual length of five bytes, must not be null, and must contain a valid SQLSTATE value.

SQL-condition-name
Specifies the name of the condition that will be returned. The SQL-condition-name must be declared within the compound statement that contains the SIGNAL statement, or within a compound statement in which that compound statement is nested.

SET MESSAGE_TEXT
Specifies a string that describes the error or warning. The string is returned in the SQLERRMC field of the SQLCA or with the GET DIAGNOSTICS statement.

diagnostic-string-expression
An expression with a data type of CHAR or VARCHAR that returns a character string of up to 1000 bytes that describes the error or warning condition. For information on how to obtain the complete message text, see GET DIAGNOSTICS (diagnostic-string-expression)

This syntax variation is only provided within the scope of a CREATE TRIGGER statement for compatibility with previous versions of DB2. To conform with the ANS and ISO standards, this form should not be used.

Notes

While any valid SQLSTATE value can be used in the SIGNAL statement, programmers should define new SQLSTATEs based on ranges reserved for applications. This practice prevents the unintentional use of an SQLSTATE value that might be defined by the database manager in a future release.

If the SQLSTATE or condition indicates that an exception is signaled:

• If a condition handler exists in the same compound statement as the SIGNAL statement, and the compound statement contains a condition handler for SQLEXCEPTION or the specified SQLSTATE or condition, the exception is handled and control is transferred to that condition handler.
If the compound statement is nested and the outer level compound statement has a condition handler for SQLEXCEPTION or the specified SQLSTATE or condition, the exception is handled and control is transferred to that condition handler.

Otherwise, the exception is not handled and control is immediately returned to the end of the compound statement.

If the SQLSTATE or condition indicates that a warning or not found condition is signaled:

- If a condition handler exists in the same compound statement as the SIGNAL statement, and the compound statement contains a condition handler for SQLWARNING, NOT FOUND, or the specified SQLSTATE or condition, the warning or not found condition is handled and control is transferred to that condition handler.
- If the compound statement is nested and an outer level compound statement contains a condition handler for SQLWARNING, NOT FOUND, or the specified SQLSTATE or condition, the warning or not found condition is handled and control is transferred to that condition handler.
- Otherwise, the warning or not found condition is not handled and processing continues with the next statement.

**Considerations for the diagnostics area:** The SIGNAL statement starts with a clear diagnostics area and sets the RETURNED_SQLSTATE to reflect the specified SQLSTATE or condition-name. If message text is specified, the MESSAGE_TEXT item of the condition area is assigned the specified value. DB2_RETURNED_SQLCODE is set to +438 or -438 corresponding to the specified SQLSTATE or condition-name.

**Examples**

**Example 1:** The following example shows an SQL procedure for an order system that signals an application error when a customer number is not known to the application. The ORDERS table includes a foreign key to the CUSTOMER table, requiring that the CUSTNO exist before an order can be inserted.

```sql
CREATE PROCEDURE SUBMIT_ORDER
(IN ONUM INTEGER,
 IN CNUM INTEGER,
 IN PNUM INTEGER,
 IN QNUM INTEGER)
LANGUAGE SQL
SPECIFIC SUBMIT_ORDER
MODIFIES SQL DATA
BEGIN
 DECLARE EXIT HANDLER FOR SQLSTATE VALUE '23503'
 SIGNAL SQLSTATE '75002'
 SET MESSAGE_TEXT = 'Customer number is not known';
 INSERT INTO ORDERS (ORDERNO, CUSTNO, PARTNO, QUANTITY)
 VALUES (ONUM, CNUM, PNUM, QNUM);
END
```

**Example 2:** The following example shows a trigger for an order system that allows orders to be recorded in an ORDERS table (ORDERNO, CUSTNO, PARTNO, QUANTITY) only if there is sufficient stock in the PARTS tables. When there is insufficient stock for an order, SQLSTATE '75001' is returned along with an appropriate error description.

```sql
CREATE TRIGGER CK_AVAIL
NO CASCADE BEFORE INSERT ON ORDERS
REFERENCING NEW AS NEW_ORDER
FOR EACH ROW MODE DB2SQL
```
WHEN (NEW_ORDER.QUANTITY > (SELECT ON_HAND FROM PARTS
    WHERE NEW_ORDER.PARTNO = PARTS.PARTNO))
BEGIN ATOMIC
    SIGNAL SQLSTATE '75001' ('Insufficient stock for order');
END
WHILE statement

The WHILE statement repeats the execution of a statement or group of statements while a specified condition is true.

Syntax

```
label: WHILE search-condition DO SQL-procedure-statement; END WHILE label
```

Description

**label**

Specifies the label for the WHILE statement. If the ending label is specified, it must be the same as the beginning label. A label name cannot be the same as the name of the SQL routine or another label within the same scope. For additional information, see [References to labels](#).

**search-condition**

Specifies a condition that is evaluated before each execution of the loop. If the condition is true, the SQL procedure statements in the loop are executed.

**SQL-procedure-statement**

Specifies a statement to be run within the WHILE loop. The statement must be one of the statements listed under [“SQL-procedure-statement” on page 2278](#).

Notes

**Considerations for the diagnostics area:** At the beginning of the first iteration of the WHILE statement, and with every subsequent iteration, the diagnostics area is cleared.

**Considerations for the SQLSTATE and SQLCODE SQL variables:** With each iteration of the WHILE statement, when the first SQL-procedure-statement is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the search condition of that WHILE statement. If the loop is terminated with a GOTO, ITERATE, or LEAVE statement, the SQLSTATE and SQLCODE values reflect the successful completion of that statement. Otherwise, after the END WHILE of the WHILE statement completes, the SQLSTATE and SQLCODE reflect the result of evaluating that search condition of that WHILE statement.

Examples

Use a WHILE statement to fetch rows from a table while SQL variable `at_end`, which indicates whether the end of the table has been reached, is 0.

```sql
WHILE at_end = 0 DO
  FETCH cI INTO
    v_firstnme, v_midinit,
    v_lastname, v_edlevel, v_salary;
  IF SQLCODE=100 THEN SET at_end=1;
  END IF;
END WHILE;
```
Appendix. Additional information for DB2 SQL

These topics contain additional information for DB2 SQL.
Limits in DB2 for z/OS

DB2 for z/OS has system limits, object and SQL limits, length limits for identifiers and strings, and limits for certain data type values.

System storage limits might preclude the limits specified in this section. The limit for items not that are not specified below is limited by system storage.

The following table shows the length limits for identifiers.

Table 213. Identifier length limits. The term byte(s) in this table means the number of bytes for the UTF-8 representation unless noted otherwise.

<table>
<thead>
<tr>
<th>Item</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>External-java-routine-name</td>
<td>1305 bytes</td>
</tr>
<tr>
<td>Name of an alias 1, auxiliary table, collection, clone table, constraint, correlation, cursor (except for DECLARE CURSOR WITH RETURN or the EXEC SQL utility), distinct type (both parts of two-part name), function (both parts of two-part name), host identifier, index, JARs, parameter, procedure, role, schema, sequence, specific, statement, storage group, savepoint, SQL condition, SQL label, SQL parameter, SQL variable, synonym, table, trigger, view, XML attribute name, XML element name</td>
<td>128 bytes</td>
</tr>
<tr>
<td>Name of an authorization ID or name of a security label.</td>
<td>8 bytes</td>
</tr>
<tr>
<td>Routine version identifier</td>
<td>64 EBCDIC bytes, and the UTF-8 representation of the name must not exceed 122 bytes.</td>
</tr>
<tr>
<td>Name of a column</td>
<td>30 bytes 1</td>
</tr>
<tr>
<td>Name of cursor that is created with DECLARE CURSOR WITH RETURN</td>
<td>30 bytes</td>
</tr>
<tr>
<td>Name of cursor that is created with the EXEC SQL utility</td>
<td>8 bytes</td>
</tr>
<tr>
<td>Name of a location</td>
<td>16 bytes</td>
</tr>
<tr>
<td>Name of buffer pool name, catalog, database, plan, program, table space</td>
<td>8 bytes</td>
</tr>
<tr>
<td>Name of package</td>
<td>8 bytes (Only 8 EBCDIC characters are used for packages that are created with the BIND PACKAGE command. 128 bytes can be used for packages that are created as a result of the CREATE FUNCTION (SQL scalar) statement, the CREATE PROCEDURE (SQL - native) statement, or the CREATE TRIGGER statement.)</td>
</tr>
<tr>
<td>Name of a profile that is created with CREATE TRUSTED CONTEXT or ALTER TRUSTED CONTEXT</td>
<td>127 bytes</td>
</tr>
</tbody>
</table>

Notes:
1. If the column name length or the distinct type schema or name length is greater than 30 Unicode bytes, truncation occurs in the sqlname field of the SQLDA when those objects are described in an application.

Table 214 shows the minimum and maximum limits for numeric values.

Table 214. Numeric limits

<table>

</tr>
<tr>
<td>Largest negative DECFLOAT(16) value(^1)</td>
<td>$-1.000000000000000000000000000000000 \times 10^{383}$</td>
</tr>
<tr>
<td>Smallest DECFLOAT(34) value(^1)</td>
<td>$-9.999999999999999999999999999999999 \times 10^{6144}$</td>
</tr>
<tr>
<td>Largest DECFLOAT(34) value(^1)</td>
<td>$9.999999999999999999999999999999999 \times 10^{6144}$</td>
</tr>
<tr>
<td>Smallest positive DECFLOAT(34) value(^1)</td>
<td>$1.000000000000000000000000000000000 \times 10^{6143}$</td>
</tr>
<tr>
<td>Largest negative DECFLOAT(34) value(^1)</td>
<td>$-1.000000000000000000000000000000000 \times 10^{6143}$</td>
</tr>
<tr>
<td>Coefficient length for DECFLOAT values</td>
<td>DECFLOAT(16) is 16 digits; DECFLOAT(34) is 34 digits</td>
</tr>
<tr>
<td>Maximum Exponent ($E_{\text{max}}$) for DECFLOAT values</td>
<td>DECFLOAT(16) is 384; DECFLOAT(34) is 6144</td>
</tr>
<tr>
<td>Minimum Exponent ($E_{\text{min}}$) for DECFLOAT values</td>
<td>DECFLOAT(16) is -383; DECFLOAT(34) is -6143</td>
</tr>
<tr>
<td>Bias for DECFLOAT values</td>
<td>DECFLOAT(16) is 398; DECFLOAT(34) is 6176</td>
</tr>
</tbody>
</table>

**Note:**
1. These are the limits for normal numbers in DECFLOAT. DECFLOAT also contains special values such as NaN and Infinity that are also valid. DECFLOAT also supports subnormal numbers that are outside of the documented range.

### The following table shows the length limits for strings.

### Table 215. String length limits

<table>
<thead>
<tr>
<th>Item</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum length of CHAR</td>
<td>255 bytes</td>
</tr>
<tr>
<td>Maximum length of GRAPHIC</td>
<td>127 double-byte characters</td>
</tr>
<tr>
<td>Maximum length of BINARY</td>
<td>255 bytes</td>
</tr>
</tbody>
</table>
Table 215. String length limits (continued)

<table>
<thead>
<tr>
<th>Item</th>
<th>Limit</th>
</tr>
</thead>
</table>
| Maximum length\(^1\) of VARCHAR | • 4046 bytes for a column in a table in a table space with 4 KB pages  
  • 8128 bytes for a column in a table in a table space with 8 KB pages  
  • 16320 bytes for a column in a table in a table space with 16 KB pages  
  • 32704 bytes for a column in a table in a table space with 32 KB pages  
  Otherwise, 32704 bytes |
| Maximum length of VARCHAR that can be indexed by an XML index | 1000 bytes after conversion to UTF-8 |
| Maximum length\(^1\) of VARGRAPHIC | • 2023 double-byte characters for a column in a table in a table space with 4 KB pages  
  • 4064 double-byte characters for a column in a table in a table space with 8 KB pages  
  • 8160 double-byte characters for a column in a table in a table space with 16 KB pages  
  • 16352 double-byte characters for a column in a table in a table space with 32 KB pages  
  Otherwise, 16352 double-byte characters |
| Maximum length\(^1\) of VARBINARY | • 4046 bytes for a column in a table in a table space with 4 KB pages  
  • 8128 bytes for a column in a table in a table space with 8 KB pages  
  • 16320 bytes for a column in a table in a table space with 16 KB pages  
  • 32704 bytes for a column in a table in a table space with 32 KB pages  
  Otherwise, 32704 bytes |
| Maximum length of CLOB | 2147483647 bytes (2 GB - 1 byte) |
| Maximum length of DBCLOB | 1073741823 double-byte characters |
| Maximum length of a character constant | 32704 UTF-8 bytes |
| Maximum length of a hexadecimal character constant | 32704 hexadecimal digits |
| Maximum length of a graphic string constant | 16352 double-byte characters (32704 bytes when expressed in UTF-8) |
| Maximum length of a hexadecimal graphic string constant | 32704 hexadecimal digits |
| Maximum length of a text string used for a scalar expression | 4000 UTF-8 bytes |
| Maximum length of a concatenated character string | 2147483647 bytes (2 GB - 1 byte) |
| Maximum length of a concatenated graphic string | 1073741824 double-byte characters |
| Maximum length of a concatenated binary string | 2147483647 bytes (2 GB - 1 byte) |
| Maximum length of XML pattern text | 4000 bytes after conversion to UTF-8 |
Table 215. String length limits  (continued)

<table>
<thead>
<tr>
<th>Item</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum length of an XML element or attribute name in an XML document</td>
<td>1000 bytes</td>
</tr>
<tr>
<td>Maximum length of a namespace uri</td>
<td>1000 bytes</td>
</tr>
<tr>
<td>Maximum length of a namespace prefix</td>
<td>998 bytes</td>
</tr>
<tr>
<td>Largest depth of an internal XML tree</td>
<td>128 levels</td>
</tr>
</tbody>
</table>

Note:
1. The maximum length can be achieved only if the column is the only column in the table. Otherwise, the maximum length depends on the amount of space remaining on a page.

The following table shows the minimum and maximum limits for datetime values.

Table 216. Datetime limits

<table>
<thead>
<tr>
<th>Item</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Smallest DATE value (shown in ISO format)</td>
<td>0001-01-01</td>
</tr>
<tr>
<td>Largest DATE value (shown in ISO format)</td>
<td>9999-12-31</td>
</tr>
<tr>
<td>Smallest TIME value (shown in ISO format)</td>
<td>00.00.00</td>
</tr>
<tr>
<td>Largest TIME value (shown in ISO format)</td>
<td>24.00.00</td>
</tr>
<tr>
<td>Smallest TIMESTAMP WITHOUT TIME ZONE value</td>
<td>0001-01-01-00.00.00.0000000000000</td>
</tr>
<tr>
<td>Largest TIMESTAMP WITHOUT TIME ZONE value</td>
<td>9999-12-31-24.00.00.000000000000</td>
</tr>
<tr>
<td>Smallest TIMESTAMP WITH TIME ZONE value</td>
<td>0001-01-01-00.00.00.000000000000 +00:00</td>
</tr>
<tr>
<td>Largest TIMESTAMP WITH TIME ZONE value</td>
<td>9999-12-31-24.00.00.000000000000 +00:00 1</td>
</tr>
<tr>
<td>TIMESTAMP precision range</td>
<td>0 to 12</td>
</tr>
<tr>
<td>TIME ZONE hour range</td>
<td>-24 to 24</td>
</tr>
<tr>
<td>TIME ZONE minute range</td>
<td>0 to 59</td>
</tr>
</tbody>
</table>

Note:
1. The maximum value is stated as a UTC value. When a timestamp without a time zone is compared to a timestamp with time zone, a necessary adjustment is made using the implicit time zone. During that adjustment, the timestamp without time zone could be converted to a value that is greater than the maximum value for a timestamp with time zone value (this could occur on operations such as comparison and assignment). This situation can be avoided by using ‘9999-12-30-00.00.00.000000000000’ as the maximum value for timestamp without time zone and ‘9999-12-30-00.00.00.000000000000 +00:00’ as the maximum value for timestamp with time zone columns.

The following table shows the DB2 limits on SQL statements.

Table 217. DB2 limits on SQL statements

<table>
<thead>
<tr>
<th>Item</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of columns that are in a table or view</td>
<td>750 or fewer (including hidden columns)</td>
</tr>
<tr>
<td>(the value depends on the complexity of the CREATE VIEW statement) or columns returned by a table function.</td>
<td>749 if the table is a dependent</td>
</tr>
<tr>
<td>Approximate maximum number of base tables in a view</td>
<td>225</td>
</tr>
<tr>
<td>SELECT, UPDATE, INSERT, MERGE, or DELETE</td>
<td></td>
</tr>
<tr>
<td>Maximum number of rows that can be inserted with a single INSERT or MERGE statement</td>
<td>32767</td>
</tr>
<tr>
<td>Item</td>
<td>Limit</td>
</tr>
<tr>
<td>---------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>Maximum row and record sizes for a table</td>
<td>See the maximum record size table under CREATE TABLE.</td>
</tr>
<tr>
<td>Maximum number of volume IDs in a storage group</td>
<td>133</td>
</tr>
</tbody>
</table>
| Maximum number of partitions in a partitioned table space or partitioned index | 64 for table spaces that are not defined with LARGE or a DSSIZE greater than 2 GB.  
4096, depending on what is specified for DSSIZE or LARGE and the page size. |
| Maximum sum of the lengths of limit key values of a partition boundary | 765 UTF-8 bytes                                                        |
| Maximum size of a partition (table space or index)                 | For table spaces that are not defined with LARGE or a DSSIZE greater than 2 GB:  
4 GB, for 1 to 16 partitions  
2 GB, for 17 to 32 partitions  
1 GB, for 33 to 64 partitions  
For table spaces that are defined with LARGE or a DSSIZE of 4 GB:  
4 GB, for 1 to 4096 partitions  
For table spaces that are defined with a DSSIZE greater than 4 GB:  
256 GB, depending on the page size (for 1 to 64 partitions for 4 KB pages, for 1 to 128 partitions for 8 KB pages, for 1 to 256 partitions for 16 KB pages, and 1 to 512 partitions for 32 KB pages) |
| Maximum size of a non-partitioned index for a partitioned table space | For 5-byte EA table spaces:  
16 TB for 4 KB pages  
32 TB for 8 KB pages  
64 TB for 16 KB pages  
128 TB for 32 KB pages  
For table spaces that are defined with LARGE:  
16 TB |
| Maximum length of an index key                                      | Partitioning index: 255-n  
Nonpartitioning index that is padded: 2000-n  
Nonpartitioning index that is not padded: 2000-n-2m  
Where n is the number of columns in the key that allow nulls and m is the number of varying-length columns in the key |
| Maximum number of bytes used in the partitioning of a partitioned index | 255 (This maximum limit is subject to additional limitations, depending on the number of partitions in the table space. The number of partitions * (106 + limit key size) must be less than 65394.) |
| Maximum number of columns in an index key                           | 64                                                                   |
| Maximum number of expressions in an index key                       | 64                                                                   |
| Maximum number of tables in a FROM clause                          | 225 or fewer, depending on the complexity of the statement           |
| Maximum number of subqueries in a statement                         | 224                                                                  |
### Table 217. DB2 limits on SQL statements (continued)

<table>
<thead>
<tr>
<th>Item</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum total length of host and indicator variables pointed to in an SQLDA</td>
<td>32767 bytes</td>
</tr>
<tr>
<td></td>
<td>2147483647 bytes (2 GB - 1 byte) for a LOB, subject to the limitations that are imposed by the application environment and host language</td>
</tr>
<tr>
<td>Maximum size of application SQLDA for any statement that references host variables or parameter markers</td>
<td>99016 bytes</td>
</tr>
<tr>
<td>Maximum length of host variable used for insert or update operation</td>
<td>32704 bytes for a non-LOB</td>
</tr>
<tr>
<td></td>
<td>2147483647 bytes (2 GB - 1 byte) for a LOB, subject to the limitations that are imposed by the application environment and host language</td>
</tr>
<tr>
<td>Maximum number of host variables or parameter markers in a statement</td>
<td>16,000</td>
</tr>
<tr>
<td>Maximum length of an SQL statement</td>
<td>2097152 bytes</td>
</tr>
<tr>
<td>Maximum number of elements in a select list</td>
<td>750 or fewer, depending on whether the select list is for the result table of static scrollable cursor¹</td>
</tr>
<tr>
<td>Maximum number of predicates in a WHERE or HAVING clause</td>
<td>Limited by storage</td>
</tr>
<tr>
<td>Maximum total length of columns of a query operation requiring sort and evaluating column functions (MULTIPLE DISTINCT and GROUP BY)</td>
<td>65529 bytes</td>
</tr>
<tr>
<td>Maximum length of a sort key</td>
<td>32707 bytes</td>
</tr>
<tr>
<td>Maximum length of a check constraint</td>
<td>3800 bytes</td>
</tr>
<tr>
<td>Maximum number of bytes that can be passed in a single parameter of an SQL CALL statement</td>
<td>32765 bytes for a non-LOB</td>
</tr>
<tr>
<td></td>
<td>2147483647 bytes (2 GB - 1 byte) for a LOB, subject to the limitations imposed by the application environment and host language</td>
</tr>
<tr>
<td>Maximum number of stored procedures, triggers, and user-defined functions that an SQL statement can implicitly or explicitly reference</td>
<td>64 nesting levels</td>
</tr>
<tr>
<td>Maximum length of the SQL path</td>
<td>2048 bytes</td>
</tr>
<tr>
<td>Maximum length of a WLM environment name in a CREATE PROCEDURE, CREATE FUNCTION, ALTER PROCEDURE, or ALTER FUNCTION statement.</td>
<td>32 bytes</td>
</tr>
<tr>
<td>Maximum number of XPath level in the XMLPATTERN clause of the CREATE INDEX statement.</td>
<td>50 nesting levels</td>
</tr>
</tbody>
</table>

**Note:**

1. If the scrollable cursor is read-only, the maximum number is 749 less the number of columns in the ORDER BY that are not in the select list. If the scrollable cursor is not read-only, the maximum number is 747.

---

The following table shows the DB2 system limits.

### Table 218. DB2 system limits

<table>
<thead>
<tr>
<th>Item</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of concurrent DB2 or application agents</td>
<td>Limited by the EDM pool size, buffer pool size, and the amount of storage that is used by each DB2 or application agent</td>
</tr>
</tbody>
</table>
Table 218. DB2 system limits (continued)

<table>
<thead>
<tr>
<th>Item</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of concurrently active audit policies</td>
<td>32</td>
</tr>
<tr>
<td>Maximum size of a non-LOB table or table space</td>
<td>128 terabytes (TB)</td>
</tr>
<tr>
<td>Maximum size of a simple or segmented table space</td>
<td>64 GB</td>
</tr>
<tr>
<td>Maximum size of a log space</td>
<td>$2^{64}$ bytes</td>
</tr>
<tr>
<td>Maximum size of an active log data set</td>
<td>4 GB minus 1 byte</td>
</tr>
<tr>
<td>Maximum size of an archive log data set</td>
<td>4 GB minus 1 byte</td>
</tr>
<tr>
<td>Maximum number of active log copies</td>
<td>2</td>
</tr>
<tr>
<td>Maximum number of archive log copies</td>
<td>2</td>
</tr>
<tr>
<td>Maximum number of active log data sets (each copy)</td>
<td>93</td>
</tr>
<tr>
<td>Maximum number of archive log volumes (each copy)</td>
<td>10000</td>
</tr>
<tr>
<td>Maximum number of databases accessible to an application or user</td>
<td>Limited by system storage and EDM pool size</td>
</tr>
<tr>
<td>Maximum number of databases</td>
<td>65217</td>
</tr>
<tr>
<td>Maximum number of implicitly created databases</td>
<td>Maximum value of the sequence SYSIBM.DSNSEQ_IMPLICITDB, with a default of 10000</td>
</tr>
<tr>
<td>Maximum number of internal objects for each database ¹</td>
<td>32767</td>
</tr>
<tr>
<td>Maximum number of indexes on declared global temporary tables</td>
<td>10000</td>
</tr>
<tr>
<td>Maximum size of an EDM pool</td>
<td>The installation parameter maximum depends on available space</td>
</tr>
<tr>
<td>Maximum number of rows per page</td>
<td>255 for all table spaces except catalog and directory tables spaces, which have a maximum of 127</td>
</tr>
<tr>
<td>Maximum simple or segmented data set size</td>
<td>2 GB</td>
</tr>
<tr>
<td>Maximum partitioned data set size</td>
<td>See item “maximum size of a partition” in Table 217 on page 2325</td>
</tr>
<tr>
<td>Maximum LOB data set size</td>
<td>256 GB</td>
</tr>
<tr>
<td>Maximum number of table spaces that can be defined in a work file database</td>
<td>500</td>
</tr>
<tr>
<td>Maximum number of tables and triggers that can be defined in a work file database</td>
<td>11767</td>
</tr>
</tbody>
</table>

Note:

1. The number of internal object descriptors (OBDs) for external objects are as follows:
   - Table space: 2
   - Table: 1
   - Index: 2
   - Check constraint: 1
   - Referential integrity relationship: 2
   - Auxiliary relationship for each LOB column: 1
   - XML relationship for each XML column: 1
   - Trigger: 1
   - View that has an INSTEAD OF trigger: 1
Reserved schema names and reserved words

Restrictions exist on the use of certain names that are used by DB2. In some cases, names are reserved and cannot be used by application programs. In other cases, certain names are not recommended for use by application programs though not prevented by the database manager.
Reserved schema names

In general, for certain objects, schema names that begin with the prefix SYS are reserved. The schema name for these objects cannot begin with SYS except for certain exceptions.

The schema name for the objects listed in the following table must follow the restrictions listed in the table.

**Recommendation:** Do not to use SESSION as a schema name.

*Table 219. Objects with schema name restrictions and exceptions.*

<table>
<thead>
<tr>
<th>Object</th>
<th>Schema name restriction</th>
<th>Schema name exceptions</th>
</tr>
</thead>
</table>
| Distinct types      | Cannot begin with SYS   | The schema name can be:
|                     |                         | • SYSADM
|                     |                         | • SYSTOOLS<sup>1</sup>                                      |
| User-defined functions | Cannot begin with SYS   | The schema name can be:
|                     |                         | • SYSADM
|                     |                         | • SYSTOOLS<sup>1</sup>
|                     |                         | • SYSFUN<sup>2</sup>                                       |
| Stored procedures   | Cannot begin with SYS   | The schema name can be:
|                     |                         | • SYSADM
|                     |                         | • SYSFUN<sup>2</sup>
|                     |                         | • SYSIBM
|                     |                         | • SYSPROC
|                     |                         | • SYSTOOLS<sup>1</sup>                                    |
| Sequences           | Cannot begin with SYS   | The schema name can be:
|                     |                         | • SYSADM                                                   |
| Triggers            | Cannot begin with SYS   | The schema name can be:
|                     |                         | • SYSADM
|                     |                         | • SYSTOOLS<sup>1</sup>                                    |
| Column masks        | Cannot begin with SYS   | The schema name can be:
|                     |                         | • SYSADM                                                   |
| Row permissions     | Cannot begin with SYS   | The schema name can be:
|                     |                         | • SYSADM                                                   |

**Notes:**
1. If the user who executes the CREATE statement has the SYSADM or SYSCtrl privilege.
2. For external user-defined scalar functions or external user-defined table functions if the user who executes the CREATE statement has the SYSADM or SYSCtrl privilege.
Reserved words

Certain words cannot be used as ordinary identifiers in some contexts because those words might be interpreted as SQL keywords. For example, ALL cannot be a column name in a SELECT statement. Each word, however, can be used as a delimited identifier in contexts where it otherwise cannot be used as an ordinary identifier. For example, if the quotation mark (”) is the escape character that begins and ends delimited identifiers, “ALL” can appear as a column name in a SELECT statement.

Certain keywords might be interpreted as ordinary identifiers in some contexts rather than as keywords. For example, in the statement SELECT * FROM SYSIBM.SYSTABLES WHERE, WHERE is interpreted as an ordinary identifier specified as a correlation name, rather than as the beginning of an incomplete WHERE clause.

New reserved words for this version of DB2 for z/OS are identified with notes in this topic. In addition, some topics in this information might indicate words that cannot be used in the specific context that is being described.

IBM SQL has additional reserved words that DB2 for z/OS does not enforce. Therefore, you should not use these additional reserved words as ordinary identifiers in names that have a continuing use. See IBM DB2 SQL Reference for Cross-Platform Development for a list of the words.

Characteristics of SQL statements in DB2 for z/OS

DB2 allows specific actions on each SQL statement, and only certain SQL statements are allowed in external routines and SQL procedures.
Actions allowed on SQL statements

Specific DB2 statements can be executed, prepared interactively or dynamically, or processed by the requester, the server, or the precompiler or coprocessor.

The following table shows whether a specific DB2 statement can be executed, prepared interactively or dynamically, or processed by the requester, the server, or the precompiler or coprocessor. The letter Y means yes.

<table>

**Note:**

1. The statement can be dynamically prepared. It cannot be issued dynamically.
2. The statement can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.
3. The statement can be dynamically prepared, but only from an ODBC or CLI driver that supports dynamic CALL statements.
4. The requesting system processes the PREPARE statement when the statement being prepared is ALLOCATE CURSOR or ASSOCIATE LOCATORS.
5. The value to which special register CURRENT SQLID is set is used as the SQL authorization ID for dynamic SQL statements only when DYNAMICRULES run behavior is in effect. The CURRENT SQLID value is ignored for the other DYNAMICRULES behaviors.
6. This statement can be used only in the triggered action of a trigger.
7. Local special registers can be referenced in a VALUES INTO statement if it results in the assignment of a single host-variable, not if it results in setting more than one value.
8. Some processing also occurs at the requester.
SQL statement data access classification for routines

Certain SQL statements can be executed in a stored procedure or in a user-defined function. Whether the statements can be executed depends on the level of SQL data access with which the routine is defined.

The following table indicates whether an SQL statement (specified in the first column) is allowed to execute in a routine with the specified SQL data access classification. The letter Y means yes.

In general, if an executable SQL statement is encountered in a routine defined as NO SQL, SQLSTATE 38001 is returned. If the routine is defined to allow some level of SQL access, SQL statements that are not supported in any context return SQLSTATE 38003. SQL statements not allowed for routines defined as CONTAINS SQL return SQLSTATE 38004, and SQL statements not allowed for READS SQL DATA return SQLSTATE 38002.

Table 221. SQL data access classification for routines (continued)
Table 221. SQL data access classification for routines (continued)

<table>
<thead>
<tr>
<th>SQL statement</th>
<th>Level of SQL data access</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NO SQL</td>
</tr>
</tbody>
</table>

Notes:

1. Although the SQL option implies that no SQL statements can be specified, non-executable statements are not restricted.
2. The stored procedure that is called must have the same or more restrictive level of SQL data access than the current level in effect. For example, a routine defined as MODIFIES SQI L DATA can call a stored procedure defined as MODIFIES SQL DATA, READS SQL DATA, CONTAINS SQL, or NO SQL. A routine defined as CONTAINS SQL can call a procedure defined as CONTAINS SQL or NO SQL.
3. The statement specified for the EXECUTE statement must be a statement that is allowed for the particular level of SQL data access in effect. For example, if the level in effect is READS SQL DATA, the statement must not be an INSERT, UPDATE, MERGE, or DELETE statement.
4. The statement is supported only if it does not contain a subquery or query-expression.

SQL control statements for external SQL procedures

SQL control statements for external SQL procedures can be used only with SQL procedures that are created with the FENCED or EXTERNAL clause. SQL control statements provide the capability to control the logic flow, declare and set variables, and handle warnings and exceptions. Some SQL control statements include other nested SQL statements.

SQL-control-statement:

Control statements are supported in SQL procedures. External SQL procedures are created by specifying either FENCED or EXTERNAL, LANGUAGE SQL, and an SQL routine body on the CREATE PROCEDURE (SQL - external) statement. The SQL routine body must be a single SQL statement which may be an SQL control statement.

The remainder of this chapter contains a description of the control statements that are supported for external SQL procedures, and includes syntax diagrams, semantic descriptions, usage notes, and examples of the use of the statements that
constitute the SQL routine body. In addition, you can find information about referencing SQL parameters and variables in References to SQL parameters and SQL variables.

The two common elements that are used in describing specific SQL control statements are:
- SQL control statements as described above
- SQL-procedure-statement

References to SQL parameters and SQL variables
SQL parameters and SQL variables can be referenced anywhere in the statement where an expression or a host variable can be specified. Host variables can be specified in SQL routines. SQL parameters and SQL variables can be referenced anywhere in the compound statement in which they are declared and can be qualified with the label name that is specified at the beginning of the compound statement.

All SQL parameters and SQL variables are considered nullable. The name of an SQL parameter or SQL variable in an SQL routine can be the same as the name of a column in a table or view that the SQL routine references. Names that are the same should be explicitly qualified. Qualifying a name clearly indicates whether the name refers to a column, SQL variable, or SQL parameter.

If the name is not qualified, the following rules describe whether the name refers to the column, the SQL variable, or the SQL parameter:
- The name is checked first as an SQL variable name and then as an SQL parameter name.
- If an SQL variable or SQL parameter by that name is not found, the name is assumed to be a column name.

The name of an SQL variable or SQL parameter in an SQL routine can be the name of an identifier that is used in certain SQL statements. If the name is not qualified, the following rules describe whether the name refers to the identifier, the SQL variable, or the SQL parameter:
- In the SET PATH and SET SCHEMA statements, the name is checked as an SQL variable name or an SQL parameter name. If an SQL variable or SQL parameter by that name is not found, the name is assumed to be an identifier.
- In the ASSOCIATE LOCATORS, CONNECT statement, the SET CONNECTION statement, and the RELEASE (connection) statement the name is used as an identifier.
SQL-procedure-statement

An SQL control statement may allow multiple SQL statements to be specified within the SQL control statement. These statements are defined as SQL procedure statements.

Syntax

```
SQL-label: SQL-control-statement SQL-statement
```

Description

*SQL-label*

Specifies a label for the statement. *SQL-label* must not be a delimited identifier that includes lowercase letters or special characters. The label must be unique within the procedure.

*SQL-control-statement*

Specifies an SQL statement that provides the capability to control logic flow, declare and set variables, and handle warnings and exceptions, as defined in this section. Control statements are supported in SQL procedures.

*SQL-statement*

Specifies an SQL statement. These statements are described in Statements.

Notes

*Comments*: Comments can be included within the body of an SQL procedure. In addition to the double-dash form of comments (--), a comment can begin with /* and end with */. The following rules apply to this form of comment:

- The beginning characters /* must be adjacent and on the same line.
- The ending characters */ must be adjacent and on the same line.
- Comments can be started wherever a space is valid.
- Comments can be continued to the next line.

*Handling errors and warnings*: Conditions can be detected within an SQL procedure by using the following methods:

- Test the special SQL variables SQLSTATE and SQLCODE.
- Issue a GET DIAGNOSTICS statement to request the condition information. See GET DIAGNOSTICS.
- Define condition handlers to detect and process conditions. See compound-statement for information about defining condition handlers.
assignment-statement (SQL control statements for external routines)

The assignment statement assigns a value to an SQL parameter or to an SQL variable.

Syntax

```
SET SQL-parameter-name = CURRENT SERVER SQL-variable-name
CURRENT PACKAGESET CURRENT PACKAGE PATH
expression
NULL
```

Description

**SQL-parameter-name**

Identifies the parameter that is the assignment target. The parameter must be specified in `parameter-declaration` in the `CREATE PROCEDURE` statement and must be defined as OUT or INOUT.

**SQL-variable-name**

Identifies the SQL variable that is the assignment target. SQL variables can be declared in a `compound-statement` and must be declared before it is used. For information on declaring SQL variables, see `compound-statement`.

**expression or NULL**

Specifies the expression or value that is the assignment source. The expression can be any expression of the type described in `Expressions` except it cannot contain a reference to local special registers (CURRENT SERVER, CURRENT PACKAGESET, or CURRENT PACKAGE PATH).

Notes

**Assignment rules**: Assignment statements in SQL procedures must conform to the SQL assignment rules. For example, the data type of the target and source must be compatible. See `Assignment and comparison` for assignment rules.

When a string is assigned to a fixed-length variable and the length of the string is less than the length attribute of the target, the string is padded on the right with the necessary number of single-byte or double-byte blanks. When a string is assigned to a variable and the string is longer than the length attribute of the variable, the value is truncated and a warning is returned.

The ENCODING bind option is not used during processing of assignments to string variables. For example, assume that the system does not use mixed or DBCS, and the system EBCDIC SBCS CCSID is 37. Character conversion will not occur on assignment even if CCSID 500 is specified for the ENCODING bind parameter for the package for the procedure.

If truncation of the whole part of a number occurs on assignment to a numeric variable, the value is truncated and a warning is returned.

**Assignments involving SQL parameters:**
• An IN parameter can appear on the left side of an assignment statement. When control returns to the caller, the original value of an IN parameter is passed to the caller.

• An OUT parameter can appear on the left or right side of an assignment statement. When control returns to the caller, the last value that is assigned to an OUT parameter is returned to the caller.

• An INOUT parameter can appear on the left or right side of an assignment statement. The first value of the parameter is determined by the caller, and the last value that is assigned to the parameter is returned to the caller.

• A LOB parameter can not be used as an output value in an SQL statement in an SQL procedure when connected to a remote site. To circumvent the restriction, use a LOB SQL variable instead of a LOB parameter.

**Considerations for SQLSTATE and SQLCODE SQL variables:** Assignment to these variables is not prohibited. However, it is not recommended as assignment does not affect the diagnostic area or result in the activation of condition handlers. Furthermore, processing an assignment to these SQL variables causes the specified values for the assignment to be overlayed with the SQL return codes returned from executing the statement that does the assignment.

**Examples**

Increase the SQL variable `p_salary` by 10 percent.

```sql
SET p_salary = p_salary + (p_salary * .10)
```

Set SQL variable `p_salary` to the null value.

```sql
SET p_salary = NULL
```

Set SQL variable `midinit` to the first character of SQL variable `midname`.

```sql
SET midinit = SUBSTR(midname,1,1)
```
CALL statement

The CALL statement invokes a stored procedure.

Syntax

```
CALL procedure-name argument-list
```
The following additional rules apply depending on how the corresponding parameter was defined in the CREATE PROCEDURE statement for the procedure:

- IN expression can contain references to multiple SQL parameters or variables. In addition to the rules stated in [Expressions for expression], expression cannot include a column name, an aggregate function, or a user-defined function that is sourced on an aggregate function.
- INOUT or OUT expression can only be a single SQL parameter or variable.

**NULL**

The parameter is a null value. The corresponding parameter of the procedure must be defined as IN and the description of the procedure must allow for null parameters.

**Notes**

See [CALL] for more information on the SQL CALL statement.

**Examples**

Call stored procedure procl and pass SQL variables as parameters.

```
CALL procl(v_empno, v_salary)
```
**CASE statement**

The CASE statement selects an execution path based on the evaluation of one or more conditions. A CASE statement operates in the same way as a CASE expression.

**Syntax**

```
CASE simple-when-clause
  searched-when-clause
    ELSE SQL-procedure-statement;
END CASE
```

**Description**

**CASE**

Begins a case-expression.

**simple-when-clause**

Specifies the expression prior to the first WHEN keyword that is tested for equality with the value of each expression that follows the WHEN keyword, and the result to be executed when those expressions are equal. If the comparison is true, the THEN statement is executed. If the result is unknown or false, processing continues to the next expression or the ELSE statement.

The data type of the expression prior to the first WHEN keyword must be comparable to the data types of each expression that follows the WHEN keywords.

**searched-when-clause**

Specifies the search-condition that is applied to each row or group of table data presented for evaluation, and the result when that condition is true. search-condition cannot contain a fullselect. If the search condition is true, the
THEN statement is executed. If the condition is unknown or false, processing continues to the next search condition or the ELSE statement.

**SQL-procedure-statement**

Specifies a statement that follows the THEN and ELSE keyword. The statement specifies the result of a searched-when-clause or a simple-when-clause that is true, or the result if no case is true. The statement must be one of the statements listed under SQL-procedure-statement.

**search-condition**

Specifies a condition that is true, false, or unknown about a row or group of table data.

**ELSE SQL-procedure-statement**

If none of the conditions specified in the simple-when-clause or searched-when-clause are true, the statements in the else-clause are executed.

If none of the conditions specified in the WHEN clause are true and an ELSE clause is not specified, an error is returned at run time, and the execution of the CASE statement is terminated.

**END CASE**

Ends a case-statement.

**Notes**

If none of the conditions specified in the WHEN clause are true and an ELSE clause is not specified, an error is returned at run time, and the execution of the CASE statement is terminated.

CASE statements that use a simple case statement WHEN clause can be nested up to three levels. CASE statements that use a searched statement WHEN clause have no limit to the number of nesting levels.

**Considerations for the SQLSTATE and SQLCODE SQL variables**

When the first SQL-procedure-statement in the CASE statement is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the expression or search conditions of that CASE statement. If a CASE statement does not include an ELSE clause and none of the search conditions evaluate to true, an error is returned.

**Examples**

*Example 1*: Use a simple case statement WHEN clause to update column DEPTNAME in table DEPT, depending on the value of SQL variable v_workdept.

```sql
CASE v_workdept
  WHEN 'A00'
    THEN UPDATE DEPT SET DEPTNAME = 'DATA ACCESS 1';
  WHEN 'B01'
    THEN UPDATE DEPT SET DEPTNAME = 'DATA ACCESS 2';
  ELSE UPDATE DEPT SET DEPTNAME = 'DATA ACCESS 3';
END CASE
```

*Example 2*: Use a searched case statement WHEN clause to update column DEPTNAME in table DEPT, depending on the value of SQL variable v_workdept.

```sql
CASE
  WHEN v_workdept < 'B01'
    THEN UPDATE DEPT SET
```
DEPTNAME = 'DATA ACCESS 1';
WHEN v_workdept < 'C01'
    THEN UPDATE DEPT SET
        DEPTNAME = 'DATA ACCESS 2';
ELSE UPDATE DEPT SET
    DEPTNAME = 'DATA ACCESS 3';
END CASE
**compound-statement**

A compound statement contains a group of statements and declarations for SQL variables, cursors, and condition handlers.

**Syntax**

![Diagram of compound statement syntax]

**Notes:**

1. Only one label: can be specified for each `SQL-procedure-statement`. If an ending label is specified for this beginning label, the labels must be the same.

**SQL-variable-declaration:**

![Diagram of SQL-variable-declaration]

**SQL-condition-declaration:**

![Diagram of SQL-condition-declaration]

**return-codes-declaration:**

![Diagram of return-codes-declaration]
handler-declaration:

```
DECLARE CONTINUE HANDLER FOR specific-condition-value SQL-procedure-statement
```

specific-condition-value:

```
SQLSTATE VALUE string-constant
```

general-condition-value:

```
SQLWARNING NOT FOUND
```

### Description

**label**

Defines the label for the code block. If the beginning label is specified, it can be used to qualify SQL variables declared in the compound statement and can also be specified on a LEAVE statement. If the ending label is specified, it must be the same as the beginning label.

**NOT ATOMIC**

NOT ATOMIC indicates that an error within the compound statement does not cause the compound statement to be rolled back.

**SQL-variable-declaration**

Declares a variable that is local to the compound statement.

**SQL-variable-name**

A qualified or unqualified name that designates a variable in an SQL procedure body. The unqualified form of SQL-variable-name is an SQL identifier and must not be a delimited identifier that contains lowercase letters or special characters. The qualified form is an SQL procedure statement label followed by a period (.) and an SQL identifier.
DB2 folds all SBCS SQL variable names to uppercase. SQL variable names should not be the same as column names. If an SQL statement contains an SQL variable or parameter and a column reference with the same name, DB2 interprets the name as an SQL variable or parameter name. To refer to the column, qualify the column name with the table name. Further, to avoid ambiguous variable references and to ensure compatibility with other DB2 platforms, qualify the SQL variable or parameter name with the label of the SQL procedure statement.

**data-type**
Specifies the data type and length of the variable. SQL variables follow the same rules for default lengths and maximum lengths as SQL procedure parameters. See [CREATE PROCEDURE (SQL - external)] for a description of SQL data types and lengths.

**DEFAULT constant or NULL**
Defines the default for the SQL variable. The variable is initialized when the SQL procedure is called. If a default value is not specified, the variable is initialized to NULL.

**RESULT_SET_LOCATOR VARYING**
Specifies the data type for a result set locator variable.

**SQL-condition-declaration**
Declares a condition name and corresponding SQLSTATE value.

**SQL-condition-name**
Specifies the name of the condition. The condition name is an SQL identifier and must not be a delimited identifier that includes lowercase letters or special characters. SQL-condition-name must be unique within the procedure body and can be referenced only within the compound statement in which it is declared.

**FOR SQLSTATE string-constant**
Specifies the SQLSTATE that is associated with the condition. The string must be specified as five characters enclosed in single quotes, and cannot be '00000'.

**return-codes-declaration**
Declares special variables called SQLSTATE and SQLCODE that are set automatically to the value returned after processing an SQL statement. Both the SQLSTATE and SQLCODE variables can be declared only in the outermost compound statement of the SQL procedure. Assignment to these variables is not prohibited; however, assignment is ignored by exception handlers, and processing the next SQL statement replaces the assigned value.

**DECLARE-CURSOR-statement**
Declares a cursor. Each cursor in the procedure body must have a unique name. An OPEN statement must be specified to open the cursor, and a FETCH statement can be specified to read rows. The cursor can be referenced only from within the compound statement. For more information on declaring a cursor, see [DECLARE CURSOR].

**handler-declaration**
Specifies a set of statements to execute when an exception or completion condition occurs in the compound statement. SQL-procedure-statement is the set of statements that execute when the handler receives control. See [SQL-procedure-statement] for information on SQL-procedure-statement.

A handler is active only within the compound statement in which it is declared.
The actions that a handler can perform are:

**CONTINUE**
Specifies that after the condition handler is activated and completes successfully, control is returned to the SQL statement that follows the statement that raised the condition. However, if the condition is an error condition and it was encountered while evaluating a search condition, as in a CASE, IF, REPEAT or WHILE statement, control returns to the statement that follows the corresponding END CASE, END IF, END REPEAT, or END WHILE.

**EXIT**
After the handler is invoked successfully, control is returned to the end of the compound statement.

The conditions that can cause the handler to gain control are:

**SQLSTATE** `string-constant`
Specifies an SQLSTATE for which the handler is invoked. The SQLSTATE cannot be '00000'.

**SQL-condition-name**
Specifies a condition name for which the handler is invoked. The condition name must be previously defined in a condition declaration.

**SQLEXCEPTION**
Specifies that the handler is invoked when an SQLEXCEPTION occurs. An SQLEXCEPTION is an SQLSTATE in which the class code is a value other than '00', '01', or '02'. For more information on SQLSTATE values, see DB2 Codes.

**SQLWARNING**
Specifies that the handler is invoked when an SQLWARNING occurs. An SQLWARNING is an SQLSTATE value with a class code of '01'.

**NOT FOUND**
Specifies that the handler is invoked when a NOT FOUND condition occurs. NOT FOUND corresponds to an SQLSTATE value with a class code of '02'.

**Notes**

The order of statements in a compound statement must be:
1. SQL variable, condition declarations, and return codes declarations
2. Cursor declarations
3. Handler declarations
4. SQL procedure statements

Compound statements cannot be nested.

Unlike host variables, SQL variables are not preceded by colons when they are used in SQL statements.

The following rules apply to handlers:
- A handler declaration that contains SQLEXCEPTION, SQLWARNING, or NOT FOUND cannot contain additional SQLSTATE or condition names.
- Handler declarations within the same compound statement cannot contain duplicate conditions.
• A handler declaration cannot contain the same condition code or SQLSTATE value more than once, and cannot contain an SQLSTATE value and a condition name that represent the same SQLSTATE value.

• A handler is activated when it is the most appropriate handler for an exception or completion condition.

• If there is no handler for an SQL error, the error is passed to the caller in the SQLCA.

• A handler cannot be activated by an assignment statement that assigns a value to SQLSTATE.

The following rules and recommendations apply to the SQLCODE and SQLSTATE SQL variables:

• A null value cannot be assigned to SQLSTATE or SQLCODE.

• The SQLSTATE and SQLCODE variable values should be saved immediately to temporary variables if there is any intention to use the values. If a handler exists for SQLSTATE, this assignment must be done as the first statement to be processed in the handler to avoid having the value replaced by the next SQL procedure statement. If the condition raised by the SQL statement is handled, the value is changed by the first SQL statement contained in the handler.

Considerations for the SQLSTATE and SQLCODE SQL variables: The compound statement itself does not affect the SQLSTATE and SQLCODE SQL variables. However, SQL statements contained within the compound statement can affect the SQLSTATE and SQLCODE SQL variables. At the end of the compound statement, the SQLSTATE and SQLCODE SQL variables reflect the result of the last SQL statement executed within the compound statement that caused a change to the SQLSTATE and SQLCODE SQL variables. If the SQLSTATE and SQLCODE SQL variables were not changed within the compound statement, they contain the same values as when the compound statement was entered.

Examples

Create a procedure body with a compound statement that performs the following actions:

• Declares SQL variables, a condition for SQLSTATE '02000', a handler for the condition, and a cursor

• Opens the cursor, fetches a row, and closes the cursor

CREATE PROCEDURE PROC1(OUT NOROWS INT) LANGUAGE SQL BEGIN
DECLARE v_firstnme VARCHAR(12);
DECLARE v_midinit CHAR(1);
DECLARE v_lastname VARCHAR(15);
DECLARE v_edlevel SMALLINT;
DECLARE v_salary DECIMAL(9,2);
DECLARE at_end INT DEFAULT 0;
DECLARE not_found CONDITION FOR '02000';
DECLARE c1 CURSOR FOR
SELECT FIRSTNME, MIDINIT, LASTNAME, EDLEVEL, SALARY
FROM EMP;
DECLARE CONTINUE HANDLER FOR not_found SET NOROWS=1;
OPEN c1;
FETCH c1 INTO v_firstnme, v_midinit,
v_lastname, v_edlevel, v_salary;
END
GET DIAGNOSTICS statement

The GET DIAGNOSTICS statement obtains information about the previous SQL statement that was executed.

See GET DIAGNOSTICS

When you need to specify a variable in a GET DIAGNOSTICS statement that is used within an SQL procedure, you would use either SQL-variable-name or SQL-parameter-name. In an embedded GET DIAGNOSTICS statement, you would use a host-variable. You can replace the instances of host-variable in the description of GET DIAGNOSTICS with SQL-variable-name or SQL-parameter-name.
GOTO statement
The GOTO statement is used to branch to a user-defined label within an SQL procedure.

Syntax

```
GOTO label
```

Description

`label`

Specifies a labeled statement at which processing is to continue.

The labeled statement and the GOTO statement must be in the same scope. The following rules apply to the scope:

- If the GOTO statement is defined in a compound statement, `label` must be defined inside the same compound statement.
- If the GOTO statement is defined in a handler, `label` must be defined in the same handler and follow the other scope rules.
- If the GOTO statement is defined outside of a handler, `label` must not be defined within a handler.

If `label` is not defined within a scope that the GOTO statement can reach, an error is returned.

A label name cannot be the same as the name of the SQL procedure in which the label is used.

Notes

Use the GOTO statement sparingly. Because the GOTO statement interferes with the normal sequence of processing, it makes an SQL procedure more difficult to read and maintain. Before using a GOTO statement, determine whether some other statement, such as an IF statement or LEAVE statement, can be used instead.

Examples

Use a GOTO statement to transfer control to the end of a compound statement if the value of an SQL variable is less than 600.

```
BEGIN
  DECLARE new_salary DECIMAL(9,2);
  DECLARE service DECIMAL(8,2);
  SELECT SALARY, CURRENT_DATE - HIREDATE
  INTO new_salary, service
  FROM EMP
  WHERE EMPNO = v_empno;
  IF service < 600
    THEN GOTO EXIT;
  END IF;
  IF rating = 1
    THEN SET new_salary =
        new_salary + (new_salary *.10);
  ELSEIF rating = 2
    THEN SET new_salary =
        new_salary + (new_salary *.05);
```
END IF;
UPDATE EMP
SET SALARY = new_salary
WHERE EMPNO = v_empno;
EXIT: SET return_parm = service;
END
IF statement

The IF statement selects an execution path based on the evaluation of a condition.

Syntax

```
IF search-condition
THEN
   SQL-procedure-statement;
ELSEIF search-condition
THEN
   SQL-procedure-statement;
ELSE
   SQL-procedure-statement;
END IF
```

Description

**search-condition**

Specifies the condition for which an SQL statement should be invoked. If the condition is unknown or false, processing continues to the next search condition until either a condition is true or processing reaches the ELSE clause.

**SQL-procedure-statement**

Specifies the statement to be invoked if the preceding search-condition is true. If no search-condition evaluates to true, then the SQL-procedure-statement following the ELSE keyword is invoked. The statement must be one of the statements listed under [SQL-procedure-statement](#).

Notes

**Considerations for the SQLSTATE and SQLCODE SQL variables:** When the first SQL-procedure-statement in the IF statement is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the search conditions of that IF statement. If an IF statement does not include an ELSE clause and none of the search conditions evaluate to true, then when the statement that follows that IF statement is executed, the SQLSTATE and SQLCODE SQL variables reflect the result of evaluating the search conditions of that IF statement.

Examples

Assign a value to the SQL variable `new_salary` based on the value of SQL variable rating.

```
IF rating = 1
    THEN SET new_salary =
        new_salary + (new_salary * .10);
ELSEIF rating = 2
```

```
THEN SET new_salary =
    new_salary + (new_salary * .05);
ELSE SET new_salary =
    new_salary + (new_salary * .02);
END IF
ITERATE statement

The ITERATE statement causes the flow of control to return to the beginning of a labeled loop.

Syntax

```
ITERATE label
```

Description

`label`

Specifies the label of the LOOP, REPEAT, or WHILE statement to which the flow of control is passed.

Examples

This example uses a cursor to return information for a new department. If the not_found condition handler is invoked, the flow of control passes out of the loop. If the value of `v_dept` is 'D11', an ITERATE statement causes the flow of control to be passed back to the top of the LOOP statement. Otherwise, a new row is inserted into the table.

```
CREATE PROCEDURE ITERATOR ()
    LANGUAGE SQL
    MODIFIES SQL DATA
    BEGIN
        DECLARE v_dept CHAR(3);
        DECLARE v_deptname VARCHAR(29);
        DECLARE v_admdept CHAR(3);
        DECLARE at_end INTEGER DEFAULT 0;
        DECLARE not_found CONDITION FOR SQLSTATE '02000';
        DECLARE c1 CURSOR FOR
            SELECT deptno,deptname,admrdept
            FROM department
            ORDER BY deptno;
        DECLARE CONTINUE HANDLER FOR not_found
            SET at_end = 1;
        OPEN c1;
        ins_loop:
        LOOP
            FETCH c1 INTO v_dept, v_deptname, v_admdept;
            IF at_end = 1 THEN
                LEAVE ins_loop;
            ELSEIF v_dept = 'D11' THEN
                ITERATE ins_loop;
            END IF;
            INSERT INTO department (deptno,deptname,admrdept)
            VALUES('NEW', v_deptname, v_admdept);
        END LOOP;
        CLOSE c1;
    END
```
LEAVE statement

The LEAVE statement transfers program control out of a loop or a compound statement.

Syntax

```
LEAVE label
```

Description

`label`

Specifies the label of the compound statement or loop to exit.

A label name cannot be the same as the name of the SQL procedure in which the label is used.

Notes

When a LEAVE statement transfers control out of a compound statement, all open cursors in the compound statement, except cursors that are used to return result sets, are closed.

Examples

Use a LEAVE statement to transfer control out of a LOOP statement when a negative SQLCODE occurs.

```
ftch_loop: LOOP
  FETCH c1 INTO v_firstnme, v_midinit,
  v_lastname, v_edlevel, v_salary;
  IF SQLCODE=100 THEN LEAVE ftch_loop;
  END IF;
END LOOP
```
**LOOP statement**

The LOOP statement executes a statement or group of statements multiple times.

**Syntax**

```
(1) label: LOOP SQL-procedure-statement ; END LOOP label
```

**Notes:**

1. Only one *label* can be specified for each *SQL-procedure-statement*.

**Description**

*label*

Specifies the label for the LOOP statement. If the ending label is specified, the beginning label must be specified, and the two must match.

A label name cannot be the same as the name of the SQL procedure in which the label is used.

*SQL-procedure-statement*

Specifies the statements to be executed in the loop. The statement must be one of the statements listed under *SQL-procedure-statement*.

**Examples**

This procedure uses a LOOP statement to fetch values from the employee table. Each time the loop iterates, the OUT parameter counter is incremented and the value of *v_midinit* is checked to ensure that the value is not a single space ('). If *v_midinit* is a single space, the LEAVE statement passes the flow of control outside of the loop.

```sql
CREATE PROCEDURE LOOP_UNTIL_SPACE(OUT counter INTEGER)
LANGUAGE SQL
BEGIN
    DECLARE v_counter INTEGER DEFAULT 0;
    DECLARE vFirstname VARCHAR(12);
    DECLARE vMidinit CHAR(1);
    DECLARE vLastname VARCHAR(15);
    DECLARE c1 CURSOR FOR
        SELECT firstnme, midinit, lastname
        FROM employee;
    DECLARE EXIT HANDLER FOR NOT FOUND
        SET counter = -1;
    OPEN c1;
    fetch_loop:
        LOOP
            FETCH c1 INTO vFirstname, vMidinit, vLastname;
            IF vMidinit = ' ' THEN
                LEAVE fetch_loop;
            END IF;
            SET v_counter = v_counter + 1;
```
END LOOP fetch_loop;
SET counter = v_counter;
CLOSE c1;
END
REPEAT statement

The REPEAT statement executes a statement or group of statements until a search condition is true.

Syntax

```
REPEAT
  SQL-procedure-statement
UNTIL search-condition
END REPEAT
```

Notes:
1. Only one label can be specified for each SQL-procedure-statement.

Description

**label**

Specifies the label for the REPEAT statement. If the ending label is specified, the beginning label must be specified, and the two must match.

A label name cannot be the same as the name of the SQL procedure in which the label is used.

**SQL-procedure-statement**

Specifies the statements to be executed. The statement must be one of the statements listed under SQL-procedure-statement.

**search-condition**

Specifies a condition that is evaluated after each execution of the REPEAT statement. If the condition is true, the REPEAT loop will exit. If the condition is unknown or false, the REPEAT loop continues.

Examples

Use a REPEAT statement to fetch rows from a table.

```
fetch_loop:
REPEAT
  FETCH c1 INTO
    v_firstnme, v_midinit, v_lastname;
UNTIL
  SQLCODE <> 0
END REPEAT fetch_loop
```
RESIGNAL statement

The RESIGNAL statement is used within a condition handler to re-raise the current condition, or to raise an alternate condition so that it can be processed at a higher level. It causes an exception, warning, or not found condition to be returned along with optional message text.

Issuing the RESIGNAL statement without an operand causes the current condition to be passed upwards.

Syntax

```
RESIGNAL SQLSTATE value
  |    SQL-variable-name
  |    SQL-condition-name
```

```
| SET MESSAGE_TEXT = diagnostic-string-expression
```

Description

**SQLSTATE value**

Specifies the SQLSTATE that will be returned. Any valid SQLSTATE value can be used. It must be a character string constant with exactly five characters that follow the rules for SQLSTATE values:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letter ('A' through 'Z').
- The SQLSTATE class (the first two characters) cannot be '00' because it represents successful completion.

If the SQLSTATE does not conform to these rules, an error occurs.

**sqlstate-string-constant**

A character string constant with a length of five bytes that is a valid SQLSTATE value.

**SQL-variable-name** or **SQL-parameter-name**

Specifies an SQL variable or SQL parameter that is defined for the procedure.

**SQL-variable-name**

Specifies an SQL variable that is declared within the compound-statement that contains the RESIGNAL statement. **SQL-variable-name** must be defined as CHAR or VARCHAR data type with a length of five bytes, must not be null, and must contain a valid SQLSTATE value.

**SQL-parameter-name**

Specifies an SQL parameter that is defined for the procedure that contains the SQLSTATE value. The SQL parameter must be defined as
a CHAR or VARCHAR value and have a length of five bytes and must not be null. The SQL parameter must contain a valid SQLSTATE value.

**SQL-condition-name**
Specifies the name of the condition that will be returned. *condition-name* must be declared within the *compound-statement*.

**SET MESSAGE_TEXT**
Specifies a string that describes the error or warning. The string is returned in the SQLERRMC field of the SQLCA or with the GET DIAGNOSTICS statement.

*diagnostic-string-expression*
An expression with a data type of CHAR or VARCHAR that returns a character string of up to 1000 bytes that describes the error or warning condition. For information on how to obtain the complete message text, see [GET DIAGNOSTICS](#).

**Notes**
While any valid SQLSTATE value can be used in the RESIGNAL statement, programmers should define new SQLSTATE values based on ranges reserved for applications. This practice prevents the unintentional use of an SQLSTATE value that might be defined by the database manager in a future release.

If the RESIGNAL statement is issued without an SQLSTATE clause or a *condition-name*, the RESIGNAL statement must be in a handler and the identical condition that activated the handler is returned. The SQLSTATE, SQLCODE, and the SQLCA associated with the condition are unchanged.

If an SQLSTATE clause or a *condition-name* was specified, the SQLCODE returned is based on the SQLSTATE value as follows:
- If the specified SQLSTATE class is either '01' or '02', a warning or not-found message is returned, and the SQLCODE is set to +438.
- Otherwise, an exception is returned and the SQLCODE is set to -438.

The other fields of the SQLCA are set as follows:
- SQLERRDx fields are set to zero.
- SQLWARNx fields are set to blank.
- SQLERRMC is set to the first 70 bytes of MESSAGE_TEXT.
- SQLERRM is set to the length of SQLERRMC.
- SQLERRP is set to ROUTINE.

When the SQLSTATE or condition indicates that an exception is returned (an SQLSTATE class other than '01' or '02'), the exception is not handled, and control is immediately returned to the end of the compound statement.

When the SQLSTATE or condition indicates that a warning (SQLSTATE class '02') is returned, the warning is not handled, and processing continues with the next statement.

When the SQLSTATE or condition indicates that a not-found condition (SQLSTATE class '02') is returned, the not-found condition is not handled, and processing continues with the next statement.
Examples

The following example detects a division by zero error. The IF statement uses a SIGNAL statement to invoke the overflow condition handler. The condition handler uses a RESIGNAL statement to return a different SQLSTATE to the client application.

```
CREATE PROCEDURE divide( IN numerator INTEGER,  
                        IN denominator INTEGER,  
                        OUT divide_result INTEGER)  
  LANGUAGE SQL  
  CONTAINS SQL  
BEGIN  
  DECLARE overflow CONDITION for SQLSTATE '22003';  
  DECLARE CONTINUE HANDLER FOR overflow  
  RESIGNAL SQLSTATE '22375';  
  IF denominator = 0 THEN  
    SIGNAL overflow;  
  ELSE  
    SET divide_result = numerator / denominator;  
  END IF;  
END;
```
RETURN statement

The RETURN statement is used to return from the routine. For SQL functions, it returns the result of the function. For an SQL procedure, it optionally returns an integer status value.

Syntax

```
RETURN expression
NULL
```

Description

expression

Specifies a value that is returned from the routine.

- If the routine is a function, expression must be specified and the value of expression must conform to the SQL assignment rules as described in Assignment and comparison. If the value is being assigned to a string variable, storage assignment rules apply.
- If the routine is a procedure, the data type of expression must be INTEGER. If expression evaluates to the null value, a value of 0 is returned.

The expression cannot include a column name or a host variable. See Expressions for information on expressions. The expression cannot contain a scalar fullselect.

NULL

The null value is returned from the SQL function. NULL is not allowed in SQL procedures.

Notes

When a RETURN statement is not used within an SQL procedure or when no value is specified: If a RETURN statement was not used to return from a procedure or if a value is not specified on the RETURN statement, one of the following values is set:

- If the procedure returns with an SQLCODE that is greater or equal to zero, the return status is set to a value of '0'.
- If the procedure returns with an SQLCODE that is less than zero, the return status is set to a value of '-1'.

When a RETURN statement is used within an SQL procedure: If a RETURN statement with a specified return value was used to return from a procedure, the SQLCODE, SQLSTATE, and message length in the SQLCA are initialized to zeros and the message text is set to blanks. An error is not returned to the caller.

When the value is returned: When a value is returned from a procedure, the caller may access the value using one of the following methods:

- The GET DIAGNOSTICS statement to retrieve the RETURN_STATUS when the SQL procedure was called from another SQL procedure.
- The parameter bound for the return value parameter marker in the escape clause CALL syntax (?=CALL...) in a CLI application.
• Directly from the SQLCA returned from processing the CALL of an SQL procedure by retrieving the value of sqle[0]. When the SQLCODE is less than zero, the sqle[0] value is not set. The application should assume a return status value of '-1'.

Examples

Use a RETURN statement to return from an SQL procedure with a status value of zero if successful or '-200' if not successful.

BEGIN
  ...
  GOTO FAIL;
  ...
SUCCESS: RETURN 0;
  FAIL: RETURN -200;
END
**SIGNAL statement**

The SIGNAL statement is used to return an error or warning condition. It causes an error or warning to be returned with the specified SQLSTATE, along with optional message text.

**Syntax**

```
SIGNAL SQLSTATE VALUE (1)
  sqlstate-string-constant
  SQL-variable-name
  SQL-parameter-name (2)

SQL-condition-name
```

**Notes:**

1. The **SQLSTATE** variation must be used within a trigger body.
2. **SQL-condition-name** must not be specified within a trigger body.
3. **signal-information** must be specified within a trigger body

**signal-information:**

```
SET MESSAGE_TEXT = diagnostic-string-expression (1)
```

**Notes:**

1. **(diagnostic-string-expression)** must only be specified within a trigger body.

**Description**

**SQLSTATE VALUE**

Specifies the SQLSTATE that will be returned. Any valid SQLSTATE value can be used. It must be a character string constant with exactly five characters that follow the rules for SQLSTATEs:

- Each character must be from the set of digits ('0' through '9') or non-accented upper case letter ('A' through 'Z').
- The SQLSTATE class (the first two characters) cannot be '00' because it represents successful completion.

If the SQLSTATE does not conform to these rules, an error occurs.

**sqlstate-string-constant**

A character string constant with a length of five bytes that is a valid SQLSTATE value.
SQL-variable-name or SQL-parameter-name
Specifies an SQL variable or SQL parameter that contains a valid SQLSTATE value.

SQL-variable-name
Specifies an SQL variable that is declared within the compound-statement. SQL-variable-name must be defined as a CHAR or VARCHAR data type, have a length of five bytes, must not be null, and must contain a valid SQLSTATE value.

SQL-parameter-name
Specifies an SQL parameter that is defined for the procedure and contains the SQLSTATE value. The SQL parameter must be defined as a CHAR or VARCHAR value, have a length of five bytes, must not be null, and must contain a valid SQLSTATE value.

SQL-condition-name
Specifies the name of the condition that will be returned. condition-name must be declared within the compound-statement.

SET MESSAGE_TEXT
Specifies a string that describes the error or warning. The string is returned in the SQLERRMC field of the SQLCA or with the GET DIAGNOSTICS statement.

diagnostic-string-expression
An expression with a data type of CHAR or VARCHAR that returns a character string of up to 1000 bytes that describes the error or warning condition. For information on how to obtain the complete message text, see GET DIAGNOSTICS.

(diagnostic-string-expression)
An expression with a data type of CHAR or VARCHAR that returns a character string of up to 1000 bytes that describes the error or warning condition. For information on how to obtain the complete message text, see GET DIAGNOSTICS.

This syntax variation is only provided within the scope of a CREATE TRIGGER statement for compatibility with previous versions of DB2. To conform with the ANS and ISO standards, this form should not be used.

Notes
While any valid SQLSTATE value can be used in the SIGNAL statement, programmers should define new SQLSTATEs based on ranges reserved for applications. This practice prevents the unintentional use of an SQLSTATE value that might be defined by the database manager in a future release.

If a SIGNAL statement is issued, the SQLCODE that is returned is based on the SQLSTATE as follows:
• If the specified SQLSTATE class is either '01' or '02', a warning or not-found message is returned, and the SQLCODE is set to +438.
• Otherwise, an exception is returned and the SQLCODE is set to -438.

The other fields of the SQLCA are set as follows:
• SQLERRRDx fields are set to zero.
• SQLWARNx fields are set to blank.
• SQLERRMC is set to the first 70 bytes of MESSAGE_TEXT.
• SQLERRML is set to the length of SQLERRMC.
• SQLERRP is set to ROUTINE.

When the SQLSTATE or condition indicates that an exception (an SQLSTATE class other than '01' or '02') is returned, one of the following actions occurs:
• If a handler exists for the specified SQLSTATE, condition, or SQLEXCEPTION, the exception is handled, and control is transferred to that handler.
• Otherwise, the exception is not handled, and control is immediately returned to the end of the compound statement.

When the SQLSTATE or condition indicates that a warning (SQLSTATE class '01') is returned, one of the following actions occurs:
• If an active handler exists for the specified SQLSTATE, condition, or SQLWARNING, the warning is handled, and control is transferred to that handler.
• Otherwise, the warning is not handled, and processing continues with the next statement.

When the SQLSTATE or condition indicates that a not-found condition (SQLSTATE class '02') is returned, one of the following actions occurs:
• If an active handler exists for the specified SQLSTATE, condition, or not-found condition, the not-found condition is handled, and control is transferred to that handler.
• Otherwise, the not-found condition is not handled, and processing continues with the next statement.

When the SIGNAL statement is issued in a handler, no active handler exists.

Using a SIGNAL statement in the body of a trigger: Within the triggered action of a CREATE TRIGGER statement, the message text can be specified using only these variations:
SIGNAL SQLSTATE sqlstate-string-constant
  SET MESSAGE_TEXT = diagnostic-string-expression
SIGNAL SQLSTATE sqlstate-string-constant
    (diagnostic-string-expression)

Examples

Example 1: The following example shows an SQL procedure for an order system that signals an application error when a customer number is not known to the application. The ORDERS table includes a foreign key to the CUSTOMER table, requiring that the CUSTNO exist before an order can be inserted.

CREATE PROCEDURE SUBMIT_ORDER
  (IN ONUM INTEGER, IN CNUM INTEGER,
   IN PNUM INTEGER, IN QNUM INTEGER)
  LANGUAGE SQL
  SPECIFIC SUBMIT_ORDER
  MODIFIES SQL DATA
BEGIN
  DECLARE EXIT HANDLER FOR SQLSTATE VALUE '23503'
    SIGNAL SQLSTATE '75002'
    SET MESSAGE_TEXT = 'Customer number is not known';
  INSERT INTO ORDERS (ORDerno, CUSTNO, PARTNO, QUANTITY)
    VALUES (ONUM, CNUM, PNUM, QNUM);
END
Example 2: The following example shows a trigger for an order system that allows orders to be recorded in an ORDERS table (ORDERNO, CUSTNO, PARTNO, QUANTITY) only if there is sufficient stock in the PARTS tables. When there is insufficient stock for an order, SQLSTATE '75001' is returned along with an appropriate error description.

```
CREATE TRIGGER CK_AVAIL
  NO CASCADE BEFORE INSERT ON ORDERS
  REFERENCING NEW AS NEW_ORDER
  FOR EACH ROW MODE DB2SQL
  WHEN (NEW_ORDER.QUANTITY > (SELECT ON_HAND FROM PARTS
                              WHERE NEW_ORDER.PARTNO = PARTS.PARTNO))
    BEGIN ATOMIC
      SIGNAL SQLSTATE '75001' ('Insufficient stock for order');
    END
```
**WHILE statement**

The WHILE statement repeats the execution of a statement or group of statements while a specified condition is true.

**Syntax**

```
label: WHILE search-condition DO SQL-procedure-statement END WHILE
```

**Notes:**
1. Only one `label` can be specified for each `SQL-procedure-statement`. If an ending label is specified for this beginning label, the labels must be the same.

**Description**

`label`

Specifies the label for the WHILE statement. If the ending label is specified, it must be the same as the beginning label.

A label name cannot be the same as the name of the SQL procedure in which the label is used.

`search-condition`

Specifies a condition that is evaluated before each execution of the loop. If the condition is true, the SQL procedure statement in the loop is executed.

`SQL-procedure-statement`

Specifies the statements to be executed in the loop. The statement must be one of the statements listed under `SQL-procedure-statement`.

**Examples**

Use a WHILE statement to fetch rows from a table while SQL variable `at_end`, which indicates whether the end of the table has been reached, is 0.

```
WHILE at_end = 0 DO
  FETCH c1 INTO v_firstname, v_midinit, v_lastname, v_edlevel, v_salary;
  IF SQLCODE=100 THEN SET at_end=1;
  END IF;
END WHILE
```
An SQLCA is a structure or collection of variables that is updated after each SQL statement executes. An application program that contains executable SQL statements must provide exactly one SQLCA, with a few exceptions.

The following exceptions exist:
- A program that is precompiled with the STDSQL(YES) option must not provide an SQLCA
- In some cases a Fortran program must provide more than one SQLCA.

In all host languages except REXX, the SQL INCLUDE statement can be used to provide the declaration of the SQLCA.

**In COBOL and assembler:**
- The name of the storage area must be SQLCA.

**In PL/I, and C:**
- The name of the structure must be SQLCA. Every executable SQL statement must be within the scope of its declaration.
- Unless noted otherwise, C is used to represent C/370™ and C/C++ programming languages.

**In Fortran:**
- The name of the COMMON area for the INTEGER variables of the SQLCA must be SQLCA1; the name of the COMMON area for the CHARACTER variables must be SQLCA2. An SQLCA definition is required for every subprogram that contains SQL statements. One is also needed for the main program if it contains SQL statements.

**In Java:**
- The DB2Sqlca class, which is an encapsulation of the SQLCA, should be used.

**In REXX:**
- DB2 generates the SQLCA automatically. A REXX procedure cannot use the INCLUDE statement. The REXX SQLCA has a somewhat different format from SQLCAs for the other languages.

**Related reference:**

- The REXX SQLCA
Description of SQLCA fields

For the most part, COBOL, C, PL/I, and assembler use the same names for the SQLCA fields, and Fortran uses different names. However, there is one instance where C, PL/I, and assembler names differ from COBOL.

The names in the following table are those provided by the SQL INCLUDE statement.

Table 222. Fields of SQLCA

<table>
<thead>
<tr>
<th>assembler, COBOL, or PL/I Name</th>
<th>C Name</th>
<th>Fortran Name</th>
<th>Data Type</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLCAID</td>
<td>sqlcaid</td>
<td>Not used.</td>
<td>CHAR(8)</td>
<td>An “eye catcher” for storage dumps, containing the text ‘SQLCA’. The sixth byte is ‘L’ if line number information is returned from parsing a dynamic statement or a native SQL procedure. The sixth byte is not set when processing an external SQL procedure.</td>
</tr>
<tr>
<td>SQLCABC</td>
<td>sqlcabc</td>
<td>Not used.</td>
<td>INTEGER</td>
<td>Contains the length of the SQLCA: 136.</td>
</tr>
<tr>
<td>SQLCODE (See note 1)</td>
<td>SQLCODE</td>
<td>SQLCOD</td>
<td>INTEGER</td>
<td>Contains the SQL return code. (See note 2)</td>
</tr>
<tr>
<td>Code</td>
<td>Means</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>Successful execution (though there might have been warning messages).</td>
<td></td>
<td></td>

<td>For a sensitive static cursor, contains the number of rows in a result table when the cursor position is after the last row (that is, when SQLCODE is equal to +100). SQLERRD(2) can also contain an internal error code.</td>
</tr>
</tbody>
</table>
### Table 222. Fields of SQLCA (continued)

<table>
<thead>
<tr>
<th>assembler, COBOL, or PL/I Name</th>
<th>C Name</th>
<th>Fortran Name</th>
<th>Data type</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLERRD(3)</td>
<td>sqlerr[2]</td>
<td>SQLERR(3)</td>
<td>INTEGER</td>
<td>Contains the number of rows that qualified to be deleted, inserted, or updated after a DELETE, INSERT, UPDATE, or MERGE statement. The number excludes rows affected by triggers, referential integrity constraints, or inserted rows that are the result of processing a FOR PORTION OF clause for a BUSINESS_TIME period. For the OPEN of a cursor for a SELECT with a data change statement or for a SELECT INTO, SQLERRD(3) contains the number of rows affected by the embedded data change statement. The value is 0 if the SQL statement fails, indicating that all changes made in executing the statement canceled. For a DELETE statement the value will be -1 if the operation is a mass delete from a table in a segmented table space and the DELETE statement did not include selection criteria. If the delete was against a view, neither the DELETE statement nor the definition of the view included selection criteria. For a TRUNCATE statement, the value will be -1. For a PREPARE statement, contains the estimated number of rows selected. If the number of rows is greater than 2 147 483 647, a value of 2 147 483 647 is returned. For a REFRESH TABLE statement, SQLERRD(3) contains the number of rows inserted into the materialized query table. For a rowset-oriented FETCH, contains the number of rows fetched. For SQLCODES -911 and -913, SQLERRD(3) contains the reason code for the timeout or deadlock. When an error is encountered in parsing a dynamic statement, or when parsing, binding, or executing a native SQL procedure, SQLERRD(3) will contain the line number where the error was encountered. The sixth byte of SQLCAID must be ‘L’ for this to be a valid line number. This value will be meaningful only if the statement source contains new line control characters. This information is not returned for an external SQL procedure.</td>
</tr>
</tbody>
</table>
**Table 222. Fields of SQLCA (continued)**

<table>
<thead>
<tr>
<th>assembler, COBOL, or PL/I Name</th>
<th>C Name</th>
<th>Fortran Name</th>
<th>Data Type</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLERRD(4)</td>
<td>sqlerrd[3]</td>
<td>SQLERR(4)</td>
<td>INTEGER</td>
<td>Generally, contains timerons, a short floating-point value that indicates a rough relative estimate of resources required (See note 4). It does not reflect an estimate of the time required. When preparing a dynamically defined SQL statement, you can use this field as an indicator of the relative cost of the prepared SQL statement. For a particular statement, this number can vary with changes to the statistics in the catalog. It is also subject to change between releases of DB2 for z/OS.</td>
</tr>
<tr>
<td>SQLERRD(5)</td>
<td>sqlerrd[4]</td>
<td>SQLERR(5)</td>
<td>INTEGER</td>
<td>Contains the position or column of a syntax error for a PREPARE or EXECUTE IMMEDIATE statement.</td>
</tr>
<tr>
<td>SQLWARN0</td>
<td>SQLWARN0</td>
<td>SQLWRN(0)</td>
<td>CHAR(1)</td>
<td>Contains a blank if no other indicator is set to a warning condition (that is, no other indicator contains a W or Z). Contains a W if at least one other indicator contains a W or Z.</td>
</tr>
<tr>
<td>SQLWARN1</td>
<td>SQLWARN1</td>
<td>SQLWRN(1)</td>
<td>CHAR(1)</td>
<td>Contains a W if the value of a string column was truncated when assigned to a host variable. Contains an N for non-scrollable cursors and S for scrollable cursors after the OPEN CURSOR or ALLOCATE CURSOR statement. If subsystem parameter DISABSCL is set to YES, the field will not be set to N for non-scrollable cursors.</td>
</tr>
<tr>
<td>SQLWARN2</td>
<td>SQLWARN2</td>
<td>SQLWRN(2)</td>
<td>CHAR(1)</td>
<td>Contains a W if null values were eliminated from the argument of an aggregate function; not necessarily set to W for the MIN function because its results are not dependent on the elimination of null values.</td>
</tr>
<tr>
<td>SQLWARN3</td>
<td>SQLWARN3</td>
<td>SQLWRN(3)</td>
<td>CHAR(1)</td>
<td>Contains a W if the number of result columns is larger than the number of host variables. Contains a Z if fewer locators were provided in the ASSOCIATE LOCATORS statement than the stored procedure returned.</td>
</tr>
<tr>
<td>SQLWARN4</td>
<td>SQLWARN4</td>
<td>SQLWRN(4)</td>
<td>CHAR(1)</td>
<td>Contains a W if a prepared UPDATE or DELETE statement does not include a WHERE clause. For a scrollable cursor, contains a D for sensitive dynamic cursors, I for insensitive cursors, and S for sensitive static cursors after the OPEN CURSOR or ALLOCATE CURSOR statement; blank if cursor is not scrollable. If subsystem parameter DISABSCL is set to YES, the field will not be set with information about cursor sensitivity.</td>
</tr>

<td>Fortran Name</td>
<td>Data type</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>--------</td>
<td>--------------</td>
<td>-----------</td>
<td>---------</td>
</tr>
<tr>
<td>SQLWARN5</td>
<td>SQLWARN5</td>
<td>SQLWRN(5)</td>
<td>CHAR(1)</td>
<td>Contains a W if the SQL statement was not executed because it is not a valid SQL statement in DB2 for z/OS. Contains a character value of 1 (read only), 2 (read and delete), or 4 (read, delete, and update) to reflect capability of the cursor after the OPEN CURSOR or ALLOCATE CURSOR statement. If subsystem parameter DISABSCL is set to YES, the field will not be set with information about the capability of the cursor.</td>
</tr>
<tr>
<td>SQLWARN6</td>
<td>SQLWARN6</td>
<td>SQLWRN(6)</td>
<td>CHAR(1)</td>
<td>Contains a W if the addition of a month or year duration to a DATE or TIMESTAMP value results in an invalid day (for example, June 31). Indicates that the value of the day was changed to the last day of the month to make the result valid.</td>
</tr>
<tr>
<td>SQLWARN7</td>
<td>SQLWARN7</td>
<td>SQLWRN(7)</td>
<td>CHAR(1)</td>
<td>Contains a W if one or more nonzero digits were eliminated from the fractional part of a number used as the operand of a decimal multiply or divide operation.</td>
</tr>
<tr>
<td>SQLWARN8</td>
<td>SQL WARN8</td>
<td>SQLWRX(1)</td>
<td>CHAR(1)</td>
<td>Contains a W if a character that could not be converted was replaced with a substitute character. Contains a Y if there was an unsuccessful attempt to establish a trusted connection.</td>
</tr>
<tr>
<td>SQLWARN9</td>
<td>SQL WARN9</td>
<td>SQLWRX(2)</td>
<td>CHAR(1)</td>
<td>Contains a W if arithmetic exceptions were ignored during COUNT or COUNT_BIG processing. Contains a Z if the stored procedure returned multiple result sets.</td>
</tr>
<tr>
<td>SQLWARNA</td>
<td>SQL WARNA</td>
<td>SQLWRX(3)</td>
<td>CHAR(1)</td>
<td>Contains a W if at least one character field of the SQLCA or the SQLDA names or labels is invalid due to a character conversion error.</td>
</tr>
<tr>
<td>SQLSTATE</td>
<td>sqlstate</td>
<td>SQLSTT</td>
<td>CHAR(5)</td>
<td>Contains a return code for the outcome of the most recent execution of an SQL statement (See note 5).</td>
</tr>
</tbody>
</table>

Notes:

1. With the precompiler option STDSQL(YES) in effect, SQLCODE is replaced by SQLCADE in SQLCA.
2. For the specific meanings of SQL return codes, see DB2 Codes.
3. In COBOL, SQLERRM includes SQLERRML and SQLERRMC. In PL/I and C, the varying-length string SQLERRM is equivalent to SQLERRML prefixed to SQLERRMC. In assembler, the storage area SQLERRRM is equivalent to SQLERRML and SQLERRMC. See the examples for the various host languages in The included SQLCA.
4. The use of timerons may require special handling because they are floating-point values in an INTEGER array. In PL/I, for example, you could first copy the value into a BIN FIXED(31) based variable that coincides with a BIN FLOAT(24) variable.
5. For a description of SQLSTATE values, see DB2 Codes.
The included SQLCA

The description of the SQLCA that is given by INCLUDE SQLCA is shown for each of the host languages.

**assembler:**

```assembly
SQLCA  DS  0F
SQLCAID DS  CL8  ID
SQLCABC DS  F    BYTE COUNT

The REXX SQLCA

The REXX SQLCA consists of a set of variables, rather than a structure. DB2 makes the SQLCA available to your application automatically.

The following table lists the variables in a REXX SQLCA.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLCODE</td>
<td>Contains the SQL return code.</td>
</tr>
<tr>
<td>SQLERRMC</td>
<td>Contains one or more tokens, separated by X'FF', that are substituted for variables in the descriptions of error conditions. It might contain truncated tokens. A message length of 70 bytes indicates a possible truncation.</td>
</tr>
<tr>
<td>SQLERRP</td>
<td>Provides a product signature and, in the case of an error, diagnostic information such as the name of the module that detected the error. For DB2 for z/OS, the product signature is 'DSN'.</td>
</tr>
<tr>
<td>SQLERRD.1</td>
<td>For a sensitive static cursor, contains the number of rows in a result table when the cursor position is after the last row (that is, when SQLCODE is equal to +100). SQLERRD(1) can also contain an internal error code.</td>
</tr>
<tr>
<td>SQLERRD.2</td>
<td>For a sensitive static cursor, contains the number of rows in a result table when the cursor position is after the last row (that is, when SQLCODE is equal to +100). SQLERRD(2) can also contain an internal error code.</td>
</tr>
<tr>
<td>SQLERRD.3</td>
<td>Contains the number of rows that qualified for the operation after an SQL data change statement (but not rows deleted as a result of CASCADE delete). For the OPEN of a cursor for a SELECT with an SQL data change statement or for a SELECT INTO, SQLERRD(3) contains the number of rows affected by the embedded data change statement. Set to 0 if the SQL statement fails, indicating that all changes made in executing the statement were canceled. Set to -1 for a mass delete from a table in a segmented table space, for a truncate operation, or a delete from a view when neither the DELETE statement nor the definition of the view included selection criteria. For rowset-oriented FETCH statements, contains the number of rows returned in the rowset. For SQLCODES -911 and -913, SQLERRD(3) contains the reason code for the timeout or deadlock. After successful execution of the REFRESH TABLE statement, SQLERRD(3) contains the number of rows inserted into the materialized query table. When an error is encountered in parsing a dynamic statement, or when parsing, binding, or executing a native SQL procedure, SQLERRD(3) will contain the line number where the error was encountered. The sixth byte of SQLCAID must be 'L' for this to be a valid line number. This value will be meaningful only if the statement source contains new line control characters. This information is not returned for an external SQL procedure.</td>
</tr>
<tr>
<td>SQLERRD.4</td>
<td>Generally, contains timerons, a short floating-point value that indicates a rough relative estimate of resources required. This value does not reflect an estimate of the time required to execute the SQL statement. After you prepare an SQL statement, you can use this field as an indicator of the relative cost of the prepared SQL statement. For a particular statement, this number can vary with changes to the statistics in the catalog. This value is subject to change between releases of DB2 for z/OS.</td>
</tr>
<tr>
<td>SQLERRD.5</td>
<td>Contains the position or column of a syntax error for a PREPARE or EXECUTE IMMEDIATE statement.</td>
</tr>
<tr>
<td>SQLERRD.6</td>
<td>Contains an internal error code.</td>
</tr>
</tbody>
</table>

SQL descriptor area (SQLDA)

An SQLDA is a collection of variables that is required for execution of the SQL DESCRIBE statement, and can be optionally used by the PREPARE, OPEN, FETCH, EXECUTE, and CALL statements. An SQLDA can be used in a DESCRIBE or PREPARE INTO statement, modified with the addresses of host variables, and then reused in a FETCH statement.

The meaning of the information in an SQLDA depends on the context in which it is used. For DESCRIBE and PREPARE INTO, DB2 sets the fields in the SQLDA to provide information to the application program. For OPEN, EXECUTE, FETCH, and CALL, the application program sets the fields in the SQLDA to provide DB2 with information:

DESCRIBE statement-name or PREPARE INTO
With the exception of SQLN, DB2 sets fields of the SQLDA to provide information to an application program about a prepared statement. Each SQLVAR occurrence describes a column of the result table.

DESCRIBE TABLE
With the exception of SQLN, DB2 sets fields of the SQLDA to provide information to an application program about the columns of a table or view. Each SQLVAR occurrence describes a column of the specified table or view.

DESCRIBE CURSOR
With the exception of SQLN, DB2 sets fields of the SQLDA to provide information to an application program about the result set that is associated with the specified cursor. Each SQLVAR occurrence describes a column of the result set.

DESCRIBE INPUT
With the exception of SQLN, DB2 sets fields of the SQLDA to provide information to an application program about the input parameter markers of a prepared statement. Each SQLVAR occurrence describes an input parameter marker.

DESCRIBE PROCEDURE
With the exception of SQLN, DB2 sets fields of the SQLDA to provide information to an application program about the result sets returned by the specified stored procedure. Each SQLVAR occurrence describes a returned result set.

OPEN, EXECUTE, FETCH, and CALL
The application program sets fields of the SQLDA to provide information about host variables or output buffers in the application program to DB2. Each SQLVAR occurrence describes a host variable or output buffer.

- For OPEN and EXECUTE, each SQLVAR occurrence describes an input value that is substituted for a parameter marker in the associated SQL statement that was previously prepared.
- For FETCH, each SQLVAR occurrence describes a host variable or buffer in the application program that is to be used to contain an output value from a row of the result.
- For CALL, each SQLVAR occurrence describes a host variable that corresponds to a parameter in the parameter list for the stored procedure.
For information on the way to use the SQLDA, see *DB2 Application Programming and SQL Guide*. 
Description of SQLDA fields

An SQLDA consists of four variables, a header, and an arbitrary number of occurrences of a sequence of variables collectively named SQLVAR.

In DESCRIBE and PREPARE INTO, each occurrence of the SQLVAR describes the column of a table. In FETCH, OPEN, EXECUTE, and CALL, each occurrence describes a host variable.

The order of the SQLVAR entries matches the order of the columns in the table or the order of the parameter markers in the SQL statement.

The SQLDA Header

The fields in the SQLDA header have different usage depending on whether the SQLDA is being used in a DESCRIBE or PREPARE INTO statement or the SQLDA is being used in a FETCH, INSERT, OPEN, EXECUTE, or CALL statement.

The following table describes the fields in the SQLDA header.

Table 224. Fields of the SQLDA header

<table>
<thead>
<tr>
<th>C name</th>
<th>assembler, COBOL or PL/I name</th>
<th>Data type</th>
<th>Usage in DESCRIBE(^1) and PREPARE INTO</th>
<th>Usage in FETCH, INSERT, OPEN, EXECUTE, and CALL</th>
</tr>
</thead>
<tbody>
<tr>
<td>sqldaid</td>
<td>SQLDAID</td>
<td>CHAR(8)</td>
<td>An “eye catcher” for storage dumps, containing the text ‘SQLDA ’.</td>
<td>A plus sign (+) in the 6th byte indicates that SQLNAME contains an overriding CCSID.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The 7th byte of the field is a flag that can be used to determine if more than one SQLVAR entry is needed for each column. For details, see <a href="#">Determining how many SQLVAR occurrences are needed</a>.</td>
<td>A '2' in the 7th byte indicates the two SQLVAR entries were allocated for each column or parameter.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>For DESCRIBE CURSOR, the field is set to 'SQLRS'. If the cursor is declared WITH HOLD in a stored procedure, the high-order bit of the 8th byte is set to 1.</td>
<td>A '3' in the 7th byte indicates that three SQLVAR entries were allocated for each column or parameter. Although three entries are never needed on input to DB2, an SQLDA with three entries might be used when the SQLDA was initialized by a DESCRIBE or PREPARE INTO with a USING BOTH clause.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>For DESCRIBE PROCEDURE, it is set to 'SQLPR'.</td>
<td>Otherwise, SQLDAID is not used.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>INTEGER</td>
<td>Length of the SQLDA, equal to SQLN(x * 44+16).</td>
<td>Length of the SQLDA, greater than or equal to SQLN(x * 44+16).</td>
</tr>
</tbody>
</table>
Table 224. Fields of the SQLDA header (continued)

<table>
<thead>
<tr>
<th>C name assembler, COBOL or PL/I name</th>
<th>Data type</th>
<th>Usage in DESCRIBE(^1) and PREPARE INTO</th>
<th>Usage in FETCH, INSERT, OPEN, EXECUTE, and CALL</th>
</tr>
</thead>
<tbody>
<tr>
<td>sqln</td>
<td>SMALLINT</td>
<td>Unchanged by DB2. The field must be set to a value greater than or equal to zero before the statement is executed. The field indicates the total number of occurrences of SQLVAR. At the very least, the number should be:</td>
<td></td>
</tr>
<tr>
<td>SQLN</td>
<td></td>
<td>• For DESCRIBE INPUT, the number of parameter markers to be described.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• For other DESCRIBE or PREPARE INTO: the number of columns of the result, or a multiple of the columns of the result when there are multiple sets of SQLVAR entries because column labels are returned in addition to column names.</td>
<td></td>
</tr>
<tr>
<td>sqld</td>
<td>SMALLINT</td>
<td>The number of columns described by occurrences of SQLVAR. Double that number if USING BOTH appears in the DESCRIBE or PREPARE INTO statement. Contains a 0 if the statement string is not a query.</td>
<td></td>
</tr>
<tr>
<td>SQLD</td>
<td></td>
<td>For DESCRIBE PROCEDURE, the number of result sets returned by the stored procedure. Contains a 0 if no result sets are returned.</td>
<td></td>
</tr>
</tbody>
</table>

Note:
1. The third column of this table represents several forms of the DESCRIBE statement:
   • For DESCRIBE output and PREPARE INTO, the column pertains to columns of the result table.
   • For DESCRIBE CURSOR, the column pertains to a result set associated with a cursor.
   • For DESCRIBE INPUT, the column pertains to parameter markers.
   • For DESCRIBE PROCEDURE, the column pertains to the result sets returned by the stored procedure.

SQLVAR entries
For each column or host variable described by the SQLDA, there are both base SQLVAR entries and extended SQLVAR entries.

Base SQLVAR entry
The base SQLVAR entry is always present. The fields of this entry contain the base information about the column or host variable such as data type code, length attribute (except for LOBs), column name (or label), host variable address, and indicator variable address.

Extended SQLVAR entry
The extended SQLVAR entry is needed (for each column) if the result
includes any LOB or distinct type\textsuperscript{40} columns. For distinct types, the extended SQLVAR contains the distinct type name. For LOBs, the extended SQLVAR contains the length attribute of the host variable and a pointer to the buffer that contains the actual length. If locators are used to represent LOBs, an extended SQLVAR is not necessary.

The extended SQLVAR entry is also needed for each column when the USING BOTH clause was specified, which indicates that both columns names and labels are returned. (DESCRIBE output is the only statement with the USING BOTH clause).

The fields in the extended SQLVAR that return LOB and distinct type information do not overlap, and the fields that return LOB and label information do not overlap. Depending on the combination of labels, LOBs and distinct types, more than one extended SQLVAR entry per column may be required to return the information. See Determining how many SQLVAR occurrences are needed.

The following table shows how to map the base and extended SQLVAR entries. For an SQLDA that contains both base and extended SQLVAR entries, the base SQLVAR entries are in the first block, followed by a block of extended SQLVAR entries, which if necessary, are followed by a second block of extended SQLVAR entries. In each block, the number of occurrences of the SQLVAR entry is equal to the value in SQLD\textsuperscript{41} even though many of the extended SQLVAR entries might be unused.

\textsuperscript{40} DESCRIBE INPUT does not return information about distinct types.

\textsuperscript{41} When an extended SQLVAR entry is present for each column for labels (and there are no LOB or distinct type columns in the result),
Table 225. Contents of SQLVAR arrays (continued)

<table>
<thead>
<tr>
<th>LOBs</th>
<th>Distinct types</th>
<th>7th byte of SQLDAID</th>
<th>SQLD</th>
<th>Minimum for SQLN</th>
<th>First set (Base)</th>
<th>Second set (Extended)</th>
<th>Third set (Extended)</th>
</tr>
</thead>
</table>

Notes:
1. DESCRIBE INPUT does not return information about distinct types.
2. The number of columns or host variables that the SQLDA describes.
3. Either LOBs, distinct types, or both are present.
4. Here, the 7th byte is set to a space and SQLD is set to two times the number of columns in the result. For all other values of the 7th byte for USING BOTH, SQLD is set to the number of columns in the result, and the 7th byte can be used to determine how many SQLVAR entries are needed for each column of the result.

**Determining how many SQLVAR occurrences are needed:**

The number of SQLVAR occurrences needed depends on the statement that the SQLDA was provided for and the data types of the columns or parameters being described.

If the USING BOTH clause was not specified for the statement and neither LOBs nor distinct types are present in the result, only one SQLVAR entry (a base entry) is needed for each column. The 7th byte of SQLDAID is set to a space. The SQLD is set to the number of columns in the result and represents the number of SQLVAR occurrences needed. If an insufficient number of SQLVAR occurrences were provided, DB2 returns a +236 warning in SQLCODE if the standards option was set. Otherwise, SQLCODE is zero.

If USING BOTH is specified and neither LOBs nor distinct types are present in the result, an extended SQLVAR entry per column is needed for the labels in addition to the base SQLVAR entry. The 7th byte of the SQLDAID is set to space. SQLD is set to the twice the number of columns in the result and represents the combined number of base and extended SQLVAR occurrences needed.

If LOBs, distinct types, or both are present in the results, one extended SQLVAR entry is needed per column in addition to the base SQLVAR entry with one exception. The exception is that when the USING BOTH clause is specified and distinct types are present in the results, two extended SQLVAR entries per column are needed. When a sufficient number of SQLVAR entries are provided in the SQLDA for both the base and extended SQLVARs, information for the LOBs and distinct types is returned. The 7th byte of SQLDAID is set to the number of SQLVAR entries that were used for each column:

1. Two SQLVAR entries per column (a base and an extended)
2. Three SQLVAR entries per column (a base and two extended)

SQLD is set to the number of columns in the result. Therefore, the value of the 7th byte of SQLDAID multiplied by the value of SQLD is the total number SQLVAR entries that were provided.

Otherwise, when an insufficient number of SQLVAR entries have been provided when LOBs or distinct types are present, DB2 indicates that by returning one of the following warnings in SQLCODE. DB2 also sets the 7th byte of SQLDAID to indicate how many SQLVAR entries are needed for each column of the result.

+237 There are insufficient SQLVAR entries to describe the data, and the data
includes distinct types. In this case, there were enough base SQLVAR entries to describe the data, so the base SQLVAR entries are set. However, sufficient extended SQLVAR entries were not provided so the distinct type names are not returned.

+238 There are insufficient SQLVAR entries to describe the data, and the data includes LOBs. In this case no information is returned in the SQLVAR entries.

+239 There are insufficient SQLVAR entries to describe the data, and the data includes distinct types. There weren't even enough base SQLVAR entries. In this case no information is returned in the SQLVAR entries.

Field descriptions of an occurrence of a base SQLVAR:

The fields of a base SQLVAR have different uses depending on the SQL statement.

The following table describes the contents of the fields of a base SQLVAR.

Table 226. Fields in an occurrence of a base SQLVAR

<table>
<thead>
<tr>
<th>C name</th>
<th>Data type</th>
<th>Usage in DESCRIBE(^1) and PREPARE INTO</th>
<th>Usage in FETCH, OPEN, EXECUTE, and CALL</th>
</tr>
</thead>
<tbody>
<tr>
<td>sqltype</td>
<td>SMALLINT</td>
<td>Indicates the data type of the column or parameter and whether it can contain null values. For a description of the type codes, see Table 228 on page 2397. For a distinct type, the data type on which the distinct type was based is placed in this field. The base SQLVAR provides no indication that this is part of the description of a distinct type.</td>
<td>Indicates the data type of the host variable and whether an indicator variable is provided. Host variables for datetime values must be character string variables. For FETCH, a datetime type code means a fixed-length character string. For a description of the type codes, see “SQLTYPE and SQLLEN” on page 2397.</td>
</tr>
<tr>
<td>sqllen</td>
<td>SMALLINT</td>
<td>The length attribute of the column or parameter. For datetime data, the length of the string representation of the value. See “SQLTYPE and SQLLEN” on page 2397 for a description of allowable values. For LOBs, the value is 0 regardless of the length attribute of the LOB. For XML, the value is 0. Field SQLLONGLEN in the extended SQLVAR contains the length attribute.</td>
<td>The length attribute of the host variable. See “SQLTYPE and SQLLEN” on page 2397 for a description of allowable values. For LOBs, the value is 0 regardless of the length attribute of the LOB. Field SQLLONGLEN in the extended SQLVAR contains the length attribute. For XML AS BLOB, CLOB, or DBCLOB, sqllen is 0 as for LOB types.</td>
</tr>
</tbody>
</table>
Table 226. Fields in an occurrence of a base SQLVAR (continued)

<table>
<thead>
<tr>
<th>C name</th>
<th>assembler COBOL, or PL/I name</th>
<th>Data type</th>
<th>Usage in DESCRIBE and PREPARE INTO</th>
<th>Usage in FETCH, OPEN, EXECUTE, and CALL</th>
</tr>
</thead>
<tbody>
<tr>
<td>sqldata</td>
<td>SQLDATA</td>
<td>pointer</td>
<td>For string columns or parameters, SQLDATA contains X'0000zzzz', where zzzz is the associated CCSID. For character strings, SQLDATA can alternatively contain X'FFFF', which indicates bit data. Not used for other types of data. For datetime columns, SQLDATA can contain the CCSID of the string representation of the datetime value. For DESCRIBE PROCEDURE, the result set locator value associated with the result set.</td>
<td>Contains the address of the host variable.</td>
</tr>
<tr>
<td>sqlind</td>
<td>SQLIND</td>
<td>pointer</td>
<td>Reserved</td>
<td>Contains the address of an associated indicator variable, if SQLTYPE is odd. Otherwise, the field is not used.</td>
</tr>
<tr>
<td>sqlname</td>
<td>SQLNAME</td>
<td>VARCHAR(30)</td>
<td>Contains the unqualified name or label of the column, or a string of length zero if the name or label does not exist. If the name is longer than 30 bytes, it is truncated at a byte boundary. For more information about column names, see <a href="#">Names of result columns</a>. For DESCRIBE PROCEDURE, SQLNAME contains the cursor name used by the stored procedure to return the result set. The values for SQLNAME appear in the order the cursors were opened by the stored procedure. For DESCRIBE INPUT, SQLNAME is not used.</td>
<td>Can contain CCSID and/or host-variable-array dimension information. DB2 interprets the third and fourth byte of the data portion of SQLNAME as the CCSID of the host variable if all of the following are true and the third and fourth byte are not X'0000': • The 6th byte of SQLDAID is '+' (X'4E') • SQLTYPE indicates the host variable is a string variable • The length of SQLNAME is 8 • The first two bytes of the data portion of SQLNAME are X'0000'. If the third and fourth byte of the data portion of SQLNAME are X'0000', DB2 uses the appropriate default CCSID. For FETCH, OPEN, INSERT, and EXECUTE, if the length of SQLNAME is 8, and the first two bytes of the data portion of SQLNAME are X'0000', DB2 interprets the fifth through eighth bytes of the data portion of the SQLNAME field as follows:</td>
</tr>
</tbody>
</table>
Table 226. Fields in an occurrence of a base SQVAR (continued)

<table>
<thead>
<tr>
<th>C name</th>
<th>assembler</th>
<th>Data type</th>
<th>Usage in DESCRIBE and PREPARE INTO</th>
<th>Usage in FETCH, OPEN, EXECUTE, and CALL</th>
</tr>
</thead>
<tbody>
<tr>
<td>sqlname</td>
<td>SQLNAME</td>
<td></td>
<td></td>
<td>* fifth and sixth bytes: a flag field that indicates the type of host variable that is being described by the current SQLDA entry. The values of this field are as follows:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>– X'0000' - host variable</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>– X'0100' - XML host variable ( XML AS BLOB, XML AS CLOB, XML AS DBCLOB)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>– X'0001' - host variable array</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>– X'0101' - XML host variable array</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>– X'0002' - special host variable that represents the value for 'n' in a multiple-row INSERT statement.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>* seventh and eighth bytes: if the sixth byte is X'01', a binary small integer (halfword) that represents the dimension of the host-variable-array, and the corresponding indicator-array if one is specified.</td>
</tr>
</tbody>
</table>

Notes:
1. The third column of this table represents several forms of the DESCRIBE statement.
   - For DESCRIBE output and PREPARE INTO, the column pertains to columns of the result table.
   - For DESCRIBE CURSOR, the column pertains to a result set associated with a cursor.
   - For DESCRIBE INPUT, the column pertains to parameter markers.
   - For DESCRIBE PROCEDURE, the column pertains to the result sets returned by the stored procedure.

Field descriptions of an occurrence of an extended SQVAR:

The fields of an extended SQVAR have different uses depending on the SQL statement.

The following table describes the contents of the fields of an extended SQVAR entry.
Table 227. Fields in an occurrence of an extended SQLVAR

<table>
<thead>
<tr>
<th>C name assembler, COBOL, or PL/I name</th>
<th>Data type</th>
<th>Usage in DESCRIBE\textsuperscript{1} and PREPARE INTO</th>
<th>Usage in FETCH, OPEN, EXECUTE, and CALL</th>
</tr>
</thead>
<tbody>
<tr>
<td>len.sqlLonglen</td>
<td>INTEGER</td>
<td>The length attribute of a LOB (BLOB, CLOB, or DBCLOB) column.</td>
<td>The length attribute of a LOB (BLOB, CLOB, or DBCLOB) host variable. DB2 ignores the SQLLEN field in the base SQLVAR for these data types. The length attribute indicates the number of bytes for a BLOB or CLOB, and the number of characters for a DBCLOB.</td>
</tr>
<tr>
<td>SQLLONGL</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>SQLLONGLEN</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>sqldatalen</td>
<td>pointer</td>
<td>Not used.</td>
<td>Used only for LOB (BLOB, CLOB, and DBCLOB) host variables.</td>
</tr>
<tr>
<td>SQLDATALEN</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

* INTEGER Reserved. Reserved.

Regardess of whether this field is used, field SQLLONGLEN must be set.
Table 227. Fields in an occurrence of an extended SQLVAR (continued)

<table>
<thead>
<tr>
<th>C name assembler, COBOL, or PL/I name</th>
<th>Data type</th>
<th>Usage in DESCRIBE(^1) and PREPARE INTO</th>
<th>Usage in FETCH, OPEN, EXECUTE, and CALL</th>
</tr>
</thead>
<tbody>
<tr>
<td>sqldatatype_name</td>
<td>VARCHAR(30)</td>
<td>A SQLTNAME field of the extended SQLVAR is set to one of the following:</td>
<td>Not used.</td>
</tr>
<tr>
<td>SQLTNAME</td>
<td></td>
<td>• For a distinct type column, the database manager sets this field to the fully qualified distinct type name. If the qualified name is longer than 30 bytes, it is truncated.</td>
<td></td>
</tr>
<tr>
<td>SQLDATATYPE-NAME</td>
<td></td>
<td>• For a label, the database manager sets this field to label.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>In the case that both a distinct type name and a label need to be returned in extended SQLVAR entries (USING BOTH has been specified), the distinct type name is returned in the first extended SQLVAR entry and the label in the second extended SQLVAR entry.</td>
<td></td>
</tr>
</tbody>
</table>

Note:
1. The third column of this table represents several forms of the DESCRIBE statement.
   • For DESCRIBE output and PREPARE INTO, the column pertains to columns of the result table.
   • For DESCRIBE CURSOR, the column pertains to a result set associated with a cursor.
   • For DESCRIBE INPUT, the column pertains to parameter markers.
   • For DESCRIBE PROCEDURE, the column pertains to the result sets returned by the stored procedure.

SQLTYPE and SQLLEN:

The contents of the SQLTYPE and SQLLEN fields of the SQLDA depends on the SQL statement that is returning the value.

The following table shows the values that can appear in the SQLTYPE and SQLLEN fields of the SQLDA. In DESCRIBE and PREPARE INTO, an even value of SQLTYPE means the column does not allow nulls, and an odd value means the column does allow nulls. In DESCRIBE INPUT statements, only odd values are returned for SQLTYPE. In FETCH, OPEN, EXECUTE, and CALL, an even value of SQLTYPE means no indicator variable is provided, and an odd value means that SQLIND contains the address of an indicator variable.

Table 228. SQLTYPE and SQLLEN values for DESCRIBE, PREPARE INTO, FETCH, OPEN, EXECUTE, and CALL

<table>
<thead>

<tr>
<td></td>
<td>DECFLOAT(34)</td>
<td>16</td>
</tr>
<tr>
<td>2448/2449</td>
<td>timestamp with time zone</td>
<td>147 for TIMESTAMP(0) WITH TIME ZONE otherwise 148+p for TIMESTAMP(p) WITH TIME ZONE</td>
</tr>
</tbody>
</table>

Note:
1. SQLLEN might be different if a date installation exit is specified.
2. SQLLEN might be different if a time installation exit is specified.
3. Field SQLLONGLEN in the extended SQLVAR contains the length attribute of the column. In REXX, the SQLVAR length attribute field name is SQLLONGL and SQLLEN is not used.
4. BIGINT is supported by other DB2 platforms.
5. p is the timestamp precision.

SQLDATA:

Depending on the data type of the string column that the SQLVAR is describing, the SQLDATA field can contain different CCSID values.

The following table identifies the CCSID values that appear in the SQLDATA field when the SQLVAR element describes a string column.
<table>
<thead>
<tr>
<th>Data type</th>
<th>Subtype</th>
<th>Bytes 1 and 2</th>
<th>Bytes 3 and 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Character</td>
<td>SBCS data</td>

<td>X'0000'</td>
<td>X'FFFF'</td>
</tr>
<tr>
<td>Graphic</td>
<td>N/A</td>
<td>X'0000'</td>
<td>CCSID</td>
</tr>
<tr>
<td>Any other data type</td>
<td>N/A</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>
Unrecognized and unsupported SQL TYPES

The values that appear in the SQLTYPE field of the SQLDA are dependent on the level of data type support available at the sender as well as at the receiver of the data. This support is particularly important as new data types are added to the product.

New data types might not be supported by the sender or receiver of the data and might not be recognized by the sender or receiver of the data. Depending on the situation, the new data type might be returned, a compatible data type that is agreed to by both the sender and the receiver of the data might be returned, or an error might occur.

When the sender and receiver agree to use a compatible data type, the following table indicates the mapping that takes place. This mapping takes place when at least one of the sender or receiver does not support the data type provided. The unsupported data type can be provided by either the application or the database manager.

Table 230. Compatible data types for unsupported data types

<table>
<thead>
<tr>
<th>Data type</th>
<th>Compatible data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWID</td>
<td>VARCHAR(40) FOR BIT DATA</td>
</tr>
</tbody>
</table>

No indication is given in the SQLDA that the data type is substituted.
The included SQLDA

Only assembler, C, C++, COBOL, and PL/I C are supported for the SQLDA that is given by INCLUDE SQLDA.

**assembler:**

```assembly
SQLTRIPL EQU C'3'
SQLDOUBL EQU C'2'
SQLSINGL EQU C''
*
   SQLSECT SAVE
*
SQLDA DSECT
SQLDAID DS CL8 ID
SQLDABC DS F BYTE COUNT
SQLN DS H COUNT SQLVAR/SQLVAR2 ENTRIES
SQLD DS H COUNT VARS (TWICE IF USING BOTH)
*
SQLVAR DS OF BEGIN VARS
SQLVARN DSECT , NTH VARIABLE
SQLTYPE DS H DATA TYPE CODE
SQLLEN DS OH LENGTH
SQLPRCSN DS X DEC PRECISION
SQLSCALE DS X DEC SCALE
SQLDATA DS A ADDR OF VAR
SQLIND DS A ADDR OF IND
SQLNAME DS H,CL30 DESCRIBE NAME
SQLSIZ EQU *-SQLDATA
SQLSVIZ EQU *-SQLVAR
*
SQLDA DSECT
SQLVAR2 DS OF BEGIN EXTENDED FIELDS OF VARS
SQLVAR2N DSECT , EXTENDED FIELDS OF NTH VARIABLE
SQLLONGL DS F LENGTH
SQLRSVDL DS F RESERVED
SQLDATAL DS A ADDR OF LENGTH IN BYTES
SQLNAME DS H,CL30 DESCRIBE NAME
*
   SQLSECT RESTORE
```

In the above declaration, SQLSECT SAVE is a macro invocation that remembers the current CSECT name. SQLSECT RESTORE is a macro invocation that continues that CSECT.

**C and C++:**

Identifying an SQLDA in C or C++

A descriptor-name can be specified in the CALL, DESCRIBE, EXECUTE, FETCH, and OPEN statements. When the host application is written in C or C++, descriptor-name can be a pointer variable with pointer notation.

For example, descriptor-name could be declared as

```c
sqlda *outsqlda;
```

Afterwords, it could be used in a statement like the following:

```sql
EXEC SQL DESCRIBE STMT1 INTO DESCRIPTOR :*outsqlda;
```
The REXX SQLDA

A REXX SQLDA consists of a set of REXX variables with a common stem. The stem must be a REXX variable name that contains no periods and is the same as the value of `descriptor-name` that you specify when you use the SQLDA in an SQL statement. DB2 does not support the INCLUDE SQLDA statement in REXX.

The following table shows the variable names in a REXX SQLDA. The values in the second column of the table are values that DB2 inserts into the SQLDA when the statement executes. Except where noted otherwise, the values in the third column of the table are values that the application must put in the SQLDA before the statement executes.

<table>
<thead>
<tr>
<th>Variable name</th>
<th>Usage in DESCRIBE and PREPARE INTO</th>
<th>Usage in FETCH, OPEN, EXECUTE, and CALL</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>stem.SQLD</code></td>
<td>The number of columns that are described in the SQLDA. Double that number if USING BOTH appears in the DESCRIBE or PREPARE INTO statement. Contains a 0 if the statement string is not a query. For DESCRIBE PROCEDURE, the number of result sets returned by the stored procedure. Contains a 0 if no result sets are returned.</td>
<td>The number of host variables that are used by the SQL statement.</td>
</tr>
</tbody>
</table>

Each SQLDA contains `stem.SQLD` of the following variables. Therefore, `1<=n<=stem.SQLD`. There is one occurrence of each variable for each column of the result table or host variable that is described by the SQLDA. This set of variables is equivalent to the SQLVAR structure in the SQLDA for other languages.

<table>
<thead>
<tr>
<th>Variable name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>stem.n.SQLTYPE</code></td>
<td>Indicates the data type of the column or parameter and whether it can contain null values. For a description of the type codes, see <a href="#">SQLTYPE and SQLLEN</a>. For a distinct type, the data type on which the distinct type was based is placed in this field. The base SQLVAR provides no indication that this is part of the description of a distinct type. Indicates the data type of the host variable and whether an indicator variable is provided. Host variables for datetime values must be character string variables. For FETCH, a datetime type code means a fixed-length character string. For a description of the type codes, see <a href="#">SQLTYPE and SQLLEN</a>.</td>
</tr>
<tr>
<td><code>stem.n.SQLLONGL</code></td>
<td>For a LOB column, the length of the string representation of the value or parameter. For a host variable that has a LOB data type, the length attribute of the host variable. For a description of supported values, see &quot;SQLTYPE and SQLEN&quot; on page 2397.</td>
</tr>
<tr>
<td><code>stem.n.SQLLEN</code></td>
<td>For a column other than a DECIMAL, NUMERIC, or LOB column, the length attribute of the column or parameter. For datetime data, the length of the string representation of the value. See <a href="#">SQLTYPE and SQLLEN</a> for a description of allowable values. For a host variable that does not have a decimal or LOB data type, the length attribute of the host variable. See <a href="#">SQLTYPE and SQLLEN</a> for a description of allowable values.</td>
</tr>
</tbody>
</table>
Table 231. Fields of a REXX SQLDA (continued)

<table>
<thead>
<tr>
<th>Variable name</th>
<th>Usage in DESCRIBE and PREPARE INTO</th>
<th>Usage in FETCH, OPEN, EXECUTE, and CALL</th>
</tr>
</thead>
<tbody>
<tr>
<td>stem.n.SQLLEN.SQLPRECISION</td>
<td>For a DECIMAL or NUMERIC column, the precision of the column or parameter.</td>
<td>For a host variable with a decimal data type, the precision of the host variable.</td>
</tr>
<tr>
<td>stem.n.SQLLEN.SQLSCALE</td>
<td>For a DECIMAL or NUMERIC column, the scale of the column or parameter.</td>
<td>For a host variable with a decimal data type, the scale of the host variable.</td>
</tr>
<tr>
<td>stem.n.SQLCCSID</td>
<td>For a string column or parameter, the CCSID of the column or parameter.</td>
<td>For a string host variable, the CCSID of the host variable.</td>
</tr>
<tr>
<td>stem.n.SQLUSECCSID</td>
<td>Not used.</td>
<td>Set to a new CCSID. If set, REXX will change the CCSID of the SQLDA.</td>
</tr>
<tr>
<td>stem.n.SQLLOCATOR</td>
<td>For DESCRIBE PROCEDURE, the value of a result set locator.</td>
<td>Not used.</td>
</tr>
<tr>
<td>stem.n.SQLDATA</td>
<td>Not used.</td>
<td>Before EXECUTE or OPEN, contains the value of an input host variable. The application must supply this value. After FETCH, contains the values of an output host variable.</td>
</tr>
<tr>
<td>stem.n.SQLIND</td>
<td>Not used.</td>
<td>Before EXECUTE or OPEN, contains a negative number to indicate that the input host variable in stem.n.SQLDATA is null. The application must supply this value. After FETCH, contains a negative number if the value of the output host variable in stem.n.SQLDATA is null.</td>
</tr>
<tr>
<td>stem.n.SQLNAME</td>
<td>The name of the n-th column in the result table. For DESCRIBE PROCEDURE, contains the cursor name that is used by the stored procedure to return the result set. The values for SQLNAME appear in the order that the cursors were opened by the stored procedure.</td>
<td>Not used.</td>
</tr>
</tbody>
</table>
DB2 catalog tables

DB2 for z/OS maintains a set of tables (in database DSNDB06) called the DB2 catalog.

About these topics

These topics describe that catalog by describing the columns of each catalog table.

The catalog tables describe such things as table spaces, tables, columns, indexes, privileges, application plans, and packages. Authorized users can query the catalog; however, it is primarily intended for use by DB2 and is therefore subject to change. All catalog tables are qualified by SYSIBM. Do not use this qualifier for user-defined tables.

The catalog tables are updated by DB2 during normal operations in response to certain SQL statements, commands, and utilities.

Additional information

Release dependency indicators: Some objects depend on functions in particular releases of DB2. If you are running on a release of DB2 and fall back to a previous release, an object that depends on the more recent release becomes frozen. The object is marked with a release dependency indicator and is unavailable until remigration.

The release dependency indicator, which is listed in the IBMREQD, RELCREATED, and RELBOUND columns of the catalog tables, shows the release of DB2 upon which the objects depend.

Important: The IBMREQD column is not a reliable indicator for indicating release dependencies. Where possible, the RELCREATED and RELBOUND columns should be used instead.

Release dependency indicators in IBMREQD, RELCREATED, and RELBOUND are defined by the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>Version 1R3 dependency indicator, not from the machine-readable material (MRM) tape</td>
</tr>
<tr>
<td>C</td>
<td>Version 2R1 dependency indicator, not from MRM tape</td>
</tr>
<tr>
<td>D</td>
<td>Version 2R2 dependency indicator, not from MRM tape</td>
</tr>
<tr>
<td>E</td>
<td>Version 2R3 dependency indicator, not from MRM tape</td>
</tr>
<tr>
<td>F</td>
<td>Version 3R1 dependency indicator, not from MRM tape</td>
</tr>
<tr>
<td>G</td>
<td>Version 4 dependency indicator, not from MRM tape</td>
</tr>
<tr>
<td>H</td>
<td>Version 5 dependency indicator, not from MRM tape</td>
</tr>
<tr>
<td>I</td>
<td>Version 6 dependency indicator, not from MRM tape</td>
</tr>
<tr>
<td>J</td>
<td>Version 6 dependency indicator, not from MRM tape</td>
</tr>
<tr>
<td>K</td>
<td>DB2 Version 7 dependency indicator, not from MRM tape</td>
</tr>
<tr>
<td>L</td>
<td>DB2 Version 8 dependency indicator, not from MRM tape</td>
</tr>
</tbody>
</table>
M  DB2 9 dependency indicator, not from MRM tape
O  DB2 10 dependency indicator, not from MRM tape
N  Not from MRM tape, no dependency

**Programming interface information**

Not all catalog table columns are part of the general-use programming interface. Whether a column is part of this interface is indicated in a column labeled “Use” in the table that describes the column. The values that “Use” can assume are as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>G</td>
<td>Column is part of the general-use programming interface</td>
</tr>
<tr>
<td>S</td>
<td>Column is part of the product-sensitive interface</td>
</tr>
<tr>
<td>I</td>
<td>Column is for internal use only</td>
</tr>
<tr>
<td>N</td>
<td>Column is not used</td>
</tr>
</tbody>
</table>

For columns for which “Use” is N or I, the name of the column and its description do not appear in the explanation of the column.

Notes:

1. The descriptions of the SYSBM.SYSOBDS and SYSBM.SYSOBD_AUX catalog tables are available only to users who work in enterprises with a DB2 10 license. For more information see Obtaining DB2 Diagnosis Guide and Reference ( ).

2. The following index types are indicated:
   - A Auxiliary
   - N Nonunique
   - U Unique
   - UC Unique clustering
   - UD Unique descending

Related concepts:
- Reorganizing the catalog

- SQL statements allowed on the catalog
SYSIBM.IPLIST table

The SYSIBM.IPLIST table allows multiple IP addresses to be specified for a given LOCATION.

Insert rows into this table when you want to define a remote DB2 data sharing group. The same value for the IPADDR column cannot appear in both the SYSIBM IPNAMES table and the SYSIBM.IPLIST table. Rows in this table can be inserted, updated, and deleted.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>LINKNAME</td>
<td>VARCHAR(24)</td>
<td>This column is associated with the value specified in the LINKNAME column in the SYSIBM.LOCATIONS table and the SYSIBM.IPNAMES table. The values of the other columns in the SYSIBM.IPNAMES table apply to the server identified by the LINKNAME column in this row.</td>
<td>G</td>
</tr>
</tbody>
</table>
| IPADDR      | VARCHAR(254)| This column contains an IPv4 or IPv6 address, or domain name of a remote TCP/IP host of the server. If WLM Domain Name Server workload balancing is used, this column must contain the member specific domain name. If Dynamic VIPA workload balancing is used, this column must contain the member specific Dynamic VIPA address. The IPADDR column must be specified as follows:  
- An IPv4 address must be left justified and is represented as a dotted decimal address. For example, '123.456.78.912' would be interpreted as an IPv4 address.  
- An IPv6 address must be left justified and is represented as a colon hexadecimal address. An example of an IPv6 address is '2001:0DB8:0000:0000:0008:0800:200C:417A', which can also be expressed in compressed form as '2001:DB8::8:800:200C:417A'.  
- A domain name is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined. An example of a domain name is 'stlmvs1.svl.ibm.com'. | G   |
| IBMREQD     | CHAR(1)     | A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators. The value in this field is not a reliable indicator of release dependencies. | G   |
SYSIBM.IPNAMES table

The SYSIBM.IPNAMES table defines the remote DRDA servers DB2 can access using TCP/IP.

Rows in this table can be inserted, updated, and deleted.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>

<td>NOT NULL</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>WITH DEFAULT 'A'</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **A**: The option is “already verified”. Outbound connection requests contain an authorization ID and no password. The authorization ID used for an outbound request is either the DB2 user’s authorization ID or a translated ID, depending upon the value of the USERNAMES column.

  The authorization ID is not encrypted when it is sent to the partner. For encryption, refer to ‘D’.

- **D**: The option is “userid and security-sensitive data encryption”. Outbound connection requests contain an authorization ID and no password. The authorization ID used for an outbound request is either the DB2 user’s authorization ID or a translated ID, depending upon the value of the USERNAMES column.

  This option indicates that the userid and security-sensitive data are to be encrypted. For non-encryption, refer to ‘A’.

- **E**: The option is “userid, password, and security-sensitive data encryption”. Outbound connection requests contain an authorization ID and a password. The password is obtained from the SYSIBM.USERNAMES table. The USERNAMES column must specify ‘O’.

  This option indicates that the userid, password, and security-sensitive data are to be encrypted. For non-security-sensitive data encryption, refer to ‘P’.

  If the applications connect to any remote server as trusted, the USERNAMES column must specify ‘O’ or ‘S’.

| IPADDR     | VARCHAR(254) NOT NULL WITH DEFAULT | This column contains an IPv4 or IPv6 address, or domain name of a remote TCP/IP host. The IPADDR column must be specified as follows:  
  • An IPv4 address must be left justified and is represented as a dotted decimal address. For example, '123.456.78.91' would be interpreted as an IPv4 address.  
  • An IPv6 address must be left justified and is represented as a colon hexadecimal address. An example of an IPv6 address is '2001:0DB8:0000:0000:0008:0800:200C:417A', which can also be expressed in compressed form as 2001:DB8::8:800:200C:417A.  
  • A domain name is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined. An example of a domain name is 'stlmvs1.svl.ibm.com'. | G   |
**SYSIBM.LOCATIONS table**

The SYSIBM.LOCATIONS table contains a row for every accessible remote server. The row associates a LOCATION name with the TCP/IP or SNA network attributes for the remote server. Requesters are not defined in this table.

Rows in this table can be inserted, updated, and deleted.

<table>
<thead>
<tr>

</tbody>
</table>
**SYSIBM.LULIST table**

The SYSIBM.LULIST table allows multiple LU names to be specified for a given LOCATION.

Insert rows into this table when you want to define a remote DB2 data sharing group. The same value for LUNAME column cannot appear in both the SYSIBM.LUNAMES table and the SYSIBM.LULIST table. Rows in this table can be inserted, updated, and deleted.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>LINKNAME</td>
<td>VARCHAR(24)</td>
<td>The value of the LINKNAME column in the SYSIBM.LOCATIONS table with which this row is associated. This is also the value of the LUNAME column in the SYSIBM.LUNAMES table. The values of the other columns in the SYSIBM.LUNAMES row apply to the LU identified by the LUNAME column in this row of SYSIBM.LULIST.</td>
<td>G</td>
</tr>
<tr>
<td>LUNAME</td>
<td>VARCHAR(24)</td>
<td>The VTAM logical unit name (LUNAME) of the remote database system. This LUNAME must not exist in the LUNAME column of SYSIBM.LUNAMES.</td>
<td>G</td>
</tr>
<tr>
<td>IBMREQD</td>

<td>A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see <a href="#">Release dependency indicators</a>. The value in this field is not a reliable indicator of release dependencies.</td>
<td>G</td>
</tr>
</tbody>
</table>

*Appendix. Additional information for DB2 SQL* 2425
SYSIBM.LUMODES table

Each row of the SYSIBM.LUMODES table provides VTAM with conversation limits for a specific combination of LUNAME and MODENAME. The table is accessed only during the initial conversation limit negotiation between DB2 and a remote LU. This negotiation is called *change-number-of-sessions* (CNOS) processing.

Rows in this table can be inserted, updated, and deleted.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>LUNAME</td>

</tr>
<tr>
<td>MODENAME</td>
<td>VARCHAR(24) NOT NULL</td>
<td>Name of a logon mode description in the VTAM logon mode table.</td>
<td>G</td>
</tr>
<tr>
<td>CONVLIMIT</td>
<td>SMALLINT NOT NULL</td>
<td>Maximum number of active conversations between the local DB2 and the other system for this mode. Used to override the number in the DSESLIM parameter of the VTAM APPL definition statement for this mode.</td>
<td>G</td>
</tr>
<tr>
<td>IBMREQD</td>
<td>CHAR(1) NOT NULL WITH DEFAULT 'N'</td>
<td>A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see <a href="#">Release dependency indicators</a>. The value in this field is not a reliable indicator of release dependencies.</td>
<td>G</td>
</tr>
</tbody>
</table>
## SYSIBM.LUNAMES table

The SYSIBM.LUNAMES table must contain a row for each remote SNA client or server that communicates with DB2.

Rows in this table can be inserted, updated, and deleted.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>LUNAME</td>
<td>VARCHAR(24)</td>
<td>Name of the LU for one or more accessible systems. A blank string indicates the row applies to clients whose LU name is not specifically defined in this table. All other column values for a given row in this table are for clients and servers associated with the row’s LU name.</td>
<td>G</td>
</tr>
<tr>
<td>SYSMODENAME</td>
<td>VARCHAR(24)</td>
<td>Mode used to establish inter-system conversations. A blank indicates the default mode IBMDB2LM (DB2 private protocol access and for collecting sysplex balancing information from remote data sharing groups). If private protocols are used to access a remote DB2 LU or if the remote LU is a member of a DB2 data sharing group, use a separate mode other than the default mode.</td>
<td>G</td>
</tr>
<tr>
<td>SECURITY_IN</td>
<td>CHAR(1)</td>
<td>This column defines the security options that are accepted by this DB2 when an SNA client connects to DB2:</td>
<td>G</td>
</tr>
</tbody>
</table>
|                 | NOT NULL WITH DEFAULT 'A' | V  The option is “verify”. An incoming connection request must include one of the following: a userid and password, a userid and RACF PassTicket, or a Kerberos security ticket. If the USERNAMES column contains 'I' or 'B', RACF is not invoked to validate incoming connection requests that contain only a userid unless one of the following situations is true:
  - The RACF access control authorization exit (DSNX@XAC) is enabled
  - The IBM supplied RACF SECLABEL resource class is active. |
|                 |                | A  The option is “already verified”. A request does not need a password, although a password is checked if it is sent. With this option, an incoming connection request is accepted if it includes any of the following: a userid, a userid and password, a userid and RACF PassTicket, or a Kerberos security ticket. |

</tr>
</tbody>
</table>
SYSIBM.SYSAUDITPOLICIES table

The SYSIBM.SYSAUDITPOLICIES table contains one row for each audit policy.

A user with SECADM authority has the privilege to select from, insert, update, or delete from this catalog table. A user with SQLADM, system DBADM, DATAACCESS, ACCESSCTRL, SYSCTRL or SYSADM authority has the privilege to select from this catalog table.

If a view is created on this catalog table, the DATAACCESS authority can perform insert, update, and delete on the view to indirectly insert, update, and delete on the catalog table.

<table>

</tbody>
</table>
**SYSIBM.SYSCOLDIST** table

The SYSIBM.SYSCOLDIST table contains one or more rows for the first key column of an index key.

Rows in this table can be inserted, updated, and deleted.

**Important:** Use care when issuing SQL statements or using tools to update statistics values in catalog tables. If such updates introduce invalid data, unpredictable results can occur, including abends for RUNSTATS and other utilities. If such problems occur, you can run the RUNSTATS utility and collect statistics at the table space level to resolve the problems, in most cases.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>

</table>
SYSIBM.SYSCOLDISTSTATS table

The SYSIBM.SYSCOLDISTSTATS table contains zero or more rows per partition for the first key column of a partitioning index or a data-partitioned secondary index.

No row is inserted if the index is a non-partitioned index. Rows in this table can be inserted, updated, and deleted.

**Important:** Use care when issuing SQL statements or using tools to update statistics values in catalog tables. If such updates introduce invalid data, unpredictable results can occur, including abends for RUNSTATS and other utilities. If such problems occur, you can run the RUNSTATS utility and collect statistics at the table space level to resolve the problems, in most cases.

SYSIBM.SYSCOLSTATS table

The SYSIBM.SYSCOLSTATS table contains partition statistics for selected columns. For each column, a row exists for each partition in the table.

Rows are inserted when RUNSTATS collects either indexed column statistics or non-indexed column statistics for a partitioned table space. No row is inserted if the table space is nonpartitioned. Rows in this table can be inserted, updated, and deleted.

**Important:** Use care when issuing SQL statements or using tools to update statistics values in catalog tables. If such updates introduce invalid data, unpredictable results can occur, including abends for RUNSTATS and other utilities. If such problems occur, you can run the RUNSTATS utility and collect statistics at the table space level to resolve the problems, in most cases.

<table>

Default indicator:

A  The column is defined as a ROWID with the GENERATED ALWAYS attribute.
B  The column is defined as a built-in data type with a default value that depends on the data type of the column.
D  The column is defined as a ROWID with the GENERATED BY DEFAULT attribute.
E  The column is defined with the FOR EACH ROW ON UPDATE and GENERATED ALWAYS attributes.
F  The column is defined with the FOR EACH ROW ON UPDATE and GENERATED BY DEFAULT attributes.
I  The column is defined with the AS IDENTITY and GENERATED ALWAYS attributes.
J  The column is defined with the AS IDENTITY and GENERATED BY DEFAULT attributes.
K  The column is defined for the implicit DOCID column for a base table that contains XML data.
L  The column is defined with the AS SECURITY LABEL attribute.
N  The column has no default value.
Q  The column is defined with the AS ROW BEGIN attribute.
R  The column is defined with the AS ROW END attribute.

</table>
| STYPE (continued) |            | When ICTYPE=T, the values are (continued):  
|                |            | I  
|                |            | COPY FULL NO  
|                |            | When ICTYPE=W or X, the values are:  
|                |            | A  
|                |            | Resetting REORG pending status or REBALANCE  
|                |            | T  
|                |            | First materializing the default value for a row change timestamp column  
|                |            | For other values of ICTYPE, the value is blank.  
| PIT_RBA        | CHAR(6)    | The meaning of the value depends on the value of the ICTYPE column:  
|                | NOT NULL   | ICTYPE='P'  
|                | WITH DEFAULT | The LRSN for the point in the DB2 log. (The LRSN is the RBA in a non-data-sharing environment) The value indicates the stop location of a point-in-time recovery.  
|                | FOR BIT DATA | If a record contains ICTYPE='P' and PIT_RBA=X'000000000000', the copy pending status is active and a full image copy is required.  
|                |            | If such a record is encountered during fallback processing of RECOVER, the recover job fails, and a point-in-time recovery is required.  
|                |            | PIT_RBA can be zero if the point-in-time recovery is completed by the fall-back processing of RECOVER, or if ICTYPE=P from a prior release of DB2.  
|                |            | ICTYPE='F' or 'I' and SHRLEVEL='C'  
|                |            | The current RBA or LRSN that corresponds to the point in the DB2 log when the SHRLEVEL CHANGE copy completes.  
|                |            | ICTYPE='F', SHRLEVEL='R' or 'C', and ICBACKUP='FC'  
|                |            | The RBA or LRSN that corresponds to the point in the DB2 log when the FlashCopy completes.  
|                |            | CTYPE='F' and SHRLEVEL 'R' or 'C', STYPE= 'T', 'N', 'Q', or 'U'  
|                |            | The RBA or LRSN that corresponds to the point in the DB2 log when the FlashCopy completes.  
|                |            | ICTYPE='M'  
|                |            | The RBA/LRSN for the end of the log when the utility completes.  
|                |            | For other all other ICTYPE values, this field contains X'000000000000'.  
| GROUP_MEMBER   | CHAR(8)    | The DB2 data sharing member name of the DB2 subsystem that performed the operation. This column is blank if the DB2 subsystem was not in a DB2 data sharing environment at the time the operation was performed.  
|                | NOT NULL   | WITH DEFAULT  
|                |            | OTYPE        | CHAR(1)    | Type of object that the recovery information is for:  
|                | NOT NULL   | WITH DEFAULT | T          | CTYPE 'I'  
|                |            |            |            | Index space  
|                |            |            |            | T            | Table space

## SYSIBM.SYSCTXTRUSTATTRS table

The SYSIBM.SYSCTXTRUSTATTRS table contains one row for each list of attributes for a given trusted context.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTEXTID</td>
<td>INTEGER</td>
<td>The internal trusted context ID.</td>
<td>G</td>
</tr>
<tr>
<td>NAME</td>
<td>VARCHAR(128)</td>
<td>Name of the trust attribute. Possible values including the following attributes:</td>
<td>G</td>
</tr>
<tr>
<td></td>
<td>NOT NULL</td>
<td>• An IPv4 address is represented as a dotted decimal IP address. An example of an IPv4 address is '9.112.46.111'.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• An IPv6 address is represented as a colon hexadecimal address. An example of an IPv6 address is '2001:0DB8:0000:0000:0008:0800:200C:417A', which can also be expressed in a compressed form as '2001:DB8::8:800:200C:417A'.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A domain name which is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A job or started task name for local applications. If the job name ends with *, any job name that matches the characters prior to * in the specified job name are considered for establishing the trusted connection.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A network access security zone name in the RACF SERVAUTH class.</td>
<td></td>
</tr>
<tr>
<td>VALUE</td>
<td>VARCHAR(254)</td>
<td>The value of the trust attribute.</td>
<td>G</td>
</tr>
<tr>
<td>CREATEDTS</td>
<td>TIMESTAMP</td>
<td>The time when the attribute is created.</td>
<td>G</td>
</tr>
<tr>
<td>IBMREQD</td>
<td>CHAR(1)</td>
<td>A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see <a href="#">Release dependency indicators</a>.</td>
<td>G</td>
</tr>
</tbody>
</table>

The value in this field is not a reliable indicator of release dependencies.
### SYSIBM.SYSDATABASE table

The SYSIBM.SYSDATABASE table contains one row for each database.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>

<td>G</td>
</tr>
</tbody>
</table>
SYSIBM.SYSDUMMY1 table

The SYSIBM.SYSDUMMY1 table contains one row. The table is used for SQL statements in which a table reference is required, but the contents of the table are not important.

Unlike the other catalog tables, which reside in Unicode table spaces, SYSIBM.SYSDUMMY1 resides in table space SYSEBCDC, which is an EBCDIC table space.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBMREQD</td>
<td>CHAR(1)</td>
<td>A value of Y indicates that the row came from the basic machine-readable</td>
<td>G</td>
</tr>
<tr>
<td></td>
<td>NOT NULL</td>
<td>material (MRM) tape. For all other values, see Release dependency indicators.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The value in this field is not a reliable indicator of release dependencies.</td>
<td></td>
</tr>
</tbody>
</table>
**SYSIBM.SYSDUMMYA table**

The SYSIBM.SYSDUMMYA table contains one row. The table is used for SQL statements in which a table reference is required, but the contents of the table are not important.

SYSIBM.SYSDUMMYA resides in table space SYSTSASC, which is an ASCII table space.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBMREQD</td>
<td>CHAR(1)</td>
<td>A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see <a href="#">Release dependency indicators</a>.</td>
<td>G</td>
</tr>
<tr>
<td></td>
<td>NOT NULL</td>
<td>The value in this field is not a reliable indicator of release dependencies.</td>
<td></td>
</tr>
</tbody>
</table>
SYSIBM.SYSDUMMYE table

The SYSIBM.SYSDUMMYE table contains one row. The table is used for SQL statements in which a table reference is required, but the contents of the table are not important.

SYSIBM.SYSDUMMYE resides in table space SYSEBCDC, which is an EBCDIC table space.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBMREQD</td>
<td>CHAR(1)</td>
<td>A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see <a href="#">Release dependency indicators</a>.</td>
<td>G</td>
</tr>
</tbody>
</table>

The value in this field is not a reliable indicator of release dependencies.
SYSIBM.SYSDUMMYU table

The SYSIBM.SYSDUMMYU table contains one row. The table is used for SQL statements in which a table reference is required, but the contents of the table are not important.

SYSIBM.SYSDUMMYU resides in table space SYSTSUNI, which is a UNICODE table space.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBMREQD</td>
<td>CHAR(1)</td>
<td>A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see <a href="#">Release dependency indicators</a>.</td>

**SYSIBM.SYSINDEXES_TREE table**

The SYSIBM.SYSINDEXES_TREE table is an auxiliary table for the PARSETREE column of the SYSIBM.SYSINDEXES table and is required to hold LOB data.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOB(1G)</td>
<td>NOT NULL</td>
<td>Internal use only.</td>
<td>I</td>
</tr>
<tr>
<td></td>
<td>WITH DEFAULT</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The SYSIBM.SYSINDEXPART table contains one row for each nonpartitioned secondary index (NPSI) and one row for each partition of a partitioning index or a data-partitioned secondary index.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>PARTITION</td>
<td>SMALLINT NOT NULL</td>
<td>Partition number; Zero if index is not partitioned.</td>
<td>G</td>
</tr>
<tr>
<td>IXNAME</td>
<td>VARCHAR(128) NOT NULL</td>

**SYSIBM.SYSINDEXSTATS table**

The SYSIBM.SYSINDEXSTATS table contains one row for each partition of a partitioning index or a data-partitioned secondary index.

Rows in this table can be inserted, updated, and deleted.

**Important:** Use care when issuing SQL statements or using tools to update statistics values in catalog tables. If such updates introduce invalid data, unpredictable results can occur, including abends for RUNSTATS and other utilities. If such problems occur, you can run the RUNSTATS utility and collect statistics at the table space level to resolve the problems, in most cases.

<td></td>
</tr>
</tbody>
</table>
The SYSIBM.SYSKEYTARGETSTATS table contains partition statistics for selected key-targets. For each key-target, a row exists for each partition in the table.

Rows are inserted when RUNSTATS collects indexed key statistics or non-indexed key statistics for a partitioned table space. No row is inserted if the table space is nonpartitioned. Rows in this table can be inserted, updated, and deleted.

**Important**: Use care when issuing SQL statements or using tools to update statistics values in catalog tables. If such updates introduce invalid data, unpredictable results can occur, including abends for RUNSTATS and other utilities. If such problems occur, you can run the RUNSTATS utility and collect statistics at the table space level to resolve the problems, in most cases.

### Column name | Data type | Description | Use
--- | --- | --- | ---
IXSCHEMA | VARCHAR(128) NOT NULL | The qualifier of the index. | G
IXNAME | VARCHAR(128) NOT NULL | The name of the index. | G
KEYSEQ | SMALLINT NOT NULL | Numeric position of the key-target in the index. | G
HIGHKEY | VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA | The highest key value. | S
HIGH2KEY | VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA | The second highest key-value. | S
LOWKEY | VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA | The lowest key value. | S
LOW2KEY | VARCHAR(2000) NOT NULL WITH DEFAULT FOR BIT DATA | The second lowest key-value. | S
PARTITION | SMALLINT NOT NULL | The partition number of the table space. | G
STATSTIME | TIMESTAMP NOT NULL WITH DEFAULT | If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01-00.00.00.000000'. The default value indicates that statistics were not collected. This is an updatable column. | G
IBMREQD | CHAR(1) NOT NULL | A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators. The value in this field is not a reliable indicator of release dependencies. | G

SYSIBM.SYSKEYTGTDISTSTATS table

The SYSIBM.SYSKEYTGTDISTSTATS table contains zero or more rows per partition for the first key-target of a data-partitioned secondary index.

Rows are inserted when RUNSTATS scans a data-partitioned secondary index. No row is inserted if the index is a secondary index. Rows in this table can be inserted, updated, and deleted.

**Important:** Use care when issuing SQL statements or using tools to update statistics values in catalog tables. If such updates introduce invalid data, unpredictable results can occur, including abends for RUNSTATS and other utilities. If such problems occur, you can run the RUNSTATS utility and collect statistics at the table space level to resolve the problems, in most cases.

</tbody>
</table>

---

Appendix. Additional information for DB2 SQL. 2559
The SYSIBM.SYSPACKAGE table contains a row for every package.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOCATION</td>
<td>VARCHAR(128) NOT NULL</td>
<td>Always contains blanks</td>
<td>S</td>
</tr>
<tr>
<td>COLLID</td>
<td>VARCHAR(128) NOT NULL</td>
<td>Name of the package collection. For a trigger package, it is the schema name of the trigger.</td>
<td>G</td>
</tr>
<tr>
<td>NAME</td>
<td>VARCHAR(128) NOT NULL</td>
<td>Name of the package.</td>
<td>G</td>
</tr>
<tr>
<td>CONTOKEN</td>
<td>CHAR(8) NOT NULL FOR BIT DATA</td>
<td>Consistency token for the package. For a package derived from a DB2 DBRM, this is either: • The &quot;level&quot; as specified by the LEVEL option when the package's program was precompiled • The timestamp indicating when the package's program was precompiled, in an internal format.</td>
<td>S</td>
</tr>
<tr>
<td>OWNER</td>
<td>VARCHAR(128) NOT NULL</td>
<td>Authorization ID of the package owner. For a trigger package, the value is the authorization ID of the owner of the trigger, which is set to the current authorization ID (the plan or package owner for static CREATE TRIGGER statement; the CURRENT SQLID for a dynamic CREATE TRIGGER statement).</td>
<td>G</td>
</tr>
<tr>
<td>CREATOR</td>
<td>VARCHAR(128) NOT NULL</td>
<td>Authorization ID of the owner of the creator of the package version. For a trigger package, the value is determined differently. For dynamic SQL, it is the primary authorization ID of the user who issued the CREATE TRIGGER statement. For static SQL, it is the authorization ID of the plan or package owner.</td>
<td>G</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>TIMESTAMP NOT NULL</td>
<td>Timestamp indicating when the package was created.</td>
<td>G</td>
</tr>
<tr>
<td>BINDTIME</td>
<td>TIMESTAMP NOT NULL</td>
<td>Timestamp indicating when the package was last bound.</td>
<td>G</td>
</tr>
<tr>
<td>QUALIFIER</td>
<td>VARCHAR(128) NOT NULL</td>
<td>Implicit qualifier for the unqualified table, view, index, and alias names in the static SQL statements of the package.</td>
<td>G</td>
</tr>
<tr>
<td>PKSIZE</td>
<td>INTEGER NOT NULL</td>
<td>Size of the base section² of the package, in bytes.</td>
<td>G</td>
</tr>
<tr>
<td>AVGSIZE</td>
<td>INTEGER NOT NULL</td>
<td>Average size, in bytes, of those sections² of the plan that contain SQL statements processed at bind time.</td>
<td>G</td>
</tr>
<tr>
<td>SYSENTRIES</td>
<td>SMALLINT NOT NULL</td>
<td>Number of enabled or disabled entries for this package in SYSIBM.SYSPKSYSTEM. A value of 0 if all types of connections are enabled.</td>
<td>G</td>
</tr>
</tbody>
</table>

² Packages are divided into sections. The base section of the package must be in the EDM pool during the entire time the package is executing. Other sections of the package, corresponding roughly to sets of related SQL statements, are brought into the pool as needed.

<td>G</td>
</tr>
<tr>
<td>IBMREQD</td>
<td>CHAR(1)</td>
<td>A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators. The value in this field is not a reliable indicator of release dependencies. RELBOUND should be used instead.</td>
<td>G</td>
</tr>
<tr>
<td>VERSION</td>
<td>VARCHAR(122)</td>
<td>Version identifier for the package. The value is blank for a trigger package (TYPE='T') and when the package is created using the BIND PACKAGE command the initial version of the package (TYPE='blank').</td>
<td>G</td>
</tr>
<tr>
<td>PDSNAME</td>
<td>VARCHAR(132)</td>
<td>For a locally bound package, the name of the PDS (library) in which the package's DBRM is a member. For a locally copied package, the value in SYSPACKAGE.PDSNAME for the source package. Otherwise, the product signature of the bind requester followed by one of the following: • For DB2 for z/OS remote requesters, the requester's location name, or IP address, or LU name enclosed in angle brackets (for example, &quot;&lt;LUSQLDS&gt;&quot;). • For non-DB2 for z/OS remote requesters, the requester's IP address or LU name enclosed in angle brackets.</td>
<td>G</td>
</tr>
<tr>
<td>DEGREE</td>
<td>CHAR(3)</td>
<td>The DEGREE option used when the package was last bound: ANY DEGREE(ANY) 1 or blank DEGREE(1). Blank if the package was migrated.</td>
<td>G</td>
</tr>
<tr>
<td>GROUP_MEMBER</td>
<td>VARCHAR(24)</td>
<td>The DB2 data sharing member name of the DB2 subsystem that performed the most recent bind. This column is blank if the DB2 subsystem was not in a DB2 data sharing environment when the bind was performed.</td>
<td>G</td>
</tr>
</tbody>
</table>
The DYNAMICRULES option used when the package was last bound:

- **B** BIND. Dynamic SQL statements are executed with DYNAMICRULES bind behavior.

- **D** DEFINEBIND. When the package is run under an active stored procedure or user-defined function, dynamic SQL statements in the package are executed with DYNAMICRULES define behavior.

  When the package is not run under an active stored procedure or user-defined function, dynamic SQL statements in the package are executed with DYNAMICRULES bind behavior.

- **E** DEFINERUN. When the package is run under an active stored procedure or user-defined function, dynamic SQL statements in the package are executed with DYNAMICRULES define behavior.

  When the package is not run under an active stored procedure or user-defined function, dynamic SQL statements in the package are executed with DYNAMICRULES run behavior.

- **H** INVOKEBIND. When the package is run under an active stored procedure or user-defined function, dynamic SQL statements in the package are executed with DYNAMICRULES invoke behavior.

  When the package is not run under an active stored procedure or user-defined function, dynamic SQL statements in the package are executed with DYNAMICRULES bind behavior.

- **I** INVOKERUN. When the package is run under an active stored procedure or user-defined function, dynamic SQL statements in the package are executed with DYNAMICRULES invoke behavior.

  When the package is not run under an active stored procedure or user-defined function, dynamic SQL statements in the package are executed with DYNAMICRULES run behavior.

- **R** RUN. Dynamic SQL statements are executed with DYNAMICRULES run behavior.

- **blank** DYNAMICRULES is not specified for the package. The package uses the DYNAMICRULES value of the plan to which the package is appended at execution time.

For a description of the DYNAMICRULES behaviors, see "Authorization IDs and dynamic SQL" on page 95.

SYSIBM.SYSPACKDEP table

The SYSIBM.SYSPACKDEP table records the dependencies of packages on local tables, views, synonyms, table spaces, indexes, aliases, functions, and stored procedures.

Access paths for SQL statements might depend on objects that DB2 does not actually use when it processes the selected access paths. Such dependencies are recorded in the SYSPACKDEP catalog table, but they are not be shown in EXPLAIN output.

<tr>
<td></td>
<td></td>
<td>blank The WITH clause was not specified on this statement. The isolation level is recorded in SYSPACKAGE.ISOLATION and in SYSPLAN.ISOLATION.</td>
<td></td>
</tr>
</tbody>
</table>

---

\(^45\) Rows in which the value of SEQNO, STMTNO, and SECTNO are zero are for internal use.

\(^46\) To convert a negative STMTNO to a meaningful statement number that corresponds to your precompile output, add 65536 to it. For example, -26472 is equivalent to +39064 (-26472 + 65536).

</tbody>
</table>
## SYSIBM.SYSPARMS table

The SYSIBM.SYSPARMS table contains a row for each parameter of a routine or multiple rows for table parameters (one for each column of the table).

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA</td>
<td>VARCHAR(128) NOT NULL</td>
<td>Schema of the routine.</td>
<td>G</td>
</tr>
<tr>
<td>OWNER</td>
<td>VARCHAR(128) NOT NULL</td>
<td>Owner of the routine.</td>
<td>G</td>
</tr>
<tr>
<td>NAME</td>
<td>VARCHAR(128) NOT NULL</td>
<td>Name of the routine.</td>
<td>G</td>
</tr>
<tr>
<td>SPECIFICNAME</td>
<td>VARCHAR(128) NOT NULL</td>
<td>Specific name of the routine.</td>
<td>G</td>
</tr>
<tr>
<td>ROUTINETYPE</td>
<td>CHAR(1) NOT NULL</td>
<td>Type of routine:</td>
<td>G</td>
</tr>
<tr>
<td>CAST_FUNCTION</td>
<td>CHAR(1) NOT NULL</td>
<td>Whether the routine is a cast function:</td>
<td>G</td>
</tr>
<tr>
<td>PARMNAME</td>
<td>VARCHAR(128) NOT NULL</td>
<td>Name of the parameter. For a table parameter, the parameter name in the row corresponding to the first column of the table is the parameter name specified on CREATE; an empty string or blanks are stored for the parameter name for the rows corresponding to the remaining columns.</td>
<td>G</td>
</tr>
<tr>
<td>ROUTINEID</td>
<td>INTEGER NOT NULL</td>
<td>Internal identifier of the routine.</td>
<td>S</td>
</tr>
</tbody>
</table>

The only way to get a value of Y is if a user creates a distinct type when DB2 implicitly generates cast functions for the distinct type.
<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWTYPE</td>
<td>CHAR(1) NOT NULL</td>
<td>The following values indicate the type of parameter described by this row:</td>
<td>G</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>P</strong></td>
<td>Input parameter.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>O</strong></td>
<td>Output parameter; not applicable for functions</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>B</strong></td>
<td>Both an input and an output parameter; not applicable for functions</td>
</tr>
<tr>

SYSIBM.SYSQUERY table

Each SYSIBM.SYSQUERY table row identifies a SQL statement. The information is used to influence access path selection when matching statements are optimized.

<table>
<thead>

**SYSIBM.SYSQUERY_AUX table**

The SYSIBM.SYSQUERY_AUX table is an auxiliary table for the STMTTEXT column of the SYSIBM.SYSQUERY table.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>STMTTEXT</td>
<td>CLOB(2M)</td>
<td>The full text of the query.</td>
<td>G</td>
</tr>
</tbody>
</table>
### SYSIBM.SYSQUERYOPTS table

The SYSIBM.SYSQUERYOPTS table contains optimization parameters for the queries that are in the SYSIBM.SYSQUERY table.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERID</td>
<td>BIGINT</td>
<td>Unique identifier for the query. This column corresponds to the QUERID column in the SYSIBM.SYSQUERY table.</td>
<td>G</td>
</tr>
<tr>
<td>COPYID</td>
<td>SMALLINT</td>
<td>The version of the plan hints for the query in this row.</td>
<td>G</td>
</tr>
<tr>
<td></td>
<td>NOT NULL</td>
<td>0</td>
<td>Current version of the plan hints.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1</td>
<td>Previous version of the plan hints used by PLAN STABILITY</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2</td>
<td>Original version of the plan hints used by PLAN STABILITY</td>
</tr>
<tr>
<td>REOPT</td>
<td>CHAR(1)</td>
<td>The value of the REOPT bind option that is in effect for the plan:</td>
<td>G</td>
</tr>
<tr>
<td></td>
<td>NOT NULL</td>
<td>1</td>
<td>REOPT(ONCE)</td>
</tr>
<tr>
<td></td>
<td></td>

The SYSIBM.SYSQUERYPLAN table contains the plan hint information for the queries in the SYSIBM.SYSQUERY table. It correlates to the SYSIBM.SYSQUERY table by the QUER YID column. For a query, there can be up to 3 copies of plan hints stored in the SYSIBM.SYSQUERYPLAN table, distinguished by the value of the COPYID column.

<table>
<thead>
<tr>
<th>Column name</th>

</table>
| DEBUG_MODE          | CHAR(1) NOT NULL WITH DEFAULT | Identifies whether or not this routine is enabled for debugging:  
1  This routine is enabled for debugging and can be debugged in a client debug session using the DB2 Unified Debugger.  
0  This routine is not enabled for debugging.  
N  This routine can never be enabled for debugging.  
blank  The LANGUAGE is not specified as JAVA, the value of ORIGIN is not 'N', or the row was created prior to Version 9. | G   |
| TEXT_ENVID          | INTEGER NOT NULL WITH DEFAULT | Internal identifier of the environment. The column is 0 if the value of ORIGIN is not 'N' or if the row was created prior to Version 9.                                                                          | G   |
| TEXT_ROWID          | ROWID NOT NULL GENERATED ALWAYS | ID to support LOB columns for source text.                                                                                                                                                               | G   |
| TEXT                | CLOB(2M) NOT NULL WITH DEFAULT | The text of the statement that created the SQL routine, including the body of the routine. In some cases, this column might instead contain the text of a statement that altered the SQL routine. In many cases, changes to routines or to objects on which routines are dependent do not update this value.  
The value is a zero-length string if the value of ORIGIN is not 'N' or if the row was created prior to Version 9. | G   |
| OWNERTYPE           | CHAR(1) NOT NULL WITH DEFAULT | Indicates the type of owner:  
blank  Authorization ID  
L  Role                                                                                                                                  | G   |
| PARAMETER_VARCHARFORM | INTEGER NOT NULL WITH DEFAULT | A non-zero value that indicates the actual representation, to a LANGUAGE C routine, of any varying length string parameter that appears in the parameter list or RETURNS clause for that routine. | G   |
| RELCREATED          | CHAR(1) NOT NULL | The release of DB2 that is used to create the object.  
Blank if created prior to Version 9.  
See Release dependency indicators for all other values.                                                                                                                                 | G   |
| PACKAGEPATH         | VARCHAR(4096)   | The value of the PACKAGE PATH option of the CREATE FUNCTION, CREATE PROCEDURE, ALTER FUNCTION, or ALTER PROCEDURE statement that created or last changed the routine. PACKAGE PATH identifies the package path to use when the routine is executed.  
A blank value indicates the package path is the same as the package path of the program that invoked the routine. | G   |
| SECURE              | CHAR(1) NOT NULL WITH DEFAULT 'N' | Indicates if the routine is secured:  
N  The routine is not secured  
Y  The routine is secured                                                                                                                 | G   |

SYSIBM.SYSSTRINGS table

The SYSIBM.SYSSTRINGS table contains information about character conversion. Each row describes a conversion from one coded character set to another.

Also refer to z/OS C/C++ Programming Guide for information on the additional conversions that are supported.

Each row in the table must have a unique combination of values for its INCCSID, OUTCCSID, and IBMREQD columns. Rows for which the value of IBMREQD is N can be deleted, inserted, and updated subject to this uniqueness constraint and to the constraints imposed by a VALIDPROC defined on the table. An inserted row could have values for the INCCSID and OUTCCSID columns that match those of a row for which the value of IBMREQD is Y. DB2 then uses the information in the inserted row instead of the information in the IBM-supplied row. Rows for which the value of IBMREQD is Y cannot be deleted, inserted, or updated. For information about the use of inserted rows for character conversion, see DB2 Installation Guide.

DB2 has two methods for character conversions and applies them in the following order:

1. Conversions specified by the various combinations of the INCCSID and OUTCCSID columns in the SYSIBM.SYSSTRINGS catalog table.
2. Conversions provided by z/OS support for Unicode. For more information, see z/OS Support for Unicode: Using Conversion Services.

If neither of these methods can be used for a particular character conversion, DB2 returns an error.

</tr>
<tr>
<td>HASHSPACE</td>
<td>BIGINT</td>
<td>For partition-by-growth table spaces this is zero. For range-partitioned universal table spaces, this is the amount of space, in KB, specified at the partition level to override the space specification at the table level. If no override is provided it will be the same as the value of HASHSPACE in the SYSIBM.SYSTABLESPACE catalog table.</td>
<td>G</td>
</tr>
<tr>
<td>HASHDATAPAGES</td>
<td>BIGINT</td>
<td>For partition-by-growth table spaces, the value is zero. For range-partitioned universal table spaces, this is the number of hash data pages that correspond to the value of the HASHSPACE column for each partition. The value is 0 for table spaces which have been changed to use hash access but have not been reorganized.</td>
<td>G</td>
</tr>
</tbody>
</table>
SYSIBM.SYSTABLEPART_HIST table

The SYSIBM.SYSTABLEPART_HIST table contains rows from SYSTABLEPART.

Rows are added or changed in this table when RUNSTATS collects history statistics. Rows in this table can also be inserted, updated, and deleted.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>PARTITION</td>
<td>SMALLINT</td>
<td>Partition number. 0 if table space is not partitioned.</td>
<td>G</td>
</tr>
<tr>

<td>G</td>
</tr>
<tr>
<td></td>
<td>NOT NULL</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For user-specified values of PRIQTY other than -1, the value is set to the primary space allocation only if RUNSTATS TABLESPACE with UPDATE(ALL) or UPDATE(SPACE) is executed; otherwise, the value is zero. PQTY is based on a value of PRIQTY in the appropriate CREATE or ALTER TABLESPACE statement. Unlike PQTY, however, PRIQTY asks for space in 1 KB units.

A value of -1 indicates that either of the following cases is true:

- PRIQTY was not specified for a CREATE TABLESPACE statement or for any subsequent ALTER TABLESPACE statements.
- -1 was the most recently specified value for PRIQTY, either on the CREATE TABLESPACE statement or a subsequent ALTER TABLESPACE statement.

If a storage group is not used, the value is 0.

<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----</td>
</tr>
<tr>
<td>ALTEREDTS</td>
<td>TIMESTAMP NOT NULL WITH DEFAULT</td>
<td>For a table, the time when the latest ALTER TABLE statement was applied. If no ALTER TABLE statement was applied, or if the row is for an alias, ALTEREDTS has the value of CREATEDTS. For a view, the time when the last ALTER VIEW REGENERATE statement was applied.</td>
<td>G</td>
</tr>
</tbody>
</table>
| DATACAPTURE | CHAR(1) NOT NULL WITH DEFAULT | Records the value of the DATA CAPTURE option for a table:  
- blank: No  
- Y: Yes  
For a created temporary table, DATACAPTURE is always blank. | G   |
| RBA1        | CHAR(6) NOT NULL WITH DEFAULT FOR BIT DATA | The log RBA when the table was created. Otherwise, RBA1 is X'000000000000', indicating that the log RBA is not known, or that the object is a view, an alias, or a created temporary table. In a data sharing environment, RBA1 is the LRSN (Log Record Sequence Number) value. | S   |
| RBA2        | CHAR(6) NOT NULL WITH DEFAULT FOR BIT DATA | The log RBA when the table was last altered. Otherwise, RBA2 is X'000000000000' indicating that the log RBA is not known, or that the object is a view, an alias, or a created temporary table. RBA1 equals RBA2 if the table has not been altered. In a data sharing environment, RBA2 is the LRSN (Log Record Sequence Number) value. | S   |
| PCTROWCOMP  | SMALLINT NOT NULL WITH DEFAULT | Percentage of rows that are compressed within the total number of active rows in the table. This number includes any row in a table space that is defined with COMPRESS YES. The value is -1 if statistics have not been gathered, or the row describes a view, alias, created temporary table, an accelerator-only table, or auxiliary table. This column can be updated. | S   |
| STATTIME    | TIMESTAMP NOT NULL WITH DEFAULT | If RUNSTATS updated the statistics, the date and time when the last invocation of RUNSTATS updated the statistics. The default value is '0001-01-01-00.00.00.000000'.  
The default value indicates that statistics were not collected. This is an updatable column. For a created temporary table, the value of STATTIME is always the default value. | G   |
| CHECKS      | SMALLINT NOT NULL WITH DEFAULT | Number of check constraints that are defined on the table. The value is 0 if either of the following conditions are true:  
- The row describes a view, an alias, a created temporary table, or a materialized query table.  
- No constraints are defined on the table. | G   |
<p>| CARDF       | FLOAT NOT NULL WITH DEFAULT -1 | Total number of rows in the table or total number of LOBs in an auxiliary table. The value is -1 if statistics have not been gathered or the row describes a view, alias, accelerator-only table, or created temporary table. This column can be updated. | S   |</p>

</tbody>
</table>
SYSIBM.SYSTABLESPACESTATS table

The SYSIBM.SYSTABLESPACESTATS table contains real time statistics for table spaces.

Rows in this table can be inserted, updated, and deleted.

Important: Use care when issuing SQL statements or using tools to update statistics values in catalog tables. If such updates introduce invalid data, unpredictable results can occur, including abends for RUNSTATS and other utilities. If such problems occur, you can run the RUNSTATS utility and collect statistics at the table space level to resolve the problems, in most cases.

In data sharing environments, the values in SYSIBM.SYSTABLESPACESTATS can be negative for short periods of time for certain situations.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>UPDATESTATETIME</td>
<td>TIMESTAMP</td>
<td>The timestamp that the row in the SYSTABLESPACESTATS table is inserted or updated.</td>
<td>G</td>
</tr>
<tr>
<td>NACTIVE</td>
<td>INTEGER</td>
<td>The number of active pages in the table space or partition.</td>
<td>G</td>
</tr>
<tr>
<td>NPAGES</td>
<td>INTEGER</td>
<td>The number of distinct pages with active rows in the partition or table space. This is an updatable column.</td>
<td>G</td>
</tr>
<tr>
<td>EXTENTS</td>
<td>SMALLINT</td>
<td>The number of extents in the table space. For multi-piece table spaces, this value is the number of extents for the last data set. For a data set that is striped across multiple volumes, the value is the number of logical extents. A null value indicates the number of extents is unknown.</td>
<td>G</td>
</tr>
<tr>
<td>LOADRLASTTIME</td>
<td>TIMESTAMP</td>
<td>The timestamp that the LOAD REPLACE utility was last run on the table space or partition. A null value indicates that the LOAD REPLACE utility has never been run on the table space or partition or that the timestamp is unknown.</td>
<td>G</td>
</tr>
<tr>
<td>REORGLASTTIME</td>
<td>TIMESTAMP</td>
<td>The timestamp the REORG utility was last run on the table space or partition, or when the REORG utility has not been run, the time when the table space or partition was created. A null value indicates that the timestamp is unknown.</td>
<td>G</td>
</tr>
<tr>
<td>REORGINSERTS</td>
<td>INTEGER</td>
<td>The number of rows or LOBs that have been inserted into the table space or partition or loaded into the table space or partition using the LOAD utility specified without the REPLACE option since the last time the REORG or LOAD REPLACE utilities were run, or since the object was created. A null value indicates that the number of inserted rows or LOBs is unknown.</td>

### SYSIBM.SYSTABSTATS_HIST table

The SYSIBM.SYSTABSTATS_HIST table contains rows from SYSTABSTATS.

Rows are added or changed in this table when RUNSTATS collects history statistics. Rows in this table can also be inserted, updated, and deleted.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>

</tbody>
</table>
SYSIBM.SYXMLSTRINGS table

Each row of the SYSIBM.SYXMLSTRINGS table contains a single string and its unique ID that are used to condense XML data. The string can be an element name, attribute name, name space prefix, or a namespace URI.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>STRINGID</td>
<td>INTEGER</td>
<td>Unique ID for the string.</td>
<td>G</td>
</tr>
<tr>

<td>G</td>
</tr>
<tr>
<td></td>
<td>NOT NULL</td>
<td>The value in this field is not a reliable indicator of release dependencies.</td>
<td></td>
</tr>
</tbody>
</table>
SYSIBM.USERNAMES table

Each row in the SYSIBM.USERNAMES table is used to carry out one outbound ID translation or inbound ID translation and “come from” checking.

Rows in this table can be inserted, updated, and deleted.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>TYPE</td>
<td>CHAR(1) NOT NULL</td>
<td>How the row is to be used:</td>
<td>G</td>
</tr>
<tr>
<td></td>
<td></td>
<td>I  For inbound translation and “come from” checking.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>O  For outbound translation.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>S  For outbound system AUTHID to establish a trusted connection.</td>
<td></td>
</tr>
<tr>
<td>AUTHID</td>
<td>VARCHAR(128) NOT NULL WITH DEFAULT</td>
<td>Authorization ID to be translated. Applies to any authorization ID if blank.</td>
<td>G</td>
</tr>
<tr>
<td>LINKNAME</td>
<td>VARCHAR(24) NOT NULL</td>
<td>Identifies the VTAM or TCP/IP network locations associated with this row.</td>
<td>G</td>
</tr>
<tr>
<td></td>
<td></td>
<td>A blank value in this column indicates this name translation rule applies to any TCP/IP or SNA partner.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>If a non-blank LINKNAME is specified, one or both of the following statements must be true:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A row exists in SYSIBM.LUNAMES whose LUNAME matches the value specified in the SYSIBM.USERNAMES LINKNAME column. This row specifies the VTAM site associated with this name translation rule.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A row exists in SYSIBM.IPNAMES whose LINKNAME matches the value specified in the SYSIBM.USERNAMES LINKNAME column. This row specifies the TCP/IP host associated with this name translation rule.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Inbound name translation and “come from” checking are not performed for TCP/IP clients.</td>
<td></td>
</tr>
<tr>
<td>NEWAUTHID</td>
<td>VARCHAR(128) NOT NULL WITH DEFAULT</td>
<td>Translated value of AUTHID. Blank specifies no translation. NEWAUTHID can be stored as encrypted data by calling the DSNLEUSR stored procedure. To send the encrypted value of AUTHID across a network, one of the encryption security options in the SYSIBM.IPNAMES table should be specified.</td>
<td>G</td>
</tr>
<tr>
<td>PASSWORD</td>
<td>VARCHAR(255) NOT NULL WITH DEFAULT</td>
<td>Password to accompany an outbound request, if passwords are not encrypted by RACF. If passwords are encrypted, or the row is for inbound requests, the column is not used. PASSWORD can be stored as encrypted data by calling the DSNLEUSR stored procedure. To send the encrypted value of PASSWORD across a network, one of the encryption security options in the SYSIBM.IPNAMES table should be specified.</td>
<td>G</td>
</tr>
<tr>
<td>IBMREQD</td>
<td>CHAR(1) NOT NULL WITH DEFAULT 'N'</td>
<td>A value of Y indicates that the row came from the basic machine-readable material (MRM) tape. For all other values, see Release dependency indicators. The value in this field is not a reliable indicator of release dependencies.</td>
<td>G</td>
</tr>
</tbody>
</table>
**SYSIBM.SYSXMLTYPMOD table**

The SYSIBM.SYSXMLTYPMOD table contains rows about the XML type modifiers of XML columns. Rows in this table can be inserted, updated and deleted.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>XML_TYPMOD_ID</td>
<td>INTEGER NOT NULL</td>
<td>An id generated for the XML type modifier, it is an identity column and primary key.</td>

</tbody>
</table>

Reorganizing the catalog

The REORG TABLESPACE utility can be run on all the table spaces in the catalog database (DSNDB06) to reclaim unused or wasted space, which can affect performance.

The utility observes the PCTFREE and FREEPAGE values specified in the ALTER INDEX statement for all the catalog indexes and the following table spaces:

- DSNDB06.SYSCOPY
- DSNDB06.SYSDDF
- DSNDB06.SYSGPAUT
- DSNDB06.SYSGRTNS
- DSNDB06.SYSHIST
- DSNDB06.SYSJAVA
- DSNDB06.SYSJAUXA
- DSNDB06.SYSJAUXB
- DSNDB06.SYSSEQ
- DSNDB06.SYSSEQ2
- DSNDB06.SYSSTR
- DSNDB06.SYSTATS
- DSNDB06.SYSUSER
- DSNDB01.SCT02
- DSNDB01.SPT01

Related tasks:

- Reserving free space for table spaces (DB2 Performance)

Catalog indexes

Indexes are defined on most catalog tables to improve catalog access.

The following table identifies the DB2 catalog tables on which indexes are defined, the columns that are in each of the indexes, and the data types of those columns.

<table>
<thead>
<tr>
<th>Table</th>
<th>Index (type)</th>
<th>Columns (data type)</th>
</tr>
</thead>
<tbody>
<tr>

New and changed catalog tables

DB2 10 introduces new catalog tables and changes to existing catalog tables.

Descriptions of the following catalog tables have been added:

- SYSIBM.SYSAUDITPOLICIES
- SYSIBM.SYSAUTOALERTS
- SYSIBM.SYSAUTOALERTS_OUT
- SYSIBM.SYSAUTORUNS_HIST
- SYSIBM.SYSAUTORUNS_HISTOU
- SYSIBM.SYSAUTOTIMEWINDOWS
- SYSIBM.SYSCONTROLS
- SYSIBM.SYSDUMMYA
- SYSIBM.SYSDUMMYE
- SYSIBM.SYSDUMMYU
- SYSIBM.SYSINDEXES_RTSECT
- SYSIBM.SYSINDEXES_TREE
- SYSIBM.SYSPACKCOPY
- SYSIBM.SYSPACKSTMT_STMT
- SYSIBM.SYSPACKSTMT_STMT
- SYSIBM.SYSPENDINGDDL
- SYSIBM.SYSPENDINGOBJECTS
- SYSIBM.SYSQUERY
- SYSIBM.SYSQUERY_AUX
- SYSIBM.SYSQUERYOPTS
- SYSIBM.SYSQUERYPLAN
- SYSIBM.SYSROUTINES_TREE
- SYSIBM.SYSS_PROFILES
- SYSIBM.SYSS_PROFILE_TEXT
- SYSIBM.SYSSTRIGGERS_STMT
- SYSIBM.SYSVIEWS_STMT
- SYSIBM.SYSVIEWS_TREE
- SYSIBM.SYXMLTYPMOD
- SYSIBM.SYXMLTYPMSHEMA

The catalog tables that are listed in the following table have new or revised columns, column values, or column descriptions to support the new capabilities in DB2 10.

<table>
<thead>
<tr>

DB2 directory tables

DB2 for z/OS maintains a set of tables (in database DSNI01) called the DB2 directory. Authorized users can query the directory; however, it is primarily intended for use by DB2 and is therefore subject to change.

About these topics

These topics describe the directory tables that allow SELECT operations by describing the columns of those tables.

Users must have one of the following privileges to execute SELECT statements on the directory tables:
- Installation SYSADM
- SYSADM
- SYSCTRL
- ACCESSCTRL
- DATAACCESS
- SECADM
- SQLADM
- System DBADM
- DBADM on DSNI01
- The SELECT privilege on a specific table

All directory tables are qualified by SYSIBM. Do not use this qualifier for user-defined tables.

The directory tables are not, in most cases, updated as part of DB2 operations.

The following table lists restrictions on SQL statements that reference directory tables:

<table>
<thead>
<tr>
<th>SQL statement</th>
<th>Restriction</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER TABLE</td>
<td><code>table-name</code> cannot specify a directory table.</td>
</tr>
<tr>
<td>ALTER TABLESPACE</td>
<td>The table space cannot be altered if it is associated with a directory table.</td>
</tr>
<tr>
<td>CREATE INDEX</td>
<td>ON <code>table-name</code> or <code>aux-table-name</code> cannot specify a directory table.</td>
</tr>
<tr>
<td>CREATE TRIGGER</td>
<td>ON <code>table-name</code> cannot specify a directory table.</td>
</tr>
<tr>
<td>DELETE</td>
<td>FROM <code>table-name</code> cannot specify a directory table.</td>
</tr>
<tr>
<td>DROP</td>
<td><code>table-name</code> cannot specify a directory table.</td>
</tr>
<tr>
<td>INSERT</td>
<td>INTO <code>table-name</code> cannot specify a directory table.</td>
</tr>
<tr>
<td>MERGE</td>
<td>INTO <code>table-name</code> cannot specify a directory table.</td>
</tr>
<tr>
<td>RENAME</td>
<td><code>source-table-name</code> cannot specify a directory table.</td>
</tr>
<tr>
<td>UPDATE</td>
<td><code>table-name</code> cannot specify a directory table.</td>
</tr>
</tbody>
</table>

Programming interface information

None of the directory table columns are part of the general-use programming interface. The column labeled “Use” in the table that describes the column indicates whether the column is part of the product-sensitive interface or is for internal, IBM use only. The values that “Use” can assume are as follows:
<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>Column is part of the product-sensitive interface</td>
</tr>
<tr>
<td>I</td>
<td>Column is for internal use only</td>
</tr>
</tbody>
</table>

For columns for which “Use” is I, the name of the column and its description do not appear in the explanation of the column.
Directory table spaces and indexes

DB2 directory tables are contained in certain table spaces and have indexes.

The following table lists the table space and indexes for each directory table and lists the index fields for each index. The indexes are in ascending order.

The directory table space, tables, and indexes are primarily intended for use by DB2 and are therefore subject to change.

Table 236. Table spaces and indexes for the directory tables

<table>
<thead>
<tr>
<th>TABLE SPACE</th>
<th>TABLE</th>
<th>INDEX</th>
<th>INDEX FIELDS</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSNDB01. ...</td>

</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>DSNLUX02</td>
</tr>
</tbody>
</table>

Note:

1. SCT02 and its index, DSNSCT02, cannot be queried from a DB2 V10 catalog.
SYSIBM.DBDR table
The DBDR table stores one row for each DBD section.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>INTEGER</td>
<td>Not used</td>
<td>S</td>

<tr>
<td>DBD_ROWID</td>
<td>ROWID</td>
<td>ID that is used to support the DBD_DATA column</td>
<td>S</td>
</tr>
<tr>
<td>DBD_DATA</td>
<td>BLOB(2G)</td>
<td>DBD data for the section</td>
<td>I</td>
</tr>
</tbody>
</table>
**SYSIBM.SYSDBD_DATA table**

The SYSIBM.SYSDBD_DATA table is an auxiliary table for the SYSIBM.DBDR table.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBD_DATA</td>
<td>BLOB(2G)</td>
<td>Contents of the DBD section.</td>
<td>I</td>
</tr>
</tbody>
</table>
**SYSIBM.SPTR table**

The SYSIBM.SPTR table stores Skeleton Package Table (SKPT) information

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPTLL</td>
<td>INTEGER</td>
<td>The length of the record.</td>

<tr>
<td>SPTSEC</td>
<td>CHAR(4) FOR BIT DATA</td>
<td>Section number.</td>
<td>S</td>
</tr>
<tr>
<td>SPTSEQ</td>
<td>CHAR(2) FOR BIT DATA</td>
<td>Sequence number within the section.</td>
<td>S</td>
</tr>
<tr>
<td>SPTBODY</td>
<td>VARCHAR(1)</td>
<td>Reserved.</td>
<td>I</td>
</tr>
<tr>
<td>SPTVER</td>
<td>VARCHAR(64)</td>
<td>Package version.</td>
<td>S</td>
</tr>
<tr>
<td>SPT_ROWID</td>
<td>ROWID</td>
<td>ROWID that DB2 creates for the LOB columns in this table.</td>
<td>S</td>
</tr>
<tr>
<td>SPT_DATA</td>
<td>BLOB(2G)</td>
<td>Internal use only.</td>
<td>I</td>
</tr>
<tr>
<td>SPT_EXPLAIN</td>
<td>BLOB(2G)</td>
<td>Internal use only.</td>
<td>I</td>
</tr>
</tbody>
</table>
**SYSIBM.SYSSPTSEC_DATA table**

The SYSIBM.SYSSPTSEC_DATA table is an auxiliary table that contains package data for the SYSIBM.SPTR table.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPT_DATA</td>
<td>BLOB(2G)</td>
<td>Contents of the SKPT section</td>
<td>I</td>
</tr>
</tbody>
</table>
### SYSIBM.SYSSPTSEC_EXPL table

The SYSIBM.SYSSPTSEC_EXPL table is an auxiliary table that contains static package explain data for the SYSIBM.SPTR table.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPT_EXPLAIN</td>
<td>BLOB(2G)</td>
<td>Contents of the SKPT section explain block</td>
<td>I</td>
</tr>
</tbody>
</table>

Appendix. Additional information for DB2 SQL  2747
The SYSLGRNX table stores recovery log ranges that record the time an index space defined with COPY YES or a table space was open for updates. This provides an efficient way for DB2 to access the appropriate log records for recovery, rather than having to scan every record in the recovery log for a particular table.

<table>
<thead>
<tr>

**SYSIBM.SYSUTIL table**

The SYSUTIL table stores status information about DB2 utilities that are active or stopped. Each record is uniquely identified by the utility identifier. Each row of the table contains the information for one utility execution step. When the utility completes, the corresponding entries in the SYSUTIL table are deleted.

<table>

Performance information for SQL application programming

Efficient applications are an important first step to good system and application performance. As you code applications that access data in DB2, consider performance objectives in your application design.

The following topics can help you understand how application programmers can consider performance as they write applications that access data in DB2 for z/OS.

Concurrency and programming

The goal is to program and prepare applications in a way that:
- Protects the integrity of the data that is being read or updated from being changed by other applications.
- Minimizes the length of time that other access to the data is prevented.

For more information about data concurrency in DB2 and recommendations for improving concurrency in your application programs, see the following topics:
- Designing databases for concurrency (DB2 Performance)
- Concurrency and locks (DB2 Performance)
- Improving concurrency (DB2 Performance)
- Improving concurrency in data sharing environments (DB2 Data Sharing Planning and Administration)

Writing efficient queries

The predicates, subqueries, and other structures in SQL statements affect the access paths that DB2 uses to access the data.

For information about how to write SQL statements that access data efficiently, see the following topics:
- Ways to improve query performance (Introduction to DB2 for z/OS)
- Writing efficient SQL queries (DB2 Performance)
Analyzing access paths

By analyzing the access path that DB2 uses to access the data for an SQL statement, you can discover potential problems. You can use this information to modify your statement to perform better.

For information about how you can use EXPLAIN tables, and SQL optimization tools such as IBM Data Studio or IBM Data Server Manager, to analyze the access paths for your SQL statements, see the following topics:

- Investigating access path problems (DB2 Performance)
- 00C200A4 (DB2 Codes)
- Investigating SQL performance by using EXPLAIN (DB2 Performance)
- Interpreting data access by using EXPLAIN (DB2 Performance)
- EXPLAIN tables (DB2 Performance)
- EXPLAIN
- Tuning SQL with Optim Query Tuner, Part 1: Understanding access paths (IBM developerWorks)
- Generating visual representations of access plans (IBM Data Studio)

Distributed data access performance

The goal is to reduce the amount of network traffic that is required to access the distributed data, and to manage the use of system resources such as distributed database access threads and connections.

For information about improving the performance of applications that access distributed data, see the following topics:

- Ways to reduce network traffic (Introduction to DB2 for z/OS)
- Managing DB2 threads (DB2 Performance)
- Improving performance for applications that access distributed data (DB2 Performance)
- Improving performance for SQL statements in distributed applications (DB2 Performance)

Stored procedures performance

For information about stored procedures and DB2 performance, see the following topics:

- Implementing DB2 stored procedures ()
- Improving the performance of stored procedures and user-defined functions (DB2 Performance)

Related concepts:

- Programming for DB2 for z/OS (Introduction to DB2 for z/OS)

DB2 XML schema repository tables

The DB2 for z/OS XML schema repository (XSR) is a set of DB2 tables where you can store XML schemas.

DB2 creates the XSR tables during installation or migration. After you add XML schemas to the DB2 XSR, you can use them to validate XML documents before you store them in XML columns.

An XML schema consists of a set of XML schema documents. To add an XML schema to the DB2 XSR, you register XML schema documents to DB2. The XML schema documents must be in the Unicode encoding scheme.

**Programming interface information**

Not all XSR table columns are part of the general-use programming interface. Whether a column is part of this interface is indicated in a column labeled “Use” in the row that describes the table column. The meaning of the values for the “Use” column is indicated in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>G</td>
<td>Column is part of the general-use programming interface</td>
</tr>
<tr>
<td>S</td>
<td>Column is part of the product-sensitive interface</td>
</tr>
<tr>
<td>I</td>
<td>Column is for IBM use only</td>
</tr>
<tr>
<td>N</td>
<td>Column is not used</td>
</tr>
</tbody>
</table>

For columns for which “Use” is N or I, the name of the column and its description do not appear in the explanation of the column.

XML schema repository (XSR) table spaces and indexes

DB2 XSR tables are contained in certain table spaces and have indexes.

The following tables list the table space and indexes for each XRS table and lists the index fields for each index. The indexes are in ascending order, except where noted.

Table 238. Table spaces and indexes for the DSNXSR database tables

<table>
<thead>
<tr>

<td>CHAR(1) NOT NULL</td>
<td>The release of DB2 that is used to create the object. See <a href="#">Release dependency indicators</a> for the values.</td>
<td>G</td>
</tr>
</tbody>
</table>

---

Note: Static SQL statements for updating this table are only allowed through the DB2-supplied XSR stored procedures.
SYSIBM.XSROBJECTGRAMMAR table

SYSIBM.XSROBJECTGRAMMAR is an auxiliary table for the BLOB column GRAMMAR in SYSIBM.SYSXSROBJECTS. It is in LOB table space SYSXSRA1.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRAMMAR</td>
<td>BLOB(250M)</td>
<td>Internal binary representation of the XML schema</td>
<td>G</td>
</tr>
</tbody>
</table>
**SYSIBM.XSROBJECTHIERARCHIES table**

The SYSIBM.XSROBJECTHIERARCHIES table contains one row for each component (document) in an XML schema to record the XML schema document hierarchy relationship.

Rows in this table can only be changed using static SQL statements issued by the DB2-supplied XSR stored procedures.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>XSROBJECTID</td>
<td>INTEGER</td>
<td>Internal identifier of the XML schema.</td>
<td>G</td>
</tr>
<tr>
<td>XSRCOMPONENTID</td>

<td></td>
<td>location URI of the primary XML schema document is stored in</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>SYSIBM.SYSXMLSTRINGS.</td>
<td></td>
</tr>
<tr>
<td>RELCREATED</td>
<td>CHAR(1)</td>
<td>The release of DB2 that is used to create the object. See</td>
<td>G</td>
</tr>
<tr>
<td></td>
<td>NOT NULL</td>
<td><a href="#">Release dependency indicators</a> for the values.</td>
<td></td>
</tr>
</tbody>
</table>
SYSIBM.XSROBJECTPROPERTY table

SYSIBM.XSROBJECTPROPERTY is an auxiliary table for the BLOB column PROPERTIES in SYSIBM.SYSXSROBJECTS. It is in LOB table space SYSXSRA2.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROPERTIES</td>
<td>BLOB(5M)</td>
<td>Contents of the additional property information of the entire XML schema.</td>
<td>G</td>
</tr>
</tbody>
</table>
The SYSIBM.XSRPROPERTY table is an auxiliary table for the BLOB column COMPONENT in SYSIBM.XSROBJECTCOMPONENTS. It is in LOB table space SYSXSRA3.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMPONENT</td>
<td>BLOB(5M)</td>
<td>Contents of the additional property information of the XML schema document.</td>
<td>G</td>
</tr>
</tbody>
</table>
EXPLAIN tables

EXPLAIN tables contain information about SQL statements and functions that run on DB2 for z/OS.

You can create and maintain a set of EXPLAIN tables to capture and analyze information about the performance of SQL statements and functions that run on DB2 for z/OS. Each row in an EXPLAIN table describes some aspect of a step in the execution of a query or subquery in an explainable statement. The column values for the row identify, among other things, the query or subquery, the tables and other objects involved, the methods used to carry out each step, and cost information about those methods. DB2 creates EXPLAIN output and populates EXPLAIN tables in the following situations:

- When an EXPLAIN statement is executed.
- At BIND or REBIND with the EXPLAIN(YES) or (ONLY) bind options. Rows are added for every explainable statement in the plan or package being bound. For a plan, these do not include statements in the packages that can be used with the plan. For either a package or plan, they do not include explainable statements within EXPLAIN statements nor do they include explainable statements that refer to declared temporary tables, which are incrementally bound at run time.
- When an explainable dynamic statement is executed and the value of the CURRENT EXPLAIN MODE special register is set to YES or EXPLAIN.
- When the DSNAEXP stored procedure executes successfully. The DSNAEXP stored procedure is deprecated.

Important: It is best to convert EXPLAIN tables to DB2 10 format during migration, or soon after migration. In DB2 10, the EXPLAIN function supports tables that have only the DB2 10, DB2 9, or Version 8 formats. However, DB2 9 format and Version 8 format EXPLAIN tables are deprecated. If you invoke EXPLAIN and DB2 9 or Version 8 tables are used, DB2 issues SQL code +20520. If tables of an unsupported format are found, DB2 issues SQL code -20008 and the EXPLAIN operation fails.

Important: If the EXPLAIN tables have any format older than the DB2 Version 8 format, or are encoded in EBCDIC, DB2 returns an error for any operation that tries inserts rows in the EXPLAIN tables.

Related tasks:

- Migration step 24: Convert EXPLAIN tables to the current format and encoding type (DB2 Installation and Migration)

Related reference:

- BIND and REBIND options for packages and plans (DB2 Commands)
- EXPLAIN
- Investigating SQL performance by using EXPLAIN (DB2 Performance)
PLAN_TABLE

The plan table, PLAN_TABLE, contains information about access paths that is collected from the results of EXPLAIN statements.

Recommendation: Do not manually insert data into system-maintained EXPLAIN tables, and use care when deleting obsolete EXPLAIN table data. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools. Certain optimization tools depend on instances of the various EXPLAIN tables. Be careful not to delete data from or drop instances EXPLAIN tables that are created for these tools.

Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

'SYSIBM'

One instance of this table can be created with the SYSIBM qualifier. DB2 and SQL optimization tools might use the table and the data that it contains. The table is created when you run job DSNTIJSG when you install or migrate DB2.

'user-ID'

You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind. They are also populated when you specify EXPLAIN(YES) or EXPLAIN(ONLY) in a BIND or REBIND command. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the prefix.SDSNSAMP library.

Optional PLAN_TABLE formats

A PLAN_TABLE instance can have a format with fewer columns than those shown in the sample CREATE TABLE statement. However instances of PLAN_TABLE must have one of the following formats:

DB2 10 format

All columns shown in the sample CREATE TABLE statement, up to and including the MERGN column (COLCOUNT=64).

DB2 9 format

All columns shown in the sample CREATE TABLE statement, up to and including the PARENT_PLANNO column (COLCOUNT=59). This format is deprecated. For information about converting tables in this format to the current format, see Migration step 24: Convert EXPLAIN tables to the current format and encoding type (DB2 Installation and Migration).

DB2 Version 8 format

All columns shown in the sample CREATE TABLE statement, up to and including the STMTTOKEN column (COLCOUNT=58). This format is
deprecated. For information about converting tables in this format to the current format, see Converting EXPLAIN tables for migration from DB2 Version 8 (DB2 Installation and Migration).

**Important:** If the EXPLAIN tables have any format older than the DB2 Version 8 format, or are encoded in EBCDIC, DB2 returns an error for any operation that tries inserts rows in the EXPLAIN tables.

**Column descriptions**

Your subsystem or data sharing group can contain more than one of these tables, including a table with the qualifier SYSIBM, a table with the qualifier DB2OSCA, and additional tables that are qualified by user IDs.

The following table shows the descriptions of the columns in PLAN_TABLE.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERYNO</td>
<td>INTEGER NOT NULL</td>
<td>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>For rows produced by EXPLAIN statements</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>For rows not produced by EXPLAIN statements</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>DB2 assigns a number that is based on the line number of the SQL statement in the source program.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in certain rare cases, the value is not guaranteed to be unique.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the SQL statement is embedded in a compiled SQL function or native SQL procedure, if the QUERYNO clause is specified, its value is used by DB2. Otherwise DB2 assigns a number based on the line number of the SQL statement in the compiled SQL function or native SQL procedure.</td>
</tr>
<tr>
<td>QBLOCKNO</td>
<td>SMALLINT NOT NULL</td>
<td>A number that identifies each query block within a query. The value of the numbers are not in any particular order, nor are they necessarily consecutive.</td>
</tr>
<tr>
<td>APPLNAME</td>
<td>VARCHAR(24) NOT NULL</td>
<td>The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column is not used, and is blank.</td>
</tr>
<tr>
<td>Column name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>PROGNAME</td>
<td>VARCHAR(128) NOT NULL</td>
<td>The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable. When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column indicates the specific name of the compiled SQL function or native SQL procedure.</td>
</tr>
<tr>
<td>PLANNO</td>
<td>SMALLINT NOT NULL</td>
<td>The number of the step in which the query that is indicated in QBLOCKNO was processed. This column indicates the order in which the steps were executed.</td>
</tr>
<tr>
<td>METHOD</td>
<td>SMALLINT NOT NULL</td>
<td>A number that indicates the join method that is used for the step:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 The table in this step is the first table that is accessed, a continuation of a previous table that was accessed, or a table that is not used.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 A nested loop join is used. For each row of the current composite table, matching rows of a new table are found and joined.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2 A merge scan join is used. The current composite table and the new table are scanned in the order of the join columns, and matching rows are joined.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3 Sorts are needed by ORDER BY, GROUP BY, SELECT DISTINCT, UNION, INTERSECT, EXCEPT, a quantified predicate, or an IN predicate. This step does not access a new table.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>4 A hybrid join was used. The current composite table is scanned in the order of the join-column rows of the new table. The new table is accessed using list prefetch.</td>
</tr>
<tr>
<td>CREATOR</td>
<td>VARCHAR(128) NOT NULL</td>
<td>The creator of the new table that is accessed in this step, blank if METHOD is 3.</td>
</tr>
</tbody>
</table>
Table 239. Descriptions of columns in PLAN_TABLE (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TNAME</td>
<td>VARCHAR(128) NOT NULL</td>
<td>The name of one of the following objects:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Table</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Materialized query table</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Created or declared temporary table</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Materialized view</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Materialized table expression</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Any of the following object names that identify intermediate results:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'DSNWFOB(qblockno)'</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The intermediate result of a UNION ALL, INTERSECT ALL, EXCEPT ALL, or an outer join that is materialized. If a view is merged, the name of the view does not appear.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'DSN_DIM_TBLX(qblockno)'</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The work file of a star join dimension table.</td>
</tr>

</tr>
<tr>
<td>TABNO</td>
<td>SMALLINT NOT NULL</td>
<td>Values are for IBM use only.</td>
</tr>
<tr>
<td>ACCESSTYPE</td>
<td>CHAR(2) NOT NULL</td>
<td>The method of accessing the new table</td>
</tr>
<tr>
<td>MATCHCALS</td>
<td>SMALLINT NOT NULL</td>
<td>For ACCESSTYPE I, IN, I1, N, NR, MX, or DX, the number of index keys that are used in an index scan; otherwise, 0.</td>
</tr>
<tr>
<td>ACCESSCREATOR</td>
<td>VARCHAR(128) NOT NULL</td>
<td>For ACCESSTYPE I, I1, N, NR, MX, or DX, the creator of the index; otherwise, blank.</td>
</tr>
<tr>
<td>ACCESSNAME</td>
<td>VARCHAR(128) NOT NULL</td>
<td>For ACCESSTYPE I, I1, N, NR, MX, or DX, the name of the index; for ACCESSTYPE P, DSNPFW(mixopseqno) is the starting pair-wise join leg in MIXOPSEQ; otherwise, blank.</td>
</tr>
<tr>
<td>INDEXONLY</td>
<td>CHAR(1) NOT NULL</td>
<td>Indication of whether access to an index alone is enough to perform the step, or Indication of whether data too must be accessed.</td>
</tr>
<tr>
<td></td>
<td>Y</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td>N</td>
<td>No</td>
</tr>
<tr>
<td>SORTN_UNIQ</td>
<td>CHAR(1) NOT NULL</td>
<td>Indication of whether the new table is sorted to remove duplicate rows.</td>
</tr>
<tr>
<td></td>
<td>Y</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td>N</td>
<td>No</td>
</tr>
<tr>
<td>SORTN_JOIN</td>
<td>CHAR(1) NOT NULL</td>
<td>Indication of whether the new table is sorted for join method 2 or 4.</td>
</tr>
<tr>
<td></td>
<td>Y</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td>N</td>
<td>No</td>
</tr>
<tr>
<td>SORTN_ORDERBY</td>
<td>CHAR(1) NOT NULL</td>
<td>Indication of whether the new table is sorted for ORDER BY.</td>
</tr>
<tr>
<td></td>
<td>Y</td>
<td>Yes</td>

<tr>
<td>SORTN_GROUPBY</td>
<td>CHAR(1) NOT NULL</td>
<td>Indication of whether the new table is sorted for GROUP BY.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Y Yes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>N No</td>
</tr>
<tr>
<td>SORTC_UNIQ</td>
<td>CHAR(1) NOT NULL</td>
<td>Indication of whether the composite table is sorted to remove duplicate rows.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Y Yes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>N No</td>
</tr>
<tr>
<td>SORTC_JOIN</td>
<td>CHAR(1) NOT NULL</td>
<td>Indication of whether the composite table is sorted for join method 1, 2 or 4.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Y Yes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>N No</td>
</tr>
<tr>
<td>SORTC_ORDERBY</td>
<td>CHAR(1) NOT NULL</td>
<td>Indication of whether the composite table is sorted for an ORDER BY clause or a quantified predicate.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Y Yes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>N No</td>
</tr>
<tr>
<td>SORTC_GROUPBY</td>
<td>CHAR(1) NOT NULL</td>
<td>Indication of whether the composite table is sorted for a GROUP BY clause.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Y Yes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>N No</td>
</tr>
<tr>
<td>Column name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>--------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TSLOCKMODE</td>
<td>CHAR(3) NOT NULL</td>
<td>An indication of the mode of lock that is acquired on either the new table, or its table space or table space partitions. If the isolation can be determined at bind time, the values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>IS  Intent share lock</td>
</tr>
<tr>
<td></td>
<td></td>
<td>IX  Intent exclusive lock</td>
</tr>
<tr>
<td></td>
<td></td>
<td>S   Share lock</td>
</tr>
<tr>
<td></td>
<td></td>
<td>U   Update lock</td>
</tr>
<tr>
<td></td>
<td></td>
<td>X   Exclusive lock</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SIX Share with intent exclusive lock</td>
</tr>
<tr>
<td></td>
<td></td>
<td>N   UR isolation; no lock</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If the isolation level cannot be determined at bind time, the lock mode is determined by the isolation level at run time is shown by the following values.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>NS  For UR isolation, no lock; for CS, RS, or RR, an S lock.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>NIS For UR isolation, no lock; for CS, RS, or RR, an IS lock.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>NSS For UR isolation, no lock; for CS or RS, an IS lock; for RR, an S lock.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SS  For UR, CS, or RS isolation, an IS lock; for RR, an S lock.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The data in this column is right justified. For example, IX appears as a blank, followed by I, followed by X. If the column contains a blank, then no lock is acquired.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If the access method in the ACCESSTYPE column is DX, DI, or DU, no latches are acquired on the XML index page and no lock is acquired on the new base table data page or row, nor on the XML table and the corresponding table spaces. The value of TSLOCKMODE is a blank in this case.</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>CHAR(16) NOT NULL</td>
<td>This column is deprecated. Use EXPLAIN_TIME instead.</td>
</tr>
<tr>
<td>REMARKS</td>
<td>VARCHAR(762) NOT NULL</td>
<td>A field into which you can insert any character string of 762 or fewer characters.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>DB2 inserts a value into this column in certain situations.</td>
</tr>
<tr>
<td>PREFETCH</td>
<td>CHAR(1) NOT NULL WITH DEFAULT</td>
<td>Indication of whether data pages are to be read in advance by prefetch:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'D'  Optimizer expects dynamic prefetch</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'S'  Pure sequential prefetch</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'L'  Prefetch through a page list</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'U'  List prefetch with an unsorted RID list</td>
</tr>
<tr>
<td></td>
<td></td>
<td>blank Unknown or no prefetch</td>
</tr>
</tbody>
</table>
### Table 239. Descriptions of columns in PLAN_TABLE (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLUMN_FN_EVAL</td>
<td>CHAR(1) NOT NULL WITH DEFAULT</td>
<td>When an SQL aggregate function is evaluated:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'R' While the data is being read from the table or index</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'S' While performing a sort to satisfy a GROUP BY clause</td>
</tr>
<tr>
<td></td>
<td></td>
<td>blank After data retrieval and after any sorts</td>
</tr>
<tr>
<td>MIXOPSEQ</td>
<td>SMALLINT NOT NULL WITH DEFAULT</td>
<td>The sequence number of a step in a multiple index operation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1, 2, ... n For the steps of the multiple index procedure (ACCESTYPE is MX, MI, MU, DX, DI, or DU), the sequence number of the OR predicate in the SQL statement. (ACCESTYPE is 'NR').</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 For any other rows</td>
</tr>
<tr>
<td>VERSION</td>
<td>VARCHAR(122) NOT NULL WITH DEFAULT</td>
<td>The version identifier for the package. Applies only to an embedded EXPLAIN statement executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable. When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column indicates the version identifier of the compiled SQL function or native SQL procedure.</td>
</tr>
<tr>
<td>COLLID</td>
<td>VARCHAR(128) NOT NULL WITH DEFAULT</td>
<td>The collection ID:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'DSNDYNAMICSQ Cache' The row originates from the dynamic statement cache</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'DSNEXPLAINMODEYES' The row originates from an application that specifies YES for the value of the CURRENT EXPLAIN MODE special register.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'DSNEXPLAINMODEEXPLAIN' The row originates from an application that specifies EXPLAIN for the value of the CURRENT EXPLAIN MODE special register.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column indicates the schema name of the compiled SQL function or native SQL procedure.</td>
</tr>
<tr>
<td>Column name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ACCESS_DEGREE</td>
<td>SMALLINT</td>
<td>The number of parallel tasks or operations that are activated by a query. This value is determined at bind time; the actual number of parallel operations that are used at execution time could be different. This column contains 0 if a host variable is used. This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.</td>
</tr>
<tr>
<td>ACCESS_PGROUP_ID</td>
<td>SMALLINT</td>
<td>The identifier of the parallel group for accessing the new table. A parallel group is a set of consecutive operations, executed in parallel, that have the same number of parallel tasks. This value is determined at bind time; it could change at execution time. This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.</td>
</tr>
<tr>
<td>JOIN_DEGREE</td>
<td>SMALLINT</td>
<td>The number of parallel operations or tasks that are used in joining the composite table with the new table. This value is determined at bind time and can be 0 if a host variable is used. The actual number of parallel operations or tasks used at execution time could be different. This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.</td>
</tr>
<tr>
<td>JOIN_PGROUP_ID</td>
<td>SMALLINT</td>
<td>The identifier of the parallel group for joining the composite table with the new table. This value is determined at bind time; it could change at execution time. This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.</td>
</tr>
<tr>
<td>SORTC_PGROUP_ID</td>
<td>SMALLINT</td>
<td>The parallel group identifier for the parallel sort of the composite table. This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.</td>
</tr>
<tr>
<td>SORTN_PGROUP_ID</td>
<td>SMALLINT</td>
<td>The parallel group identifier for the parallel sort of the new table. This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.</td>
</tr>
</tbody>
</table>
Table 239. Descriptions of columns in PLAN_TABLE (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PARALLELISM_MODE</td>
<td>CHAR(1)</td>
<td>The kind of parallelism, if any, that is used at bind time:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>C  Query CP parallelism.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>I  Query I/O parallelism. Query I/O parallelism is deprecated and is likely to be removed in a future release.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>X  Sysplex query parallelism. Sysplex query parallelism is deprecated and is likely to be removed in a future release.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns, if the method that it refers to does not apply, or if the plan or package was bound prior to DB2 10.</td>
</tr>
<tr>
<td>MERGEJOIN_COLS</td>
<td>SMALLINT</td>
<td>The number of columns that are joined during a merge scan join (Method=2). This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.</td>
</tr>
<tr>
<td>CORRELATION_NAME</td>
<td>VARCHAR(128)</td>
<td>The correlation name of a table or view that is specified in the statement. If no correlation name exists, then the column is null. This column contains the null value if the plan or package was bound using a plan table with fewer than 43 columns. Otherwise, it can contain null if the method that it refers to does not apply.</td>
</tr>
<tr>
<td>PAGE_RANGE</td>
<td>CHAR(1) NOT NULL WITH DEFAULT</td>
<td>Indication of whether the table qualifies for page range screening, so that plans scan only the partitions that are needed.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Y  Yes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>blank  No</td>
</tr>
<tr>
<td>JOIN_TYPE</td>
<td>CHAR(1) NOT NULL WITH DEFAULT</td>
<td>The type of join:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>F  FULL OUTER JOIN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L  LEFT OUTER JOIN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>P  Pair-wise join</td>
</tr>
<tr>
<td></td>
<td></td>
<td>S  Star join</td>
</tr>
<tr>
<td></td>
<td></td>
<td>blank  INNER JOIN or no join</td>
</tr>
<tr>
<td></td>
<td></td>
<td>RIGHT OUTER JOIN converts to a LEFT OUTER JOIN when you use it, so that JOIN_TYPE contains L.</td>
</tr>
<tr>
<td>GROUP_MEMBER</td>
<td>VARCHAR(24) NOT NULL WITH DEFAULT</td>
<td>The member name of the DB2 that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.</td>
</tr>
<tr>
<td>IBM_SERVICE_DATA</td>
<td>VARCHAR(254) FOR BIT DATA</td>
<td>This column contains values that are for IBM use only.</td>
</tr>
<tr>
<td>Column name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| WHEN_OPTIMIZE       | CHAR(1) NOT NULL WITH DEFAULT | When the access path was determined:  
|                     |                          | **blank**: At bind time, using a default filter factor for any host variables, parameter markers, or special registers.  
|                     |                          | **B**: At bind time, using a default filter factor for any host variables, parameter markers, or special registers; however, the statement is re-optimized at run time using input variable values for input host variables, parameter markers, or special registers. The bind option REOPT(ALWAYS), REOPT(AUTO), or REOPT(ONCE) must be specified for reoptimization to occur.  
|                     |                          | **R**: At run time, using input variables for any host variables, parameter markers, or special registers. The bind option REOPT(ALWAYS), REOPT(AUTO), or REOPT(ONCE) must be specified for this to occur.  
| QBLOCK_TYPE         | CHAR(6) NOT NULL WITH DEFAULT | For each query block, an indication of the type of SQL operation that is performed. For the outermost query, this column identifies the statement type.  
| BIND_TIME           | TIMESTAMP NOT NULL WITH DEFAULT | This column is deprecated. Use EXPLAIN_TIME instead.  
| OPTHINT             | VARCHAR(128) NOT NULL WITH DEFAULT | A string that you use to identify this row as an optimization hint for DB2. DB2 uses this row as input when choosing an access path.  

Appendix. Additional information for DB2 SQL
<table>
<thead>
<tr>
<th>Column name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HINT_USED</td>
<td>VARCHAR(128) NOT NULL WITH DEFAULT</td>
<td>One of the following values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'APREUSE' When an access path was successfully reused because the APREUSE option was specified at bind or rebind.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'opthint-value' When PLAN_TABLE access path hints are used. opthint-value is the value of the OPTHINT column for the hint that was used.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'SYSQUERYPLAN query-id' When statement-level access path hints are used. query-id is the value of the QUERYID column in the SYSQUERYPLAN catalog table for the hint.</td>
</tr>

Table 239. Descriptions of columns in PLAN_TABLE (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTEREF</td>
<td>SMALLINT NOT NULL</td>
<td>If the referenced table is a common table expression, the value is the top-level query block number.</td>
</tr>
<tr>
<td>STMTTOKEN</td>
<td>VARCHAR(240)</td>
<td>User-specified statement token.</td>
</tr>
<tr>
<td>PARENT_PLANNO</td>
<td>SMALLINT NOT NULL</td>
<td>Corresponds to the plan number in the parent query block where a correlated subquery is invoked. Or, for non-correlated subqueries, corresponds to the plan number in the parent query block that represents the work file for the subquery.</td>
</tr>
<tr>
<td>BIND_EXPLAIN_ONLY</td>
<td>CHAR(1) NOT NULL</td>
<td>Identifies whether the row was inserted because a command specified the EXPLAIN(ONLY) option.</td>
</tr>
<tr>
<td>SECTNOI</td>
<td>INTEGER NOT NULL</td>
<td>The section number of the statement. The value is taken from the same column in SYSPACKSTM or SYSSTMT tables and can be used to join tables to reconstruct the access path for the statement. This column is applicable only for static statements. The default value of -1 indicates EXPLAIN information that was captured in DB2 9 or earlier.</td>
</tr>
<tr>
<td>EXPLAIN_TIME</td>
<td>TIMESTAMP NOT NULL</td>
<td>The time when the EXPLAIN information was captured:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>All cached statements</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the statement entered the cache, in the form of a full-precision timestamp value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Non-cached static statements</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the statement was bound, in the form of a full precision timestamp value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Non-cached dynamic statements</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>When EXPLAIN was executed, in the form of a value equivalent to a CHAR(16) representation of the time appended by 4 zeros.</td>
</tr>
<tr>
<td>MERGC</td>
<td>CHAR(1) NOT NULL</td>
<td>Indicates whether the composite table is consolidated before the join.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'Y' Yes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'N' No</td>
</tr>
<tr>
<td>MERGN</td>
<td>CHAR(1) NOT NULL</td>
<td>Indicates whether the new table is consolidated before the join</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'Y' Yes, the new table is consolidated before the join.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'N' No, the new table is not consolidated before the join.</td>
</tr>
</tbody>
</table>

Notes:

1. For PLAN_TABLE rows in which ACCESSTYPE='A' and QBLOCK_TYPE='SELECT', the values of all other columns except QUERYNO, APPLNAME, and PROGNAME are the default values for those columns.
2. In rows that are used for optimization hints, NULL values in the following columns indicate a hint for no parallelism:
   - PARALLELISM_MODE
   - ACCESS_PGROUP_ID
   - JOIN_PGROUP_ID

3. In rows that are used for optimization hints, NULL values in the following columns indicate a hint for no parallel sort:
   - SORTN_PGROUP_ID
   - SORTC_PGROUP_ID

4. The ACCESSTYPE column contains the following values:
   - 'A' The query is sent to an accelerator server.
   - 'DI' By an intersection of multiple DOCID lists to return the final DOCID list
   - 'DU' By a union of multiple DOCID lists to return the final DOCID list
   - 'DX' By an XML index scan on the index that is named in ACCESSNAME to return a DOCID list
   - 'E' By direct row access using a row change timestamp column.
   - 'H' By hash access. If an overflow condition occurs, the hash overflow index that is identified by ACCESSCREATOR and ACCESSNAME is used.
   - 'HN' By hash access using an IN predicate, or an IN predicate that DB2 generates. If a hash overflow condition occurs, the hash overflow index that is identified in ACCESSCREATOR and ACCESSNAME is used.
   - 'I' By an index (identified in ACCESSCREATOR and ACCESSNAME)
   - 'IN' By an index scan when the matching predicate contains an IN predicate and the IN-list is accessed through an in-memory table.
   - 'II' By a one-fetch index scan
   - 'M' By a multiple index scan. A row that contains this value might be followed by a row that contains one of the following values:
     - 'DI'
     - 'DU'
     - 'MH'
     - 'MI'
     - 'MU'
     - 'MX'
   - 'MH' By the hash overflow index named in ACCESSNAME. A row that contains this value always follows a row that contains M.
   - 'MI' By an intersection of multiple indexes. A row that contains this value always follows a row that contains M.
   - 'MU' By a union of multiple indexes. A row that contains this value always follows a row that contains M.
   - 'MX' By an index scan on the index named in ACCESSNAME. When the access method MX follows the access method DX, DI, or DU, the table is accessed by the DOCID index by using the DOCID list that is returned by DX, DI, or DU. A row that contains this value always follows a row that contains M.
   - 'N' One of the following types:
     - By an index scan when the matching predicate contains the IN keyword
     - By an index scan when DB2 rewrites a query using the IN keyword
   - 'O' By a work file scan, as a result of a correlated subquery.
   - 'NR' Range list access.
   - 'P' By a dynamic pair-wise index scan
   - 'R' By a table space scan
'RW' By a work file scan of the result of a materialized user-defined table function
'V' By buffers for an INSERT statement within a SELECT
blank Not applicable to the current row
5. The QBLOCK_TYPE column contains the following values:

'SELECT'
  SELECT

'INSERT'
  INSERT

'UPDATE'
  UPDATE

'MERGE'
  MERGE

'DELETE'
  DELETE

'SELUPD'
  SELECT with FOR UPDATE OF

'DELCUR'
  DELETE WHERE CURRENT OF CURSOR

'UPDCUR'
  UPDATE WHERE CURRENT OF CURSOR

'CORSUB'
  Correlated subselect or fullselect

'TRUNCATE'
  TRUNCATE

'NCOSUB'
  Noncorrelated subselect or fullselect

'TABLEX'
  Table expression

'TRIGGR'
  WHEN clause on CREATE TRIGGER

'UNION'
  UNION

'UNIONA'
  UNION ALL

'INTERS'
  INTERSECT

'INTERA'
  INTERSECT ALL

'EXCEPT'
  EXCEPT

'EXCEPTA'
  EXCEPT ALL

'PRUNED'
  DB2 does not generate an access path for the query because the query
is guaranteed to qualify zero rows, such as the case of an always-false
WHERE clause. For example: WHERE 0=1

6. DB2 inserts a value into the REMARKS column at bind or rebind when the
EXPLAIN(ONLY) option is specified and reuse or comparison fails for an
access path. The value might include the following information:
   • A reason code that corresponds to the reason codes in SQLCODE +395 when
     reuse fails
   • The name of the unmatched PLAN_TABLE column for which comparison
     failed
   • A string that identifies that unmatched rows where found

The PLAN_TABLE_HINT_IX index

The PLAN_TABLE_HINT_IX index improves prepare performance when access
path hints are used. This index is required for all types of statement-level
optimization hints. The PLAN_TABLE_HINT_IX index is optional, although
strongly recommended, for PLAN_TABLE access path hints.

The statement that creates the PLAN_TABLE_HINT_IX index is included as part of
the DSNTESC member of the SDSNSAMP library.

Related concepts:

DSN_COLDIST_TABLE

The column distribution table contains non-uniform column group statistics that are obtained dynamically by DB2 from non-index leaf pages.

Recommendation: Do not manually insert data into system-maintained EXPLAIN tables, and use care when deleting obsolete EXPLAIN table data. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools. Certain optimization tools depend on instances of the various EXPLAIN tables. Be careful not to delete data from or drop instances EXPLAIN tables that are created for these tools.

Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

'SYSIBM'
One instance of this table can be created with the SYSIBM qualifier. DB2 and SQL optimization tools might use the table and the data that it contains. The table is created when you run job DSNTIJSG when you install or migrate DB2.

'user-ID'
You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind. They are also populated when you specify EXPLAIN(YES) or EXPLAIN(ONLY) in a BIND or REBIND command. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the prefix.SDSNSAMP library.

Column descriptions

The following table shows the descriptions of the columns in the DSN_COLDIST_TABLE table.
<table>
<thead>
<tr>
<th>Column name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERYNO</td>
<td>INTEGER NOT NULL</td>
<td>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>For rows produced by EXPLAIN statements</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>For rows not produced by EXPLAIN statements</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>DB2 assigns a number that is based on the line number of the SQL statement in the source program.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in certain rare cases, the value is not guaranteed to be unique.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the SQL statement is embedded in a compiled SQL function or native SQL procedure, if the QUERYNO clause is specified, its value is used by DB2. Otherwise DB2 assigns a number based on the line number of the SQL statement in the compiled SQL function or native SQL procedure.</td>
</tr>
<tr>
<td>APPLNAME</td>
<td>VARCHAR(128) NOT NULL</td>
<td>The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column is not used, and is blank.</td>
</tr>
<tr>
<td>PROGNAME</td>
<td>VARCHAR(128) NOT NULL</td>
<td>The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column indicates the specific name of the compiled SQL function or native SQL procedure.</td>
</tr>
<tr>
<td>Column name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>COLLID</td>
<td>VARCHAR(128) NOT NULL</td>
<td>The collection ID:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>'DSNDYNAMICSQLCACHE'</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The row originates from the dynamic statement cache</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>'DSNEXPLAINMODEYES'</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The row originates from an application that specifies YES for the value of the CURRENT EXPLAIN MODE special register.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>'DSNEXPLAINMODEEXPLAIN'</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The row originates from an application that specifies EXPLAIN for the value of the CURRENT EXPLAIN MODE special register.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column indicates the schema name of the compiled SQL function or native SQL procedure.</td>
</tr>
<tr>
<td>GROUP_MEMBER</td>
<td>VARCHAR(128) NOT NULL</td>
<td>The member name of the DB2 that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.</td>
</tr>
<tr>
<td>SECTNOI</td>
<td>INTEGER NOT NULL</td>
<td>The section number of the statement. The value is taken from the same column in SYSPACKSTMT or SYSTMT tables and can be used to join tables to reconstruct the access path for the statement. This column is applicable only for static statements. The default value of -1 indicates EXPLAIN information that was captured in DB2 9 or earlier.</td>
</tr>
<tr>
<td>VERSION</td>
<td>VARCHAR(122) NOT NULL</td>
<td>The version identifier for the package. Applies only to an embedded EXPLAIN statement executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column indicates the version identifier of the compiled SQL function or native SQL procedure.</td>
</tr>
</tbody>
</table>

<tr>
<td>Column name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| TYPE        | CHAR(1) NOT NULL | The type of statistics:  
|             |           | C  Cardinality  
|             |           | F  Frequent value  
|             |           | H  Histogram  
|             |           | T  Real-time table cardinality  
|             |           | L  Real-time column cardinality (unique index only)  
|             |           | P  real-time partition cardinality |
| CARDF       | FLOAT NOT NULL | For TYPE='C', the number of distinct values for the column group. For TYPE='H', the number of distinct values for the column group in a quantile indicated by the value of the QUANTILENO column. For TYPE='T', a value related to real-time statistics table values that are determined by the COLVALUE column. For TYPE='L', a value related to a real-time statistics column value that is determined by the COLVALUE column. The QUANTILENO column contains the column number. The NAME column contains the column name. For TYPE='P', a value related to real-time statistics partition value that is determined by the COLVALUE column. The QUANTILENO column contains the partition number. |
| COLGROUPCOLNO | VARCHAR(254) NOT NULL FOR BIT DATA | The identity of the set of columns associated with the statistics. If the statistics are only associated with a single column, the field contains a zero length. Otherwise, the field is an array of SMALLINT column numbers with a dimension equal to the value in the NUMCOLUMNS column. This is an updatable column. |
| NUMCOLUMNS  | SMALLINT NOT NULL | Identifies the number of columns associated with the statistics. |
| FREQUENCYF  | FLOAT NOT NULL | The percentage of rows in the table with the value that is specified in the COLVALUE column when the number is multiplied by 100. For example, a value of '1' indicates 100%. A value of '.153' indicates 15.3%. |
| QUANTILENO  | SMALLINT NOT NULL | The ordinary sequence number of a quantile in the whole consecutive value range, from low to high. This column is not updatable. For TYPE='L', this column contains the column number. For TYPE='P', the column contains the partition number. |
| LOWVALUE    | VARCHAR(2000) NOT NULL FOR BIT DATA | For TYPE='H', this is the lower bound for the quantile indicated by the value of the QUANTILENO column. Not used if the value of the TYPE column is not 'H'. This column is not updatable. |

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the `prefix.SDSNSAMP` library.
## Column descriptions

The following table describes the columns of DSN_DETCOST_TABLE.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERYNO</td>
<td>INTEGER NOT NULL</td>
<td>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>For rows produced by EXPLAIN statements</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>For rows not produced by EXPLAIN statements</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>DB2 assigns a number that is based on the line number of the SQL statement in the source program.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in certain rare cases, the value is not guaranteed to be unique.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the SQL statement is embedded in a compiled SQL function or native SQL procedure, if the QUERYNO clause is specified, its value is used by DB2. Otherwise DB2 assigns a number based on the line number of the SQL statement in the compiled SQL function or native SQL procedure.</td>
</tr>
<tr>
<td>QBLOCKNO</td>
<td>SMALLINT NOT NULL</td>
<td>A number that identifies each query block within a query. The value of the numbers are not in any particular order, nor are they necessarily consecutive.</td>
</tr>
<tr>
<td>APPLNAME</td>
<td>VARCHAR(24) NOT NULL</td>
<td>The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable.</td>
</tr>
<tr>
<td>PROGNAME</td>
<td>VARCHAR(128) NOT NULL</td>
<td>The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.</td>
</tr>
<tr>
<td>PLANNO</td>
<td>SMALLINT NOT NULL</td>
<td>The plan number, a number used to identify each mini-plan with a query block.</td>
</tr>
<tr>
<td>OPENIO</td>
<td>FLOAT(4) NOT NULL</td>
<td>The Do-at-open IO cost for non-correlated subquery.</td>
</tr>
<tr>
<td>OPENCPU</td>
<td>FLOAT(4) NOT NULL</td>
<td>The Do-at-open CPU cost for non-correlated subquery.</td>
</tr>
<tr>
<td>OPENCOST</td>
<td>FLOAT(4) NOT NULL</td>
<td>The Do-at-open total cost for non-correlated subquery.</td>

Related reference:

[Support Portal: IBM DB2 Analytics Accelerator for z/OS](#)
The filter table, DSN_FILTER_TABLE, contains information about how predicates are used during query processing.

Recommendation: Do not manually insert data into system-maintained EXPLAIN tables, and use care when deleting obsolete EXPLAIN table data. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools. Certain optimization tools depend on instances of the various EXPLAIN tables. Be careful not to delete data from or drop instances EXPLAIN tables that are created for these tools.

Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

'SYSIBM'
One instance of this table can be created with the SYSIBM qualifier. DB2 and SQL optimization tools might use the table and the data that it contains. The table is created when you run job DSNTIJSG when you install or migrate DB2.

'user-ID'
You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind. They are also populated when you specify EXPLAIN(YES) or EXPLAIN(ONLY) in a BIND or REBIND command. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the prefix.SDSNSAMP library.
Column descriptions

The following table describes the columns of DSN_FILTER_TABLE.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
</table>
| QUERYNO     | INTEGER NOT NULL | A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:
For rows produced by EXPLAIN statements
   The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.
For rows not produced by EXPLAIN statements
   DB2 assigns a number that is based on the line number of the SQL statement in the source program.
   When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in certain rare cases, the value is not guaranteed to be unique.
   When the SQL statement is embedded in a compiled SQL function or native SQL procedure, DB2 assigns a number that is based on the line number of the SQL statement in the compiled SQL function or native SQL procedure.
| QBLOCKNO    | SMALLINT NOT NULL | A number that identifies each query block within a query. The value of the numbers are not in any particular order, nor are they necessarily consecutive. |
| PLANNO      | SMALLINT         | The plan number, a number used to identify each miniplan with a query block. |
| APPLNAME    | VARCHAR(24) NOT NULL | The name of the application plan for the row. Applies only to statements that are explained when binding a plan. A blank indicates that the column is not applicable. |
| PROGNAME    | VARCHAR(128) NOT NULL | The name of the program or package containing the statement being explained. Applies only to statements that are explained as the result of binding a plan or package. A blank indicates that the column is not applicable. |

**DSN_FUNCTION_TABLE**

The function table, DSN_FUNCTION_TABLE, contains descriptions of functions that are used in specified SQL statements.

**Recommendation:** Do not manually insert data into system-maintained EXPLAIN tables, and use care when deleting obsolete EXPLAIN table data. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools. Certain optimization tools depend on instances of the various EXPLAIN tables. Be careful not to delete data from or drop instances EXPLAIN tables that are created for these tools.

**Qualifiers**

Your subsystem or data sharing group can contain more than one of these tables:

'**SYSIBM**'

One instance of this table can be created with the SYSIBM qualifier. DB2 and SQL optimization tools might use the table and the data that it contains. The table is created when you run job DSNTIJSG when you install or migrate DB2.

'**user-ID**'

You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind. They are also populated when you specify EXPLAIN(YES) or EXPLAIN(ONLY) in a BIND or REBIND command. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

**Sample CREATE TABLE statement**

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the *prefix*.SDSNSAMP library.

**Column descriptions**

The following table describes the columns of DSN_FUNCTION_TABLE.
Table 243. Descriptions of columns in DSN_FUNCTION_TABLE

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
</table>
| QUERYNO     | INTEGER NOT NULL WITH DEFAULT | A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:  
**For rows produced by EXPLAIN statements**  
The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.  
**For rows not produced by EXPLAIN statements**  
DB2 assigns a number that is based on the line number of the SQL statement in the source program.  
When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in certain rare cases, the value is not guaranteed to be unique.  
When the SQL statement is embedded in a compiled SQL function or native SQL procedure, if the QUERYNO clause is specified, its value is used by DB2. Otherwise DB2 assigns a number based on the line number of the SQL statement in the compiled SQL function or native SQL procedure. |
| QBLOCKNO    | INTEGER NOT NULL WITH DEFAULT | A number that identifies each query block within a query. The value of the numbers are not in any particular order, nor are they necessarily consecutive. |
| APPLNAME    | VARCHAR(24) NOT NULL WITH DEFAULT | The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable. |
| PROGNAME    | VARCHAR(128) NOT NULL WITH DEFAULT | The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable. |
| COLLID      | VARCHAR(128) NOT NULL WITH DEFAULT | The collection ID:  
'DSN_DYNAMICSQLCACHE'  
The row originates from the dynamic statement cache  
'DSN_EXPLAINMODEYES'  
The row originates from an application that specifies YES for the value of the CURRENT EXPLAIN MODE special register.  
'DSN_EXPLAINMODEEXPLAIN'  
The row originates from an application that specifies EXPLAIN for the value of the CURRENT EXPLAIN MODE special register.  
When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column indicates the specific name of the compiled SQL function or native SQL procedure. |

| Checking how DB2 resolves functions by using DSN_FUNCTION_TABLE |

([DB2 Application programming and SQL])
**DSN_KEYTGTDIST_TABLE**

The key-target distribution table contains non-uniform index expression statistic that are obtained dynamically by the DB2 optimizer.

**Recommendation:** Do not manually insert data into system-maintained EXPLAIN tables, and use care when deleting obsolete EXPLAIN table data. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools. Certain optimization tools depend on instances of the various EXPLAIN tables. Be careful not to delete data from or drop instances EXPLAIN tables that are created for these tools.

**Qualifiers**

Your subsystem or data sharing group can contain more than one of these tables:

'SYSIBM'

One instance of this table can be created with the SYSIBM qualifier. DB2 and SQL optimization tools might use the table and the data that it contains. The table is created when you run job DSNTIJSG when you install or migrate DB2.

'user-ID'

You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind. They are also populated when you specify EXPLAIN(YES) or EXPLAIN(ONLY) in a BIND or REBIND command. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

**Sample CREATE TABLE statement**

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the prefix.SDSSAMP library.

**COLUMN descriptions**

The following table shows the descriptions of the columns in the DSN_KEYTGTDIST_TABLE table.
<table>

</tbody>
</table>
DSN_PREDICAT_TABLE

The predicate table, DSN_PREDICAT_TABLE, contains information about all of the predicates in a query.

Recommendation: Do not manually insert data into system-maintained EXPLAIN tables, and use care when deleting obsolete EXPLAIN table data. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools. Certain optimization tools depend on instances of the various EXPLAIN tables. Be careful not to delete data from or drop instances EXPLAIN tables that are created for these tools.

Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

'SYSIBM'

One instance of this table can be created with the SYSIBM qualifier. DB2 and SQL optimization tools might use the table and the data that it contains. The table is created when you run job DSNTIJSG when you install or migrate DB2.

'user-ID'

You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind. They are also populated when you specify EXPLAIN(YES) or EXPLAIN(ONLY) in a BIND or REBIND command. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the prefix.SDSNSAMP library.
## Column descriptions

The following table describes the columns of the DSN_PREDICAT_TABLE

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERYNO</td>
<td>INTEGER NOT NULL</td>
<td>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>For rows produced by EXPLAIN statements</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>For rows not produced by EXPLAIN statements</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>DB2 assigns a number that is based on the line number of the SQL statement in the source program.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in certain rare cases, the value is not guaranteed to be unique.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the SQL statement is embedded in a compiled SQL function or native SQL procedure, if the QUERYNO clause is specified, its value is used by DB2. Otherwise DB2 assigns a number based on the line number of the SQL statement in the compiled SQL function or native SQL procedure.</td>
</tr>
<tr>
<td>QBLOCKNO</td>
<td>SMALLINT NOT NULL</td>
<td>A number that identifies each query block within a query. The value of the numbers are not in any particular order, nor are they necessarily consecutive.</td>
</tr>
<tr>
<td>APPLNAME</td>
<td>VARCHAR(24) NOT NULL</td>
<td>The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable.</td>
</tr>
<tr>
<td>PROGNAME</td>
<td>VARCHAR(128) NOT NULL</td>
<td>The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.</td>
</tr>
<tr>
<td>PREDNO</td>
<td>INTEGER NOT NULL</td>
<td>The predicate number, a number used to identify a predicate within a query.</td>
</tr>
</tbody>
</table>

**Related concepts:**

- Predicates
- Predicates and access path selection (DB2 Performance)
The parallel tasks table, DSN_PTASK_TABLE, contains information about all of the parallel tasks in a query.

Recommendation: Do not manually insert data into system-maintained EXPLAIN tables, and use care when deleting obsolete EXPLAIN table data. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools. Certain optimization tools depend on instances of the various EXPLAIN tables. Be careful not to delete data from or drop instances EXPLAIN tables that are created for these tools.

Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

'SYSIBM'
One instance of this table can be created with the SYSIBM qualifier. DB2 and SQL optimization tools might use the table and the data that it contains. The table is created when you run job DSNTIJSG when you install or migrate DB2.

'user-ID'
You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind. They are also populated when you specify EXPLAIN(YES) or EXPLAIN(ONLY) in a BIND or REBIND command. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the prefix.SDSNSAMP library.
## Column descriptions

The following table describes the columns of DSN_PTASK_TABLE.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
</table>
| QUERYNO     | INTEGER NOT NULL | A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:  
**For rows produced by EXPLAIN statements**  
The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.  
**For rows not produced by EXPLAIN statements**  
DB2 assigns a number that is based on the line number of the SQL statement in the source program.  
When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in certain rare cases, the value is not guaranteed to be unique.  
When the SQL statement is embedded in a compiled SQL function or native SQL procedure, if the QUERYNO clause is specified, its value is used by DB2. Otherwise DB2 assigns a number based on the line number of the SQL statement in the compiled SQL function or native SQL procedure. |
| QBLOCKNO    | SMALLINT NOT NULL | A number that identifies each query block within a query. The value of the numbers are not in any particular order, nor are they necessarily consecutive. |
| PGDNO       | SMALLINT NOT NULL | The parallel group identifier within the current query block. This value corresponds to the value of the GROUPID column in DSN_PGROUP_TABLE table rows. |
| APPLNAME    | VARCHAR(24) NOT NULL | The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable. |
| PROGNAME    | VARCHAR(128) NOT NULL | The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable. |
| LPTNO       | SMALLINT NOT NULL | The parallel task number. |
| KEYCOLID    | SMALLINT       | The key column ID (KEY range only). |
| DPSI        | CHAR(1) NOT NULL | Indicates if a data partition secondary index (DPSI) is used. |
| LPTLOKEY    | VARCHAR(40) FOR BIT DATA | The low key value for this key column for this parallel task (KEY range only). |

</table>

**Notes:**
1. The name of these columns originally contained the # symbol as the last character in the names. However, the names that contain these characters are obsolete and are no longer supported.

---

PSPI
**DSN_QUERYINFO_TABLE**

The query information table, DSN_QUERYINFO_TABLE, contains information about the eligibility of query blocks for automatic query rewrite, information about the materialized query tables that are considered for eligible query blocks, reasons why ineligible query blocks are not eligible, and information about acceleration of query blocks.

---

**Recommendation:** Do not manually insert data into system-maintained EXPLAIN tables, and use care when deleting obsolete EXPLAIN table data. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools. Certain optimization tools depend on instances of the various EXPLAIN tables. Be careful not to delete data from or drop instances EXPLAIN tables that are created for these tools.

**Qualifiers**

Your subsystem or data sharing group can contain more than one of these tables:

**userID** You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind, or rebind, a plan or package with the EXPLAIN(YES) option. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDNSAMP library.

**Sample CREATE TABLE statement**

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the prefix.SDNSAMP library.

Table 249. Descriptions of columns in DSN_QUERYINFO_TABLE (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
</table>
| QI_DATA           | CLOB(2M) NOT NULL WITH DEFAULT | When TYPE='A':  
|                   |                         | • For REASON_CODE values other than 0, this value is the description of the REASON_CODE value.  
|                   |                         | • For a REASON_CODE value of 0, this value is the statement text, after it is converted for processing by the accelerator. |
| SERVICE_INFO      | BLOB(2M) NOT NULL WITH DEFAULT | IBM internal use only.                                                                                                                        |
| QB_INFO_ROWID     | ROWID NOT NULL GENERATED ALWAYS | IBM internal use only.                                                                                                                        |

Notes:
1. The REASON_CODE column has the following values:
   0 The query block qualifies for routing to an accelerator server. The values of QINAME1 and QINAME2 identify the accelerator server. For example, for version 1 of the IBM DB2 Analytics Accelerator for z/OS, the associated data mart name is recorded in the QINAME2 column, with the following naming convention: data-mart-name@accelerator-name@digits.
   1 No active accelerator server was found when EXPLAIN was executed.
   2 Special register CURRENT QUERY ACCELERATION is set to NONE.
   3 DB2 classified the query as a short-running query, or DB2 determined that sending the query to an accelerator server provided no performance advantage.
   4 The query is not read-only.
   6 The cursor is defined as a scrollable cursor or rowset cursor.
   7 The query references objects with multiple encoding schemes.
   8 The FROM clause of the query specifies a data change table reference.
   9 The query contains a table expression with one or more correlated references to other tables in the same FROM clause.
   10 The query contains a reference to a recursive common table expression.
   11 The query contains an unsupported expression. The text of the expression is in QI_DATA.
   12 The query references a table that meets one of the following conditions:  
      • The table is not defined in the accelerator server.  
      • The table is defined in the accelerator server, but is not enabled for processing by an accelerator.  
   13 The accelerator server that contains the tables that are referenced by the query is not started.
   14 A column that is referenced in the query was altered by DB2 after the data was loaded in the accelerator server.
The query uses functionality that is available only in DB2 for z/OS Version 10 new-function mode or later, and the functionality is not supported by the accelerator server.

The query is an INSERT statement, but the DB2 subsystem parameter DSN6SPRM.QUERY_ACCEL_OPTIONS does not specify option 2 to enable its acceleration.

The accelerator server is not at the correct level and does not support a function in the SQL statement. The QI_DATA column contains the function text or expression text that is using the unsupported function for the accelerator server.

The rowset cursor is declared WITH RETURN or runs remotely or under an SQL PL routine.

The query contains a correlated subquery that is not supported for acceleration.

For IBM internal use only.

[Support Portal: IBM DB2 Analytics Accelerator for z/OS](#)
The query table, **DSN_QUERY_TABLE**, contains information about a SQL statement, and displays the statement before and after query transformation.

Unlike other EXPLAIN tables, rows in **DSN_QUERY_TABLE** are not populated for static SQL statements at BIND or REBIND with the EXPLAIN(YES) option.

**Recommendation:** Do not manually insert data into system-maintained EXPLAIN tables, and use care when deleting obsolete EXPLAIN table data. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools. Certain optimization tools depend on instances of the various EXPLAIN tables. Be careful not to delete data from or drop instances EXPLAIN tables that are created for these tools.

**Qualifiers**

Your subsystem or data sharing group can contain more than one of these tables:

- `'SYSIBM'`
  One instance of this table can be created with the SYSIBM qualifier. DB2 and SQL optimization tools might use the table and the data that it contains. The table is created when you run job DSNTIJSG when you install or migrate DB2.

- `'user-ID'`
  You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind. They are also populated when you specify EXPLAIN(YES) or EXPLAIN(ONLY) in a BIND or REBIND command. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

**Sample CREATE TABLE statement**

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the prefix.SDSNSAMP library.

</tbody>
</table>
DSN_SORT_TABLE

The sort table, DSN_SORT_TABLE, contains information about the sort operations required by a query.

Recommendation: Do not manually insert data into system-maintained EXPLAIN tables, and use care when deleting obsolete EXPLAIN table data. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools. Certain optimization tools depend on instances of the various EXPLAIN tables. Be careful not to delete data from or drop instances EXPLAIN tables that are created for these tools.

Qualifiers

Your subsystem or data sharing group can contain more than one of these tables:

'SYSIBM'

One instance of this table can be created with the SYSIBM qualifier. DB2 and SQL optimization tools might use the table and the data that it contains. The table is created when you run job DSNTIJSG when you install or migrate DB2.

'user-ID'

You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind. They are also populated when you specify EXPLAIN(YES) or EXPLAIN(ONLY) in a BIND or REBIND command. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

Sample CREATE TABLE statement

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the prefix.SDSNSAMP library.
## Column descriptions

The following table describes the columns of DSN_SORT_TABLE.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERYNO</td>
<td>INTEGER NOT NULL</td>
<td>A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>For rows produced by EXPLAIN statements</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>For rows not produced by EXPLAIN statements</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>DB2 assigns a number that is based on the line number of the SQL statement in the source program.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in certain rare cases, the value is not guaranteed to be unique.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the SQL statement is embedded in a compiled SQL function or native SQL procedure, if the QUERYNO clause is specified, its value is used by DB2. Otherwise DB2 assigns a number based on the line number of the SQL statement in the compiled SQL function or native SQL procedure.</td>
</tr>
<tr>
<td>QBLOCKNO</td>
<td>SMALLINT NOT NULL</td>
<td>A number that identifies each query block within a query. The value of the numbers are not in any particular order, nor are they necessarily consecutive.</td>
</tr>
<tr>
<td>PLANNO</td>
<td>SMALLINT NOT NULL</td>
<td>The plan number, a number used to identify each miniplan with a query block.</td>
</tr>
<tr>
<td>APPLNAME</td>
<td>VARCHAR(24) NOT NULL</td>
<td>The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable.</td>
</tr>
<tr>
<td>PROGNAME</td>
<td>VARCHAR(128) NOT NULL</td>
<td>The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable.</td>
</tr>
</tbody>
</table>

When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column is not used, and is blank.
<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLLID</td>
<td>VARCHAR(128) NOT NULL</td>
<td>The collection ID:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'DSNDYNAMICSQLCACHE' The row originates from the dynamic statement cache</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'DSNEXPLAINMODEYES' The row originates from an application that specifies YES for the value of the CURRENT EXPLAIN MODE special register.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'DSNEXPLAINMODEEXPLAIN' The row originates from an application that specifies EXPLAIN for the value of the CURRENT EXPLAIN MODE special register.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column indicates the schema name of the compiled SQL function or native SQL procedure.</td>
</tr>
<tr>
<td>SORTEC</td>
<td>CHAR(5) NOT NULL WITH DEFAULT</td>
<td>Indicates the reasons for sort of the composite table. The reasons are shown as a series of bytes:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Byte 1 is 'G' if the reason is GROUP BY, or otherwise blank.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The second byte is 'J' if the reason is JOIN, or otherwise blank.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Byte is 'O' if the reason is ORDER BY, or otherwise blank.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The fourth by is 'U' if the reason is uniqueness, or otherwise blank.</td>
</tr>
<tr>
<td>SORTN</td>
<td>CHAR(5) NOT NULL WITH DEFAULT</td>
<td>Indicates the reasons for sort of the new table. The reasons are shown as a series of bytes:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The first byte is 'G' if the reason is GROUP BY, or otherwise blank.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The second byte is 'J' if the reason is JOIN, or otherwise blank.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The third byte is 'O' if the reason is ORDER BY, or otherwise blank.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The fourth by is 'U' if the reason is uniqueness, or otherwise blank.</td>
</tr>
<tr>
<td>SORTNO</td>
<td>SMALLINT NOT NULL</td>
<td>The sequence number of the sort.</td>
</tr>
<tr>
<td>KEYSIZE</td>
<td>SMALLINT NOT NULL</td>
<td>The sum of the lengths of the sort keys.</td>
</tr>
<tr>
<td>ORDERCLASS</td>
<td>INTEGER NOT NULL</td>
<td>IBM internal use only.</td>
</tr>
<tr>
<td>EXPLAIN_TIME</td>
<td>TIMESTAMP NOT NULL</td>
<td>The time when the EXPLAIN information was captured:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>All cached statements</strong> When the statement entered the cache, in the form of a full-precision timestamp value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Non-cached static statements</strong> When the statement was bound, in the form of a full precision timestamp value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Non-cached dynamic statements</strong> When EXPLAIN was executed, in the form of a value equivalent to a CHAR(16) representation of the time appended by 4 zeros.</td>
</tr>
</tbody>
</table>
Table 252. DSN_SORT_TABLE description (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GROUP_MEMBER</td>
<td>VARCHAR(24) NOT NULL</td>
<td>The member name of the DB2 that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.</td>
</tr>
<tr>
<td>SECTNOI</td>
<td>INTEGER NOT NULL</td>
<td>The section number of the statement. The value is taken from the same column in SYSPACKSTMT or SYSSTMT tables and can be used to join tables to reconstruct the access path for the statement. This column is applicable only for static statements. The default value of -1 indicates EXPLAIN information that was captured in DB2 9 or earlier.</td>
</tr>
<tr>
<td>VERSION</td>
<td>VARCHAR(122) NOT NULL</td>
<td>The version identifier for the package. Applies only to an embedded EXPLAIN statement executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable. When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column indicates the version identifier of the compiled SQL function or native SQL procedure.</td>
</tr>
</tbody>
</table>
The statement cache table, DSN_STATEMENT_CACHE_TABLE, contains information about the SQL statements in the statement cache, information captured as the results of an EXPLAIN STATEMENT CACHE ALL statement.

**Recommendation:** Do not manually insert data into system-maintained EXPLAIN tables, and use care when deleting obsolete EXPLAIN table data. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools. Certain optimization tools depend on instances of the various EXPLAIN tables. Be careful not to delete data from or drop instances EXPLAIN tables that are created for these tools.

**Qualifiers**

Your subsystem or data sharing group can contain more than one of these tables:

**userID** You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind. They are also populated when you specify EXPLAIN(YES) or EXPLAIN(ONLY) in a BIND or REBIND command. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

Unlike other EXPLAIN tables, no instance of DSN_STATEMENT_CACHE_TABLE is created under the SYSIBM qualifier.

**Sample CREATE TABLE statement**

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the prefix.SDSNSAMP library.

### Column descriptions

The following table shows the descriptions of the columns in DSN_STATEMENT_CACHE_TABLE.

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STMT_ID</td>
<td>INTEGER NOT NULL</td>
<td>The statement ID; this value is the EDM unique token for the statement.</td>
</tr>
<tr>
<td>STMT_TOKEN</td>
<td>VARCHAR(240)</td>
<td>The statement token; you provide this value as an identification string.</td>
</tr>
</tbody>
</table>

<tr>
<td>STAT_SUS_LOCK</td>
<td>FLOAT NOT NULL</td>
<td>The accumulated wait time for lock requests for the statement.</td>
</tr>
<tr>
<td>STAT_SUS_SWIT</td>
<td>FLOAT NOT NULL</td>
<td>The accumulated wait time for synchronous execution unit switch for the statement.</td>
</tr>
<tr>
<td>STAT_SUS_GLCK</td>
<td>FLOAT NOT NULL</td>
<td>The accumulated wait time for global locks for this statement.</td>
</tr>
<tr>
<td>STAT_SUS_OTHR</td>
<td>FLOAT NOT NULL</td>
<td>The accumulated wait time for read activity that is done by another thread.</td>
</tr>
<tr>
<td>STAT_SUS_OTHW</td>
<td>FLOAT NOT NULL</td>
<td>The accumulated wait time for write activity done by another thread.</td>
</tr>
<tr>
<td>STAT_RIDLIMT</td>
<td>INTEGER NOT NULL</td>
<td>This column is deprecated. Use STAT_SORTB instead.</td>
</tr>
<tr>
<td>STAT_RIDSTOR</td>
<td>INTEGER NOT NULL</td>
<td>This column is deprecated. Use STAT_SORTB instead.</td>
</tr>
<tr>
<td>EXPLAIN_TS</td>
<td>TIMESTAMP NOT NULL</td>
<td>The timestamp for when the statement cache table is populated.</td>
</tr>
<tr>
<td>SCHEMA</td>
<td>VARCHAR(128) NOT NULL</td>
<td>The value of the CURRENT SCHEMA special register.</td>
</tr>
<tr>
<td>STMT_TEXT</td>
<td>CLOB(2M) NOT NULL</td>
<td>The statement that is being explained.</td>
</tr>
<tr>
<td>STMT_ROWID</td>
<td>ROWID NOT NULL</td>
<td>The ROWID of the statement.</td>
</tr>
<tr>
<td>BIND_RO_TYPE</td>
<td>CHAR(1) NOT NULL</td>
<td>The current specification of the REOPT option for the statement.</td>
</tr>
<tr>
<td>BIND_RA_TOT</td>
<td>INTEGER NOT NULL</td>
<td>The total number of REBIND commands that have been issued for the dynamic statement because of the REOPT(AUTO) option.</td>
</tr>
<tr>
<td>GROUP_MEMBER</td>
<td>VARCHAR(24) NOT NULL WITH DEFAULT</td>
<td>The member name of the DB2 that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.</td>
</tr>
<tr>
<td>STAT_EXECCB</td>
<td>BIGINT NOT NULL</td>
<td>The number of times this statement has been run. For a statement with a cursor, this is the number of OPENs.</td>
</tr>
<tr>
<td>STAT_GPAGB</td>
<td>BIGINT NOT NULL</td>
<td>The number of getpage operations that are performed for the statement.</td>
</tr>
<tr>
<td>STAT_SYNRB</td>
<td>BIGINT NOT NULL</td>
<td>The number of synchronous buffer reads that are performed for the statement.</td>
</tr>
<tr>
<td>STAT_WRITB</td>
<td>BIGINT NOT NULL</td>
<td>The number of buffer write operations that are performed for the statement.</td>
</tr>
<tr>
<td>STAT_EROWB</td>
<td>BIGINT NOT NULL</td>
<td>The number of rows that are examined for the statement.</td>
</tr>
<tr>
<td>STAT_PROWB</td>
<td>BIGINT NOT NULL</td>
<td>The number of rows that are processed for the statement.</td>
</tr>
</tbody>
</table>
### Table 253. Descriptions of columns in DSN_STATEMENT_CACHE_TABLE (continued)

<table>
<thead>

Table 253. Descriptions of columns in DSN_STATEMENT_CACHE_TABLE (continued)

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCELERATED</td>
<td>CHAR(10)</td>
<td>Identifies whether a cached dynamic statement was prepared for acceleration to an accelerator server. Possible values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'NO' The cached statement was not prepared for acceleration. This is the default value. This value also applies to cached statements under the following conditions:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The query acceleration behavior was not specified or was explicitly set to NONE when the dynamic statement was prepared.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A query acceleration behavior other than ALL was specified when the dynamic statement was prepared. DB2 did not prepare the statement for acceleration because it did not qualify for acceleration based on the query acceleration behavior that was specified.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'YES' The cached statement was prepared for acceleration to an accelerator server based on the query acceleration behavior that was specified. If query acceleration behavior is specified when a dynamic statement is prepared, DB2 can consider this cache entry for a possible cache match during the prepare operation of the dynamic statement. If query acceleration behavior is not specified, or is explicitly set to NONE when the statement is prepared, DB2 does not consider this cache entry for a cache match during the prepare operation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'NEVER' The cached statement was not prepared for acceleration to an accelerated server, because the statement can never be accelerated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• If the query acceleration behavior is set to ENABLE, ENABLE WITH FAILBACK, or ELIGIBLE for the prepare of the statement, DB2 considers this cache entry first as a possible cache match during the prepare operation. This action verifies whether the statement was cached previously as one that can never be accelerated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• If the query acceleration behavior is set to ALL for the prepare of the statement, DB2 does not consider this cache entry as a possible cache match during the prepare operation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• If the query acceleration behavior is not specified, or is explicitly set to NONE for the prepare of the statement, DB2 does not consider this cache entry as a possible cache match during the prepare operation.</td>
</tr>
<tr>
<td>Column name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ACCELERATED (continued)</td>
<td></td>
<td>'ACCEL-ONLY' The cached statement was prepared for acceleration to an accelerator. The statement references at least one accelerator-only table and can only be prepared to execute in the accelerator server. If query acceleration behavior is specified when a dynamic statement is prepared, DB2 can consider this cache entry for a possible cache match during the prepare operation of the dynamic statement. If query acceleration behavior is not specified, or is explicitly set to NONE when the statement is prepared, DB2 does not consider this cache entry for a cache match during the prepare operation. Query acceleration behavior is specified by either the QUERY_ACCELERATION subsystem parameter, the QUERYACCELERATION bind option, or the CURRENT QUERY ACCELERATION special register, and depends on their order of precedence. The order of precedence (lowest to highest) is: • The QUERY_ACCELERATION subsystem parameter • The QUERYACCELERATION bind option, if specified • An explicit SET CURRENT QUERY ACCELERATION statement</td>
</tr>
<tr>
<td>STAT_ACC_ELAP</td>
<td>BIGINT</td>
<td>The accumulated elapsed time for the accelerator.</td>

<tr>
<td></td>
<td></td>
<td>'YES' The statement is a candidate for acceleration when an accelerator server is available to the DB2 subsystem.</td>
</tr>
<tr>
<td>ACCELERATOR_NAME</td>
<td>VARCHAR(128)</td>
<td>The concatenated name of the accelerator server that processed the query.</td>
</tr>
</tbody>
</table>

Notes:
1. If the specified value exceeds 2147483647, the column contains the value 2147483647.
2. Statistics are cumulative, across executions of the same statement, and across threads, if the value of COLLID is DSNDYNAMICSQLCACHE. If the value of
COLLID is DSNEXPLAINMODEYES, the values are for a single run of the statement only. If the value of COLLID is DSNEXPLAINMODE EXPLAIN, the values of all statistics columns are 0.

3. The column is not applicable when the value of the COLLID column is 'DSNEXPLAINMODEYES' or 'DSNEXPLAINMODEEXPLAIN'
**DSN_STMTMNT_TABLE**

The statement table, DSN_STMTMNT_TABLE, contains information about the estimated cost of specified SQL statements.

**Recommendation:** Do not manually insert data into system-maintained EXPLAIN tables, and use care when deleting obsolete EXPLAIN table data. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools. Certain optimization tools depend on instances of the various EXPLAIN tables. Be careful not to delete data from or drop instances EXPLAIN tables that are created for these tools.

**Qualifiers**

Your subsystem or data sharing group can contain more than one of these tables:

'SYSIBM'

One instance of this table can be created with the SYSIBM qualifier. DB2 and SQL optimization tools might use the table and the data that it contains. The table is created when you run job DSNTIJSG when you install or migrate DB2.

'user-ID'

You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind. They are also populated when you specify EXPLAIN(YES) or EXPLAIN(ONLY) in a BIND or REBIND command. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

**Sample CREATE TABLE statement**

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the prefix.SDSNSAMP library.
Column descriptions

The following table describes the content of each column in STATEMENT_TABLE.

Table 254. Descriptions of columns in DSN_STATEMENT_TABLE

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
</table>
| QUERYNO     | INTEGER NOT NULL WITH DEFAULT | A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:
  **For rows produced by EXPLAIN statements**
  The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.
  **For rows not produced by EXPLAIN statements**
  DB2 assigns a number that is based on the line number of the SQL statement in the source program. When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in certain rare cases, the value is not guaranteed to be unique.
  When the SQL statement is embedded in a compiled SQL function or native SQL procedure, if the QUERYNO clause is specified, its value is used by DB2. Otherwise DB2 assigns a number based on the line number of the SQL statement in the compiled SQL function or native SQL procedure. |
| APPLNAME    | VARCHAR(24) NOT NULL WITH DEFAULT | The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable. When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column is not used, and is blank. |
| PROGNAME    | VARCHAR(128) NOT NULL WITH DEFAULT | The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable. When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column indicates the specific name of the compiled SQL function or native SQL procedure. |
| COLLID      | VARCHAR(128) NOT NULL WITH DEFAULT | The collection ID:
  'DSNDYNAMICSQLCACHE'
  The row originates from the dynamic statement cache
  'DSNEXPLAINMODEYES'
  The row originates from an application that specifies YES for the value of the CURRENT EXPLAIN MODE special register.
  'DSNEXPLAINMODEEXPLAIN'
  The row originates from an application that specifies EXPLAIN for the value of the CURRENT EXPLAIN MODE special register. When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column indicates the schema name of the compiled SQL function or native SQL procedure. |
<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GROUP_MEMBER</td>
<td>VARCHAR(24) NOT NULL WITH DEFAULT</td>
<td>The member name of the DB2 that executed EXPLAIN. The column is blank if the DB2 subsystem was not in a data sharing environment when EXPLAIN was executed.</td>
</tr>
</tbody>
</table>
| EXPLAIN_TIME | TIMESTAMP NOT NULL WITH DEFAULT | The time when the EXPLAIN information was captured:  
  **All cached statements**  
  When the statement entered the cache, in the form of a full-precision timestamp value.  
  **Non-cached static statements**  
  When the statement was bound, in the form of a full precision timestamp value.  
  **Non-cached dynamic statements**  
  When EXPLAIN was executed, in the form of a value equivalent to a CHAR(16) representation of the time appended by 4 zeros. |
| STMT_TYPE    | CHAR(6) NOT NULL WITH DEFAULT | The type of statement being explained. Possible values are:  
  SELECT  
  INSERT  
  UPDATE  
  MERGE  
  DELETE  
  TRUNCATE  
  SELECT with FOR UPDATE OF  
  DELETE WHERE CURRENT OF CURSOR  
  UPDATE WHERE CURRENT OF CURSOR |
| COST_CATEGORY| CHAR(1) NOT NULL WITH DEFAULT | Indicates if DB2 was forced to use default values when making its estimates. Possible values:  
  A  
  Indicates that DB2 had enough information to make a cost estimate without using default values.  
  B  
  Indicates that some condition exists for which DB2 was forced to use default values. See the values in REASON to determine why DB2 was unable to put this estimate in cost category A. |
<p>| PROCMS       | INTEGER NOT NULL WITH DEFAULT | The estimated processor cost, in milliseconds, for the SQL statement. The estimate is rounded up to the next integer value. The maximum value for this cost is 2147483647 milliseconds, which is equivalent to approximately 24.8 days. If the estimated value exceeds this maximum, the maximum value is reported. If an accelerator is used, the difference is reflected in this value. |</p>
<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROCSU</td>
<td>INTEGER NOT NULL</td>
<td>The estimated processor cost, in service units, for the SQL statement. The estimate is rounded up to the next integer value. The maximum value for this cost is 2147483647 service units. If the estimated value exceeds this maximum, the maximum value is reported. If an accelerator is used, this value represents the estimated cost including any impact of acceleration.</td>
</tr>
<tr>
<td>REASON</td>
<td>VARCHAR(254) WITH DEFAULT</td>
<td>A string that indicates the reasons for putting an estimate into cost category B.</td>
</tr>
<tr>
<td>ACCELMODEL</td>
<td>ELIGIBLE</td>
<td>The query is eligible for acceleration.</td>
</tr>
<tr>
<td>ACCELMODEL</td>
<td>NOT ELIGIBLE</td>
<td>The query is not eligible for acceleration.</td>
</tr>
<tr>
<td>HAVING</td>
<td>CLAUSE</td>
<td>A subselect in the SQL statement contains a HAVING clause.</td>
</tr>
<tr>
<td>HOST</td>
<td>VARIABLES</td>
<td>The statement uses host variables, parameter markers, or special registers.</td>

<tr>
<td>OPTIMIZATION</td>
<td>HINTS</td>
<td>An statement-level access path, or PLAN_TABLE access path hint is applied to the statement, or APREUSE(ERROR/WARN) is applied for the package.</td>
</tr>
<tr>
<td>PROFILEID</td>
<td>value</td>
<td>When profile monitoring is used for the statement, the value of the PROFILEID column in SYSIBM.DSN_PROFILE_TABLE.</td>
</tr>
<tr>
<td>REFERENTIAL</td>
<td>CONSTRAINTS</td>
<td>Referential constraints of the type CASCADE or SET NULL exist on the target table of a DELETE statement.</td>
</tr>
<tr>
<td>TABLE</td>
<td>CARDINALITY</td>
<td>The cardinality statistics are missing for one or more of the tables that are used in the statement, or the statement used materialized views or table expressions.</td>
</tr>
<tr>
<td>TRIGGERS</td>
<td></td>
<td>Triggers are defined on the target table of an insert, update, or delete operation.</td>
</tr>
<tr>
<td>UDF</td>
<td></td>
<td>The statement uses user-defined functions.</td>
</tr>
<tr>
<td>TOTAL_COST</td>
<td>FLOAT NOT NULL</td>
<td>The overall estimated cost of the statement. If an accelerator is used, the benefit is reflected in this value. Use this value for reference purposes only. DB2 does not always choose the access path that has the lowest TOTAL_COST value. DB2 also uses other factors during access path selection, such as the reliability of the filter factor estimates.</td>
</tr>
<tr>
<td>Column name</td>
<td>Data type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>SECTNOI</td>
<td>INTEGER NOT NULL WITH DEFAULT</td>
<td>The section number of the statement. The value is taken from the same column in SYSPACKSTMT or SYSSTMT tables and can be used to join tables to reconstruct the access path for the statement. This column is applicable only for static statements. The default value of -1 indicates EXPLAIN information that was captured in DB2 9 or earlier.</td>
</tr>
<tr>
<td>VERSION</td>
<td>VARCHAR(122) NOT NULL WITH DEFAULT</td>
<td>The version identifier for the package. Applies only to an embedded EXPLAIN statement executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable. When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column indicates the version identifier of the compiled SQL function or native SQL procedure.</td>
</tr>
</tbody>
</table>

DSN_STRUCT_TABLE
The structure table, DSN_STRUCT_TABLE, contains information about all of the
query blocks in a query.

Recommendation: Do not manually insert data into system-maintained EXPLAIN
tables, and use care when deleting obsolete EXPLAIN table data. The data is
intended to be manipulated only by the DB2 EXPLAIN function and optimization
tools. Certain optimization tools depend on instances of the various EXPLAIN
tables. Be careful not to delete data from or drop instances EXPLAIN tables that
are created for these tools.

Qualifiers
Your subsystem or data sharing group can contain more than one of these tables:
'SYSIBM'
One instance of this table can be created with the SYSIBM qualifier. DB2
and SQL optimization tools might use the table and the data that it
contains. The table is created when you run job DSNTIJSG when you
install or migrate DB2.
'user-ID'
You can create additional instances of EXPLAIN tables that are qualified by
user ID. These tables are populated with statement cost information when
you issue the EXPLAIN statement or bind. They are also populated when
you specify EXPLAIN(YES) or EXPLAIN(ONLY) in a BIND or REBIND
command. SQL optimization tools might also create EXPLAIN tables that
are qualified by a user ID. You can find the SQL statement for creating an
instance of these tables in member DSNTESC of the SDSNSAMP library.

Sample CREATE TABLE statement
You can find a sample CREATE TABLE statement for each EXPLAIN table in
member DSNTESC of the prefix.SDSNSAMP library.
### Column descriptions

The following table describes the columns of DSN_STRUCT_TABLE

<table>
<thead>
<tr>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
</table>
| QUERYNO     | INTEGER NOT NULL | A number that identifies the statement that is being explained. The origin of the value depends on the context of the row:  
**For rows produced by EXPLAIN statements**  
The number specified in the QUERYNO clause, which is an optional part of the SELECT, INSERT, UPDATE, MERGE, and DELETE statement syntax.  
**For rows not produced by EXPLAIN statements**  
DB2 assigns a number that is based on the line number of the SQL statement in the source program. When the values of QUERYNO are based on the statement number in the source program, values that exceed 32767 are reported as 0. However, in certain rare cases, the value is not guaranteed to be unique.  
When the SQL statement is embedded in a compiled SQL function or native SQL procedure, if the QUERYNO clause is specified, its value is used by DB2. Otherwise DB2 assigns a number based on the line number of the SQL statement in the compiled SQL function or native SQL procedure. |
| QBLOCKNO    | SMALLINT NOT NULL | A number that identifies each query block within a query. The value of the numbers are not in any particular order, nor are they necessarily consecutive. |
| APPLNAME    | VARCHAR(24) NOT NULL | The name of the application plan for the row. Applies only to embedded EXPLAIN statements that are executed from a plan or to statements that are explained when binding a plan. A blank indicates that the column is not applicable. When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column is not used, and is blank. |
| PROGNAME    | VARCHAR(128) NOT NULL | The name of the program or package containing the statement being explained. Applies only to embedded EXPLAIN statements and to statements explained as the result of binding a plan or package. A blank indicates that the column is not applicable. When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column indicates the specific name of the compiled SQL function or native SQL procedure. |
| PARENT      | SMALLINT NOT NULL | The parent query block number of the current query block in the structure of SQL text; this is the same as the PARENT_QBLOCKNO in PLAN_TABLE. |
| TIMES       | FLOAT NOT NULL | The estimated number of rows returned by Data Manager; also the estimated number of times this query block is executed. |
| ROWCOUNT    | INTEGER NOT NULL | The estimated number of rows returned by RDS (Query Cardinality). |
| ATOPEN      | CHAR(1) NOT NULL | Whether the query block is moved up for do-at-open processing; 'Y' if done-at-open; 'N': otherwise. |

|            |                    | When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column indicates the schema name of the compiled SQL function or native SQL procedure.  
| VERSION    | VARCHAR(122) NOT NULL WITH DEFAULT | The version identifier for the package. Applies only to an embedded EXPLAIN statement executed from a package or to a statement that is explained when binding a package. A blank indicates that the column is not applicable.  
|            |                    | When the SQL statement is embedded in a compiled SQL function or native SQL procedure, this column indicates the version identifier of the compiled SQL function or native SQL procedure.  

Appendix. Additional information for DB2 SQL
**DSN_VIEWREF_TABLE**

The view reference table, DSN_VIEWREF_TABLE, contains information about all of the views and materialized query tables that are used to process a query.

**Recommendation:** Do not manually insert data into system-maintained EXPLAIN tables, and use care when deleting obsolete EXPLAIN table data. The data is intended to be manipulated only by the DB2 EXPLAIN function and optimization tools. Certain optimization tools depend on instances of the various EXPLAIN tables. Be careful not to delete data from or drop instances EXPLAIN tables that are created for these tools.

**Qualifiers**

Your subsystem or data sharing group can contain more than one of these tables:

'SYSIBM'

One instance of this table can be created with the SYSIBM qualifier. DB2 and SQL optimization tools might use the table and the data that it contains. The table is created when you run job DSNTIJSG when you install or migrate DB2.

'user-ID'

You can create additional instances of EXPLAIN tables that are qualified by user ID. These tables are populated with statement cost information when you issue the EXPLAIN statement or bind. They are also populated when you specify EXPLAIN(YES) or EXPLAIN(ONLY) in a BIND or REBIND command. SQL optimization tools might also create EXPLAIN tables that are qualified by a user ID. You can find the SQL statement for creating an instance of these tables in member DSNTESC of the SDSNSAMP library.

**Sample CREATE TABLE statement**

You can find a sample CREATE TABLE statement for each EXPLAIN table in member DSNTESC of the prefix.SDSNSAMP library.
## Column descriptions

</tbody>
</table>
Tables that support query acceleration

To interact with accelerator servers, DB2 requires two tables that record characteristics of those accelerator servers: SYSACCELERATORS and SYSACCELERATEDTABLES. In addition, DB2 requires the SYSACCELERATEDPACKAGES table, which records the characteristics of packages that are bound with the QUERYACCELERATION and GETACCELARCHIVE bind options.

The following table lists the table space and indexes for these tables, and lists the index fields for each index. The indexes are in ascending order, except where noted.

<table>
<thead>
<tr>
<th>TABLE SPACE</th>

<tr>
<td></td>
<td></td>
<td><strong>N</strong>. No static SQL query is bound to retrieve archived data from the accelerator. If the static query also is not bound for acceleration, the query is bound to run in DB2. If the static query is bound for acceleration because the QUERYACCELERATION bind option is specified, when the application is run the query is routed to the accelerator. However, the query retrieves only active data on the accelerator. Archived data is not retrieved.</td>
<td></td>
</tr>
</tbody>
</table>
|                     |                | **Y**. If the static query is bound for acceleration, the query retrieves archived data on the accelerator when the application runs if the following criteria is met:  
  • The QUERYACCELERATION bind option is also specified.  
  • The static SQL query references an accelerated table that has partitioned data archived on an accelerator.  
  If the static query cannot be bound for acceleration, DB2 fails the BIND or REBIND PACKAGE operation with an error message for that query. |     |

### Sample user-defined functions

Some sample user-defined functions are provided with DB2. You can use the functions in your applications just as you would use other user-defined functions, or as examples to help you define your own user-defined functions.

- To use these functions in your applications: Use the functions only if installation job DSNTEJ2U, which prepares the functions for use, has been run. Because the external programs that implement the logic of the sample functions are written in C and C++, the installation job requires that your site has IBM C/C++ for z/OS. For information on installation job DSNTEJ2U, see *DB2 Installation Guide*.

- If you want to use these functions as examples to help you define and implement your own user-defined functions: Data set *prefix*::SDSNSAMP contains the code for the sample functions.

- The detailed descriptions of the functions include their external program names and specific names. The functions are in schema DSN8. The functions are defined to treat character or graphic string parameters, both input and output, as EBCDIC-encoded data.

<td>Year, day, month</td>
</tr>
<tr>
<td>YYYY-MM-DD</td>
<td>Year, month, day</td>
</tr>
<tr>
<td>YYYY-XX-D</td>
<td>Year, day, month</td>
</tr>
<tr>
<td>YYYY-XX-DD</td>
<td>Year, day, month</td>
</tr>
</tbody>
</table>

where:
- **D**: Suppress leading zero if the day is less than 10
- **DD**: Retain leading zero if the day is less than 10
- **M**: Suppress leading zero if the month is less than 10
- **MM**: Retain leading zero if the month is less than 10
- **MONTH**: Use English-language name of month
- **XX**: Use a capital Roman numeral for month
- **YY**: Use a year format without century
- **YYYY**: Use a year format with century

The ALTDATE function demonstrates how you can create an overloaded function—a function name for which there are multiple function instances. Each instance supports a different parameter list enabling you to group related but distinct functions in a single user-defined function. The ALTDATE function has two forms.

**Form 1: ALTDATE(output-format)**

This form of the function converts the current date into the specified format.

- **output-format**
  A character string that matches one of the 34 date formats that are shown above. The character string must have a data type of VARCHAR and an actual length that is not greater than 13 bytes.

  The result of the function is VARCHAR(17).

**Form 2: ALTDATE(input-date, input-format, output-format)**

This form of the function converts a date (input-date) in one user-specified format (input-format) into another format (output-format).

- **input-date**
  The argument must be a date or a character string representation of a date
in the format specified by *input-format*. The character string must have a
data type of VARCHAR and an actual length that is not greater than 17
bytes.

*input-format*
A character string that matches one of the 34 date formats that are shown
above. The character string must have a data type of VARCHAR and an
actual length that is not greater than 13 bytes.

*output-format*
A character string that matches one of the 34 date formats that are shown
above. The character string must have a data type of VARCHAR and an
actual length that is not greater than 13 bytes.

The result of the function is VARCHAR(17).

The following table shows the external and specific names for the two forms of the
function, which are based on the input to the function.

<table>
<thead>
<tr>
<th>Conversion type</th>
<th>Input arguments</th>
<th>External name</th>
<th>Specific name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Current date</td>
<td>output-format</td>
<td>DSN8DUAD</td>
<td>DSN8.DSN8DUADV</td>
</tr>
<tr>
<td>User-specified date</td>
<td>input-date</td>
<td>DSN8DUAD</td>
<td>DSN8.DSN8DUADV</td>
</tr>
<tr>
<td></td>
<td>input-format</td>
<td>DSN8DUAD</td>
<td>DSN8.DSN8DUADV</td>
</tr>
<tr>
<td></td>
<td>output-format</td>
<td>DSN8DUAD</td>
<td>DSN8.DSN8DUADV</td>
</tr>
</tbody>
</table>

*Example 1:* Convert the current date into format 'DD MONTH YY', a format that
will include any leading zero for the month, the name of the month in English,
and the year without the two digits for the century.

VALUES DSN8.ALTDATE( 'DD MONTH YY' );

*Example 2:* Convert the current date into format 'D.M.YYYY', a format that will
suppress any leading zero for the day or month and include the year with the
century.

VALUES DSN8.ALTDATE( 'D.M.YYYY' );

*Example 3:* Convert the current date into format 'YYYY-XX-DD', a format that will
include the century, the month of the year as a roman numeral, and the day of
the month with any leading zero.

VALUES DSN8.ALTDATE( 'YYYY-XX-DD' );

*Example 4:* Convert a date in the format of 'DD MONTH YYYY' to a date in the
format of 'YYYY/MM/DD'.

VALUES DSN8.ALTDATE( '11 November 1918',
'DD MONTH YYYY',
'YYYY/MM/DD' );

The result of the above example is '1918/11/18'.
Example 5: Convert the date that employee 000130 was hired, a date in ISO format, into the format of 'D.M.YY'.

```
SELECT FIRSTNAME || ' ' || LASTNAME || ' was hired on ' || DSNB.ALTDATE( HIREDATE, 'YYYY-MM-DD', 'D.M.YY' )
FROM EMP
WHERE EMPNO = '000130';
```

Assuming that the HIREDATE is '1971-07-28', the above example returns: 'DELORES QUINTANA was hired on 28.7.71'.

2874 SQL Reference
ALTTIME

The ALTTIME function returns the current time in the specified format or converts a user-specified time from one format to another.

```
ALTTIME(input-time, input-format, output-format)
```

The schema is DSN8.

The ALTTIME function returns the current time in one of the following formats or converts a user-specified time from one of the formats to another:

- `H:MM AM/PM`  
- `HH:MM:SS AM/PM`  
- `H.MM`  
- `H.MM`  
- `H.MM:SS`  
- `HH.MM`  
- `HH.MM:SS`  
- `H.MM.SS`  
- `HH.MM.SS`

where:

- `H`: Suppress leading zero if the hour is less than 10
- `HH`: Retain leading zero if the hour is less than 10
- `M`: Suppress leading zero if the minute is less than 10
- `MM`: Retain leading zero if the minute is less than 10
- `AM/PM`: Return time in 12-hour clock format, else 24-hour

The ALTTIME function demonstrates how you can create an overloaded function—a function name for which there are multiple function instances. Each instance supports a different parameter list enabling you to group related but distinct functions in a single user-defined function. The ALTTIME function has two forms.

**Form 1: ALTTIME(output-format)**

This form of the function converts the current time into the specified format.

output-format

A character string that matches one of the 8 time formats that are shown above. The character string must have a data type of VARCHAR and an actual length that is not greater than 14 bytes.

The result of the function is VARCHAR(11).

**Form 2: ALTTIME(input-time, input-format, output-format)**

This form of the function converts a time (input-date) in one user-specified format (input-format) into another format (output-format).

input-time

The argument must be a time or a character string representation of a time in the format specified by input-format. A character string argument must have a data type of VARCHAR and an actual length that is not greater than 11 bytes.

input-format

A character string that matches one of the 8 time formats that are shown above. The character string must have a data type of VARCHAR and an actual length that is not greater than 14 bytes.

output-format

A character string that matches one of the 8 time formats that are shown
The character string must have a data type of VARCHAR and an actual length that is not greater than 14 bytes.

The result of the function is VARCHAR(11).

The following table shows the external program and specific names for the two forms of the function, which are based on the input to the function.

<table>
<thead>
<tr>
<th>Conversion type</th>
<th>Input arguments</th>
<th>External name</th>
<th>Specific name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Current time</td>
<td>output-format (VARCHAR)</td>
<td>DSN8DUAT</td>
<td>DSN8.DSN8DUATV</td>
</tr>
<tr>
<td>User-specified time</td>
<td>input-time (VARCHAR)</td>
<td>DSN8DUCT</td>
<td>DSN8.DSN8DUCTVVV</td>
</tr>
<tr>
<td></td>
<td>input-format (VARCHAR)</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>output-format (VARCHAR)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Example 1: Convert the current time into a 12-hour clock format without seconds, 'H:MM AM/PM'.
VALUES DSN8.ALTIME('H:MM AM/PM');

Example 2: Convert the current time into a 24-hour clock format without seconds, 'HH.MM'.
VALUES DSN8.ALTIME('HH.MM');

Example 3: Convert the current time into a 24-hour clock format with seconds, 'HH.MM.SS'.
VALUES DSN8.ALTIME('HH.MM.SS');

Example 4: Convert '00:00:00', a time in 24-hour clock format with seconds, to a time in 12-hour clock format without seconds.
VALUES DSN8.ALTIME('00:00:00','HH:MM:SS','HH:MM AM/PM');

The function returns '12:00 AM'.

Example 5: Convert '00:00:00', a time in 24-hour clock format with seconds, to a time in 12-hour clock format without seconds and without any leading zero on the hour.
VALUES DSN8.ALTIME('06.42.37','HH.MM.SS','H:MM AM/PM');

The function returns '6:42 AM'.
CURRENCY

The CURRENCY function returns a value that is formatted as an amount with a user-specified currency symbol and, if specified, one of three symbols that indicate debit or credit.

\[
\text{CURRENCY}(\text{input-amount}, \text{currency-symbol}, \text{credit/debit-indicator})
\]

The schema is DSN8.

input-amount
An expression that specifies the value to be formatted. The expression must be a floating-point value.

currency-symbol
A character string that specifies the currency symbol. The string must have a data type of VARCHAR and an actual length that is not greater than 2 bytes.

credit/debit-indicator
A character string that specifies the symbol that is included with the result to indicate whether the value is negative or positive. The string must have a data type of VARCHAR and an actual length that is not greater than 5 bytes. If credit/debit-indicator is not specified or is the value null, the result is formatted without an indicator symbol. You can specify the following symbols:

- **CR/DB**
  *Bank style.* Negative input values are appended with 'DB'; positive input values are appended with 'CR'.

- **+/−**
  *Arithmetic style.* Negative input values are prefixed with a minus sign ‘−’; positive values are formatted without symbols.

- **( )**
  *Accounting style.* Negative input values are enclosed in parentheses ‘( )’; positive values are formatted without symbols.

The result of the function is VARCHAR(19).

The CURRENCY function uses the C language functions strftime to facilitate formatting of money amounts and setlocale to initialize strftime for local conventions. If setlocale fails, the CURRENCY function returns an error.

The following table shows the external program and specific names for CURRENCY. The specific names differ depending on the input to the function.

<table>
<thead>
<tr>
<th>Input arguments</th>
<th>External name</th>
<th>Specific name</th>
</tr>
</thead>
<tbody>
<tr>
<td>input-amount</td>
<td>DSN8DUCY</td>
<td>DSN8.DSN8DUCYFV</td>
</tr>
<tr>
<td>currency-symbol</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

| input-amount    | DSN8DUCY      | DSN8.DSN8DUCYFVV |
| currency-symbol |               |               |

Appendix. Additional information for DB2 SQL
Example 1: Express \( -1234.56 \) as an amount in US dollars, using the bank style debit/credit indicator to indicate whether the value is negative or positive.

VALUES DSN8.CURRENCY( -1234.56, '$', 'CR/DB' );

The result of the function is '$1,234.56 DB'.

Example 2: Express \( -1234.56 \) as an amount in Deutsche marks, using the accounting style debit/credit indicator to indicate whether the value is negative or positive.

VALUES DSN8.CURRENCY( -1234.56, 'DM', '(/) ' );

The result of the function is '(DM 1,234.56)'.

Example 3: Express \( -1234.56 \) as an amount in Canadian dollars, using the accounting style debit/credit indicator to indicate whether the value is negative or positive.

VALUES DSN8.CURRENCY( -1234.56, 'CD', '*/-' );

The result of the function is '-CD 1,234.56'.
DAYNAME

The DAYNAME function returns the name of the weekday on which a given date falls. The name is returned in English.

\[ \text{DAYNAME(input-date)} \]

The schema is DSN8.

**input-date**

A valid date or valid character string representation of a date. A character string representation The string must have a data type of VARCHAR and an actual length that is not greater than 10 bytes. The date must be in ISO format.

The result of the function is VARCHAR(9).

The DAYNAME function uses the IBM C++ classIDate.

The following table shows the external and specific names for DAYNAME. The specific names differ depending on the data type of the input argument.

<table>
<thead>
<tr>
<th>Input arguments</th>
<th>External name</th>
<th>Specific name</th>
</tr>
</thead>
<tbody>
<tr>
<td>input-date</td>
<td>DSN8EUDN</td>
<td>DSN8.DSN8EUDNV</td>
</tr>
<tr>
<td>input-date (VARCHAR)</td>
<td>DSN8EUDN</td>
<td>DSN8.DSN8EUDND</td>
</tr>
</tbody>
</table>

**Example 1:** For the current date, find the day of the week.

VALUES DSN8.DAYNAME( CURRENT DATE );

**Example 2:** Find the day of the week on which leap year falls in the year 2008.

VALUES DSN8.DAYNAME( '2008-02-29' );

The result of the function is 'Friday'.

**Example 3:** Find the day of the week on which Delores Quintana, employee number 000130, was hired.

SELECT FIRSTNME || '' || LASTNAME || '' || ' was hired on ' || DSN8.DAYNAME( HIREDATE ) || ' ', || CHAR( HIREDATE ) FROM EMP WHERE EMPNO = '000130';

The result of the function is 'DELORES QUINTANA was hired on Wednesday, 1971-07-28'.

Appendix. Additional information for DB2 SQL
MONTHNAME

The MONTHNAME function returns the calendar name of the month in which a given date falls. The name is returned in English.

\[ \text{MONTHNAME}(\text{input-date}) \]

The schema is DSN8.

\textit{input-date}

A valid date or valid character string representation of a date. A character string representation must have a data type of VARCHAR and an actual length that is no greater than 10 bytes. The date must be in ISO format.

The result of the function is VARCHAR(9).

The MONTHNAME function uses the IBM C++ class IDate.

The following table shows the external and specific names for MONTHNAME. The specific names differ depending on the data type of the input argument.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|}
\hline
\textbf{Input arguments} & \textbf{External name} & \textbf{Specific name} \\
\hline
\textit{input-date} (VARCHAR) & DSN8EUMN & DSN8.DSN8EUMNV \\
\hline
\textit{input-date} (DATE) & DSN8EUMN & DSN8.DSN8EUMND \\
\hline
\end{tabular}
\end{table}

\textit{Example 1:} For the current date, find the name of the month.

\begin{verbatim}
VALUES DSN8.MONTHNAME( CURRENT DATE );
\end{verbatim}

\textit{Example 2:} Find the month of the year in which Delores Quintana, employee number 000130, was hired.

\begin{verbatim}
SELECT FIRSTNAME || ' ' || LASTNAME || ' was hired in the month of ' || DSN8.MONTHNAME( HIREDATE ) || CHAR( HIREDATE ) FROM EMP WHERE EMPNO = '000130';
\end{verbatim}

The result of the function is 'DELORES QUINTANA was hired in the month of July'.
**TABLE_LOCATION**

The TABLE_LOCATION function searches for an object and returns the location name of the object after any alias chains have been resolved.

\[ \text{TBLFP\_LOCATION}(\text{object-name}, \text{object-schema}, \text{location-name}) \]

The schema is DSN8.

The starting point of the resolution is the object that is specified by `object-name` and, if specified, `object-schema` and `location-name`. If the starting point does not refer to an alias, the location name of the starting point is returned. The resulting name can be of a table, view, or undefined object. The function returns a blank if there is no location name.

**object-name**

A character expression that specifies the unqualified name to be resolved. The unqualified name is usually of an existing alias. `object-name` must have a data type of VARCHAR and an actual length that is no greater than 18 bytes.

**object-schema**

A character expression that represents the schema that is used to qualify the value specified in `object-name` before resolution. `object-schema` must have a data type of VARCHAR and an actual length that is no greater than 8 bytes.

If `object-schema` is not specified or is null, the default schema is used for the qualifier.

**location-name**

A character expression that represents the location that is used to qualify the value specified in `object-name` before resolution. `location-name` must have a data type of VARCHAR and an actual length that is no greater than 16 bytes.

If `location-name` is not specified or is null, the location name is equivalent to “any”.

The result of the function is VARCHAR(16). If `object-name` can be null, the result can be null; if `object-name` is null, the result is the null value.

The following table shows the external and specific names for TABLE_LOCATION. The specific names differ depending on the number of input arguments to the function.

<table>
<thead>
<tr>
<th>Input arguments</th>
<th>External name</th>
<th>Specific name</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>object-name</code> (VARCHAR)</td>
<td>DSN8DUTI</td>
<td>DSN8.DSN8DUTILV</td>
</tr>
<tr>
<td><code>object-name</code> (VARCHAR)</td>
<td>DSN8DUTI</td>
<td>DSN8.DSN8DUTILVV</td>
</tr>
<tr>
<td><code>object-schema</code> (VARCHAR)</td>
<td>DSN8DUTI</td>
<td>DSN8.DSN8DUTILVV</td>
</tr>
</tbody>
</table>
Table 263. External and specific names for TABLE_LOCATION (continued)

<table>
<thead>
<tr>
<th>Input arguments</th>
<th>External name</th>
<th>Specific name</th>
</tr>
</thead>
<tbody>
<tr>
<td>object-name</td>
<td>DSN8DUTI</td>
<td>DSN8.DSN8DUTILVVV</td>
</tr>
<tr>
<td>object-schema</td>
<td></td>
<td></td>
</tr>
<tr>
<td>location-name</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Example: Assume that:
- DSN8.ALIAS_RS_SYSTABLES is an alias of SYSIBM.SYSTABLES at location name 'REMOTE_SITE'.
- The CURRENT SQLID is DSN8.

Use TABLE_LOCATION to find the location name where the base object for ALIAS_RS_SYSTABLES resides.

```
VALUES DSN8.TABLE_LOCATION( 'ALIAS_RS_SYSTABLES' );
```

The result of the function is 'REMOTE_SITE'.

The TABLE_NAME function searches for an object and returns the unqualified name of the object after any alias chains have been resolved.

The schema is DSN8.

The starting point of the resolution is the object that is specified by object-name and, if specified, object-schema and location-name. If the starting point does not refer to an alias, the unqualified name of the starting point is returned. The resulting name can be of a table, view, or undefined object.

**object-name**

A character expression that specifies the unqualified name to be resolved. The unqualified name is usually of an existing alias. object-name must have a data type of VARCHAR and an actual length that is no greater than 18 bytes.

**object-schema**

A character expression that represents the schema that is used to qualify the value specified in object-name before resolution. object-schema must have a data type of VARCHAR and an actual length that is no greater than 8 bytes.

If object-schema is not specified or is null, the default schema is used for the qualifier.

**location-name**

A character expression that represents the location that is used to qualify the value specified in object-name before resolution. location-name must have a data type of VARCHAR and an actual length than is no greater than 16 bytes.

If location-name is not specified or is null, the location name is equivalent to “any”.

The result of the function is VARCHAR(128). If object-name can be null, the result can be null; if object-name is null, the result is the null value.

The following table shows the external and specific names for TABLE_NAME. The specific names differ depending on the number of input arguments to the function.

<table>
<thead>
<tr>
<th>Input arguments</th>
<th>External name</th>
<th>Specific name</th>
</tr>
</thead>
<tbody>
<tr>
<td>object-name (VARCHAR)</td>
<td>DSN8DUTI</td>
<td>DSN8.DSN8DUTINV</td>
</tr>
<tr>
<td>object-name (VARCHAR)</td>
<td>DSN8DUTI</td>
<td>DSN8.DSN8DUTINVV</td>
</tr>
<tr>
<td>object-schema (VARCHAR)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Appendix. Additional information for DB2 SQL 2883
<table>
<thead>
<tr>
<th>Input arguments</th>
<th>External name</th>
<th>Specific name</th>
</tr>
</thead>
<tbody>
<tr>
<td>object-name</td>
<td>DSN8DUTI</td>
<td>DSN8.DSN8DUTINVVV</td>
</tr>
<tr>
<td>object-schema</td>
<td></td>
<td></td>
</tr>
<tr>
<td>location-name</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Example: Assume that:
- DSN8.VIEW_OF_SYSTABLES is a view of SYSIBM.SYSTABLES.
- DSN8.ALIAS_OF_VIEW is an alias of DSN8.VIEW_OF_SYSTABLES.
- The CURRENT SQLID is DSN8.

Use `TABLE_NAME` to find the name of the base object for ALIAS_OF_VIEW.

```sql
VALUES DSN8.TABLE_NAME( 'ALIAS_OF_VIEW' );
```

The result of the function is 'VIEW_OF_SYSTABLES'.
**TABLE_SCHEMA**

The TABLE_SCHEMA function searches for an object and returns the schema name of the object after any synonyms or alias chains have been resolved.

The schema is DSN8.

The starting point of the resolution is the object that is specified by `objectname` and `objectschema`. If the starting point does not refer to an alias or synonym, the schema name of the starting point is returned. The resulting schema name can be of a table, view, or undefined object.

**object-name**

A character expression that specifies the unqualified name to be resolved. The unqualified name is usually of an existing alias. `object-name` must have a data type of `VARCHAR` and an actual length that is no greater than 18 bytes.

**object-schema**

A character expression that represents the schema that is used to qualify the value specified in `object-name` before resolution. `object-schema` must have a data type of `VARCHAR` and an actual length that is no greater than 8 bytes.

If `object-schema` is not specified or is null, the default schema is used for the qualifier.

**location-name**

A character expression that represents the location that is used to qualify the value specified in `object-name` before resolution. `location-name` must have a data type of `VARCHAR` (and an actual length that is no greater than 16 bytes.

If `location-name` is not specified or is null, the location name is equivalent to "any".

The result of the function is `VARCHAR(128)`. If `object-name` can be null, the result can be null; if `object-name` is null, the result is the null value.

The following table shows the external and specific names for TABLE_SCHEMA. The specific names differ depending on the number of input arguments.

<table>
<thead>
<tr>
<th>Input arguments</th>
<th>External name</th>
<th>Specific name</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>object-name</code> (VARCHAR)</td>
<td>DSN8DUTI</td>
<td>DSN8.DSN8DUTISV</td>
</tr>
<tr>
<td><code>object-name</code> (VARCHAR)</td>
<td>DSN8DUTI</td>
<td>DSN8.DSN8DUTISVV</td>
</tr>
</tbody>
</table>

Appendix. Additional information for DB2 SQL 2885
### Table 265. External and specific names for function `TABLE_SCHEMA` (continued)

<table>
<thead>
<tr>
<th>Input arguments</th>
<th>External name</th>
<th>Specific name</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>object-name</code> (VARCHAR)</td>
<td>DSN8DUTI</td>
<td>DSN8.DSN8DUTISVVV</td>
</tr>
<tr>
<td><code>object-schema</code> (VARCHAR)</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>location-name</code> (VARCHAR)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Example: Assume that:
- DSN8.ALIAS_OF_SYSTABLES is an alias of SYSIBM.SYSTABLES.
- The CURRENT SQLID is DSN8.

Find the name of the schema of the base table for ALIAS_OF_SYSTABLES.

```sql
VALUES DSN8.TABLE_SCHEMA( 'ALIAS_OF_SYSTABLES' );
```

The result of the function is `'SYSIBM'`. 
The WEA\textsc{ther} function returns information from a TSO data set as a DB2 table. The TSO data set contains sample weather statistics for various cities in the United States. The statistics are returned to the client with a row for each city and a column for each statistic. The WEA\textsc{ther} function is provided primarily to help you design and implement table functions.

\begin{verbatim}
WEATHER(input-data-set-name) RETURNS TABLE(
  name-of-city VARCHAR(30)
  temperature-in-fahrenheit INTEGER
  percent-humidity INTEGER
  wind-direction VARCHAR(5)
  wind-velocity INTEGER
  barometer FLOAT
  forecast VARCHAR(25)
)
\end{verbatim}

The schema is DSN8.

Unlike the other sample user-defined functions, which are scalar functions, WEA\textsc{ther} is a table function. WEA\textsc{ther} shows how to use a table function to make non-relational data available to a client for manipulation by SQL.

\textit{input-data-set-name}

The name of the TSO data set that contains sample weather statistics. The name is a character string with a data type of VARCHAR and an actual length that is not greater than 44 bytes.

The result of the function is a DB2 table with the following columns. Each column can be null.

\begin{itemize}
  \item \textit{name-of-city} VARCHAR(30)
  \item \textit{temperature-in-fahrenheit} INTEGER
  \item \textit{percent-humidity} INTEGER
  \item \textit{wind-direction} VARCHAR(5)
  \item \textit{wind-velocity} INTEGER
  \item \textit{barometer} FLOAT
  \item \textit{forecast} VARCHAR(25)
\end{itemize}

The external program name for the function is DSN8DUWF, and the specific name is DSN8.DSN8DUWF.

\textit{Example}: Find the name of and the forecast for the cities that have a temperature less than 25 degrees.

\begin{verbatim}
SELECT CITY, FORECAST
FROM TABLE(DSN8.WEATHER('prefix.SDSNIVPD(DSN8LWC)')) AS W
WHERE TEMP_IN_F < 25
ORDER BY CITY;
\end{verbatim}
This example returns:

<table>
<thead>
<tr>
<th>Location</th>
<th>Weather Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bessemer, MI</td>
<td>Slight chance of snow</td>
</tr>
<tr>
<td>Cheyenne, WY</td>
<td>Continued cooling</td>
</tr>
<tr>
<td>Helena, MT</td>
<td>Heavy snow</td>
</tr>
<tr>
<td>Pierre, SD</td>
<td>Continued cold</td>
</tr>
</tbody>
</table>
Information resources for DB2 10 for z/OS and related products

Information about DB2 10 for z/OS and products that you might use in conjunction with DB2 10 is available online in IBM Knowledge Center or on library websites.

**Obtaining DB2 for z/OS publications**

Current DB2 10 for z/OS publications are available from the following websites:

Links to IBM Knowledge Center and the PDF version of each publication are provided.

DB2 for z/OS publications are also available for download from the IBM Publications Center [http://www.ibm.com/shop/publications/order](http://www.ibm.com/shop/publications/order).

In addition, books for DB2 for z/OS are available on a CD-ROM that is included with your product shipment:

- **DB2 10 for z/OS Licensed Library Collection, LK5T-7390, in English.** The CD-ROM contains the collection of books for DB2 10 for z/OS in PDF format. Periodically, IBM refreshes the books on subsequent editions of this CD-ROM.

**Installable information center**

You can download or order an installable version of the Information Management Software for z/OS Solutions Information Center, which includes information about DB2 10 for z/OS, QMF, IMS, and many DB2 Tools for z/OS products. You can install this information center on a local system or on an intranet server. For more information, see [http://www-01.ibm.com/support/knowledgecenter/SSEPEK_11.0.0/com.ibm.db2z11.doc/src/alltoc/installabledzic.html](http://www-01.ibm.com/support/knowledgecenter/SSEPEK_11.0.0/com.ibm.db2z11.doc/src/alltoc/installabledzic.html).
Notices

Programming interface information

This information is intended to help you to code SQL statements. This information primarily documents General-use Programming Interface and Associated Guidance Information provided by DB2 10 for z/OS. This information also documents Product-sensitive Programming Interface and Associated Guidance Information provided by DB2 10 for z/OS.

General-use Programming Interface and Associated Guidance Information

General-use Programming Interfaces allow the customer to write programs that obtain the services of DB2 10 for z/OS.

Product-sensitive Programming Interface and Associated Guidance Information

Product-sensitive Programming Interfaces allow the customer installation to perform tasks such as diagnosing, modifying, monitoring, repairing, tailoring, or tuning of this IBM software product. Use of such interfaces creates dependencies on the detailed design or implementation of the IBM software product. Product-sensitive Programming Interfaces should be used only for these specialized purposes. Because of their dependencies on detailed design and implementation, it is to be expected that programs written to such interfaces may need to be changed in order to run with new product releases or versions, or as a result of service.

Product-sensitive Programming Interface and Associated Guidance Information is identified where it occurs by the following markings:

PSPI

Product-sensitive Programming Interface and Associated Guidance Information...

Trademarks

IBM, the IBM logo, and ibm.com® are trademarks or registered marks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the web at "Copyright and trademark information" at: http://www.ibm.com/legal/copytrade.shtml

Linux is a registered trademark of Linus Torvalds in the United States, other countries, or both.

Microsoft, Windows, Windows NT, and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.

UNIX is a registered trademark of The Open Group in the United States and other countries.

Java and all Java-based trademarks and logos are trademarks or registered trademarks of Oracle and/or its affiliates.
Terms and conditions for product documentation

Permissions for the use of these publications are granted subject to the following terms and conditions:

**Applicability:** These terms and conditions are in addition to any terms of use for the IBM website.

**Personal use:** You may reproduce these publications for your personal, noncommercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative work of these publications, or any portion thereof, without the express consent of IBM.

**Commercial use:** You may reproduce, distribute and display these publications solely within your enterprise provided that all proprietary notices are preserved. You may not make derivative works of these publications, or reproduce, distribute or display these publications or any portion thereof outside your enterprise, without the express consent of IBM.

**Rights:** Except as express ally granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the publications is detrimental to its interest or, as determined by IBM, the above instructions are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

IBM MAKES NO GUARANTEE ABOUT THE CONTENT OF THESE PUBLICATIONS. THE PUBLICATIONS ARE PROVIDED "AS-IS" AND WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO IMPLIED WARRANTIES OF MERCHANTABILITY, NON-INFRINGEMENT, AND FITNESS FOR A PARTICULAR PURPOSE.
Privacy policy considerations

IBM Software products, including software as a service solutions, (“Software Offerings”) may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user, or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering’s use of cookies is set forth below.

This Software Offering does not use cookies or other technologies to collect personally identifiable information.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

Glossary

The glossary is available in IBM Knowledge Center.

See the [Glossary] topic for definitions of DB2 for z/OS terms.
